# Generativity in design research: the case of developing a genre of action-based mathematics learning activities

*Educational research is often of limited use to designers, as it typically offers descriptions of or explanations for how education was or currently is. In this paper we argue that generalizability is not enough; what deserves more attention is generativity. Designers and educators need actionable knowledge on how education could be. To substantiate the criterion of generativity, we here develop the construct of a design genre—a theory-driven class of designs targeting a particular form of learning. As an example we discuss the evolution of an action-based genre of embodied design through iterative theory-design clarifications. Initially instantiated in the form of activities for promoting the understanding of proportional reasoning, the genre has been elaborated through the process of applying it to additional notions such as parabolas and trigonometry. We argue that this genre was generative for design, theory development, and methodological innovation.*

*Keywords: Mathematics curriculum, generalization, sensory experience, instructional design, learning theory.*

## Generativity

Educational research mostly investigates practice “as it was” or “as it is.” Generating new desirable types of education—“as it could be”—has largely been left to practitioners and designers. With its focus on generalizability, educational theories typically provide little help to designers or educators in making design decisions, for example on how to use new tools, develop a new teaching approach, or achieve new learning goals (Klaassen & Kortland, 2013). It has been argued that educational research is a linking science (Dewey, 1900) or a design science (Glaser, 1976), more similar to engineering, medicine, and management than to physics, biology, or psychology. What linking or design sciences are looking for is “actionable knowledge” (Argyris, 1996). Design research originates in the wish to produce such actionable, advisory knowledge (Bakker, 2018).

Discussing the role of theory in design research, diSessa and Cobb (2004) distinguished several kinds of theory such as grand theories, orienting frameworks, frameworks for action, and domain-specific theories. The authors observe that the more general such theories are, the less informative these typically are to the designer or educator. In their view, “theory must do real design work in generating, selecting, and validating design alternatives at the level at which they are consequential for learning” (p. 77). An example of what they consider good innovation is the general construct of socio mathematical norms, yet they admit this notion is not very prescriptive for design.

In line with the aforementioned need to produce actionable knowledge, we propose that educational researchers should not just care about generalizability (deriving general ideas from empirical specificities) but also about *generativity* (deriving ideas for specific design solutions from general principles). The aim of this paper is to argue that so-called *design genres* (Abrahamson, 2014), as

theory-driven types of designs targeting a particular form of learning, offer useful knowledge to educational researchers, design researchers, and designers alike. We also submit that design genres may fulfill the criteria of generalizability and generativity in the sense if they are research-based and productive in generating new actionable knowledge, but also provide concrete advice on how to design tasks in this particular genre (cf. Watson & Othani, 2015). Thus they would fulfill the role theories should play in design research according to diSessa and Cobb (2004).

To illustrate the notion of generativity, we explore how the formulation of such a genre facilitated the process of creating similar designs outside of the source laboratory. We reflect on the evolution of an *action-based genre of embodied design* (see Figures 1 and 2). This design genre originated in Abrahamson's Embodied Design Research Laboratory (Berkeley), and was extended by Shvarts in Moscow and Bakker, Alberto, and colleagues in Utrecht to other mathematical domains. In terms of design, we reflect on a set of general and generative principles that slowly developed through iterative cycles of collaborative design research.

**Figure 1: Solving a movement riddle in the Mathematics Imagery Trainer, a child learns to move physically in a new way that is then articulated formally as governed by a proportional function**

**Figure 2: Five versions of the MIT-proportion applications: (a) parallel bars; (b) parallel with full screen feedback; (c) orthogonal bars; (d) orthogonal with full screen feedback; (e) rectangle feedback**

### **A prototypical action-based design for proportion**

Our design research is inspired by a range of philosophical positions and cognitive-science research arguing for the embodied origin and nature of cognition (Dreyfus & Dreyfus, 1999)—none of which yielded specific ideas for design. Accordingly, we sought to develop and evaluate action-based learning activities that could potentially support students' sensorimotor grounding of mathematical content. As part of our research program, we deliberately focus on mathematical domains beyond

simple arithmetic to explore whether theories of embodiment hold promise for more advanced topics too.

Figure 2 presents a set of schematic screen images featuring computer-based materials we have been exploring (there are also versions with lines or grids, and with numbers). These activities build on, yet extend, earlier research by Abrahamson and colleagues on the Mathematics Imagery Trainer for Proportion (MIT-proportion). Clinical research on the MIT-proportion has demonstrated the emergence of students' sensorimotor schemes, as they attempt to satisfy the task specifications: First, manipulate two virtual objects on the screen so that the bars (2a) or entire screen (2b) becomes green; and then move both objects simultaneously keeping the green feedback. Unknown to the students, the favorable feedback of green appears only if the objects they manipulate make for a particular proportion between key magnitudes relative to a spatial frame of reference, for example a 1:2 ratio between the heights of the two bars in Figure 2a or between the y- and x-axis, linear extensions in Figure 2c.

We found patterns in students' solution process on these tasks that could be summarized well in Piagetian terms of reflective abstraction (Abrahamson, Shayan, Bakker, & Van der Schaaf, 2016). Eye-tracking technology allowed us to study the emergence of sensorimotor action schemes in more detail than hitherto possible. For example, the gaze data showed that students focus their attention at particular locations on the screen so as to coordinate their bimanual movement. We came to understand these sensory behaviors as evidence that students were developing *attentional anchors*, spontaneous perceptual constructions that facilitate the enactment of challenging movements by focalizing the coordination of motor actions. That is, we were witnessing the emergence of new goal-oriented sensorimotor schemes. For example, Figure 3a shows a typical scan path when students keep the bars green (see Duijzer, Shayan, Bakker, Van der Schaaf, & Abrahamson, 2017, for an automated analysis of patterns in how students looked in particular areas of interest). Students look halfway up along the tall bar before they express the insight that it is twice as tall as the shorter bar. Arriving at this insight took between 10 seconds and 9 minutes.

**Figure 3: (a) typical scan path when trying to keep the bars green while moving them up. (b–e) attentional anchors when keeping green in the orthogonal task with full screen color feedback**

## Expanding a genre of action-based embodied designs

Intending to expand this genre of educational designs, we varied on the initial interactive activity along several dimensions, such as mathematical domain, the form of interactive feedback, or characteristics of input movements (bimanual/unimanual, in the air in front of the screen / on a touchscreen or a tablet / via touchpad). These new designs were somewhat intuitive, unstructured, or loosely meditated. While we were aiming to keep the core of the design, stating just what that core

might be was still work in progress. We found ourselves in a situation not unlike a child participating in a cognitive developmental psychology experiment investigating the emergence of categorical reasoning (Vygotsky, 1962): Tasked to select from a pool of colored geometrical shapes a set of some yet-to-be-defined class, the child groups a red and a yellow triangle, since they both are triangles, but then adds a yellow circle, since it too is yellow, and then, perhaps, a trapezoid, since it is similar in another way. In this process of iteratively varying on different aspects of the design, we came to recognize a need to articulate the limits of variation that would keep intact some constant qualities of this genre's essential features, whatever these would turn out to be.

### **Orthogonal design for proportional reasoning**

Urged by a request from a high school mathematics teacher, Lee, Hung, Negrete and Abrahamson (2013) envisioned a first variant on the original MIT-proportion activity, in which the hands would move not in parallel but orthogonally. This variant, which expands the original activity from 1D to 2D, was implemented at Utrecht University (Figures 2c–e; 3b). The new task demanded of students to solve the challenging movement problem of coordinating simultaneous motor action along orthogonal axes. Figures 3b–e include a student's eye fixations (the orange blobs overlain on screenshots from the video-recording). The student told us he is imagining a diagonal line connecting his left- and right-hand index fingertips and that he is moving *this diagonal line* sideways to the right, keeping constant the line's angular orientation to the base line. As such, the diagonal line constituted an attentional anchor for this student and others who arrived at similar solutions. We speculate that this sensorimotor scheme—a bimanual coordination oriented on a perceptual construction—could serve as the foundation for further developing various mathematical concepts, such as function, covariation, or slope. This task elicited rich geometrical language as students explained their strategy, including reference to angles, lines, rectangles, triangles et cetera.

### **Conic sections**

It has been shown that visualization of the parabola as a vase-like curve on a surface may lead to a wrong conceptualization (Aspinwall, Shaw, & Presmeg, 1996). As an alternative Shvarts designed opportunities for individual students to experience a parabola as a locus of equidistant points (MIT-parabola, see Figure 4a–b). The solution is to move Vertex C on the screen such that it is equidistant from a straight horizontal line (Vertex B directly below Vertex C, running along the parabola's directrix) and a separate point (Vertex A, fixed on the parabola's focus). Consistent with the embodied-design principle that semiotic symbols should be absent in the initial activity (Abrahamson, 2014), only a triangle is featured on the screen during the first stage of the task (the dashed lines in Figure 4 are for illustration only and are never shown to the students). Once students had accomplished the embodied task and were ready to mathematize their solution in the form of the canonical parabola formula, the axes were introduced. Dual eye-tracking of this activity (i.e., of both the tutor and the student) revealed the traces of attentional anchors along the triangle's median. These traces appeared in the eye movements both of the students and the tutors (Shvarts & Abrahamson, 2018).

**Figure 4: (a, b) MIT-parabola; and (c–d) MIT-area. The dashed lines were not shown to the students**

Yet another task (MIT-area, see Figures 4c–d) implies another conic section, the hyperbole: The top left vertex of a rectangle on the screen was fixed, while a participant was moving the opposite vertex to change the size and form of the rectangle. The rectangle turned green if it had a particular area. The eye-movement data (blue) demonstrate a simple attentional anchor of fixating in the center of the rectangle (Figures 4c-d) while grasping the area by extrafoveal vision.

### Trigonometry

Alberto, Bakker, Van Aalst, Boon and Drijvers (submitted) designed a new task in the same genre, now for trigonometry (MIT-trig). The student slides the left-hand fingertip on the perimeter of a unit circle and the right-hand fingertip on a sine graph (Figure 5). Whenever the radian value on the circle corresponds to the  $x$ -value in the sine graph, the frame around these two objects becomes green. The student needs to keep the frame green while moving both hands. Analysis of a case-study participant indicates that she used an attentional anchor on a segment connecting the two fingers, which seemed to help her keep the two fingers at the same height. Mathematized, this came to mean that the left- and right- fingertip positions are equally “high” or “low” on the grid, thus sharing the same  $y$ -value,  $\sin(x)$ . This awareness appeared to support her bimanual coordination process of keeping green while moving.

**Figure 5: The frame is green if the radian (unit circle, left) and  $x$ -value (sine graph, right) correspond**

### A reflection on theoretically driven and empirically grounded principles

We have referred to the set of embodied tasks discussed above as exemplars of a design genre, an action-based genre of embodied design (Abrahamson, 2014). In so doing, we conceptualize a design

genre as capturing both the “why” and “how” of generating learning activities in the form of a set of principles that instantiate the theoretical presumptions concerning the process of learning (the “why”) and that guide a designer through the design process (the “how”). The embodied design framework builds on enactivist and dynamic systems theory to stipulate the creation of a goal-oriented task that calls for a sensorimotor investigation of the problem field. The design *core objective* is that students’ new knowledge will emerge in a form of sensorimotor coordination constituted as a solution for a motor problem (Bernstein, 1967), when they encounter unexpected constraints in the course of attempting to accomplish the activity task. The student’s solution to the enactment problem is a new sensorimotor coordination applied to a spontaneous construction of an attentional anchor in the perceptual field; this new perceptuomotor scheme constitutes an embodied form of mathematical knowledge underlying the task design. The motor coordination undergoes automation that frees space for mathematical reflection and cultural referencing.

As design genres evolve, theoretically driven design objectives settle as definitive and essential principles guide the process of designing new activities. At the same time, the introduction of new activities as plausible exemplars of the genre may challenge both conscious and unconscious assumptions, causing a team to rethink the principles that had been taken as definitive and essential. Wherever a resolution cannot be reached, new research questions may emerge. For example, the design dimension of *feedback*, which had not been on the fore of our agenda, drew our interest only once we realized the variable effect of feedback on attention: An abrupt change of color or contour within the visual field may attract overt attention and thus disrupt the vulnerable construction of new eye-movement patterns governing manual control. The solution in MIT-trig was to introduce a rectangular frame around the central interactive arena (Figure 5). This rectangle creates a uniform stimulus amenable to peripheral vision, thus enabling the student to retain foveal vision on the virtual manipulatives. That said, we recognize that there is much more for us and our colleagues to learn and experiment so as to optimize for design decisions along the dimension of feedback.

Another design dimension in need of further research is that of *uni-* vs. *bimanuality*. Is bimanuality an essential attribute of the genre? Our current designs entail both bi- and unimanual tasks. A simplistic assumption would be that two hands are necessary to provoke the need for new coordination. Moreover, much of mathematics is relational in nature. However it could be that coordinations are formed between manual and visual tracking of object on the screen. We are currently devising a study to investigate this problem. Thus the theory–design dialectics determining the research team’s iterative efforts contributes to the theoretical rather than empirical generalization of the activities into a design genre (Davydov, 1990).

## Conclusions

In this paper we proposed that design genres do not only allow for generalizability but also generativity. We have argued that the emerging design genre illustrated here was generative: It helped in making concrete design decisions and thus in speeding up the design process outside of the source laboratory. Note that this was also possible due to our attempts to generalize while designing: By framing any design decision as a case of a more general theoretical idea (cf. Abrahamson, 2018), we were able to identify features of the design that were important in achieving particular goals (e.g.,

development of sensorimotor action schemes that were relevant grounding for mathematical reasoning). Based on these features, new designs were developed for promoting reasoning about other mathematical topics.

As a bonus we can also highlight the notion of *generativity* in a more research-oriented sense: The innovative designs led to phenomena of learning that could hitherto not be studied, and thus led to many new research questions. Given the multimodal nature of students' observed sensorimotor behaviors, we were urged to draw on multidisciplinary bodies of literature, including sports and kinesiology, such as the construct of an attentional anchor developed by Hutto and Sánchez-García (2015). Throughout, we have debated what counts as mathematical activity. If students coordinate two hands in a way that we consider mathematically relevant, in what sense does this capacity constitute a precursor to conceptual understanding? Would the sensorimotor experience enable them to evoke the meaning of particular mathematical signs and reason through relevant problems? What design features help to promote reflection and argumentation? Is there any evidence that students re-use the sensorimotor schemes that have proved useful in earlier tasks?

The design-research approach to develop theory by design has generated methodological contributions, too, for example dual eye-tracking, by which we can now investigate student–student or student–tutor joint attention. Such research settings, where people collaboratively develop new sensorimotor action schemes, open up new areas of multidisciplinary research that accounts for intersubjective multimodal coordination processes (Shvarts & Abrahamson, 2018). Contemporary educational theory appears to lack powerful conceptual and methodological frameworks for studying these processes. It is hence also at this level of motivating and developing new research programs that, we believe, design genres can be generative.

Aforementioned types of generativity may also impact educational practice. We speculate that the learning of many mathematical topics across the curriculum (function, covariation, etc.) can be supported by activities in the same design genre. When students recognize a new task as related to a previous task, the instrumentation phase could be more efficient. Finally, we expect that evidence of design genre's generativity for design, theory, and methods will make design research more appealing to researchers, educators, and policymakers.

## Acknowledgment

We thank Rosa Alberto for interesting conversations about the prospects of interspersing mainstream mathematical curriculum with embodied action-based learning activities.

# Theory, methodology and design as an insightful bundle: a case of dual eye-tracking student-tutor collaboration on an embodied mathematical task

Anna Shvarts

Utrecht University, the Netherlands; [a.y.shvarts@uu.nl](mailto:a.y.shvarts@uu.nl)

*Keywords: Eye movements, research methodology, epistemology.*

While the importance of reflection on methodological dimension for the networking theories was already stated (e.g. Bikner-Ahsbals & Prediger 2014), here we claim that educational design is another essential dimension in distinguishing a phenomenon that might be unattainable as far as it has not been lit by a particular theory-methodology-design bundle. In this poster, we explore a bundle of a culture-historical approach, dual eye-tracking (DUET) method, and action-based interactive design; we argue that these three aspects being taken together form a lens that manifests in the teaching/learning process a *perception-action system* that is *distributed* between the tutor and student. The argument is based on multimodal data from student-tutor collaboration on interactive activity, where a student was required to discover a parabola in an embodied way as a set of points equidistant from the focus and directrix (Shvarts & Abrahamson, 2018).

**Theory-methodology coupling.** A culture-historical approach provides us both with the theory and methodology for investigating the psyche's development, and yet they are interconnected. Vygotsky proposes an "experimental-genetic method" that aims to restore the development process and to expose the higher psychic functions in the form of moving, "flowing flood" (Vygotsky, 1978). This method involves the active participation of a researcher in interaction with a pupil that, unlikely to natural science, do not distort the data, but on the contrary allow the genesis of mathematical functions to emerge. A theoretical presumption here is the social nature of psychological functions that emerge in intersubjective interactions. In our study, an experimenter interacts with the student as a tutor, and later interaction is reproduced between the just-instructed participant and a new pupil. DUET appears to be a perfect way to investigate this collaboration: while often eye-movements are interpreted with the presumption of the *eye-mind hypothesis*, the data from DUET might be perceived as evidence of a psychic function as distributed between a student and a tutor. Then *joint attention* is not a result of initiation or response by single participants, but a functional end that emerges from "the multiple pathways" (Yu & Smith, 2016, p. 18) within their system.

**Theory-design coupling.** Traditionally from Vygotsky's point of view, communication between a student and a teacher is considered as mediated by some cultural artifacts, signs. However, Roth argues that in his late writing Vygotsky departs from the mediation as a primary mechanism that serves communication (Roth, 2018). This embodied character of collaboration is particularly accessible in an activity which is deliberately designed so that introduction of mathematical notations is postponed to the moment when a student has experienced mathematical concepts in an embodied way (Abrahamson, Shayan, Bakker, & van der Schaaf, 2015). The involvement of a student and a tutor in a motor problem that required formation of a new sensory-motor coordination allowed us to trace this function as socially distributed.

**Method-design coupling.** As eye-tracking let us observe oculomotor spatially articulated activity, we shall involve the participants in the design that benefits from an eye-tracking observation. The embodied action-based design is particularly suitable as it provides an opportunity for the learner to elaborate mathematical knowledge at first in the form of sensory-motor coordination. It is through eye-tracking we may gather empirical evidence of *attentional anchors* — the perceptual aspects of sensory-motor coordination that serves the efficiency of movement (Abrahamson et al., 2015).

**Theory-methodology-design bundle.** A combination of all three couplings let some phenomena surface; we present the one phenomenon that seems to be of great importance for educational science. While the students' eye-movements manifested emerging *attentional anchors*, the same was found in the tutors' oculomotor behavior, whether they were a researcher or an instructed participant. Thus, we obtained evidence of embodied coupling between the student and tutor: The tutor's perception is *as if* it regulates the student's action. While de facto it is the student who conducts the movements, the tutor enacts these movements in their imagination thus anticipating student's progress in learning and sensing her *micro-zone of proximal development*. This coordination between student's action and tutor's perception allows us introducing *intersubjectively distributed perception-action system* that evolves in the teaching/learning process.

Shall this be a local phenomenon of particular activity under the particular lens? We argue that this theory-methodology-design bundle does not limit generalization of the findings: The phenomenon of an intersubjectively distributed perception-action system is made spatially articulated due to the design settings, visible through dual eye-tracking methodology and understood under the light of Vygotsky's theory of irreducibly collaborative teaching/learning. Finally, it becomes influential far beyond particular experimental settings just like the phenomenon of diffraction of light and its dual wave-particle nature goes far beyond the settings in which it was spotted.

*This paper explores new developments in affect theory for studying the circulation of affect across mathematics classrooms. We use Maxine Sheets-Johnstone's term "affectivity" to characterize the responsive nature of bodies and the potential scaling-up through sympathy and coordinated movement. We examine cooperative classroom tasks that entail sympathetic coordinated movements, including diverse kinds of often imperceptible body movement (gesture, face, eye, foot, etc.). We discuss how mathematical concepts are assembled through the affective bonds that form when students participate in these tasks. Our methodology is notable for how it bridges three scales: (1) the micro-phenomenological scale of the pre-individual affect, (2) the individual scale of human movement, and (3) the transindividual scale of collective endeavour (the making of a concept).*

**Keywords:** Affect, sympathy, collaborative tasks, movement, materiality.

### Introduction

Research into the various ways that the human body factors in mathematics education has recently expanded, as new theoretical developments and innovative experimental methods have introduced significant insights about the material dimensions of teaching and learning. Some have criticized this work for how it downplays the role of the environment more broadly, while others have expressed concerns that, even as it attends more carefully to the role of the body in teaching and learning, it seems to support a mind/body split, with continued emphasis on individual cognition rather than collective and distributed learning experiences. These concerns are linked to the methodological use of design experiments that are all too often narrowly focused on individual experience. This narrow focus on the individual is particularly pronounced when we turn to research on the role of affect in mathematics education, which has typically focused on the relationship between beliefs, attitudes and emotions within individual bodies (McLeod & Adams, 1989; Zan et al., 2006).

The socio-cultural turn tried to correct this narrow focus and looked to emotions as socially organised phenomena that are constituted in discourse and shaped by relations of power, but this approach tends to lose sight of the specific practices entailed in mathematical behaviour. Moreover, most socio-cultural studies of the emotional dimension of mathematics continue to assign particular emotions to particular students, who show frustration or anxiety or joy, as they encounter the socio-cultural rituals of school mathematics (Radford, 2015). Such an approach remains focused on the individual, rather than the affective ecology, and tends to black-box the mathematics. More recent attempts to move from beliefs to "affective systems" show promise in their attempt to study *ensembles* of emotions, feelings, attitudes, beliefs, and conceptions (Philippou & Christou, 2002),

and in their recognition that affect is dynamic and variable in intensity (Pepin & Roesken-Winter, 2015). And yet we find the research therein continues to methodologically emphasize expressions of belief and value, through reliance on conventional research methods, such as interviews and self-reporting, without actually operationalizing key ideas from systems theory (Varela & Depraz, 2005) and without tapping the extensive work outside of psychology on affective networks (Massumi, 2015). Moreover, attending to the dynamics of emotional or motivational states in a classroom or other learning community are still rare (Hannula, 2012).

In this paper we pursue a theory of affect that better helps us follow the *movement* of affect across learning events with multiple and diverse participants, in such a way that the mathematics itself is imbricated within the process. This involves delving deeper into the affective nature of mathematical practices which are lived in and through material practices. For that purpose, we turn to recent work on affect in the humanities. Since the 2000s, scholars across the humanities have pursued what is known as the *affective turn* (Clough & Haley, 2007; Gregg & Seigworth, 2010). Shifting away from psychological approaches that focus on affect as individual judgements of value (like, dislike, happy, unhappy), this new approach aims to study the *collectively dispersed nature of affect across a material ecology* (Gregg & Seigworth, 2010). In particular, we follow Massumi (2015) and Sheets-Johnstone (2009, 2011) in studying affect and emotion less as that which is produced and possessed by a psychological subject, and more as an impersonal intensive flow across relational and provisional learning assemblages. We use the term ‘learning assemblage’ to designate the way learning is achieved through affective resonances and the assembling of diverse agencies. The challenge is then to develop research methods that lend themselves to the study of complex ecologies of material-mathematical practices.

Our approach is significant for how it moves away from the individualistic theories of cognitive psychology towards a renewed interest in (1) the somatic and embodied expressions of affect, as bodily organic forces rather than ideational enactments of interior states and (2) the transindividual collective nature of circulating affect. The flow of affect contracts and expands across an event, recruiting our bodies and participation to varying degrees, where affect is itself a kind of pre-conscious micro-movement. The notion of “degree” is crucial here, as it underscores how affect can be contracted in one body and not another with varying intensity. This approach studies classrooms as dynamic affective ecologies and tracks the way that learning rests fundamentally on somatic and unconscious ways of moving together. Concepts emerge and settle in such an environment as a function of sympathy (de Freitas, 2018). We believe that sympathy is the seed of learning because it affords opportunities for collaborative inventive practices. We emphasize this point, because it helps open up discussion of how achievements in classrooms are truly collective insofar as they are *done through us (and not by us)*. This directs attention to the collective nature of learning.

In this paper we discuss briefly a teaching experiment to show how mathematical concepts can be coordinated through affect and sympathetic relations. In particular, we focus on the coordinated movements of two girls in a grade nine classroom, Barbara and Lucrezia, while they are working on a specific task. We track the way that the task brought forth opportunities for these two girls to develop new forms of relationality in their shared achievement, and that their coordinated

movements are directly linked to the complex set of differentials and gradients that comprise the circle concept under study. The methodology involved a teaching experiment that *primed the classroom* so that the circle concept could only be achieved through a coordination of different kinds of movement. In other words, the mathematical task demanded a sympathetic coordination between students. Our initial video analysis focused on the verbal and the gestural. A second analysis focused on micro-movements (head orientation, facial expression, rhythm and speed of coordination) which involved new coding methods that were then combined with field notes from classroom observation. Although not adequate space here to present our methods in detail, we discuss briefly how the data can be analysed in terms of affective ecologies (for more see de Freitas, Ferrara, & Ferrari, 2018).

### Theoretical framework for multi-scale analysis

The words emotion and affect are commonly used together, not always with too much care for their different meanings. Here, we draw on the work of Maxine Sheets-Johnstone (2009, 2011), to help distinguish these terms, and to build a theory of affectivity that lends itself to an analysis of pre-individual and trans-individual activity. Sheets-Johnstone is at pains to show how emotions are not only “coping mechanisms” that evaluate or appraise or cope with the sudden break-down of rational discernment. She describes *affectivity* as the fundamental “responsivity” of life, drawing on a long line of phenomenology. Affectivity characterizes the way bodily activity is implicated in collective feelings (common sensibility) but also in pre-conscious sensibility. Affectivity thus characterizes the responsive pre-conscious nature of bodies, how they turn away or lean in, and at the same time how they join with other bodies in coordinated movements. For Sheets-Johnstone, there is a congruency between affect and bodily motion, precisely because affect is lived through bodily movement. In other words, the dynamics of feelings (of comfort, agony, excitement, ...) coincide with micro-facial expression, minute changes in bodily posture, foot-tapping rhythms, changes in heart rate, etc. She posits that “the affective and the kinetic are clearly dynamically congruent; emotion and movement coincide” (Sheets-Johnstone, 2009, p. 377). For Sheets-Johnstone, emotions are not enacted, but *emerge in movement*. She critiques the term ‘enaction’ because it continues to posit an interior state that is then enacted.

And yet we note that delight, grief, remorse, etc, all move different bodies in different ways, and that one needs to reckon with that essential heterogeneity in the emotional landscape. We therefore need to extend her work to better address this heterogeneity in experience. Our theoretical approach aims to attend to the important *tensions* and indeed corporeal *incongruencies* sustained in collective endeavours. We turn to the concept of *sympathy* to better understand how distinctive and disparate movements inform the affective dimensions of learning. The word sympathy comes from ancient Greek (*sumpátheia*) and refers to the state of *feeling together*, derived from a composite of *fellow* and *feeling* (Schliesser, 2015). Sympathy is a complex concept with a complex history. Over the centuries, the notion of sympathy has been used to describe all sorts of activity—everything from contagious yawn catching to cosmological harmony (Brouwer, 2015). In the 19<sup>th</sup> century, work in physiology defined sympathy as the “action of sensation, the coordination of organs in the body, and the ‘social principle’ that allows ‘fellow-feeling’ to emerge in a society.” (Forget, 2003, pp.

291–292). Sympathy involves an association achieved through imagination and reason (body-mind), as well as an ethical or perhaps normative action to modify one's own actions so as to *feel with* the other. Importantly, there is no uni-directional sympathy—there is always at least two different agencies engaged. Sympathy is a kind of *agreement* between bodies, when they are mutually affected by each other and sustain a tension. We caution that such agreement is not erasure of otherness, as is often the case with appeals to empathy (Schliesser, 2015). Sympathy is “something to be reckoned with, a bodily struggle”; not a matter of identification or ‘putting oneself in the other’s shoes’ but a matter of modulating related movements—a process of *becoming other that does not erase the other* (Deleuze & Parnet, 2007, p. 53). A sympathetic coordination is not a bland alignment, nor an identification amongst parts, nor the creation of a unified homogeneous assemblage, but rather describes the assembling of heterogeneous agencies and powers. For the purposes of this paper, we suggest that sympathy involves (1) a *contagion* of feeling, (2) a *common sense* or shared sensibility, and (3) a *compassion* for the other. Below we discuss how affectivity and sympathy can help us theorize the ways that mathematical concepts are lived through embodied encounters. Our theoretical approach is meant to bring many scales together – the pre-individual affect, the individual body, the transindividual collaboration of the two girls, and finally the fanning out of affect across the whole class.

## Participants and video data

The teaching experiment involved WiiGraph technology, an interactive software application that uses Wii remotes’ multiple features to detect and graphically display the location of two users (*a, b*) as they move along life-size number lines (Nemirovsky, Bryant, & Meloney, 2012). The experiment took place in a secondary school in Northern Italy, as part of a wider study carried out during regular mathematics lessons. The study involved a class of 30 grade 9 students (aged 15–16) in activities aimed at introducing the concept of function through a graphical approach using digital technology. In this excerpt, the students (Lucrezia and Barbara) move the Wii remotes in order to create a circle graph on a screen. WiiGraph assembles the girls’ collective movement as the partial derivatives of the circle. In other words, as they move their bodies, the graph captures their instantaneous speeds  $db/dt$  and  $da/dt$ . The girls’ speeds must be different but coordinated for the combined effect to compose a circle. The two Wii remotes must be moved with a rhythmic pattern, and indeed at related rates of changing speed, in order to achieve the effect. The movement is thus directly linked to the mathematical relationships. We focus here on how affect circulates across minute movements as the two girls coordinate their activity to explore the circle concept. There is ample evidence of disagreement (shrugging shoulders and shaking heads) as they discuss their strategy, and indeed these tensions are the important friction that sustains a sympathetic coordination. We see that the learning assemblage evolves through these tensions, when sympathy becomes a bodily struggle. A relationship of response-ability emerges through sympathetic coordinated movement. In the transcript below, R is the researcher (second author), while L and B indicate the two girls.

<p>L: More or less like this</p> <p>B: We get a thing of this kind, maybe (<i>B tilts her head, raises her eyebrow as she raises her hand, twists her torso and smiles</i>) (1)</p> <p><i>L and B both look at the screen</i></p> <p>L: For me, no... (<i>L giggles</i>)</p> <p>B: Let's try</p> <p>L: ... cuz, when you were here, I was here (<i>by crossing arms, points to the two extremes</i>) (2) (<i>L emphasizes their difference, then slouches and shrugs a little</i>)</p>	 <table border="1" data-bbox="1086 539 1390 600"> <tr> <td>1</td><td>2</td></tr> </table>	1	2		
1	2				
<p>B: Hm hm, a little more. You've to be here, like this, pock (<i>B questions L's account, and further models for L, now using her two separate hands to mimic both her and L's movements. "Pock" marks the point when the second hand reaches the maximum distance</i>) (3-4)</p> <p>L: But if you go fast (<i>L raises pitch, as though sceptical, but with humour. Then shakes her head, and offers mocking smile</i>)</p> <p>B: Well, fast, it's up to us (<i>B shrugs a little, slows slightly, but continues to move both hands to-fro</i>) (5-6)</p>	 <table border="1" data-bbox="1086 936 1390 996"> <tr> <td>3</td><td>4</td></tr> </table>  <table border="1" data-bbox="1086 1191 1390 1252"> <tr> <td>5</td><td>6</td></tr> </table>	3	4	5	6
3	4				
5	6				
<p>R: Can you tell me (<i>the two girls both turn towards R</i>), excuse me, please, tell us what you've decided to do, what you're deciding to do</p>					
<p>B: We're thinking that, because she's in front of me, we stand like this, kind of, if I start here, she starts (<i>B points with the other hand to a middle position. She uses confident voice and L nods approvingly</i>) (7, 8), I start here, she starts like this, when I will arrive here, she will follow me (<i>performs again a back and forth movement with L</i>) (9), a little, she will be there when I will be here (10)</p> <p>L: While she goes backward (<i>L interjects, and nods, looking at R</i>)</p>	 <table border="1" data-bbox="1086 1554 1390 1615"> <tr> <td>7</td><td>8</td></tr> </table>  <table border="1" data-bbox="1086 1809 1390 1870"> <tr> <td>9</td><td>10</td></tr> </table>	7	8	9	10
7	8				
9	10				
<p>R: Will the speed at which you move matter?</p> <p>L: Yes, yes (<i>L confidently nods repeatedly</i>)</p>					

B:	We have to move at the same distance, at the same speed, and at a constant speed
<i>L begins nodding in agreement, but interjects as though to correct B</i>	
L:	With the same rhythm, but she starts before, and I follow her ( <i>L reaches her hand out and flaps the air between the two girls as she speaks</i> )
B:	We decide the speed, but we have to move at the same speed and at a constant speed between us ( <i>B is incorrect in this claim</i> ). <i>L begins by nodding, then shakes her head a little, indicating some mixture of dis/agreement, but says nothing</i>

Table 1: B and L's discussion about how to make a circle

## Data analysis and discussion

In the beginning of the project, Barbara was reluctant to take part in group work: she expressed herself in long meandering statements that often confused her class mates. In the process of the teaching experiment, we noticed a serious change in Barbara's position and relationality within the class, although some students continued to dismiss her contributions. Lucrezia, in contrast, was initially silent and timid in class. She also experienced a change in her way of engaging in collective discussions, becoming more willing to intervene and express her opinion, as the experiment unfolded. The two girls came forward to join the collaborative effort of creating a circle, despite their very different ways of being in the class. We can see the way that the productive intensity of the task comes from the various contrasts or tensions that are entailed—there are two girls, each with their own life history; two orthogonal directions to be performed; two very different movements to produce the one graph. Sympathy is the coming together of these contrasts, not so one obliterates the other, but instead as an onto-creative act in which new joint learning comes forth.

The graph of the circle (eventually achieved) is a truly collaborative effect, *a doing done through the individuals (rather than by the individuals)*. The circle is made through Lucrezia and Barbara, an achievement that emerges between the cooperating agencies. This is a task that demands all three components of a sympathetic relation: (1) there is a circulation of feeling as minute facial expressions and changes in bodily posture occur, the two girls leaning in and out, attending to the micro-scale corporeal signals that circulate beneath consciousness; (2) there is a common sense or shared sensibility in the shared obligation to follow each other and work with a shared objective (the circle concept); (3) there is the compassion for the other, and the care of ensuring that others are coming along, moderating the tensions that sustain any learning assemblage. Barbara and Lucrezia are both individually eager to achieve the circle, but all too aware that this achievement depends entirely on coordinating with the independent movements of the other.

The two girls are together determined to make a circle, and there is a shared intensity while the power to lead shifts back and forth. And yet such moving-together and power-switching is successful precisely because the two girls are coordinating at the pre-individual scale of micro gestures and *petites perceptions*. The task itself has created an opportunity for shared affect and transindividual sympathy. The flow of affect recruits other student bodies by varying degrees, when the class “oohs” and “aahs” and someone says “beautiful” as the periodic functions are shown

alongside the circles. We hear the affective tone of these responses, and can track the rippling effect across the class, as the emotion fans out. Other student bodies shift in their seats, lean in and squint, as evidence of a sympathetic investment in the collective endeavour. As Massumi (2015) claims, sympathy “can reverberate across a relational field, faster than the field of conscious calculation.” (p. 84). For him, this is how the micro ethnographic scale reverberates out to other scales: “it is a defining characteristic of complex environments that the extremes of scale are sensitive to each other, attuned to each other’s modulations. This is what makes them oscillatory. They can perturb each other” (p. 10). Affectivity can “channel” through the individual body, reverberating out to the larger scales. *The pre-individual scale of affect can be studied for how it fuels an enveloping social-emotional space in the classroom.*

## Conclusion

We stress here that the dynamic movement buried in the mathematical concept is significant. This teaching experiment helps the students grasp the many different ways in which related movements are at work in the apparently fixed and familiar figure of the circle, deepening their understanding of the geometric concept. Thus, the task itself reveals how the affective bonds of coordinated movement are inherent to the circle concept. The task itself demands that the students form assemblages in ways that are productive of collaboratively and responsibly learning together. In this case, the bodily agreement or coordination produces rich mathematical thinking—an assembling of gradients and directions that speaks directly to the circle concept and the associated periodic functions. As the students act, they also perceive these graphs on the screen. This expanded sensitivity points to the complex entanglement of affect and concept, demonstrating how innovative technologies add to our understanding of fundamental aspects of mathematics learning. The amorphous concept of circle is implicated in mathematical activity in different ways, distinctively inflected by the flow of affect between Barbara and Lucrezia. Similarly, other mathematical concepts, if considered as dynamic and variable, are embodied in different material practices (de Freitas & Ferrara, 2015; de Freitas & Sinclair, 2017). Rather than reduce all experiences of mathematics to the same emotional note, our approach attends to the nuanced or tonal differences between one experience and another. Our aim is to attend to the specific and dynamic configuration of affect that *is* mathematics in all its multiplicity.

*To theorize the study of students' transfer of mathematical reasoning, we integrate Lobato's theory of actor-oriented transfer, Thompson's theory of quantitative reasoning, and Marton's variation theory. Linking theory and method, we argue for an expansion of design possibilities for researchers' investigations of students' transfer of reasoning. To bolster our argument, we provide empirical data of a secondary student's transfer of a particular form of reasoning—covariational reasoning. Our research has implications for researchers' development of new theoretical and methodological approaches to investigate complex phenomena, such as students' mathematical reasoning.*

*Keywords: Transfer of learning, reasoning, learning theories, instructional design,*

Investigating students' transfer of mathematical reasoning is a complex, multifaceted endeavor. We identify three key elements of this endeavor. The first two elements focus on students' perspectives: students' engagement in mathematical reasoning and students' transfer of their mathematical reasoning. The third element focuses on researchers' design of mathematical task sequences to engender students' mathematical reasoning. We view these elements to be interconnected, and in our theorizing of these elements, we work to address this interconnectedness.

Networking theories can take a variety of forms, depending on the degree of connections between and among theories, as well as researchers' goals with connecting theories (Bikner-Ahsbabs & Prediger, 2010). We are working to locally integrate theories (Bikner-Ahsbabs & Prediger, 2010), in which we extend beyond combining or coordinating theories to explain empirical phenomena, to building new theories. Specifically, we integrate Lobato's (2003) theory of actor-oriented transfer, Thompson's (2011) theory of quantitative reasoning, and Marton's (2015) variation theory to theorize our study of students' transfer of a particular form of reasoning—covariational reasoning.

We aim to extend possibilities for researchers to investigate students' transfer. We argue that researchers can investigate students' transfer of mathematical reasoning by research designs other than pre- and post-tasks. To provide backing for our argument, we share empirical data of a secondary student's transfer of a particular form of reasoning—covariational reasoning (Thompson & Carlson, 2017). We address implications for researchers' development of new theoretical and methodological approaches to investigate complex phenomena, such as students' mathematical reasoning.

## Integrating theories to investigate students' transfer of covariational reasoning

Task designers, teachers, and researchers share a goal of promoting students' mathematical reasoning. While mathematical reasoning comprises students' mental activity, in our view, it is impossible to

separate students' mental activity from their embodied experiences (English, 2013). Interacting with mathematical tasks can provide students opportunities to engage in mathematical reasoning. By mathematical task, we mean something more than a problem statement. From our perspective, tasks encompass the intentions of a task designer, the implementation of a task by a teacher/researcher, students' interaction with the task, and physical materials associated with the task (Johnson, Coles, & Clarke, 2017). Ideally, when students develop a form of mathematical reasoning, they could engage in that form of reasoning on subsequent tasks and in different situations.

We aim to infer students' reasoning based on their observable behavior. In our view, students are experts in their own mathematical reasoning, and our role is to elicit and explain that reasoning. Our stance on students' reasoning influences our assumptions about the viability of their reasoning. First, we do not assume that students working on a task will share our goals for the task (e.g., Johnson, Coles, & Clarke, 2017). Second, we acknowledge that students may engage in mathematical reasoning that is different from the reasoning we intend. Third, we assume students' different forms of reasoning to be viable and productive. Hence, we do not seek to "fix" students' reasoning. Rather, we seek to understand and engender students' mathematical reasoning, in its myriad forms.

Employing a transfer lens, researchers can investigate how students might engage in different forms of mathematical reasoning across a range of tasks and situations. Yet, researchers' perspectives on transfer impact what researchers may construe as evidence of students' transfer of reasoning (Lobato, 2003; 2014; Marton, 2006). To address the problem of investigating transfer of students' reasoning, we employ an actor-oriented transfer perspective (Lobato, 2003; 2014), because it affords researchers the opportunity to gather evidence of transfer of reasoning beyond forms of reasoning that a researcher may intend.

From an actor-oriented transfer perspective, transfer is generalization, rather than application (Lobato, 2003; 2014). Meaning, students who generalize some form of reasoning from one task to another would engage in transfer, even if they do not apply a particular solution method. Hence, an actor-oriented transfer perspective broadens the scope of what is possible for students to transfer. Furthermore, a researcher's theoretical perspective on transfer impacts methods used to gather evidence of students' transfer. Researchers employing an actor-oriented transfer perspective examine students' constructions of similarities across tasks, rather than students' task performance (Lobato, 2003; 2014). Because students' mathematical reasoning is not the same as task performance, an actor-oriented transfer perspective is a productive theoretical lens to use to investigate students' reasoning.

We focus on students' engagement in and transfer of a particular form of reasoning—covariational reasoning—which is critical for students' development of a conception of function (Thompson and Carlson, 2017). We draw on Thompson's theory of quantitative reasoning (Thompson, 2011; Thompson & Carlson, 2017) to explain our perspective on covariational reasoning. When students engage in covariational reasoning, they form and interpret relationships between attributes they conceive of as capable of varying and possible to measure. For example, consider a situation involving a toy car moving around a track. A student engaging in covariational reasoning could form and interpret relationships between different attributes, such as the toy car's distance traveled around the track and its distance from some stationary object. Because an actor-oriented transfer perspective

focuses on students' generalization rather than performance, it is a useful theoretical lens to explain invariance in students' engagement in quantitative (and covariational) reasoning across tasks and situations (Thompson, 2011).

Researchers employing a variation theory perspective (Kullberg, Kempe, & Marton, 2017; Marton, 2006; 2015) consider critical aspects of objects of learning (intended objects of learning), problematize ways in which to provide students opportunities to experience those critical aspects (enacted objects of learning), and acknowledge the viability of learning that students actually demonstrate (lived objects of learning). Although we focus on a particular form of reasoning—covariational reasoning—we acknowledge that students may engage in or transfer forms of reasoning other than what we intend. From a variation theory perspective, students discern the similar (and generalize) because they discern difference, and consequently, designers should design opportunities for students to experience difference. Simply put, variation (in terms of difference) is a necessary condition for students to experience discernment.

Networking theories is useful for addressing complexities inherent in investigations of students' mathematical reasoning. For example, our investigation of students' transfer of covariational reasoning is intertwined with students' creation and interpretation of dynamic graphs in a Cartesian coordinate system. Drawing on Variation Theory, we considered critical aspects to include the types of attributes that students would encounter (e.g., length measures), the motion of objects in physical space (e.g., up/down, left/right, curving paths), and the representation of those attributes in a Cartesian coordinate system. Accordingly, we varied those critical aspects to provide opportunities for students to engage in covariational reasoning.

Networking (coordinating) Thompson's theory of quantitative reasoning and Marton's variation theory of learning, Johnson, McClintock, Hornbein, Gardner, and Grieser (2017) explained how researchers could design learning experiences to engender students' discernment of critical aspects of covariation. We extend this research in two ways. First, we connect the investigation of students' transfer of reasoning, employing an actor-oriented transfer perspective on transfer. Second, we build from coordinating theories to locally integrating theories, to contribute to theory development.

### **Extending design possibilities for actor-oriented transfer**

Lobato (2014) identified four criteria on which researchers should base claims of actor-oriented transfer. We summarize these claims, centering students' mathematical reasoning, which is our focus. First, students should demonstrate a change in reasoning on transfer tasks, from a pre-interview to a post-interview. Second, students should demonstrate the new reasoning during interview tasks occurring between the pre- and post-interviews. Third, researchers should provide evidence that students' reasoning during the interview tasks influenced their reasoning on the post-interview tasks. Fourth, researchers should provide evidence that changes in students' reasoning in a post-interview occurred as a result of their work on the interview tasks, and was not just a spontaneous occurrence.

We posit an extension of design possibilities for researchers employing an actor-oriented transfer perspective. From our perspective, inherent in Lobato's (2014) design criteria is an assumption that researchers design transfer tasks that are separate from interview tasks. We argue that by leveraging Variation Theory in task design, researchers can investigate students' transfer by analyzing students'

reasoning on subsequent tasks across a set of interviews. In making this argument, we follow Cobb's (2007) recommendation for theory expansion rather than replacement. In particular, we aim to expand design possibilities, rather than to replace one design type with another design type.

### **An empirical example: A task sequence and a student's work**

To illustrate how we locally integrated theories, we provide an example from the work of a 9<sup>th</sup> grade student, Aisha, during three individual, task-based interviews, conducted by Johnson. Task sequences in each interview had a different background (first a Ferris Wheel, second a Cannon Man, and finally a Toy Car), given by a computer animation. Aisha worked on a tablet (an iPad), with pencil and paper available. In each task sequence, Aisha sketched and/or interpreted different Cartesian graphs to represent a relationship between attributes in a situation given in an animation.

The Cannon Man and Toy Car task sequences were more involved than the Ferris Wheel task sequence. For the Ferris Wheel, Aisha needed to sketch only one graph. For the Cannon Man and Toy Car, Aisha explored change in individual attributes, manipulating dynamic segments located on the horizontal and vertical axes. Next, Aisha sketched a graph representing a relationship between both attributes. Then, Aisha repeated the process for a second graph with attributes represented on different axes. After sketching each graph, Aisha viewed a computer-generated graph. Transcripts that follow are from each interview. Figure 1 shows graphs that Aisha drew in each interview. The Cannon Man and Toy Car graphs shown in Figure 1 (middle, right) are the second Cartesian graph that Aisha drew during each interview.

**Figure 1: Aisha's Ferris Wheel, Cannon Man, and Toy Car graphs, respectively**

#### **Ferris Wheel**

Johnson asked Aisha to sketch a graph relating a Ferris wheel cart's height from the ground and total distance traveled, around one revolution of the Ferris wheel. While sketching the graph shown in Figure 1, left, Aisha explained why she drew the graph the way that she did.

Aisha: I feel like the height would be more like the line (sketches a line, Figure 1, left). Distance would be more like the rise and run of the situation (sketches small segments, Figure 1, left). Cause you're using the rise and run to find the line, and you need to use the distance to find the height.

#### **Cannon Man**

Johnson asked Aisha to sketch a graph relating a Cannon Man's height from the ground and total distance traveled, with the height on the horizontal axis and the distance on the vertical axis. After

Aisha sketched the graph shown in Figure 1, middle, Johnson asked her to explain how her graph showed Cannon Man's height and distance.

Johnson: Can you show me how you see the height increasing and decreasing in this purple graph? (Points to the curved graph Aisha drew, Figure 1, middle)

Aisha: It's (the height's) increasing here, since it's (the graph's) backwards in my opinion (Sketches green dots, beginning on bottom left near the vertical axis, then moving outward, Figure 1, middle). Decreasing here. (Continues to sketch green dots, until getting close to the vertical axis, adding arrows after sketching dots, Figure 1, middle)

Johnson: How is the distance changing?

Aisha: (Turns iPad so that vertical axis is horizontal. Draws arrow parallel to vertical axis, Figure 1, middle.) That way. Continues to get bigger.

### **Toy Car**

Prior to sketching the graph shown in Figure 1, right, Aisha stated, without prompting from Johnson, that distance traveled was the "same as the Cannon Man." Johnson asked Aisha to clarify.

Johnson: So, you said the total distance traveled is like the Cannon Man. Why is that like the Cannon Man again? Cause Cannon Man goes up and down, and this one moves around. How are those things the same?

Aisha: Just because Cannon Man is coming back down, doesn't mean his distance is going down. His distance is still rising.

To explore change in each of the individual attributes, Aisha manipulated dynamic segments located on the horizontal and vertical axes. For the total distance, Aisha began at the origin, continually moving the segment up, along the vertical axis. She explained: "I moved it up. It continuously went up, because the distance doesn't decrease. The total distance traveled doesn't decrease." For the distance from the shrub, Aisha began to the right of the origin, initially moving the segment to the left, and then to the right. She explained: "I moved it (the segment) to the left, because it (the Toy Car) was getting closer to the shrub. Then, when it (the Toy Car) started to turn, I started to moved it (the segment) back up to the right, because it (the Toy Car) was getting closer to the shrub." Next, Aisha sketched the graph shown in Figure 1, right. After viewing the computer-generated graph, Aisha explained what she thought the curved graph represented. Aisha stated: "This (moving her finger from left to right along the horizontal axis) is tracking the distance from the shrub, and this (moving her finger along the curved graph, beginning near the horizontal axis) is also tracking the distance."

### **Employing individual theories as analytic lenses**

We explain how we draw on individual theories to analyze Aisha's transfer of covariational reasoning. While we present the accounts separately, we conceive of these accounts as something more than complementary. In our view, each theoretical lens is like one of the intertwined strands of a braid or cord.

### **Thompson's theory of quantitative reasoning**

In our task design, we made strategic choices about the kinds of attributes that students would represent in graphs. In particular, we selected length attributes (e.g., height, distance) because we anticipated it would be less difficult for students to conceive of measuring length attributes than for other kinds of attributes, such as area or volume. During clinical interviews, Johnson asked students to represent ways in which individual attributes were varying (e.g., increasing and/or decreasing), and to explain how graphs they sketched represented different attributes.

For the Cannon Man and Toy Car, Aisha provided evidence of engaging in an early form of covariational reasoning. In contrast, for the Ferris wheel, Aisha attempted to show how one might obtain one value given another value. For the Cannon Man and Toy Car, Aisha conceived of both attributes as possible to measure and capable of varying. Her graphs (Figure 1, middle, right) represented both attributes, one varying in a single direction (increasing), and another varying in different directions (increasing and decreasing).

### **Marton's Variation Theory**

For the Cannon Man and Toy Car task sequences, we incorporated patterns of variation and invariance to provide opportunities for Aisha to discern critical aspects of covariation (intended object of learning). First, Aisha could vary each attribute individually, then both attributes together. Second, Aisha repeated the process for a new Cartesian graph with the same attributes represented on different axes. We designed each of the first two elements against a background of invariance (e.g., the Cannon Man). Next, we repeated the first two elements against a new background (e.g., the Toy Car). When creating a new background, we varied different elements while keeping other elements the same. In particular, we varied the motion of the object (e.g., the Toy Car moved in a curved line; Cannon Man moved up and down), while keeping the kinds of attributes (length measures) invariant.

When Aisha interacted with the Cannon Man task sequence, she discerned differences between the motion of the Cannon Man (up/down) and the total distance traveled (enacted object of learning). After interacting with both the Cannon Man and Toy Car task sequences, Aisha discerned that the differences in the motion of the Cannon Man and the Toy Car did not impact the total distance traveled, which still increased in both situations (lived object of learning). We argue that the opportunity to experience difference in the motion of objects for the Cannon Man and Toy Car contributed, in part, to Aisha's transfer of covariational reasoning.

### **Lobato's theory of actor-oriented transfer**

We adapted Lobato's (2014) criteria to align with Aisha's work during the task sequence we reported. We analyzed for evidence of the following: (1) Aisha's change in reasoning from the first interview (Ferris Wheel) to the third interview (Toy Car); (2) Aisha's engagement in covariational reasoning during the second interview; (3) Influence of Aisha's reasoning during the second interview on her reasoning during the third interview; and (4) Attribution of Aisha's changed reasoning to the interview tasks, rather than to a spontaneous occurrence.

For the Ferris Wheel, Aisha provided evidence that she was doing something other than engaging in covariational reasoning (1). We interpret that Aisha was conceiving of how she might use a formula

or rule to determine one amount (height), given another amount (distance). For the Cannon Man, Aisha demonstrated evidence of engaging in covariational reasoning (2). Rather than attempting to show how one might obtain one value given another value, she conceived of both attributes as possible to measure and capable of varying. Aisha's explanations provide evidence of how she construed similarities in an attribute (total distance), common to the Toy Car and the Cannon Man (3). We interpret Aisha's reasoning for the Toy Car to be influenced by her reasoning for the Cannon Man (4). First, Aisha identified a common attribute across both the Toy Car and the Cannon Man (total distance). Second, Aisha related the toy car's total distance traveled and its distance from the shrub. Third, Aisha's substantial change from the Ferris Wheel to the Toy Car strongly suggests that her reasoning for the Cannon Man influenced her reasoning for the Toy Car.

### **Locally integrating theories to theorize the “tension of intentions” in task design**

In integrating these theories, we aim to theorize the “tension of intentions” when researching task design to account for the student perspective. We aim to position students' perspectives as being just as viable as the perspectives of designers, teachers, and researchers. Accordingly, we aim not to place one theory as hierarchically superior to another, but rather to weave together the theories into a new form. In so doing, we bring together different assumptions: Students' reasoning depends on their conceptions of attributes as being possible to measure and capable of varying (Thompson's theory of quantitative reasoning), students discern difference, rather than sameness (Marton's Variation Theory); and transfer depends on the student perspective (Lobato's theory of actor-oriented transfer).

To claim that we can integrate theories, we need to address their epistemological roots (Bikner-Ahsbahr & Prediger, 2010). Lobato's and Thompson's theories have roots in students' conceptions, which makes integrating those theories more straightforward. In contrast, Marton's theory has roots in students' experience. We argue that both students' conceptions and experiences are central to their learning opportunities. For example, in our research, students' experiences with Cartesian graphs and students' conceptions of attributes were both central to their covariational reasoning. Through centering the student perspective, we integrate these different theories.

### **Conclusion: Rethinking design possibilities for transfer studies**

We view a reflexive relationship between theoretical perspectives and research methods. Employing alternative transfer perspectives, such as an actor-oriented transfer perspective, can result in innovations in methods to investigate transfer. A variation theory lens afforded us novel opportunities to design for and investigate students' transfer of covariational reasoning. Rather than designing a set of pre- and post-tasks, that in our view were structurally similar, we designed task sequences that incorporated difference within and across backgrounds of invariance. Analyzing across students' work on the task sequences, we gathered evidence of students' transfer of reasoning from an actor-oriented transfer perspective. Overall, we acknowledge that the perspectives of designers, teachers, and researchers can impact students' opportunities to engage in mathematical reasoning. In our theorizing, we aim to address this tension of intention, by centering the student perspective.

**Acknowledgment.** The development of the digital task sequences was supported by a US National Science Foundation Grant (DUE-1709903). Opinions, findings, and conclusions are the authors.

*This paper argues for creating learning trajectories of children's mathematics by integrating evidence of shifts in the mathematics of students, theory of goal-directed instructional design, and evidence of instructional supports. We networked two theories in support of this stance: a radical constructivist theory of learning, and Duality, Necessity, Repeated Reasoning (DNR)-based instruction. We exemplify how our networking of theories guided methodological choices by drawing on a program of research aimed at understanding and supporting students' ways of understanding quadratic growth as a representation of a constantly changing rate of change. We close by discussing challenges for creating and sharing learning trajectories.*

*Keywords: Learning trajectory, constructivism, cognition, learning theories, epistemology.*

## Learning trajectories in mathematics education

Attention to learning trajectories and progressions remains a prominent strand of research in mathematics education (e.g., Clements & Sarama, 2004). The influence of this domain of research is evident in the development of mathematics standards (e.g., National Governor's Association Center for Best Practices, 2010; UK Department of Education, 2009), funding priorities, topics conferences (e.g., the Third International Realistic Mathematics Education Conference), and special reports (e.g., Daro, Mosher, & Corcoran, 2011). Given the relatively wide-spread promulgation of trajectories and progressions in our discourse in research and practice, there is a need to articulate theoretical and methodological foundations of learning and teaching (Simon, 2013). This paper argues for the importance of creating learning trajectories as research-based models of teaching and learning that take seriously a commitment to understanding and supporting students' mathematics.

The notion of a learning trajectory has different meanings among mathematics education researchers. Simon's (1995) original discussion offered a description of a *hypothetical learning trajectory (HLT)* consisting of "the learning goal, the learning activities, and the thinking and learning in which students might engage" (p. 133). An HLT constitutes a starting point for task design, and is then modified into a learning trajectory based on empirical data, often in the form of a teaching experiment. Clements and Sarama (2004) described a learning trajectory as an elaboration of children's thinking and learning in a specific mathematical domain, connected to a conjectured route through a set of tasks. These definitions emphasize the construct as a tool for *hypothesizing* what students might understand about a particular mathematical topic and how that understanding may change over time in interaction with carefully designed tasks and teaching actions.

Building on this body of work, we argue that the main purpose of a learning trajectory is to effectively convey the relationships between teaching, task-design, and shifts in student

conceptions. We advocate for a stance that articulates an integrated system of ways of bringing about conceptual change in the mathematics of students in relation to theory-driven instructional support. Thus, in order to create learning trajectories, we need mutually informing theories of learning and teaching. This paper elaborates two such theories, the radical constructivist theory of learning and Duality, Necessity, and Repeated Reasoning-based instruction, and identifies how these two related theories influence our methodological approach to building learning trajectories. We provide an example situated in a rate of change approach to quadratic function.

## **Theoretical and epistemological framing**

### **A theory of learning mathematics**

In discussing the theory that guides our approach to crafting learning trajectories, we address three major issues: (a) distinguishing students' mathematics from the mathematics of students, (b) leveraging the epistemic student, and (c) leveraging a model of learning. Theory of instructional design is treated in the next section.

Learning trajectories articulate students' evolving conceptions within a particular instructional context. In order to do this, we distinguish from our own mathematics as researchers and teachers, our students' mathematics, and the models we create of our students' mathematics. The need to distinguish our own mathematics from students' mathematics is borne out of our epistemological stance. We consider mathematical knowledge to develop as part of a process in which children gradually construct and then experience a reality as external to themselves (von Glasersfeld, 1995; Piaget, 2001). From this perspective, knowledge is considered viable if it stands up to experience, enables one to make predictions, and allows for the enactment of desired objectives.

The term *students' mathematics* refers to the models students construct to organize, comprehend, and control their experiences – i.e., students' knowledge. The *mathematics of students* is the set of models we construct of our students' knowledge (Steffe & Olive, 2010). Often there is little distinction between these two notions in curricula or in standards documents. We believe, however, that the mathematical knowledge we attribute to students in the creation of a learning trajectory must be viewed as different from our own knowledge. Our goal is to determine how to engender and explain students' productive thinking. By distinguishing our mathematics from the students' mathematics, we recognize that students bring significant knowledge to bear when engaging in school mathematics, and we position students as logical, coherent thinkers and doers of mathematics. The job of establishing a learning trajectory then becomes one of explaining students' thinking in a way that portrays it as coherent and internally consistent (Steffe, 2004).

Individual students differ in their personal backgrounds, knowledge, and dispositions. A learning trajectory should depict not one particular student or group of students, but rather the *epistemic student*. An epistemic student is an organization of schemes that researchers build to explain students' characteristic mathematical activity and how that activity changes in the context of teaching (Steffe & Norton, 2014). Researchers construct epistemic students through teaching interactions with specific students, but epistemic students are not specific to those particular interactions. Instead we conceive them to be useful models of students' schemes that one can leverage to describe, explain, and predict the mathematical actions of similar students who may be

operating at the same level.

Formulating an explanation of changes in students' concepts and operations is not merely an empirical matter. We also bring to bear a set of conceptual tools in order to interpret students' activity and problem solving. These tools have their origins in the radical constructivist (RC) model of knowing (von Glasersfeld, 1995; Piaget, 2001). For the purposes of learning trajectory construction, we rely particularly on the constructs of mental operation, scheme, assimilation and accommodation, and abstraction. A *mental operation* is an internalized, reversible mental action that is an element of a larger structure, such as a scheme, constituted by the coordination of operations. A *scheme* is an organization of actions or operations which enables anticipation of results without having to engage in mental activity. As an example, Piaget (2001) described the mental operation of combining objects (such as addition). Several successive additions are the equivalent of a single addition (so one can compose additions), and they can be inverted into the operation of taking away, or subtraction.

Treating new material as something already known is an act of *assimilation*. When assimilating, one encounters an experience and incorporates it into a scheme. When the enactment of a scheme results in an unexpected outcome, a learner may experience perturbation or disequilibrium. One response can be a change in the learner's recognition, in effect spurring a reorganization of one's scheme. This reorganization is *accommodation*, which many consider to be the source of conceptual change.

### **DNR-based instructional design**

The theory of DNR-based instruction (*Duality, Necessity, and Repeated Reasoning*; Harel, 2008a; 2008b) informs our instructional design principles. Drawing on the RC theory of knowing, Harel (2008b) noted that "any observations humans claim to have made is due to what their mental structure attributes to their environment" (p. 894). He emphasized that researchers' observations are merely models of students' conceptions; using our language, these are models of the mathematics of students (Harel, 2013). Drawing on the mechanisms of assimilation and accommodation, Harel (2013) characterized knowing as a developmental process that proceeds through a back-and-forth between the two in order to reach equilibrium.

The duality principle addresses two forms of knowledge, *Ways of Understanding* (WoU) and *Ways of Thinking* (WoT). WoU can be thought of as subject matter, consisting of students' definitions, theorems, proofs, problems, and their solutions (Harel, 2008a). WoT are students' conceptual tools, such as deductive reasoning, heuristics, and beliefs about mathematics (Harel, 2013). The Duality Principle states that students develop WoT through the production of WoU, and, conversely, the WoU they produce are afforded and constrained by their WoT (Harel, 2008a). We contend that the mathematical content of a learning trajectory must be formulated in terms of both WoU and WoT.

The *necessity principle* states that in order for students to learn the mathematics we intend to teach them, they must have an intellectual need for it (Harel, 2008b). We can engender intellectual need through problematic situations that necessitate the creation of new knowledge in order to be resolved. Finally, the repeated reasoning principle addresses the need for teachers to ensure that their students internalize, retain, and organize knowledge (Harel, 2008a). Repeated reasoning should not be confused with drill and practice of routine problems. Rather, it is an instructional

principle that advocates providing students with sequences of problems that require thinking through puzzling situations and solutions; the problems must respond to students' intellectual need.

## Methodological approach and rationale

Our methodological approach to establishing learning trajectories is a direct consequence of our theoretical and epistemological framing. We elaborate how our networked theories (RC, DNR-based instruction) informed our methodologies. We describe three aspects: (a) leveraging theory to create an HLT, (b) ongoing refinement of an HLT into an LT through enacting a teaching experiment, and (c) finalization of an LT through retrospective analysis.

### Creation of an HLT

We enact a form of design-based research to simultaneously engender and study innovative forms of learning (Cobb & Gravemeijer, 2008). The planning phase involves creating an HLT (Simon, 1995) informed by the networking of the RC theory of learning and the theory of DNR-based instruction. Our HLT was a tentative progression of student concepts and associated tasks that we hypothesized would necessitate a WoU that quadratic functions represent a constantly-changing rate of change between two covarying quantities. Simultaneously, our aim was to support a WoT that functions can be representations of covariation and can be explored and understood through a covariational lens (Thompson & Carlson, 2017). Consequently, we devised a dynamic representation of proportionally-growing rectangles in which students could investigate situations that, to us, entailed the three continuously covarying quantities, height, length, and area (Figure 1).

The relationship between height,  $h$ , and area,  $A$ , can be expressed as  $A = ah^2$  where  $a$  is the ratio of length to height. We wanted the students to develop the following specific WoUs: (a) the rate of change of a rectangle's area grows at a constantly-changing rate for each same-unit increase in height (or length); (b) the rate of the rate of change of the rectangle's area is constant for same-unit height (or length) increases; (c) given a height  $h$ , the rectangle's area could be determined by  $ah^2$ ; and (d) the rate of the rate of change of area is dependent on the change in height. In order to engender these WoUs, we devised tasks in which students had to predict the nature of growth, determine areas for specific height values and vice versa, and decide whether given tables of values represented rectangles that grew in proportion to one another or not. See Ellis (2011) for an elaboration of the mathematics.

Figure 1: A growing rectangle and associated table of height-area values

### Teaching experiment: Ongoing refinement of an HLT into a tentative LT

Drawing from the theories we networked, we engaged in an in-depth, 15-day teaching experiment following the method of Steffe and Thompson (2000). We taught 15 lessons to a group of 6 middle-

grades students (ages 13- 14) who were enrolled in pre-algebra (3 students), algebra (2 students), and geometry (1 student). The second author was the teacher-researcher (TR). One purpose of a teaching experiment is to gain direct experience with students' mathematical reasoning, which affords the creation and testing of hypotheses about the mathematics of students in real time. This means that our mathematical tasks were not wholly predetermined, but instead were created and revised on a daily basis in response to hypothesized models of students' mathematics. Because our problem context relied on area models, it was important to first identify the students' existing schemes and operations for area. After conducting pre-interviews and developing an initial model of the mathematics of students, we created new tasks to necessitate more robust constructions of area as not dependent on whole-unit iterations. During and between each session, we engaged in an iterative cycle of (a) teaching actions, (b) assessment and model building of students' thinking, and (c) task revision and creation on an ongoing basis. In this manner, during each session, we continually revised our HLT into a tentative, empirically based LT.

### Retrospective analyses: Finalizing an LT

In addition to our ongoing analysis, we relied on retrospective analysis to inform the development of a learning trajectory as a model of the mathematics of students (Steffe & Thompson, 2000). One purpose of retrospective analysis is to build a model of the epistemic student and to characterize students' changing WoU and WoT throughout the course of the teaching experiment. A secondary purpose, for us, was to contextualize and explain changes in students' schemes and operations with respect to the tasks and teaching actions they encountered. We aimed to elaborate features of tasks, teacher moves, questioning, and socio-mathematical norms that supported the students' scheme accommodation. Our inclusion of instructional supports into a learning trajectory relied both on our analyses of empirical data and on our understandings of the local instructional theories grounding our design and enactment of the teaching experiment. Figure 2 identifies the goals, tools and constructs we leveraged in order to create a learning trajectory. Notice how the primary and secondary aims are linked to a coordination of RC and DNR-based instructional design theories.

Analytic Aim	Goals, Tools and Constructs
Primary Aim: Identify the mathematics of students	<i>Identify</i> WoU and WoT: Describe (a) students' mathematical definitions, theorems, and concepts; (b) heuristics, reasoning, strategies, and beliefs about mathematics
	<i>Characterize</i> WoU and WoT: Identify operations and schemes
	<i>Exemplify</i> WoU and WoT: Provide data evidence of specific WoU and WoT
Secondary Aim: Contextualize and explain changes in the mathematics of students	Identify <i>shifts</i> in WoU and WoT: Articulate instances of scheme accommodation and abstraction
	Identify <i>task features</i> fostering shifts: Identify the WoU necessitated by each task; clarify relationships between tasks elements and students' existing WoU
	Identify <i>instructional supports</i> fostering shifts: Determine teacher moves promoting accommodation and abstraction; characterize student engagement and discourse; identify socio-mathematical norms

Figure 2: Analytic aims, goals, tools, and constructs for creating a learning trajectory

### An excerpt of a learning trajectory for quadratic function

In our previous work, we identified WoT and WoU in students' learning of quadratic function from a rates of change perspective (Fonger, Dogan, & Ellis, 2017). Below, we provide an example of a

link between goal-directed instructional supports and a shift in student thinking (i.e., an excerpt of a LT). We focus on one shift from a student's WoU that (a) the rate of the rate of change of the rectangle's area is constant with  $\Delta x$  implicit, to (b) the rate of the rate of change of area is dependent on  $\Delta x$ , which is explicit. In the excerpt, the students had already created well-ordered tables for the growing rectangles (Figure 3). They had also attended to the constantly changing rate of change of area as determined by finding area increases for same-unit increases in, but there was a lack of coordination of change in area with change in height. Prompted to explain the growth in area of a 2 cm by 3 cm rectangle (Task A), one student said, "It goes 4.5 and then 7.5 and then 10.5 and then...just keeps going." In this manner, the students attended to the area's growth, but did not coordinate it with growth in height or length. In response, the TR prompted the students to draw diagrams of the growing area, predicting that the act of drawing would necessitate a coordination of height and area. The students' drawing activity did necessitate a coordination, but many students kept the change in height implicit, as evidenced by their language "every time." For instance, Jim drew a picture of a growing 2 cm by 3 cm rectangle and explained the rate of change of area as "how many new squares it's gaining *every time* it grows."

In an attempt to further encourage an explicit coordination of the rate of area with a quantified change in height, the TR asked the students to create a table for a 2 cm x 5 cm growing rectangle (Task B), anticipating that the students would make tables with different height increments. This did occur: For instance, Jim created a table in which  $\Delta x$  was 1 cm, and Daeshim created a table with  $\Delta x$  as 2 cm (Figure 3). The different tables resulted in a conflict about whether the constantly-changing rate of change of area should be 5 cm<sup>2</sup> or 20 cm<sup>2</sup> until one student, Jim, realized that the rate depended on  $\Delta x$ : "I'm going up by 1's and they're going up by evens." After a class discussion in which the students agreed that the rate could legitimately be either 5 cm<sup>2</sup> or 20 cm<sup>2</sup>, depending on  $\Delta x$ , Jim exclaimed, "Your rate of growth can change no matter what!" In subsequent days the TR encouraged the students to think about other proportionally-growing rectangles, and, ultimately, to draw diagrams relating changes in area to the rectangles' dimensions. These diagrams further emphasized explicit attention to all three quantities, height, length, and area, and enabled the students to explicitly link the change in area to the change in height. For instance, Daeshim determined that the rate of the rate of change of area would be twice the area of the original rectangle; Jim found that it would be equivalent to twice the length for any 1 cm by  $L$  cm rectangle.

**Figure 3: Jim and Daeshim's well-ordered tables for a 2x5 growing rectangle**

We propose that a learning trajectory should include not only an articulation of particular WoUs and the shifts between them, but also a hypothesized connection between these shifts and specific instructional supports. Although space constraints limit an in-depth discussion of all of the

instructional supports in play, we see that the instructional move to prompt diagram drawing necessitated a functional accommodation: students began to attend to and then coordinate increases in height and length, not just area. In addition, the open structure of the task to determine rates of change of area for a 2 cm by 5 cm rectangle further encouraged explicit attention to  $\Delta x$ .

## Discussion

In the domain of research on learning trajectories, attention to a theory of instructional design is lacking. Moreover, methodological approaches to creating learning trajectories as a retrospective practice are scant in the literature. In this research we networked RC and DNR-based theories to inform our methods of task development, pedagogical actions, and retrospective analyses. This approach and the resulting product (i.e., an empirical LT for quadratic growth) are novel and not elaborated in the literature thus far.

This paper contributes to an understanding of how a networking of theoretical assumptions can guide methodological choices in establishing learning trajectories. Specifically, we argue for learning trajectories research to be guided by theoretical lenses on the mathematics of students as well as on a theory of instructional design. In this domain of research, there is a need for researchers to move beyond a focus on creating hypothetical learning trajectories, attending to their methods of creating learning trajectories.

This paper makes explicit the theoretical perspectives undergirding our approach to learning trajectories research. One challenge we see is leveraging learning trajectories as a way to not only frame a study (e.g., in creating hypothetical learning trajectories), but to also retrospectively create and share learning trajectories in ways that are consistent with the theories undergirding their creation. This research illustrates one approach for addressing the challenge of creating learning trajectories as empirically based models of an interweaving of shifts in students' mathematical understandings and goal-directed, theoretically grounded instructional practices.

# Conceiving teaching trajectories in the form of series of problems: a step for the theoretical reconstruction of the Hungarian Guided Discovery approach

Katalin Gosztonyi

Eötvös Loránd University of Budapest, Hungary; [kgosztonyi@caesar.elte.hu](mailto:kgosztonyi@caesar.elte.hu)

*In this article I introduce the term “series of problems” to give an account on a phenomenon existing in Hungarian mathematics education, the conception of long teaching trajectories based on problems. I will present a long research process aiming to reveal a “theory in act” hidden behind this phenomenon, and discuss the methodological tools developed in order to access to these hidden theoretical bases. The first part of the paper presents the historical-epistemological-didactical analysis of the origins of the Hungarian approach in question; the second part discusses the analysis of teachers’ work, and introduces the idea of reverse engineering aiming to reveal the implicit principles to the teachers’ design practice.*

*Keywords: Series of problems, Guided Discovery approach, Reverse engineering, Teaching trajectories, Hungarian mathematics education*

## Introduction

In Hungary, there exists a tradition of mathematics education through problem solving and mathematical inquiry called “felfedezettő matematikaoktatás” that I translate as “Guided Discovery” (GD) approach. This approach was originally developed and practiced for the education of gifted students, but the reform movement of T. Varga, realized in the 1960s and ‘70s, transformed it into a basis of general mathematics education and a guiding principle of the official curriculum for primary and lower secondary school (Halmos & Varga, 1978). The approach is still recognized by Hungarian specialists of mathematics education as relevant and coherent with modern educational trends. At the same time, it is practiced in ordinary classes only by a narrow circle of teachers, and its dissemination poses problems. Furthermore, the approach exists only “in act;” its theoretical description has never been developed. Although Varga actively participated in the international discourse on mathematics education in the ‘60s and ‘70s, and developed his conception at the same time as Brousseau or Freudenthal<sup>1</sup>, his publications were mostly focused on experimentation and curriculum development, and less on the theoretical description of the underlying conception.

This article treats a step of a longer research project aiming to reconstitute the underlying theory of Varga’s approach. I consider this reconstruction necessary for several reasons. On the one hand, it is an inevitable first step for its large-scale implementation, for the development of more adapted resources and teacher education programs. On the other hand, it is necessary to introduce Varga’s work to the current international discussion on Inquiry Based Mathematics Education: to enrich

---

<sup>1</sup> Varga and Freudenthal met quite late when both of their conceptions were already well developed, but they mutually recognized each other’s work and perceived conceptual proximities (Varga, 1975).

both the international discourse by the specificities of Varga's approach and the Hungarian mathematics education by the dialogue with other approaches.

In this paper, I focus on one important aspect of the Hungarian approach: the long and complex teaching trajectories shaped by series of problems. The concept of Series of Problems appears to be crucial in this approach, both for curriculum and resource-developers and for teachers (Gosztonyi, 2015a). However, a theoretical understanding of this phenomenon is missing. Originally, the term “series of problems” was introduced in the frame of an interdisciplinary history of science project as a more or less undetermined methodological tool to analyze the structure of historical texts (Bernard, 2015). In this specific Hungarian context, by “series of problems” (SoP) I mean a list of problems with a conscious ordering which is relevant for an (or several) educational purpose(s). In what follows I will discuss the relevance of this notion for the Hungarian context, the difficulties to develop theoretical frames and methodological tools for the analysis of SoP, and the research process of this development.

In the first part of the article, I briefly summarize how a combined, historical-epistemological-didactical analysis of Varga's reform contributed to reveal the main principles of the GD approach. In the second part, I present an ongoing analysis of nowadays teachers' work, developed in the frame of a larger research project focused on Varga's legacy (MTA-ELTE project)<sup>2</sup>. I suggest to describe the methodology of this analysis as *reverse engineering*<sup>3</sup>: a progressive elucidation of the hidden principles of this “theory in act”, starting from teacher's actual designs.

## Back to history

The first step for the reconstruction of the GD approach was to go back to its origins, in the frame of a comparative study between Varga's reform and the contemporary French “Mathématiques modernes” reform, carrying out their combined, historical, epistemological and didactical analysis, based on written sources (Gosztonyi, 2015b). The analysis of the historical context of the reforms pointed out, among other things, the crucial role of mathematicians in defining the epistemological foundations of mathematics and its teaching: a “bourbakist” epistemology in the French case, and a “heuristic” one in the Hungarian case. The didactical analysis of different sources (curricula, textbooks, teachers' handbooks) showed the epistemology be one of the main driving forces for realizing the reforms.

One of the theoretical frameworks used for the didactical analysis was Brousseau's *Theory of Didactical Situations* (1998). This theory proved to be powerful to reveal important characteristics of each reform – but also insufficient to explain some specificities of Varga's one. One of the most important aspects is the long teaching trajectories shaped by SoP.

Brousseau developed his theory from the 1970s, in the French context of the debates following the “Mathématiques modernes.” Thus, the emergence of the theory goes back to the historical context I

studied. The comparison of an early experimentation of Brousseau with Varga's works contributed to understand their conceptual differences.

### **Characteristics of the Hungarian Guided Discovery approach and the importance of SoP**

The analyses described above helped to identify some main characteristics of the GD approach. In the background of Varga's reform project, a quite coherent "heuristic" epistemology of mathematics and of mathematics education can be outlined in the 20<sup>th</sup> century's Hungarian mathematical culture (Gosztonyi, 2016), represented by mathematicians living in Hungary as well as by Pólya and Lakatos. These thinkers considered mathematics to be a continuously progressing and changing human creation, and as a social, dialogic activity. The development of mathematics appeared as a collective process based on a diversity of experience, driven by problems, attempts of solutions, and new questions emerging from these attempts. They posited that mathematical knowledge only could be attained through the experience of mathematical creation, and thus students should be guided through similar discovery processes.

The idea of organizing problems into ordered series appears often in the writings of these authors. For example, R. Péter's book popularizing mathematics, *Playing with infinity* (Peter, 1961) is written as an interesting inquiry story where one question invites the other. Pólya's work, especially later books like *Induction and analogy* (1954), also present inquiry processes shaped by series of problems, and analyses their structure.

This epistemology deeply influenced Varga's "Complex Mathematics Education Reform" conception (Gosztonyi, 2015b). The coherence of his curriculum is assured by a parallel treatment of different mathematical themes. Elements of mathematical knowledge are introduced through long, progressive processes (taking often several years), based on numerous small, concrete problem situations. Problems crossing different themes contribute to the variety of experiences. In the treatment of these problem situations, collective discussions led by the teacher play a crucial role. The use of various manipulative tools and representations, playfulness, students' autonomy and creativity are also in the focus of the reform project.

In the teacher's handbooks related to Varga's reform, researchers can find numerous commentaries on the importance of organizing problems into series. Primary school teachers' handbooks describe a number of activities with ideas for their repetitions, variations, and ordering. However, the principles of the organization are dispersed in the books and rarely generalized. The handbooks insist on the importance of teachers' autonomous work on conceiving of long teaching processes on their own. In middle-school textbooks, new knowledge is often introduced by fictive dialogues of students around short series of problems.

### **Analysis of published examples**

Although SoP play a central role in Varga's conception, they are seldom theorized. Problem collections used to be presented without commentaries about tasks' connections and their possible roles in a teaching process. Furthermore, mostly fragments of SoP are published; long-term series are rarely presented. Some specific historical documents, however, present more detailed examples and furnish enough commentary to understand the logic and the purpose of their construction.

One example is the above mentioned book of R. Péter, describing in one of the chapters a classroom situation driven by a dialectic of problems, attempts of solutions and new problems motivated by these attempts. The text is written in a literary style; thus, its structuration by problems is not obvious at the first glance, but the rich meta-discourse makes possible to identify the problems and to understand the rationale behind the structuring of the text (Gosztonyi, 2015a).

In the documentation of Varga's reform, one of the most transparent examples is the introduction of combinatorics in primary school. Here, a double structuration of the series can be identified. On one hand, a sub-series is related to a given material, varying several variables and progressively introducing restrictions (e.g., building colored towers, building colored towers with a given height, finding all towers with a given height, varying the number of colors and levels, using a color only once, using the same color several times but not for neighbor levels, and so on). On the other hand, same or similar tasks are repeated with different materials (e.g., building towers with Cuisenaire rods, coloring flags or drawing houses, creating words with given letters, writing melodies with musical notes, and so on). The ordering is not strict here, but a progression in the abstraction should be respected by teachers. The observation of the analogies between these tasks serves as a basis for generalization and abstraction.

The comparison of this example with Brousseau's above mentioned teaching progression revealed important differences between the two authors' conceptions, and contributed to understanding the role of SoP in the Hungarian case. For Brousseau, the progression is based on one "fundamental problem situation," and a decontextualization (through phases of institutionalization) is necessary for the passage to other situations. For Varga, the progression is based on a diversity of problems and their convenient ordering to favor progressive generalization through the recognition of links between the problems. (Gosztonyi, 2017).

In summary, the analysis of written documents representing the heritage of the Hungarian GD approach, confirms the importance of SoP in the planning of teaching by GD, identifies some key principles concerning the role and the structuration of SoP, and highlights tools to analyze and represent SoP (e.g., by graph representations or the structuration by main and sub-series).

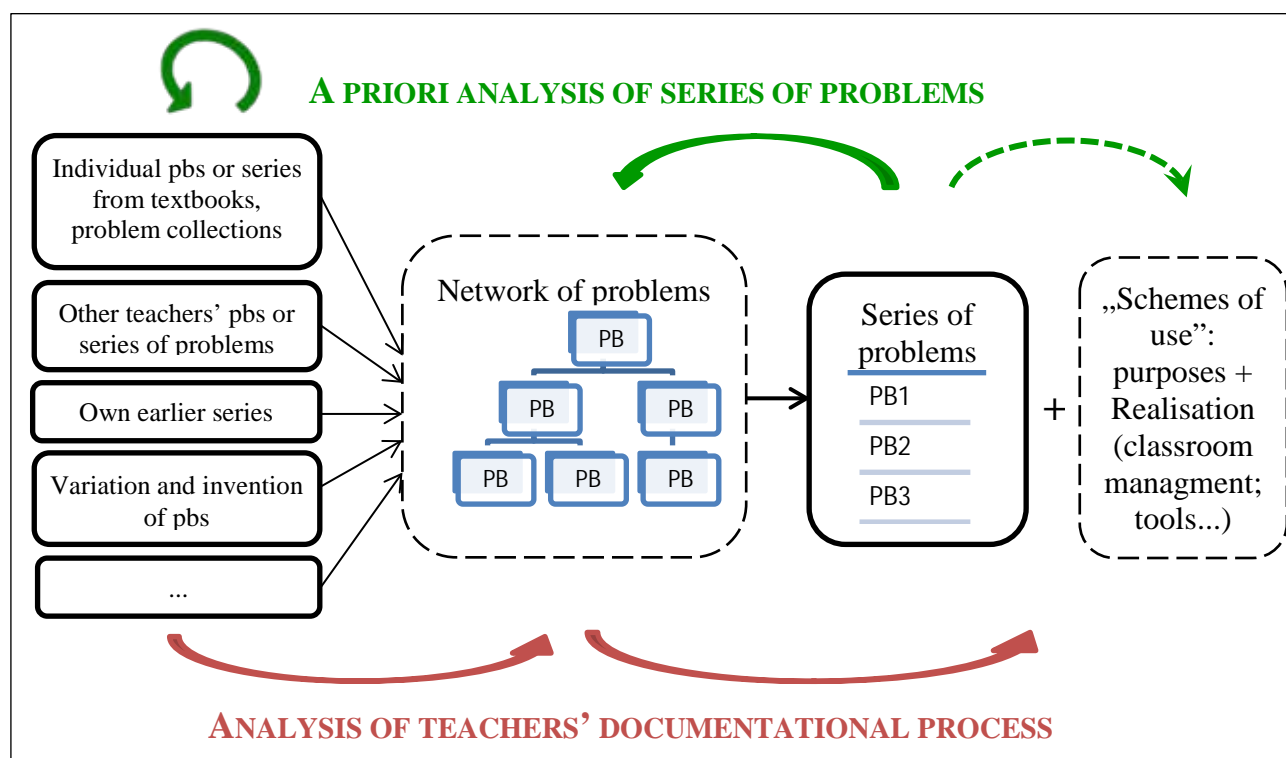

### **Analysis of teachers' work designing Series of Problems**

Subsequent research steps involve analyzing the GD approach of expert teachers, drawing on the key principles and analytic tools described above. Several of these teachers reacted vividly when I proposed the term "Series of Problems" to them. It resonated with the kind of planning they considered crucial. However, they rarely make these practices explicit.

The documents created by these expert teachers typically contained a list of problems, with or without solutions. But the documents are only a skeleton of their planned teaching process. Essential elements remain implicit: the main teaching goals, the organization of classroom work, the planned discussions, and choices and adaptations they consider to make 'on the spot', depending on the students' reactions (e.g., change of order, omission of some problems or introduction of new ones). Furthermore, these projects are conceived as long-term developments, even for several years, and only parts of them appear in written documents. Expert teachers confirm having a complex

network of problems in mind that they can mobilize in order to create problem series and to adapt them to their aims and to the students' needs or interest—during preparation or in the classroom.

Gaining access to these complex implicit networks is necessary but quite challenging. Its reconstruction is an iterative process, combining two approaches: (1) an a priori analysis on the principles revealed by the analysis of historical documents, and (2) a study of the expert teachers' documentational processes (in the sense of Gueudet & Trouche, 2010).

**Figure 1: Analysis of Series of Problems**

(the visible elements are marked with bold, the hidden ones with broken outline)

For the MTA-ELTE project, a mixed group of researchers, teacher trainers and expert teachers of the GD approach was created in order to fulfill a double aim: analyzing the expert teachers' practices (with a special focus on SoP), and fostering dissemination of the approach by developing resources and teacher education programs. However, complex negotiations were necessary to meet the interest and expectations of each participant. While I felt necessary to focus first on the analysis of teachers' practices, this was not motivating and relevant enough for the participating teachers. Thus, we decided to develop a collection of commented examples of SoP. The purpose of this collection under preparation was not to offer ready-made resources for teaching, but generic examples, which introduce the reader into the practice of using and preparing SoP. In addition, preparing commented examples also served the project's research aim: for teachers to explicate their teaching purposes and principles of structuration of SoP. I call this procedure *reverse engineering*. Starting from teachers' existing designs of SoP, researchers reconstruct tacit principles driving teachers' choices during the design of these trajectories.

In the first step, teachers were asked to provide examples from their own practice of what they consider SoP. The received examples were of quite different nature: SoP of short and long-term sequences; SoP to introduce new mathematical notions, SoP to explore heuristic strategies, and SoP to serve diagnostic purposes. Confronting the new and previously analyzed examples led to discussion on various questions: classification of purposes, different structuration principles, and forms of representation. These discussions evoked new examples. For example, most SoP consisted of short sequences at the beginning, because this was easier to document for teachers; but during the discussions, they all agreed about the importance of long-term planning, leading to the description of long trajectories built by SoP.

In the next step, teachers were asked to write commentaries to their SoP, addressing colleagues unfamiliar with the GD approach, focusing on the didactical aims of their trajectories and on explaining the SoP-structure. The group is currently comparing these first writings in order to define the main elements to be included in each commentary.

In the further phases of the project, the MTA-ELTE project team will conduct experiments; giving commented examples to non-expert teachers, and asking them to use the examples as inspiration to develop their own teaching trajectories, and offer them consultation with expert teachers of the group. This part of the project will give evidence of how well the created resources may mediate the GD-approach and provoke further exploring of the expert teachers' practices.

### Eszter's case

Eszter is an expert teacher of our group, a high school teacher for 20 years. As a long-term example, she proposed an example taken from geometry<sup>4</sup>, built around the concepts of incidence and distance in the Euclidean plane/space, equidistant sets (loci) of points, and especially a “core” problem: finding the equidistant points from three different lines in the plane. This series covers a very long period: It starts at the first year of high school, and some parts of it concern the last year's curriculum. Although some notable theorems of higher level mathematics appear in the series (in a problematized form), the aim of the SoP, according to Eszter, is not to learn these theorems, but to familiarize students with the above mentioned concepts, related mathematical techniques and problem solving skills through the exploration of interesting geometrical questions.

The first version consisted of a “core” series of four problems with increasing complexity about the loci of points (red dots in Figure 2). In this “core sub-series”, the order of the problems is strict. This order is intended to make the latter, more difficult problems progressively available for students. Several other sub-series are conceived, based on this core, exploring different mathematical themes (blue dots), including space

**Figure 2: Eszter's graph**

(Simplified version)

<sup>4</sup> The complete collection of problems can be found here:

[https://drive.google.com/open?id=1Nhe5DbX3Wgs29l75GhTlrGN8\\_5rs1-yl](https://drive.google.com/open?id=1Nhe5DbX3Wgs29l75GhTlrGN8_5rs1-yl)

analogies, angles and similarities, and the boundaries of geometry and combinatorics. Eszter immediately proposed a graph to represent the structure of the SoP. Her arrows showed complex mathematical or didactical interdependences between the problems, but also illustrated the flexibility of the structure which is not visible in the simple numerated list of problems. Some problems or sub-series are sequential, while for other problems, the order can be freely chosen. The representation of this structure helps the reader to understand which problems could be deleted without impacting a longer trajectory, or where new problems could be inserted.

After a first discussion, we agreed that it would be useful to complete this SoP with a preparatory part which treated the lower secondary school level prerequisites. Thus, Eszter added a new part to her graph (green dots in Figure 2). As she explained, the problems of this part serve for diagnostic purposes in her high school work. They also fill possible gaps in students' knowledge. The problems presented illustrate different types of tasks which have to be explored in order to prepare students for the “core.” More tasks can be inserted, depending on the students' needs. In order to make this “typology” more accessible, Eszter added a coding system to the graph (e.g. D stands for distance, L for loci of points, S for space analogies). Some subgroups of problems are related to some of these codes, but many problems have multiple codes. The network of problems is less hierarchic here than in other parts leaving more flexibility to the teacher. However, the discussion also revealed some further hidden interdependences of the ordering. This suggests that Eszter's didactical choices are even more complex than what was in her current version of the graph. Another iterative process of discussions and the preparation of representations is necessary to reveal implicit choices.<sup>5</sup>

The discussions with Eszter led to a progressive exploration of her design and its guiding choices, while the graph representation plays the role of a mediator. Her case also shows individual specificities beyond the common principles shared with the colleagues (e.g. Eszter accords even more importance to the flexibility in her SoP than most of her colleagues).

## Conclusion

This paper presented a research process aiming to make explicit a “theory in act” existing in the Hungarian context of mathematics education and to develop theoretical bases and methodological tools to analyze the work of the teachers who follow this approach. The first phase of this process consisted in the analysis of the historical sources of the approach with complex research tools from history, epistemology and didactics, while the current second phase is focused on teachers work. The process is essentially iterative; the analysis of the epistemological background offered some first steps to reveal main principles of the hidden theory. The use of existing didactical theories in the analysis of Varga's reform documents helped not only to reveal its characteristics but also to point out the limits of the use of those theories, specificities of the GD approach which needs new theoretical development to be analyzed. These studies helped to choose the aspects to focus on while analyzing teachers' work—the structuration of teaching trajectories by SoP being one of them. The principles revealed by these analyses and the tools developed by case studies of

---

<sup>5</sup> A more detailed version of the graph was presented in form of a poster at CERME 11.

representative written examples contribute to interpret the teachers' designs but also to provoke teachers to make their guiding principles explicit. Collective discussion and interpretation of the teachers' designs led to further elucidation of the fundamental principles of the approach and to the development of tools to investigate their design process. The term "reverse engineering" is used to describe the iterative process of exploring teachers' designs and describing their guiding design principles. Through reverse engineering, "theories in act" about SoP will be gained, so they may contribute to the discourse on Inquiry Based Mathematics Education (Artigue & Blomhøj, 2013).

# Students' learning paths about ratio and proportion in geometry: an analysis using Peirce's theory of signs

Georgia Bampatsikou<sup>1</sup>, Triandafillos A. Triandafillidis<sup>2</sup>, Stefanos Asimopoulos<sup>3</sup>  
and Kostas Hatzikiriakou<sup>4</sup>

<sup>1,2,3,4</sup> University of Thessaly, Greece; [mpampats@uth.gr](mailto:mpampats@uth.gr), [ttriant@uth.gr](mailto:ttriant@uth.gr), [asimstef@uth.gr](mailto:asimstef@uth.gr),  
[kxatzkyr@uth.gr](mailto:kxatzkyr@uth.gr)

*In this paper we use Peirce's theory of signs to analyze the conceptions of four twelve-year-old students on ratio and proportion while solving geometric problems of the stretchers/shrinkers type. The students participated in a series of interdisciplinary activities based on the principle of the camera obscura. We will present the learning paths of these students as chains of signification described in terms of Peircean semiosis. We will emphasize the challenges that they encountered during the reconstruction of their initial ideas and we will classify their conceptualizations in terms of Peirce's classification of Signs.*

**Keywords:** *Peirce, Semiotics, Classes of Signs, Ratio and Proportion, Elementary School.*

## Introduction

In the 1990s semiotics has started to gain momentum as an analytical tool among researchers in the field of mathematics education (Presmeg, Radford, Roth & Kadunz, 2018; Sáenz-Ludlow & Kadunz, 2016). By and large semiotics is the study of how signs come to signify, a theory of “signification” (Presmeg, Radford, Roth, & Kadunz, 2016, p. 1). Mathematics, as a highly symbolic practice, calls for a study of the nature of sign systems in order to understand the processes of its teaching and learning (Sáenz-Ludlow, 2006). In the same decade, mathematics education research was marked by the development of theoretical constructs that acknowledged the social origins of knowledge and consciousness. In these paradigms, knowledge and consciousness are seen as products of communication embedded in experiences that take place in historically-, culturally- and geographically-inscribed contexts (Lerman, 2000). Knowledge and experience, then, are co-constructed, as the one partakes in shaping the other. As this process is replete with signs, semiotics may elucidate the production of mathematical meaning by learners, as well the shaping of contexts that support learners' conduct with mathematical content and practices.

In our paper, we will use Peircean semiotic theory to analyze instances of the development of four twelve-year-old students' ideas concerning ratio and proportion, as they participated in a series of interdisciplinary tasks based on the principle of camera obscura. Charles Sanders Peirce (1839–1914) was an American philosopher, logician, mathematician, scientist, and semiotician. Contrary to other semioticians' claim for an essentialist dyadic structure between a ‘signifier’ and a ‘signified’, Peirce suggested that a Sign signifies only when it is interpreted in one's mind. He argued for a triadic structure for the process of semiosis among the *Sign* or *Representamen* (signifier), the *Object* (signified), and the *Interpretant*. The Interpretant, the most innovative and distinctive feature in Peirce's account on semiosis, refers to the interpretation and nature of the Sign and Object relation. The Interpretant, as we will have the chance to see later on, has the potential to generate a new Sign, thus moving the signification process towards a higher level of interpretation and generalization (Sáenz-Ludlow & Kadunz, 2016).

By analyzing students' participation in these activities, we will explore how their learning paths constitute chains of signification described in terms of Peircean semiosis (Sáenz-Ludlow, 2003), as Signs transform to more mature thoughts that become a kind of new knowledge. We suggest that Peirce's ten classes of Signs may constitute an analytical 'tool' that can be used by researchers and teachers alike for deconstructing and classifying students' conceptualizations, not only in ratio and proportion tasks, but in other instructional situations as well. We present this analytical tool in the section that follows, along with an outline of Peirce's semiotics emphasizing the process of semiosis.

## Theoretical considerations

Even though he provided various definitions, Peirce defined "a Sign as anything which is so determined by something else, called its Object, and so determines an effect upon a person, which effect I call its Interpretant, that the latter is thereby mediately determined by the former" (Peirce, 1998, pp. 478). The Interpretant, coming as the most groundbreaking and distinguishing characteristic of Peirce's account on semiosis, refers to the understanding that we have of the Representamen and Object relation. According to Peirce signification is not a dyadic relation, as a Sign signifies only when it is interpreted in one's mind. The Interpretant does not refer to the user but to the interpretation, the meaning that is generated for a user (Atkin, 2013).

The importance of Interpretant is clearly visible in the process of *semiosis*, in which Signs transform to other thoughts that are more mature and become a kind of knowledge. When the relation of an Object<sub>(1)</sub>, a Representamen<sub>(1)</sub> and an Interpretant<sub>(1)</sub> is established, the Interpretant<sub>(1)</sub> is potentially converted to a Representamen<sub>(2)</sub> for a new Object<sub>(2)</sub> and determines a new and more advanced Interpretant<sub>(2)</sub>, and so on. The conceptual process of *semiosis* is theoretically unlimited, as the chain of meaning-making continues to new Signs interpreting a prior Sign or set of Signs (Figure 1).

**Figure 1: The infinite process of semiosis**

However, in practice this process becomes limited by force of habit (Parker, 1998).

Peirce suggested that each of the three interrelated components of a Sign, namely Representamen, Object, and Interpretant, can be separated into a trichotomy. Representamens signify their Objects not through all their features, but in virtue of qualities, existential facts, or conventions and laws. In the first trichotomy, Signs then can be classified as *Qualisigns*, *Sinsigns*, and *Legisigns* respectively. The Representamen is the form in which the Sign appears, the spoken or written form of a word for instance, whereas the Sign is the whole meaningful ensemble. Peirce also believed that the nature of the Object constrains the nature of the Sign in terms of what is required for a successful signification. He thought about three categories of Objects, then, which were qualitative, existential or physical, and conventional or law-like in nature, constituting the second trichotomy. Thus, when a Sign reflects qualitative features of an Object, then the Sign is an *Icon*. When there is physical connection to its Object, then the sign is called an *Index*, and when there is a rule or law between it and its Object, then the sign is called a *Symbol*. The icon is an intuitively familiar trichotomy, as portraits, paintings, or diagrams fall under the *Icons* category. *Indices* may include fingers pointing to something or somewhere and proper names, while *Symbols* comprise broad speech acts like

assertion and judgment. Last, but not least, Peirce thought that Signs could be classified in terms of their relation with their Interpretant. In this third trichotomy, he suggested three categories by identifying qualities, existential facts, or conventional features as the basis for classifying the Sign in terms of its Interpretant. If the Sign determines an Interpretant by focusing our understanding of the Sign upon the qualitative features it employs in signifying its Object, then the Sign is classified as a *Rheme*. If a Sign determines an Interpretant by focusing our understanding of the sign upon the existential features that it employs in signifying an Object, then the Sign is a *Dicent*. Finally, if a Sign determines an Interpretant by focusing our understanding on some conventional or law-like features employed in signifying the Object, then the Sign is a *Delome*, or as Peirce frequently—but confusingly—called it, an *Argument* (Atkin, 2013; Colapietro, 1989; Freadman, 1996).

These three previous trichotomies produce combinations that are called ‘classes’. In order to categorize a Sign in these classes, we have to ask three questions: 1) What is the relation of the Sign with itself? (1<sup>st</sup> trichotomy), 2) What is the relation between the Sign and its Object? (2<sup>nd</sup> trichotomy), and 3) What is the relation between the Sign and its Object for its Interpretant? (3<sup>rd</sup> trichotomy). The kind of relation that answers the first question qualifies the second, which in turn qualifies the third. Once though we characterize a Representamen as, for example, a Qualisign, which is at the first level of the first trichotomy, the relation of the Sign to its Object and its Interpretant in the second and third trichotomy has to be at the first level as well, as the Sign cannot be related to an Object and an Interpretant from a higher level. According to these restrictions, then, the classes of Signs are ten (see Table 1). Even though the classes are hierarchically related, every link in the chain of signification does not necessarily constitute a more mature conceptual construct than those in the preceding links of the chain. Thus, in the highest level of Representamen, the Interpretant may be a Rheme (classes V, VI and VIII). Signs of this kind appear often in the mathematics classroom, as students may be familiar with representations of mathematical ideas but their interpretations about them may still be vague or confined to these representations. The chain of signification as outlined in the beginning of this section, along with Pierce’s taxonomy of Signs, may allow us to analyze the continuum of students’ conceptualization (i.e. learning path) of ‘complex’ concepts like ratio and proportion (Sáenz-Ludlow, 2003).

**Table 1: Peirce’s classes of Signs**

	S = R, O, I
I	Qualisign, Icon, Rheme
II	Sinsign, Icon, Rheme
III	Sinsign, Index, Rheme
IV	Sinsign, Index, Dicent
V	Legisign, Icon, Rheme
VI	Legisign, Index, Rheme
VII	Legisign, Index, Dicent
VIII	Legisign, Symbol, Rheme
IX	Legisign, Symbol, Dicent
X	Legisign, Symbol, Delome

### **An experimentation on ratio and proportion**

We implemented the analytical tool that we outlined in the previous section in a data set produced from a research study that aimed to highlight students' ideas about ratio and proportion in geometry. Students’ ideas about these concepts were produced through their participation in a series of tasks that were part of an interdisciplinary experimentation. In particular, we wanted to address the two following questions: a) what are the conceptualizations of twelve-year-old students about ratio and proportion related to geometrical shapes; and b) how these conceptualizations could be modified through their participation in a series of interdisciplinary tasks. According to Lamon (1993), the

*stretchers/shrinkers* type of ratio and proportion problems, which have reference to geometry, pose difficulty for students in terms of recognizing their multiplicative structure. The students' strategies for solving ratio and proportion problems in a geometric context are the *nonconstructive strategies* of 'avoiding', 'visual or additive', and 'pattern-building'; the 'preproportional', 'qualitative proportional', and 'quantitative proportional' types of reasoning, which are considered as *constructive strategies*. The common ineffective strategy that students use in order to solve similar problems is the 'visual or additive strategy', which stresses the aforementioned students' difficulty with the multiplicative structure (Lamon, 1993).

Students worked in pairs for a total of seven 90-minute sessions over a period of 3 weeks. In this paper we will discuss the learning paths of four out of the eight students who participated in the study, those of George, Helen, Bill, and Peter. The tasks that comprised our research were based on an experimental construct that followed the principle of the rectilinear propagation of light in the *camera obscura*. We used this device in order to depict proportional geometrical shapes. In most tasks students had to investigate the similarity of rectangles formed by tiny led light sources placed on their vertices and their image on a screen placed behind the pinhole on a plane parallel to that of the rectangle. The use of this model gave us the opportunity to negotiate in a non-typical way the concepts of multiplicative relationships, internal and external ratios and also connect fractions with ratio and proportion. According to the Science and Mathematics programs of study, the students were familiar with the concepts at hand. Research data was comprised of the teacher-researcher's fieldnotes (first author), the fieldnotes of a 'non-participant' observer, the transcripts of the recordings in each pair, as well as the students written work.

In the tasks of the initial diagnostic assessment, which was silent and individual, we asked students to draw the parents of a little boy fish, whose body and tail were isosceles right-angled triangles of different size (students were familiar with this fish as it is the main character in a widely-read series of children's books in Greek). The only direction we gave to the students was that the parents needed to be similar to the boy but larger. In the second session of the experimentation we asked students to find the relation between two rectangles that were similar. Students were only aware that one of the rectangles was bigger in size than the other. In the third session, in one of the tasks, we gave students a number of rectangles of various sizes and we asked them to find which of these were similar. In the fourth session of the experimentation, we gave students a rectangle ( $7 \times 3$  cm) and we asked them to draw a similar one knowing only the length of one of its sides (11.2 cm). In a summative assessment during the final session, which was silent and individual as the initial diagnostic assessment, we asked students to investigate regular hexagons in terms of their similarity.

### **Students' chains of signification**

In the task of the diagnostic assessment, the four students spontaneously measured the length of the sides of the triangles that comprised the little boy fish. They concluded that the triangles were isosceles, making no reference though to the measure of the angles in the two triangles. While drawing the parents, five of the students followed an additive strategy, without paying attention to the proportion between the size of the triangles of the body and tail of the boy fish and those of his parents. Helen and Bill tried to ensure that the triangles were isosceles to begin with, and that the measure of the interior angles matched roughly the ones in the boy's body and tail. So they drew the

two equal sides of the body and the tail of the parents by increasing their length by the same amount. For example, in drawing the father, one student increased the two sides from 5 to 8cm for the body and from 2.5 to 4.7cm for the tail. While drawing the third side of the triangles, though, the students realized that they could not enlarge this third side in same the manner that they had enlarged the other two. So, they increased the length of the third side as much as was needed in order to complete the triangles in their drawing. George designed one parent by doubling the sides of both triangles, thus paying attention to the interior angle in their drawings, but used an additive strategy for the other parent since they thought that they could multiply with a whole number (*Qualisign, Icon, Rheme*; in this case, the Sign constructed by the student is interpreted by the student as being of the same nature and quality with the given fish boy with O1: the multiplicative structure in the stretchers/shrinkers problems, R1: the students' drawings, and I1a: the use of multiplication and addition interchangeably and that ratio needs to be a whole number). Peter used multiplication for both parents, choosing the numbers 3 and 2 as operators for the father and the mother respectively (*Sinsign, Icon, Rheme*; the Sign is interpreted by the student as possibly standing for its Object with O1: the multiplicative structure in the stretchers/shrinkers problems, R1: the drawings and I1b: that multiplication as probably related to ratio and proportion).

In the second session, the four students spontaneously measured the lengths of their sides and Helen and Bill suggested that they should “find the difference between their lengths” (*Qualisign, Icon, Rheme*; the Sign is interpreted by the student as being of the same nature and quality with the given Representamen, with O2: the multiplicative structure of stretchers/shrinkers problems, R2: oral sentence, I2a: the relation between the two similar rectangles can be expressed by subtraction of their lengths). George, who had used a multiplicative strategy in drawing one parent and an additive in the other in the diagnostic assessment, disagreed by saying that “we need to divide to find out how many they are” (*Sinsign, Index, Rheme*; the Sign is interpreted by the student as possibly standing for another event-index, with O2: the multiplicative structure of stretchers/shrinkers problems, R2: oral sentence, I2b: division is related to ratio and proportion). At this point, Peter, who had used a multiplicative strategy in drawing both parents, disagreed, by saying “since we say twice or three times, we have multiplication” (*Legisign, Icon, Rheme*; is a type/law, a ‘regularity of the indefinite future’ that is interpreted by the student as possibly standing for its Object, with O2: the multiplicative structure of stretchers/shrinkers problems, R2: oral sentence, I2c: multiplication is related to ratio and proportion). Taking advantage of these statements, the researcher suggested that they should try both ideas, subtraction and division. In their first attempt, having completed the subtractions, they did not reach to a conclusion concerning the relation between the two rectangles. In their second attempt, instead of multiplication, which is directly related to the multiplicative strategy, the students decided to use division by dividing the larger by the smaller number. Having observed that the two quotients were equal when rounded to one decimal point, the four students concluded that we could ascertain whether two rectangles are similar by using division.

In the third session, the four students measured the sides of the rectangles and circled the similar ones on their sheet showing preproportional reasoning. Only George chose to express the relation between the similar rectangles by making a clear reference to the operator that constituted them as similar, showing qualitative proportional reasoning (*Legisign, Index, Rheme*; is a type interpreted by the student as possibly standing for its Object - another event, with O3: the multiplicative

structure of stretchers/shrinkers problems, R3: written expression, I3: division is related to ratio and proportion and the concept of unit plays a role to the result).

At the first part of the fourth session, the four students used the internal ratio ( $\text{length } 1 \div \text{length } 2 = \text{breadth } 1 \div \text{breadth } 2$ ) in their calculations, and after they had drawn the desired rectangle they used the external ratio ( $\text{length } 1 \div \text{breadth } 1 = \text{length } 2 \div \text{breadth } 2$ ) simply to check their answer without realizing that both ratios could be used interchangeably in order to express the desired relation between the rectangles (*Legisign, Icon, Rheme*; is a type/law, a ‘regularity of the indefinite future’ interpreted by the student as possibly standing for its Object, with O4: the internal and external ratio of similar shapes, R4: arithmetic operations, I4: the relation of similarity can be found with operations between lengths and widths, widths and lengths, and widths-widths and lengths-lengths and also ratios are pure numbers, without measurement). In the second part of this session, in an attempt to enhance the qualitative proportional reasoning through the use of mathematical terminology in the ‘stretchers/shrinkers’ tasks, we asked the students to express division in an alternative way. So expressions of the kind “seven divided by two” transformed to “seven over two,” especially from George and Peter, implicating thus a fractional terminology in the discussion (*Legisign, Symbol, Rheme*; is a type interpreted by the student as possibly standing for its Object-law, with O5: fractions are directly related to ratios, R5: oral sentences, I5: division can be alternatively expressed with a fraction and their terminology). All of the students though tended to always select the largest number as the numerator, as it was more convenient in the subsequent calculations. So we gave them a similar rectangle on the screen that was reduced in size and asked them to express the reduction with a fraction. All of them claimed that the answer for the reduction was “3.5 over 1.5, because in this way we begin from what it was (i.e. the length of the rectangle formed by the led light sources) and then we have the ‘reduced’ one” (i.e. the length of the rectangle on the screen).” The researcher then made a reference to maps their relation to the size of the actual land that they represent, and the four students immediately recognized that the ratio in the legend can be as small as 1 over 50000 (*Legisign, Symbol, Delome/Argument*; is a type interpreted by the student as semiotically standing for its Object-law, with O6: the role of numerators and denominators in ratios, R6: oral sentences, I6: flashback to maps and the various ratios in order to express the reduction may follow the same principles as in this situation). After this discussion, Bill, George, Helen, and Peter concluded that “the numerator expresses the representation on the map and the denominator the physical representation,” and therefore the fraction that expresses the relation between the rectangles can be larger or smaller than 1 when it represents a stretch or a shrink (*Legisign, Symbol, Rheme*; is a type interpreted by the student as possibly standing for its Object-law, with O7: the role of numerators and denominators in fractions, R7: oral sentences, I7: there is a fixed way to express the enlargement or zooming out and numerators and denominators determine the result).

In the tasks of the summative assessment, Bill, George, Helen, and Peter were able to transfer successfully the understanding that they had built in relation to similar rectangles in the sessions of the experimentation (*Legisign, Symbol, Dicent*; is a type interpreted by the student as physically standing for its Object-law, with O8: the multiplicative structure of stretchers/shrinkers problems and the role of numerators and denominators in ratios, R8: written sentences and written expressions, I8: the appropriate way to express ratios for enlargement or reduction, without measurements).

As we can see, the four students started the sessions (diagnostic assessment) with vague ideas about ratio and proportion in geometrical shapes. Only Peter used multiplicative strategy in all tasks while the other students used the additive strategy. In the instructional sessions that followed, it became evident that students produced arguments in order to support their statements. As a result of this effort some of the students constructed conceptualizations that fall in the upper levels in Peirce's list of Sign classes. In the summative session they managed to transfer their knowledge to a new context. The development of the four twelve-year-old students' conceptualizations concerning ratio and proportion while working on tasks that required the stretching and shrinking of rectangles and regular hexagons, were the Signs that the students constructed. Following Pierce's classification of Signs and the strategies students used while working on these tasks, the criteria used to classify the students' Signs can be summarized as below (Table 2):

**Table 2: Signs constructed by the students**

Sessions of Experimentation	Students' Signs according to ten classes of Peirce	
1 <sup>st</sup> : diagnostic assessment with individual tasks	Qualisign, Icon, Rheme (I) Sinsign, Icon, Rheme (II)	Bill, George, Helen Peter
2 <sup>nd</sup> : conservation of properties in stretcher/shrinker problems	Qualisign, Icon, Rheme (I) Sinsign, Index, Rheme, (III) Legisign, Icon, Rheme (V)	Bill, Helen George Peter
3 <sup>rd</sup> : stress of the multiplicative strategy	Legisign, Icon, Rheme (V) Legisign, Index, Rheme (VI)	Bill, George, Helen Peter
4 <sup>th</sup> : enhancement of multiplicative strategy by similar rectangles and ratios of lengths and widths	Legisign, Symbol, Rheme (VIII)	Bill, George, Helen, Peter in plenary session
division related to fraction, terminology, role of numerator and denominator, legend of maps	Legisign, Symbol, Delome (X) Legisign, Symbol, Rheme (VIII)	George, Peter Bill, George, Helen, Peter in plenary session
5 <sup>th</sup> : summative assessment with individual tasks	Legisign, Symbol, Dicent (IX)	Bill, George, Helen, Peter

## Closing Remarks

The learning process is affected by many factors, such as students' ideas, the interaction between them, the context, the tasks, the representations involved, etc. This means that the learning process is neither rectilinear nor individual; it is 'fluid' and infinite, and includes a number of conceptualizations. Following Peirce's suggestions on how to make our ideas clear, the meaning of a concept or a sign consists in the habit to which it gives rise in the interpreter, be it either a habit of action or a habit of thought. This habit guides future actions, and is forever on trial in the light of upcoming experiences (Triandafillidis, 2002). We see students' chains of signification side by side to their activity sequences while they engage with tasks in an elaborated Hypothetical (Teaching) Learning Trajectory that a teacher/researcher has designed. By using Peirce's classes of Signs then, we expand the work of other researchers who have used Peirce's theory of Signs to analyze the learning process based on the triadic nature of a Sign's three components. Our work may also assist a teacher/researcher to concretize students' produced Signs, the ideas that are involved, to what extent students become familiar with the concepts, and also mark those characteristics of the tasks that turn students' conceptualizations to higher level Signs, i.e. habits of action or thought that

would endure future trials. In other words, it may help a teacher/researcher to apprehend turning points in students' activity sequences and the distance of a student's Sign from the mathematical goal(s) that she has set, as well as to take appropriate instructional actions in order to support the construction of Signs that are more mature and more relevant to the mathematical ideas at hand.

*In current approaches of mathematics education at the upper secondary level, activities proposed to students involve several domains in interaction. After studying activities about modelling or functions, we question here the development in many mathematical curricula around the world of activities involving computer programming, sometimes labelled “coding” or “algorithmics”. The motivation of this paper is that a suitable theoretical framework is required to make sense of students’ work in activities involving various domains, taking into account the semiotic dimension as well as the use of instruments, and the contents and reasoning specific to each domain.*

*Keywords: Connected Working Spaces, computer programming, modelling, functions, mathematics and other domains.*

## Introduction

We are concerned with teaching/learning situations associating mathematical domains and other domains, and problems arising in these situations. Here are three examples. First, with regard to co-variation and functions, many researchers stress the need to offer students domains of sensual experience of co-variation for instance by way of dynamic geometry before or in parallel with formal approaches of functions. Modelling is another activity associating domains of everyday experience or scientific or professional domains in order that students make sense of mathematical notions and processes. Finally, there is now a big emphasis in many curricula on the introduction of programming (or algorithmics, or coding) into mathematical activities. Our concern, looking at real classroom situations or even experimental situations, is the lack of connection between the experience in the other domains and the mathematical formalism, techniques, etc. There is also a lack of connection between the processes of solving and reasoning in other domains on one side and in mathematics on the other side. In this paper, we consider especially the case of computer programming in mathematics education. Few research studies have been done in this area (Lagrange, 2014) and then this paper is based upon a recent doctoral research study carried out by the second author (Laval, 2018). We have two aims: to discuss how current theoretical frameworks analyze various aspects of activities involving mathematics and other domains, and to propose a framework, taking into account comprehensively these aspects.

## Theoretical developments and question

Classically, activities involving mathematics and other domains are analysed by considering that entities involved in the task appear under different semiotic representations, each pertaining to a field. This is the “multi-representation” view. Among the many theoretical approaches of multi-representations, we start from Duval’s (2006) consideration of the plurality of representations for a given object. For Duval there is no other ways of gaining access to the mathematical objects but to

produce some semiotic representations and he stresses that representations are organized in semiotic systems. In a semiotic system, some representations are called “registers” and there is a need for a specific focus on processes of work inside and between the registers. In this multi-representational approach, activities for students in different fields are considered helpful because of the opportunities they offer for working on different semiotic representations and coordinating these. In spite of the usefulness of frameworks like Duval’s, the “multi-representation” view is for us too reductively semiotic and cannot alone really make sense of activities involving several fields in interaction, and of their potentialities. In some curricula, much emphasis has been put on the work on representations and students can be fluent in the processes of conversion and treatments, but this does not necessarily imply a deep understanding of notions at stake. For instance, even when students are proficient in dealing with the four classical representations of functions (verbal, symbolic, graphic, and tabular), fundamental aspects of functions (correspondence, co-variation, mapping, etc.) and their coordination remain problematic.

Another framework for making sense of activities of coordinating different domains (especially mathematical domains) is by Douady (1986). For Douady, a setting is constituted of objects from a branch of mathematics, of relationship between these objects, their various expressions and the mental images associated with these objects. When students solve a problem, they can consider this problem in different settings. Switching from one setting to another is important in order that students progress and that their conceptions evolve. According to authors like Perrin-Glorian (2004), it is sometimes difficult to distinguish the representational and the settings approaches, especially when a phase of work can be thought of both as a switch between settings and as a conversion of representations. Actually, rather than contradicting, the two approaches complement: beyond its mathematical contents, each setting offers specific semiotic systems, and coordinating the settings also implies coordinating the semiotic systems.

Another concern is how instruments are taken into account in the students’ mathematical activity. Twenty years ago, sophisticated calculators became available for students’ work and a framework was developed: the instrumental approach of the use of digital technologies to teach and learn mathematics. This approach has been inspired by research work in cognitive ergonomics but researchers like Lagrange (1999) insisted on the intertwined development of knowledge related to the instrument and of knowledge about mathematics in an instrumental genesis. This is important because otherwise an instrumental approach would be only a psychological framework with little insight for mathematics education. Authors like Bartolini Bussi & Mariotti (2008) also noted that the use of instruments and the associated reflection involve a lot of signs that, for a student, may have not immediately a mathematical meaning, and they propose the idea of “semiotic mediation” to refer to the classroom activity necessary in order to ensure the productivity of the work with instruments at a semiotic level.

Each framework, multi-representation, coordination of mathematical settings and instrumental approach, puts a focus on a specific dimension: the semiotic processes or on the contents and reasoning, or on the use of instruments (Figure 1). We present the framework of connected working spaces, taking into account comprehensively these three dimensions in order to address work in mathematical domains as well as in non-mathematical domains where mathematical notions can

take sense. This framework was proposed by Minh & Lagrange (2016) and by Lagrange (2018) for activities related respectively to functions and to modelling and we question here its utility for addressing the new challenge brought about by activities involving computer programming in mathematics education.

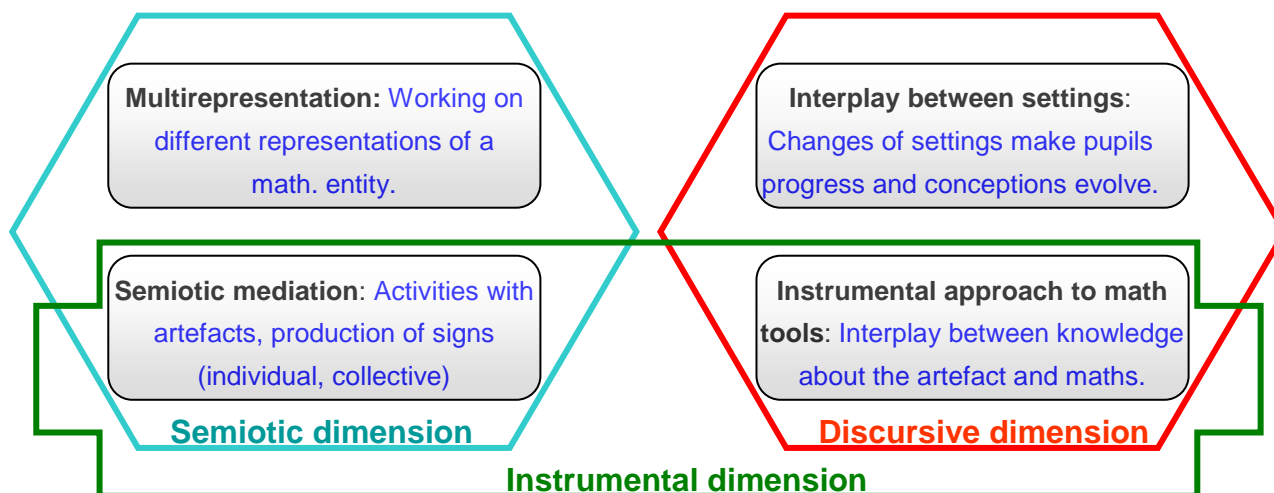

Figure 1: Four frameworks, three dimensions.

## Connected Working Spaces

The framework of the Mathematical Working Spaces (MWS) allows characterizing the way the concepts make sense in a given work context. According to Kuzniak & Richard (2013) a MWS is an abstract space organized to ensure the mathematical work in an educational setting. Work in a MWS is organized around three dimensions:

- Semiotic: use of symbols, graphics, concrete objects understood as signs.
- Instrumental: construction using artefacts (geometric figure, graphs, program...)
- Discursive: justification and proof using a theoretical frame of reference.

Activities considered in this paper involve several domains, and for each of these domains, a working space. The framework of “Connected Working Spaces” has been introduced in order to give account of how connections between Working Spaces bring meaning to the concepts involved. This extended MWS framework takes into account the semiotic and instrumental dimensions as well as the contents and mode of reasoning, in different domains of activity and their interaction in a mathematical activity. Then it is not contradictory with the theoretical developments outlined above (Figure 1), but it rather aims to organize them in a comprehensive structure. What we expect from this framework is to help building and analysing situations on a given topic involving a mathematical and another domain, identifying the three dimensions in the corresponding Working Spaces, contrasting these and looking for possibilities of connection.

## Connecting Algorithmic and Mathematical Working Spaces: The Intermediate Value Theorem (IVT)

Activities involving computer programming in mathematics education connect two distinct Working Spaces: an Algorithmic Working Space (AWS) and a Mathematical Working Space

(MWS). In the continuation of this paper we will focus on a particular topic that can be considered both from a computer science and a mathematical point of view: the solution of an equation  $f(x)=0$  for a given function  $f$  defined on a closed interval  $[a ; b]$ . We will consider this topic relatively to how it can be a subject for secondary students' work, that is to say how it implies connecting the two Working Spaces. From a computer programming point of view, specific algorithms allow approaching solutions as close as possible. We consider algorithms able to find, for an arbitrary precision  $e$ , an interval  $[u ; v]$  with the property  $P(e)$ :  $|u - v| < e$  and  $f(u) \times f(v) \leq 0$ . The simplest algorithm scans iteratively the sub intervals of length  $e$ , until finding a suitable one (Figure 2, left). A more efficient algorithm is based on dichotomy (Figure 2, right). In the corresponding AWS, the semiotic dimension is characterized by specific marker of iterative (While...) and alternative (If...) treatments and by variables, whose value, as a difference with mathematical variables, change along the treatment by way of the specific operation of assignment (sign  $\leftarrow$  in Figure 1). Mathematical expressions are also involved. The associated semiotic system can be at stake for students not fluent in algebra, especially the notation  $f(\dots)$ . There is a strong instrumental dimension, since algorithms are intended to be executed by an automatic device and it is expected that execution will help students to make sense of the formalism. The discursive dimension is characterized by questions like the termination of an algorithm (does it terminate in a finite number of steps?), its effectivity (does it return an appropriate solution?) and its efficiency (how many steps are necessary for a given set of data?).

A scan algorithm	A dichotomy algorithm
$u \leftarrow a$	$u \leftarrow a$
$v \leftarrow a + e$	Else
While $f(u) \times f(v) > 0$	$v \leftarrow b$
$u \leftarrow u + e$	While $v - u > e$
$v \leftarrow \min(b, v + e)$	$m \leftarrow \frac{u+v}{2}$
End While	If $f(u) \times f(m) > 0$ then
Return $[u; v]$	$u \leftarrow m$
	Endif
	End While
	Return $[u; v]$

**Figure 2: Algorithms approximating a solution of an equation  $f(x)=0$ .**

From a mathematical point of view, the Intermediate Value Theorem (IVT) guarantees the existence of a solution on the interval  $[a ; b]$  under the sufficient conditions:  $f$  is continuous and  $f(a) \times f(b) < 0$ . The corresponding MWS has a strong discursive dimension: it includes properties of functions like continuity and monotonicity; it is focused on a mathematical solution, rather than on a process of approximation. A classical proof is based on two adjacent sequences. In addition to the usual mathematical formalism, the semiotic dimension is then characterized by the formalism of infinite sequences, different from the iterative variables of the algorithms, although both are defined by way of the dichotomy method. Students are introduced progressively into these notions and formalism from 10<sup>th</sup> to 12<sup>th</sup> grade. The instruments here are paper and pencil calculations, and graphical display of functions. Figure 3 summarizes the dimensions in the two Working Spaces.

### Organizing the Working Spaces: A classroom experiment

The outcome of the above analysis is that the algorithms and the theorem have different targets: while the IVT is about solutions, the algorithms aims at obtaining an interval with the property  $P(e)$ .

Mathematical Working Space	Algorithmic Working Space
<ul style="list-style-type: none"> <li>• Discursive dimension: <ul style="list-style-type: none"> <li>– Focus on a mathematical solution,</li> <li>– Properties of functions.</li> </ul> </li> <li>• Semiotic dimension: <ul style="list-style-type: none"> <li>– Usual mathematical formalism,</li> <li>– Formalism of infinite sequence.</li> <li>– Graphs (iconic).</li> </ul> </li> <li>• Instrumental dimension: <ul style="list-style-type: none"> <li>– Paper and pencil calculations, Graphs.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Discursive dimension: <ul style="list-style-type: none"> <li>– Focus on process of approximation: termination, effectivity, efficiency.</li> </ul> </li> <li>• Semiotic dimension: <ul style="list-style-type: none"> <li>– Specific markers of treatments.</li> <li>– Variables.</li> <li>– Mathematical expressions.</li> </ul> </li> <li>• Instrumental dimension: <ul style="list-style-type: none"> <li>– Execution by automatic device.</li> </ul> </li> </ul>

**Figure 3: The Working Spaces**

However, there are clear links. First, the IVT ensures that, with the sufficient condition of continuity, an interval with the property  $P(e)$  actually contains one or more solutions, and the corollary that, with the additional sufficient condition of monotonicity, it contains the unique solution. Second, the algorithms, especially the dichotomy algorithm provides a mode of generation of sequences that play a crucial role in a proof of the IVT. From these links, different organisations of the MWS and the AWS can be envisioned. In a first organization, after being taught about the IVT, students can work on the algorithms with a function verifying the sufficient conditions in order to get an approximation of the solution. We name this organisation “application”: computer programming is considered as an application of “pure” mathematics. This is the most common scheme that we found when looking at textbooks in France. As for us, we envision other organisations making the Working Spaces interact more closely. It is because, as we wrote above, knowledge is at stake in both Working Spaces, and interaction can help understanding. Working on an algorithm, and after proving that the returned interval has the property  $P(e)$ , students can experiment on diverse functions, in order to infer sufficient conditions for the IVT. They can then work on a proof by conceiving recurrent sequences from the iterative variables in the algorithm.

### Classroom situations

We designed classroom situations in order to test the hypothesis that, transitioning from “application” to other organisations, students make connections between Working Spaces in the various dimensions. The situations were implemented in three French classes at 10<sup>th</sup>, 11<sup>th</sup> and 12<sup>th</sup> grade in order to get evidence about the work of students with different mathematical attainments. Each class had around 30 students and had nothing particular with regard to the work expected. The duration of each situation was between one-half and one hour. The students had worked before on the dichotomy method for discrete numbers (Laval, 2016) and this work was mainly in the AWS. Otherwise they had no previous experience in the domain, except that, for the 12<sup>th</sup> graders, the IVT had been introduced and not proved. A first situation was “application”: a continuous monotonic function was given and the dichotomy method was exposed by way of a flow chart. The students had to give some evidence of the existence of a unique solution, and to implement the method for this function in a textual programming environment allowing execution. The situation was intended to make students work in the AWS and MWS and coordinate these especially in the semiotic and discursive dimensions. Then, in a second situation, with the same function and the same programming environment, students had to complete a scan algorithm where the condition of continuation (following While) was missing. While this situation clearly involves the AWS in the

three dimensions, the MWS is in the background, both with regard to the formalism and to the properties of the function.

We analyse here particularly two subsequent situations. A situation was intended to make students aware of sufficient conditions for the IVT, by encountering functions for which the dichotomy algorithm does not return a suitable interval. They were requested to implement and execute a dichotomy algorithm for “hidden” functions, i.e., functions that students could use in the algorithm and display graphs, but whose formula was not given. Students had to answer the question “does the interval returned by the algorithm actually contain the unique solution?” See an example in Figure 4. The task is reflective, both in the AWS and the MWS: evaluating the effectivity of the algorithm at a mathematical level. The students were expected to be influenced toward an affirmative answer by the “application” situation where mathematical effectivity was not discussed. Students at 12th grade knew the IVT, but were expected not to focus on sufficient conditions, because all examples treated before were continuous monotonic functions. However, the students were expected to double check by graphing the functions, or computing values. This connection between the AWS and the MWS involves the instrumental and the discursive dimensions.

**Figure 4: A situation to make students aware of sufficient conditions for the existence of a solution.**

The last situation was implemented only for 12<sup>th</sup> grade students. Students were invited to build a proof of the IVT, using adjacent sequences and the dichotomy method. The semiotic dimensions of the MWS and the AWS are at stake in this task, with a process of conversion, from the iteration on variables in the AWS, to sequences in the MWS. In the discursive dimensions the convergence of the sequences had to be inferred from the fact that  $P(e)$  holds for arbitrary  $e$ . However, the convergence does not prove that the limit is a solution, and students were expected to use explicitly a theorem on continuous functions and sequences, and another about the compatibility of limit and order. This work is specific to the MWS and had been prepared by the focus on sufficient conditions in the third situation.

### Observation and evaluation

In the situation with the “hidden” functions (Figure 4), the students considered that the very small interval returned by the algorithm was an evidence of the existence of a single solution. Most students reconsidered this finding after graphing and recognizing the unusual shape of the graph. They calculated the values of the function at the boundaries of the intervals returned by the algorithm for decreasing values of the threshold  $e$  and found values of the function decreasing at the left boundary and increasing at the right boundary. They deduced that these intervals approach a

pole rather than a solution. The outcome of this third situation is that, except for a few 10<sup>th</sup> graders, the students made a clear distinction between the effectivity of the algorithm in the AWS and its effectivity to approach a solution in the MWS. 11<sup>th</sup> and 12<sup>th</sup> graders had a notion of sequences and convergence that helped them to consider more closely the phenomenon.

As mentioned before, the situation on the proof of the IVT was implemented only at 12<sup>th</sup> grade. At the beginning, the students were confused, not connecting sequences and the IVT, which they thought related to functions. Then some of them proposed to look at the values of the boundaries of the intervals along the execution of the dichotomy algorithm for a particular function. This is a typical answer:

The sequences  $(u_n)$  and  $(v_n)$  are adjacent because  $(u_n)$  is increasing,  $(v_n)$  is decreasing and  $(v_n - u_n)$  becomes closer to zero when  $n$  becomes bigger and bigger. Then these two sequences converge towards a common limit  $c$ . Because  $f$  is continuous,  $f(u_n)$  and  $f(v_n)$  converge towards  $f(c)$  which is zero. The theorem is proved by way of the computer for a particular function.

This “proof” is a mix of observation (behaviour of the sequences, value of  $f(c)$ ) and deduction (convergence of the sequences) and, for the students it is valid only for one function. Within the duration of this situation students could not go much beyond. Only one observed that a proof of the behaviour of the sequences could be made by induction. For us, the students adequately took advantage of the work in the AWS but in some way stayed halfway between the AWS that produces evidence on an example, and the MWS in which a formal proof for a generic function was expected. Students had no difficulty to operate the semiotic conversion from computer variables to sequences. In contrast, their answer witnesses a notion of proof still confusing instrumental evidence and mathematical reasoning.

Instrumental		Semiotic	
AWS (execution)	$\longleftrightarrow$	MWS (graph)	AWS (iterative variables) $\longleftrightarrow$ MWS (recurrent sequences)
Discursive		Instrumental-Discursive	
AWS (effectivity)	$\longleftrightarrow$	MWS (existence)	AWS (observation of variables' behavior) $\longleftrightarrow$ MWS (partial proof of IVT)

**Figure 5: Connections by students in the situation of Figure 4 (left) and in the proof of the IVT (right).**

## Conclusion

This paper investigates the usefulness of the Connected Working Spaces framework for addressing activities for students involving distinctive domains and especially computer programming and mathematics. We used this framework for designing a classroom experiment to test a hypothesis: for a particular topic involving computer programming and mathematics, it is possible to characterize an AWS and a MWS, and to create situations in order that students make fruitful connections between these Working Spaces in the three dimensions, semiotic, instrumental and discursive. We observed a variety of connections validating this hypothesis (Figure 5). In the situation of Figure 4, students operated the delicate coordination of the discursive dimensions in the AWS and the MWS by combining work in the instrumental dimensions. In the proof of the IVT, the students took advantage of the work in the instrumental and discursive dimensions of the AWS for their discursive work in the MWS, although they were only partially successful. Previous studies

about functions and modelling already gave insight into a potential of the Connected Working Spaces framework and this paper extends the analysis to computer programming and mathematics education. It also witnesses of a framework that do not contradict with other approaches like multi-representation, settings and instruments but rather connects these in a comprehensive analysis of students' work.

*Abstract: Teachers worldwide are using social media as a professional development resource. In studying social media as 'a place' for teachers' professional development, we investigated large Facebook groups with themes connected to teaching and learning in compulsory schools. The interaction in these groups was analysed within the framework of systemic functional grammar. In order to reveal knowledge known and shared by teachers as a community, we have also used Shulman's (1987) framework. Most posts received responses and this response is in line with the expected response pattern. The speech functions 'Questions' and 'Offers' were most common. Further, most posts addressed subject specific knowledge. The multi-theoretical approach used when researching mathematics teachers' professional development in self-organized online groups showed that these large Facebook groups facilitated professional learning.*

*Keywords: Functional grammar, mathematics teachers, PCK, professional development, social media.*

### Introduction

Studies have shown that Swedish mathematics teachers, to a large extent, participate in self-organized online groups both while working as well as during their free time (e.g., van Bommel & Liljekvist, 2015; van Bommel & Liljekvist, 2016). Moreover, participation in online communities is a global phenomenon: teachers worldwide are using social media as a professional development resource (e.g., Bissessar, 2014; Patahuddin & Logan, 2015; Tour, 2017). Hence, in studying social media as 'a place' for teachers' professional development, we investigated large Facebook groups with themes connected to teaching and learning in compulsory schools. It is well known that the subject being taught is in the centre of teachers' work (e.g., Kansanen & Meri, 1999; Shulman, 1987). Subject-specific Facebook groups (e.g., mathematics education) in an online teacher community may therefore imply a higher potential for professional development, and the subject-specific theme (e.g., mathematics for primary school) of some of the teacher self-organized online groups make these groups particularly interesting to study.

If we want to understand the conditions for informal professional learning in online communities better, we have to acknowledge the change of the setting and develop theories that take such change into account (Liljekvist, 2017; Liljekvist, van Bommel, & Olin-Scheller, 2018). Our study investigate these online communities at three levels: descriptive level (van Bommel & Liljekvist, 2016), interaction level (Randahl, Olin-Scheller, van Bommel, & Liljekvist, 2017), and the motivational level. These three levels give us an opportunity to answer the questions: how and what do teachers

discuss in the groups. However, this paper goes beyond such a question and addresses the theoretical frameworks we used to capture a variety of aspects of this practice, in order to identify signs of a professional approach (Talbert, 2010) in these communities. Further, the paper addresses the need to go beyond a specific theory when researching this phenomenon and a brief description is given of how the analytical framework was adapted to the context and empirical findings.

According to Little (2002), locating professional development in teachers' communities of practice directs attention to three considerations: (I) the representations of practice (e.g., how school practices become known and shared); (II) the practice orientation (e.g., whether or not the teacher community improves teaching, and how this interaction advances or impedes teacher learning); (III) the interaction norms (e.g., how participation and interaction are organized, and how this organization supports teacher learning and practice reform).

Hence, to understand how these practices become known and shared, the interaction in these groups was analysed within the framework of systemic functional grammar (Halliday & Matthiessen, 2013). Due to Facebook's construction with posts and comments, language (in a broad sense) is used to initiate exchanges in all conversations, for giving and demanding information, goods, and services. In addition, when analysing the practices represented and to reveal knowledge known and shared by teachers as a community (Little, 2002), we have used Shulman's (1987) framework. These two frameworks allowed us to categorize teachers' professional communities both in a general way and in relation to subject-specific education. Combining the two frameworks gives us more than two single descriptions: it provides us with a possibility to deepen the analysis of our data and reveals other aspects of mathematics teaching.

## Analytical framework

### Speech functions as enacting interpersonal relations

People use language to interact with others or to express their view about the world and how they interpret it. Within the framework of Systemic Functional Linguistics (SFL), this is described as the meta functions of the language (Halliday & Matthiessen, 2013). Halliday and Matthiessen distinguish between three meta functions of language, that is, its ideational, interpersonal, and textual functions. The ideational function is a matter of expressing how one sees the world and how one interprets this experience. The interpersonal function concerns how the text creates a relationship between speaker and listener. Finally, the textual function concerns aspects that make language relevant, which is sometimes looked upon as a "help-function" to organize and mediate.

Dealing with relation-making processes in online groups, we concentrate on the interpersonal function. In a conversation, the speaker not only plays an initiating role in exchanging information, but also requires something of the listener. "Typically, therefore", Halliday & Matthiessen (2013, p. 135) conclude, "an 'act' of speaking is something that might more appropriately be called an **interact**: it is an exchange, in which giving implies receiving and demanding implies giving a response" (bold in original). In the semantic system of speech function, anyone can initiate either a giving or a demanding exchange in the conversation. That is, we can give or ask for information and we can offer someone something or ask someone to do something. These four primary speech functions: statement, question, offer, and command (see, e.g., Halliday & Matthiessen, 2013) were mapped on the posts in

a group. It is therefore possible to analyse what the teacher wanted to accomplish when posting in the group by asking what speech function was used.

Further, the response given can be analysed as either *expected* or *discretionary* responses (Holmberg & Karlsson, 2006). For instance, the desired response to a question is an answer and the discretionary response is to neglect to answer. Hence, it is possible to uncover interactional patterns in online groups. For example, when making a statement, a member of a group can acknowledge as well as contradict a particular matter, indicating that statements may initiate discussions. Another example: if posts mainly evoke the desired responses, this could indicate a community of trust. Finally, when posting a question, a teacher expects someone in the group to have the answer as well as being willing to give it. In this way, questions can reveal the knowledge base of the group.

### **Disclosing the shared professional knowledge**

In the knowledge base framework, Shulman (1987) outlines seven categories that he suggests constitute the teacher's understanding needed to promote comprehensive student learning. His framework incorporates teacher awareness of various educational aspects, such as content, pedagogy, and organization: content knowledge (CK); general pedagogical knowledge (PK); curriculum knowledge (CuK); pedagogical content knowledge (PCK); knowledge of learners (KoL); knowledge of educational context (KEC); and, knowledge of educational ends (KEE).

Together these categories serve as a way to visualize the shared professional knowledge in these Facebook groups, organized by and for teachers. However, we learnt from our empirical material that three of the categories (i.e., CK; PCK; and KoL) were difficult to differentiate from each other (van Bommel & Liljekvist, 2016; Randahl et al., 2017). These categories appeared simultaneously in many posts, hence, we decided to use an overarching category (PCK+) in further analysis, as we did not need a finer-grained analysis in this part of the study. By doing so, we adopt the framework to the Scandinavian/German educational tradition where the relation between the teaching, studying and learning activities in the classroom “the didactic relation” (e.g., Kansanen & Meri, 1999) is considered the professional knowledge base.

### **Method**

The data were collected from large Facebook groups. The groups are formed and maintained by teachers, that is, self-organized and not initiated by schools, the Ministry of Education, researchers, etc. It is plausible that every member in the group has a connection to the education field, since the administrator of the group checks a member's affiliation to a school when entering the group. Through membership, one can post and comment. At the time of data collection, the groups were open for the general public to read. In this paper, we include the results from the analysis of three strategically selected Swedish Facebook groups with a theme connected to mathematics education, each with, at time of data collection, between 2000 and 15 000 members. The groups are labelled MA1–3.

By scrutinizing the activity pattern in the groups, a stratified random sample of posts could be conducted based on time of the school year (for a detailed description see van Bommel, Liljekvist, & Olin-Scheller [2018]). This method makes it possible to draw conclusions of the interaction on the

groups as a whole. Eighty-four to ninety-eight initial posts were collected per group with a total of 1762 responses to these initial posts. The average amount of responses per initial post differed from 3.1 in MA3 to 10.1 in MA2. The interaction sometimes contained images (77 in total), documents (13 instances) or links to other sites (229 instances).

The posts were categorized using the analytical framework developed from speech functions (Halliday & Matthiessen, 2013) and the knowledge-base framework (Shulman, 1987). Coding reproducibility was ensured via a multi-step process, where both inter and intra coder reliability was examined. All four authors were involved in the coding process, and all data was coded by at least two persons. Furthermore, the responses on the posts were analysed to confirm the coding of speech functions, as the response validates the speech function (e.g., Holmberg, 2011). Finally, the internal consistency of the categories was controlled for by scrutinizing all posts in each category, to ensure that all posts coded in each category were consistently coded. The procedure described, in which we recorded every step in the sampling, coding, and categorization, made it possible to backtrack, retrace, and correct errors made in the coding process.

## Data

Below, four examples from our data are given (translated into English for this paper), including one or two of the responses to give some insight in the direction of the conversation. The examples will be referred to in the section results and the categorizations for each framework are stated in brackets, along with the number of responses.

Example 1: (Question, PCK+, 23 responses, 2 likes)

Initial post: Hi, I would need some tips for a thematic theme on length. The students are in grade 2 and have not previously reviewed cm, dm, m or how to measure. Anyone who has some good / cool lesson tip / tasks I could use. Thanks in advance!

Response: Estimate how long things are, then measure...

Response: We take one-meter-robes and dm-robes out to the forest and try to find objects of such length.

Example 2: (Question, CK, 13 responses, 4 likes)

Initial post: We discussed the definition of a circle in our team – What would you say, does a circle have one side or no side at all?

Response: No sides, closed curve

Example 3: (Offer, PCK+, 6 responses, 163 likes)

Initial post: We measure outdoors! An elephant of 3.5m, a whale of 15m and a crocodile of 6m  
 [Several images of outdoor work included]

Response:   Fun! What a cute crocodile!

Example 4: (Statement, PCK+, 0 responses, 7 likes)

Initial post: Problem solving increases student performance in mathematics. [link to blog]

## Results

### Interactional patterns exposed by speech functions

Each post was analysed with a focus on the interpersonal function, which concerns the relationship-making process (Table 1). The four speech functions, that is, statement, question, offer, and command, convey what the teacher wants to accomplish when posting in the group. The speech functions ‘Questions’ and ‘Offers’ dominated as shown in Table 1.

**Table 1: The distribution of speech functions in each group**

	Statement	Question	Offer	Command	Total
MA1 ( $n=90$ )	5	48	34	3	90
MA2 ( $n=84$ )	9	44	25	6	84
MA3 ( $n=84$ )	8	12	56	8	84
Total ( $N=258$ )	22	104	115	17	258

To examine the interactional patterns and exchanges of the teachers posting in these groups, the responses to each post were analysed. The results show that 85.3% of all posts get responses. Most responses (80 %) are in line with the expected response pattern, that is, what the teachers wanted to accomplish when posting in the groups. In the examples above, we see that the questions received numerous responses (Example 1 and 2) whereas the statement (Example 4) did not receive any responses at all.

### Knowledge addressed

To indicate the practice known and shared (Little, 2002), Shulman’s (1987) framework was used for the analysis. Using Shulman’s categories, the content of the initial posts could be analysed giving a descriptive overview of the content addressed by the teachers in these communities. These descriptive results were then combined with the previously described results regarding the interaction patterns in each group. As Questions and Offers dominated, we focus on these two speech functions (Table 2).

The analysis showed that most *Questions* deal with PCK+, that is, issues regarding subject-specific teaching and learning. Example 1 illustrates such posts. This overall pattern is similar in all groups (see Table 2). However, few questions were raised in MA3 so the pattern is not as distinct as in the other groups.

Further, the results regarding the *Offers* in the posts show that, similar to the category *Questions*, mainly subject specific knowledge (PCK+) were shared (Table 2) as illustrated by Example 3. In MA3, a few more posts offered content knowledge (CK), similar to Example 2. MA3 also distinguished itself from the other groups in the number of posts unrelated to Shulman’s framework (38.2%). Many of these posts contained mathematical jokes or humorous video clips related to mathematics.

## Summary

The interaction that is the foundation of the Facebook groups is centered on asking for and sharing subject-specific knowledge (PCK+). Most posts received responses, and the responses were of the expected kind. The online groups were therefore mainly used as forums for making subject-specific education known and shared, but, broadly speaking, not as forums for discussion. Having used a stratified random sample, conclusions can be drawn regarding typical interaction patterns in large self-organized groups.

**Table 2: Knowledge addressed in Questions and Offers**

	Questions				Offers			
Knowledge base	MA1	MA2	MA3	Total	MA1	MA2	MA3	Total
PCK+	33	23	6	<b>62</b>	22	12	16	<b>50</b>
CK	2	6	4	<b>12</b>	0	2	11	<b>13</b>
PK	2	8	0	<b>10</b>	4	2	2	<b>8</b>
KEC	4	5	2	<b>11</b>	1	0	1	<b>2</b>
KEE	3	2	3	<b>8</b>	3	3	4	<b>10</b>
Total	44	44	15	<b>103</b>	30	19	34	<b>83</b>
Unrelated	7	5	0		3	5	21	

## Discussion

In this paper, we have shown how two different frameworks enlighten different aspects of our data. When combining these frameworks, a new dimension of the data becomes discernible in terms of the way in which the mathematics teachers use self-organized online groups to advance their professional collaboration and professional development. More specifically, we were able to analyse what teachers wanted to accomplish when engaging in such groups. Further, we could see which parts of the teaching practice became visible. This is an important result, as it is an empirical question of whether the characteristics of groups of teachers working together are those of a community where professional development may occur. Since teachers' professional community is extended to social media (Liljekvist et al., 2018; Macià & García, 2016; Tour, 2017), we aimed at empirically investigating teachers' interaction in self-organized groups, addressing subject-specific knowledge, in order to understand how the groups are used as resources for professional development. The multi-theoretical approach used shows that these large Facebook groups display the characteristics of groups of teachers that merits professional development.

The teachers' online interaction is oriented towards practice to enhance students' learning; therefore, as Little (2002) illustrates in her studies of within-school teacher communities, the issues raised are closely tied to the teachers' everyday professional lives. The subject-specific themes of the groups seem to structure the interaction towards the PCK+, which could be described as the centre of teachers' knowledge base, or more specifically, the "didactic relation" between the teaching-

studying-learning activities (Kansanen & Meri, 1999). The teaching practice that becomes known and shared (Little, 2002) in the three Facebook groups is characterized by a focus on pedagogical content knowledge, learners, and the material and methods used in the classroom. In forthcoming studies, it is now possible to go further and inquire into posts and comments to reveal the individual themes within the PCK+ category, for instance, what kind of subject is at play, and if and how teachers learn in these communities.

The representations of practice in the groups display the same pattern in what teachers want to accomplish when posting; they request knowledge from and offer knowledge to colleagues, and illustrate and share practices. This is in line with our understanding regarding professional learning communities in schools (cf. Little, 2002). By combining systemic functional grammar and the knowledge-base framework, we can go beyond the context of social media interaction and explain how teachers use the resources in self-organized groups to develop their collective knowledge on pedagogical and subject-specific issues related to their everyday practice. Furthermore, these three Facebook groups are used in only a limited way as an arena for debating and discussing school policy matters. This is indicated by the small proportion of statements (22 of the 258 relevant posts), by the fact that most statements get responses that merely confirm the content in question, and by the educational aspects focused on in the posts. Here, a focus on educational context and educational ends would have indicated an interest in such matters. Discussions around such issues might occur in other Facebook groups with such themes. We want to conclude that the willingness to respond and to share knowledge and teaching methods in the self-organized groups facilitates rather than impedes professional development.

# Extending Yackel and Cobb's sociomathematical norms to ill-structured problems in an inquiry-based classroom

Katie Makar<sup>1</sup> and Jill Fielding-Wells<sup>2</sup>

<sup>1</sup>The University of Queensland, Australia; [k.makar@uq.edu.au](mailto:k.makar@uq.edu.au)

<sup>2</sup>Australian Catholic University, Australia; [jill.wells@acu.edu.au](mailto:jill.wells@acu.edu.au)

*The aim of this paper is to extend and adapt Yackel and Cobb's (JRME, 1996) identification of sociomathematical norms in mathematical inquiry to problems that are ill-structured. The background theory influenced the design and local theory development of the research. This paper uses excerpts from an upper primary classroom to address the ill-structured mathematical inquiry question, Which bubble gum is the best? Two norms are illustrated: (1) mathematising the ambiguity in an inquiry question, and (2) using the inquiry question to check progress towards a solution. Children demonstrated productive social norms and emergence of the sociomathematical inquiry norm of mathematising, but using the inquiry question was less prevalent. In both cases, children found it challenging to productively coordinate their everyday (relevant) and mathematical knowledge.*

*Keywords: Sociomathematical norms; mathematical inquiry; mathematising; knowledge building*

## Problem statement and literature

Yackel and Cobb (1996; Yackel, Cobb, & Wood, 1991) explicate social and sociomathematical norms as central to learning mathematics in a classroom that practices inquiry. Social norms consist of expectations within the learning community, such as actively listening to peers and explaining and justifying one's solution (Makar, Bakker, & Ben-Zvi, 2015). Sociomathematical norms are distinct from social norms to highlight an epistemic focus unique to mathematical activity (Kazemi & Stipek, 2001). Sociomathematical norms overlap with but do not coincide with Brousseau's didactic contract (Laborde & Perrin-Glorian, 2005). For example, social and sociomathematical norms tend to place more emphasis on the social environment than a didactic contract (Allan, 2017).

Yackel and Cobb (1996) illustrated sociomathematical norms through examples in a second-grade classroom in which a teacher and his students discussed possible solutions and solution methods of mathematical problems. Yackel and Cobb emphasised an inquiry approach (distinct from a traditional approach), which allowed and encouraged students to contribute their ideas to create a collective learning environment. In their paper, Yackel and Cobb point out a taken-as-shared perspective of mathematical difference (including novelty and efficiency) and what constituted an acceptable mathematical explanation (justification, argument). The examples in their paper were closed-ended and well-structured in that the questions were clearly stated and had a single correct answer.

Although much of school mathematics is focused on closed-ended problems, there is a further set of problems utilised in inquiry-based learning. These are open-ended in nature and/or contain ambiguities in the problem statement or method of solution (ill-structured). In ill-structured problems, the problem statement, purpose, or method of solution contains ambiguities that must be (re)negotiated (Reitman, 1965). Well-structured problems contain complete information, limit the

solution process to a set of known and organised principles and procedures, and knowable solutions, whereas ill-structured problems often require integration of knowledge (integrated, domain-specific and contextual), may require information beyond the problem, have multiple or no solutions or solution pathways, hold uncertainty around success criteria (determining if the problem has been solved), and require personal judgement and interpersonal negotiations (Jonassen, 2010). The importance of ill-structured problems has been highlighted in the literature as indicative of problems encountered outside of school, in everyday life and the professions (Jonassen, 2010; Yeo, 2017). For example, the question “How long does it take to get to the airport?” can be solved mathematically (as well as by experience or authority), but the answer may be dependent on the purpose (flying out or picking someone up, weighing the implications of being early or late, level of precision needed) and context (traffic, method of transport). In many applied problems, the initial question requires the solver to reformulate it into one that can be solved using a mathematical investigation (e.g., by clarifying ambiguities, being explicit about measures and assumptions, etc.). Research on ill-structured problems can be complex and highly context contingent. Tasks and solution pathways are less explicit, problem contexts and purposes often contain uncertainties or emergent constraints that may require responsive action, and success criteria can be implicit, subjective or absent.

This paper explores how Yackel and Cobb’s (1996) sociomathematical norms could be extended to the solution of ill-structured problems in which the ambiguities of the problem are negotiated and the solution depends on an argument based on mathematical evidence (Makar et al., 2015). The research question under investigation is, *What sociomathematical norms were evident in an inquiry-based classroom addressing an ill-structured mathematical problem?* To address our research question, the paper analysed a lesson to identify sociomathematical norms specifically related to mathematical inquiry of an ill-structured problem driven by the inquiry question, *Which bubble gum is the best?*

The authors’ interests are to develop research with close proximity to classroom practice in order to better understand and facilitate teaching and learning at the level of the classroom (Cobb & Yackel, 1996). We see theory as contributing to coherence across the diversity of mathematics education research by developing common languages and lenses to better share, build on, critique, improve and adapt research findings to practice. In this light, the contribution of this paper to TWG17 is three-fold: (1) re-emphasise the utility of Yackel and Cobb’s (1996) foundational theory on sociomathematical norms by re-working and extending the theory to broader and more contemporary notions of mathematical inquiry, thus facilitating its application to practice; (2) re-imagine sociomathematical norms to theoretically unite the diversity of research on mathematical inquiry; that is, the paper invites mathematics education researchers to build on Yackel and Cobb’s work to elaborate the practical and theoretical application of sociomathematical norms across a diverse set of contexts for learning mathematics; and (3) acknowledge and value the influence of researchers’ background theory on epistemological and methodological decisions and insights from research. Elaborating and unifying the concepts and language of sociomathematical norms can provide more coherent body of research in mathematics education to improve its application to classroom practice. Better alignment and explicit discussion of researchers’ epistemological lenses in relation to methodological decisions is essential to interpret, adapt and translate research findings across contexts.

## Methodological approach

The study took knowledge building (Scardamalia & Bereiter, 2006) as its background theory, valuing how knowledge develops collectively through active discourse, the goal is idea improvement rather than “truth”, and understanding is emergent. The methodological focus therefore did not isolate actions of the teacher or individual students, but analysed collective activities in context.

### Setting and data

The data come from a multi-age classroom (children aged 10-12 years) of about 25 students in a low socioeconomic community in semi-rural Australia. We drew on video data from a class that conducted a mathematical inquiry around the question, *Which bubble gum is the best?* Students identified valued and measurable characteristics of bubble gum, developed appropriate measures, collected data on 3-4 brands of bubble gum and used their data to determine the best bubble gum.

Classroom videos were retrospectively analysed using an approach adapted from Powell, Francisco and Maher (2003). To respond to the research question, sections of video logs from the lessons were highlighted that provided insights into sociomathematical norms specifically related to ill-structured problems. Videos of these sections were reviewed again to be more selective in relation to the purpose. For example, highlighting was removed if episodes illustrated only social norms. Remaining highlighted episodes were transcribed and annotated to elaborate potential sociomathematical norms. From these episodes, a storyline was constructed to make sense of annotations by seeking connections between the inquiry problem, interpretations of students and teacher’s actions, mathematical ideas that emerged and potential evidence of sociomathematical norms. This was a non-linear process supported by the background theory that often required returning to observe video, refine or rework interpretations, or enlarge or reduce contexts around episodes. Narrative was drafted to draw out local theory and further reflect on insights unique to each episode. In the process of writing, the selection of excerpts was narrowed to maximise insights and coherence in relation to the research question.

### Classroom context

The teacher was experienced in teaching mathematics through inquiry after participating in research and professional development on mathematical inquiry by the first author for a number of years. The students were accustomed to working collaboratively, which was evident from the ease with which they worked with peers (freely generating and critiquing ideas, seeking approval from group before recording on a common page, keeping one another on task). Their collaborative social norms could be considered routine (Yackel et al., 1991), however their experience in solving ill-structured problems was limited. Therefore, the teacher was more explicit in co-constructing expectations with the class about acceptable activity when working in mathematical inquiry.

As argued in Yackel and Cobb (1996), an expectation within mathematical inquiry is for students to work towards autonomy. The teacher demonstrated this expectation in whole class discussions to have students generate ideas, with her explicitly privileging those that she wanted students to adopt as valued. Students worked collaboratively to devise and carry out a solution as the teacher rotated between groups to check and support their progress. She also paused the class regularly when she saw common issues to discuss as a whole class.

## Illustrating norms of mathematical inquiry with ill-structured problems

We identified two sociomathematical inquiry norms in the lesson that specifically aimed to build student autonomy in solving ill-structured problems in mathematical inquiry. First, we illustrate the norm of mathematising the ambiguity in the inquiry question (*Which bubble gum is the best?*) so it could be investigated mathematically. Mathematising involves “translating a realistic problem into the symbolic mathematical world, and vice versa” (Jupri & Drijvers, 2015, p. 2483). Second, we illustrate the norm of using the inquiry question to drive and self-check progress. This second norm is different than mathematising. The use of the inquiry question during the solution process required students to shuttle back and forth between the real and the mathematical worlds, re-checking if their mathematical processes and evidence were still progressing the real world problem.

### Mathematising

The teacher first oriented students towards mathematising the inquiry question. Her actions indicated that she was co-constructing the norm of mathematising as an expected activity in solving ill-structured inquiry problems, making explicit their obligations towards working autonomously. After introducing the inquiry question, the teacher led a whole class discussion to generate ideas to compare the brands of bubble gum. Students’ early suggestions were general, so the teacher pressed students to extend their ideas as a step towards productively mathematising by considering possible measures.

Oliver: Um, you could chew the bubble gum and then see which one is the best.

Teacher: So what would I be measuring, Oliver? [Oliver: Um, the taste, the texture.] Ok, so hang on a minute, there’s some good ideas! So I could measure the taste, texture. What do you mean by texture, Oliver?

Oliver: Uh, how it feels.

Teacher: Yes, ok. ... What else would I be measuring for bubble gum to be the best? Imagine you are a supermarket and you decide I can only stock one bubble gum. Which one will I stock? How will I know it’s the best?

The teacher set a possible purpose for students to come up with relevant criteria that could be investigated mathematically. Not all ideas were relevant, which may be an artefact that school mathematics often does not often trigger sense-making (Schoenfeld, 1991). For example, students suggested examining which gum was healthiest, comparing smell, packaging, size, market, weight, dimensions (length, width, height), ingredients. The teacher recorded their ideas, emphasising ideas that were relevant and measurable in her intonation (“Yeah! The smell!”) and queried, but did not discount others (“Market? What do you mean by market?”). Yackel and Cobb (1996) point to this as a way that teachers signify productive ideas without explicitly labelling ideas as “good” or “bad”.

After recording students’ ideas, the teacher supported them to mathematise the problem by coming up with ways of measuring valued qualities. Students had no experience with non-conventional measures, so their suggestions (size, graphs, columns, packets) reflected familiar mathematics or personal knowledge, but not coordination of relevant and mathematical. The teacher was patient and continued to ask for ways they might compare taste (relevance) until she found an idea that she could build on to mathematise comparison of taste.

Adele: Vote out of 10?

Teacher: Ah, so you'd do a survey? Oh, thank you! And you said a vote out of 10, so in actual fact that's giving them a rating. ... If I want to measure taste, I can't measure it with a ruler. ... (Draws a number line labeled 0 to 5) Where you would place the bubble gum if this [one] is the best and this [other one] is the worst? What number would you give it (the best one)?

Oliver: I would give it a 4  $\frac{1}{2}$ .

Teacher: 4  $\frac{1}{2}$ ? So how would you show that on there, Oliver (points to the number line)? (Oliver gets up and points to the space between 4 and 5.)

The teacher used the opportunity to explicitly teach students about rating scales as a tool to mathematise the problem. She left the students' ideas on the board (both productive and less so) and reiterated the task to start them off in their collaborative groups. Allowing students to wrestle initially demonstrated that the teacher expected them to generate and develop ideas to mathematise the problem. She didn't leave them unsupported, however, and used skilled questioning to press their ideas to be relevant and produce mathematical evidence. A group wanting to weigh the bubble gum were asked, "Does it have to be the heaviest to be the best bubble gum? ... Which of those [ideas] is the most important, do you think?". She left them to decide whether to include weight. In other groups, she probed how they would record their measures and responded "Ooo! High five!" when a student suggested a table. She further probed, "Talk about what that table is going to look like, Jack. What it's going to have in it?" The guidance was moderated according to the progress of the group, but the expectation to work autonomously was consistent. For groups who struggled, the teacher spent more time pressing their thinking to deepen or refocus their ideas to make progress, then moved on.

Teacher: What are we measuring?

Charlotte: Taste.

Teacher: Rightio, what else?

Students: The smell. The width

Amelia: If you can smell it, you can see how strong it is.

Teacher: Ok, so you're going to smell how strong it is. ... How would you show me you are measuring smell? So how will I know out of your 4 pieces of bubble gum, which one smells the best? ...

Amelia: Well, we'll smell it first and then we'll write it down. [Teacher: What will you write down?] How, what we think, what, how strong it is in our opinion. ...

William: We'll put 1, 2, 3, 4, 5 on it.

Teacher: ... Draw it for me, William. ... What does 1, 2, 3, 4, 5 stand for?

In this example, the teacher pressed students to be specific so that they could operationalise their ideas through mathematising the problem. Later, the teacher was giving instructions to a teacher aide and was overheard by a student.

Teacher: [Are] they up to tasting?

Teacher Aide: Yeah. ... They've done a scale for smell. ...

Teacher: [Ask] what else can they do with it? They can blow bubbles and stuff like that and try and see if they can measure and how they would go about doing that as well.

Noah: You know you just gave us the answers! We can blow bubbles!

Noah's comment indicated that the teacher violated a classroom norm, that in mathematising the problem, students should generate their own criteria and measures for what makes bubble gum "best". Because norms are not visible, they are often only detected when a member of the community breaks the norm (Yackel & Cobb, 1996). Noah's comment assisted us to identify mathematising as an emergent norm of mathematical inquiry with ill-structured problems.

### Focus on the inquiry question

Students' ideas were often too vague or not relevant to the question. Therefore, another norm the teacher worked to instil was the value of the inquiry question to help students locate relevant measures and keep them on track towards a solution. In the example below, she noted that students were falling into patterns of mathematical activity that neglected sense-making. She modelled using the inquiry question as a way for them to self-check sense-making as they worked.

Teacher: Ok, just stop for a moment. Eyes up here. ... (Talks about one group drawing a graph.) But if you are drawing a graph, you really need to think, "Well, what am I showing on the graph?" ... You have to come back to the question *Which bubble gum is the best?* With all of your results, at the end of the day, you have to come back to that question. ... You have to be able to tell me which one is the best and justify why our bubble gum is the best. ... By *saying* it's the best is not proving anything. Your results have to prove it. ... Jack's group is looking at a table of results and they're doing some graphing, other people are looking at scale ratings, fantastic idea! ... If you need scales, how many will you need? How many lines will you draw? How many tables will I need? You need to look at what you are measuring, how I will record that information?

The teacher maintained an expectation of autonomy in using the inquiry question to check progress. She often stopped at groups, checked one element and moved on, indicating an expectation that students work autonomously. One group was weighing bubble gum when the teacher arrived.

Teacher: Ok, so if you are going to tell me that that bubble gum is the heaviest, does that mean it's the best?

Sam: No, I think that Hubba Bubba (brand of bubble gum), because it—

Teacher: So what is the point of telling me that that bubble gum is the heaviest if it doesn't tell me which one is the best? Because my question is *Which bubble gum is the best?*

Sam: Well, it's more popular—

- Teacher: ... I'm understanding what you're saying, but I'm just concerned that the testing you're doing is not going to show me anything. At the end of the day, your testing has to show me which bubble gum is the best.
- Delia: Hubba Bubba because it's got the strongest smell, it's more popular and more people would buy it.
- Teacher: So was there any point in weighing it? ... Do we need to know which one is heavier when we want to know which one is the best?

The teacher continued to press students on connecting their activity to sense-making (Kazemi & Stipek, 2001) through the inquiry question. Sam and Delia's additional contributions (Hubba Bubba is more popular) connected their everyday knowledge to the inquiry question, but not to evidence the group had collected (weight). Using the inquiry question to guide their investigation was more abstract than mathematising in that students needed to step back and reflect on a larger purpose of the activity. We did not see evidence of students self-monitoring their progress with the inquiry question in this lesson and suspect it would take much more time to develop into a norm than mathematising.

## Discussion

In this paper, we addressed the research question, *What sociomathematical norms were evident in an inquiry-based classroom addressing an ill-structured mathematical problem?* We considered mathematical inquiry in solving ill-structured problems using mathematical evidence (Makar et al., 2015). Two sociomathematical inquiry norms were illustrated during a lesson in which students addressed the mathematical inquiry question, *Which bubble gum is the best?*

- Ill-structured inquiry questions need to be mathematised through relevant and mathematical measures in order to be solved.
- The inquiry question is used to guide and check progress and mathematical evidence towards a solution.

These two were considered sociomathematical inquiry norms because they are central to mathematical inquiry in that (1) the question contains ambiguities that require negotiation in order to mathematise it into an operational investigation, and (2) a mathematical inquiry is driven by an inquiry question and its solution and evidence must respond to the inquiry question. Acknowledging these as useful norms to develop in an inquiry classroom can assist teachers in initiating, maintaining and extending student autonomy when addressing ill-structured inquiry problems in mathematics.

Theory adds coherence to a field by developing common language and lenses through which to gain insights and improve practice while acknowledging that researchers' background theory affects what is researched and how. Yackel and Cobb's (1996) research on sociomathematical norms has had a significant effect in progressing the mathematical reform agenda. Their work identified sociomathematical norms to ensure that teaching both improved social practices and focused on mathematics (Kazemi & Stipek, 2001). Given the nature of distinctive types of mathematical tasks (Yeo, 2017) and efforts to extend students' mathematical experiences to more open-ended problems, it would be useful for the field to extend the types of sociomathematical norms that would be useful in different forms of mathematical activity. We hope this paper makes some progress on this mission.

# Understanding powers–individual concepts and common misconceptions

Christos Itsios<sup>1</sup> and Bärbel Barzel<sup>2</sup>

<sup>1</sup>University of Duisburg-Essen, Germany; [christos.itsios@uni-due.de](mailto:christos.itsios@uni-due.de)

<sup>2</sup>University of Duisburg-Essen, Germany; [baerbel.barzel@uni-due.de](mailto:baerbel.barzel@uni-due.de)

*The topic of powers and exponents is generally considered one major obstacle for learners in schools and universities. Our main goal is to answer the question: How can we bridge the gap between individual conceptions in students' minds and the relevant mental models (Grundvorstellungen) to conceptualize powers? With reference to this learning object, two tasks from our test instrument and initial results are presented, which are part of our diagnostic tool to enable the uncovering of students' individual images and misconceptions in the area of powers, by means of comparing the prescriptive with the descriptive level of relevant mental models.*

*Keywords: Grundvorstellung, conceptual change, understanding, mental models, powers.*

## Introduction

Even though the subject of power expressions and its modern exponential notation has been dealt with for a long time (Euler, 1770), it seems that students of all ages still face difficulties when confronted with them, as well as with exponentiation in general. That has been documented over the years, mainly in school settings (e.g. Confrey & Smith, 1994; Pitta-Pantazi et al., 2007; Avcu, 2010). The key issue seems to be the lack of understanding of basic rules and algorithms used to manipulate powers. To guard against such occurrences, there is a need for a *conceptual change* in students' minds (vom Hofe & Blum, 2016, p. 237), in order to gain a deeper understanding on the conceptual level. Hahn and Prediger (2008) have proposed that opportunities for conceptual change should even precede the introduction of rules on the procedural level, or as Sfard (1995) puts it: "Operational thinking must be replaced by structural"<sup>1</sup>. This proposition considers the distinction of knowledge into *conceptual* and *procedural* knowledge (Hiebert & Lefevre, 1986). Taking the above into consideration, we pose a twofold question: Which mental models (*Grundvorstellungen*, vom Hofe & Blum, 2016) should students form for a confident and flexible manipulation of power expressions, and which individual models do they have? To answer this, we first concern ourselves with the identification of adequate mental models through a subject matter analysis and an expert survey. On the basis thereof, we carry out a design research study, where we go from a first pilot study to developing test items, over to a number of three cycles, to aid us in achieving a final version of our diagnosis instrument. Our goal is to find out what students' individual mental models are and whether they are consistent with the desirable normative models. In the present article, after setting the theoretical background, we will provide some insights into our methodology and evaluate the potential explanatory power on a small item sample of the test instrument.

---

<sup>1</sup> An extended discussion of this can be found in Long (2005, pp. 62f).

## Theoretical Background

In this section we will present the theoretical approaches used in the study to operationalize understanding. First, an outline of the construct of mental models or *Grundvorstellungen* (vom Hofe & Blum, 2016) together with related terminology used in international literature will be given. Furthermore, the various transformations between representations will be displayed, since they play an essential role for successfully dealing with mathematical concepts. This sets the basis for the generation of the items used in the test instrument.

### The concept of Grundvorstellungen (GVs)

Particularly when modeling with the help of mathematics, one needs to activate the suitable GV(s) to translate between the “real word” and the “world of mathematics”, which in turn—when successfully performed—means, that the topic has been understood (Bossé, Adu-Gyamfi, & Cheetham, 2011, p. 117). The concept of *Grundvorstellungen*, or *mental models*, has a long tradition in German subject-matter didactics. It is used to describe the connection between mathematics and reality on a conceptual level (vom Hofe & Blum, 2016). Three aspects of GVs can be distinguished. The *normative aspect* constitutes the basic idea of the concept; it is to be understood prescriptively as the desired status to be reached when understanding a concept. The *descriptive aspect* characterizes the individual perceptions and notions of learners; it is, therefore, a representation of the students’ conceptualization. Finally, the *constructive aspect* compares the normative and the descriptive aspect to provide some insight concerning students’ difficulties of understanding, as well as offer solutions for overcoming misconceptions (Hefendehl-Hebeker et al., 2019).

Considering that the concept has also been referred to as a theory, our view is the one offered by Radford, who mentions: “... Mogens Niss (1999) contends that a theory in math education has two goals. First, it entails a descriptive purpose, aimed at increasing understanding of the phenomena studied. Second, it has a normative purpose, aimed at developing instructional design.” (Radford, 2012, p. 4). Moreover, Hefendehl-Hebeker et al. (2019) add: “... the approach of the GV concept combines normative and descriptive methods with a constructive aim. In this sense, analyses of students’ work based on the GV concept typically do not remain at the descriptive level but lead to indications of a constructive ‘repairing’ of the analyzed problems.” (p. 35).

To differentiate and clarify the concept from internationally used terms we should mention the theoretical proximity of GVs to *concept image* and *concept definition* (Tall & Vinner, 1981). Although both approaches refer to understanding of mathematics using Piaget’s cognitive psychology (vom Hofe 1998) and constructivism (Hahn & Prediger 2008) as background theories, GVs are mostly understood in their normative level, as a didactic category for teachers to make explicit which mental models are appropriate for understanding the specific mathematical concept or operation. To differ clearly between the normative mental models according to the mathematical concept and the descriptive mental models in students’ minds, some authors replace the descriptive aspect with the term *individual mental models* (e.g. Prediger 2008). Vom Hofe (1998) uses the term *basic model* as a prescriptive notion and *individual image* as a descriptive notion, explaining his integrative view as a “holistic view of mathematical thinking and doing,” offering “methodical and

theoretical possibilities for combining normative didactic conceptions with descriptive and interpretive working methods” (p. 326).

Furthermore, Soto-Andrade and Reyes-Santander (2011) compare Grundvorstellungen with Lakoff & Nunez’s (2000) *conceptual metaphors*. The similarity of both is constituted by a similar mechanism of transmission: Real experience is the source domain allowing for concept formation, the goal is to provide abstract concepts with meaning. However, they differ in the aspect of their implementation in practice and in that through GVs, preexisting mathematical concepts are represented, rather than constructed. In this paper we will use the terms *normative* and *descriptive aspect* of GVs to mean *mental models* for the former and *individual models* for the latter, as used in Prediger (2008), according to Fischbein’s definition of a mental model as a “meaningful interpretation of a phenomenon or a concept” (Fischbein, 1989, p. 12). Following the conceptual change theory, we will refer to the descriptive aspect in a competence-oriented meaning, rather than adhere to a deficit-oriented analysis. The formation of GVs is the key element of concept formation, thus, also entails conceptual change (Kleine, Jordan, & Harvey, 2005).

### Grundvorstellungen of Powers

From the normative point of view, there are four aspects that can be extracted and considered as mental models for powers with natural numbers as both the base and the exponent. Following a literature review<sup>2</sup>, a subject matter analysis and an expert survey our preliminary results were presented in a first draft (Itsios & Barzel, 2018). After further expert talks, the identified mental models were redrafted and rephrased. These are:

- (GV1) *Repeated Multiplication (RM)*: this mental model can appear in two different ways—a more dynamic one (RM-d), describing a temporal-successive process where new objects emerge, e.g. the repeated doubling of a number of bacteria per hour, and a more static one (RM-s), focusing on the end result of a repeated action, as a whole or an object, describing the end result of a repeated action, e.g. a binary tree.
- (GV2) *Combinatory Conception (CC)*: this refers to the number of possible permutations with repetition (number of n-tuples), e.g. there are  $10^5$  possible combinations for a lock with five cylinders, each using a digit from 0 to 9.
- (GV3) *Stretching by the same factor (SF)*: this represents a magnification without the emergence of new objects, e.g.  $5^2$  can mean zooming into an image twice with a five-fold magnification.

### Transformations among Different Representations

When learning a mathematical concept, students should engage in three actions as proposed by Lesh, Post and Behr (1987): *recognition* of the concept in multiple representations, flexible *manipulation* within these representations and *translation* between different representations. A

---

<sup>2</sup> Although we do not adopt the theoretical framework of combining embodied mathematics with conceptual metaphors, we acknowledge the work done in Mowat (2010), as this offers a database of mathematics teachers’ concept images on exponentiation.

stable use of multiple representational systems can be a guarantee for an easier development of concepts in mathematics and demonstrating mathematical understanding can mean being competent in the manipulation of these systems. These systems can vary from equations, graphs and tables to diagrams, charts or even verbal and written forms (Goldin, 2002, p. 197; Pape & Tchoshanov, 2001, p. 120). There is even a stipulation in the specific content of powers, that conceptual connections between representations is a prerequisite for deeper understanding of concepts (Nataraj & Thomas, 2012, p. 557). These transformations among representations set the basis for the design of our test instrument, which will be introduced in the next section.

## Design and Methodology

A first draft of the test instrument was designed using 20 items in total, including three open-ended questions and 17 calculation tasks. For the construction of the items, the aforementioned GVs, as well as most appropriate transformations among representations were taken into consideration, to make the test as comprehensive as possible. This was then tested with a sample of 117 subjects (87 civil and mechanical engineering and 30 university mathematics students) and after a first assessment all responses were categorized according to the frequency of their occurrence. Then, together with the right answer, the three most frequent wrong answers were used as possible choices for each item. The final version comprises the initial three open-ended questions, one calculation task and 16 single-choice items. Following a baseline diagnosis, a total of 176 Grade 10 students from two different schools<sup>3</sup> were tested in the main study, with the purpose of determining individual conceptions as well as to detect which GVs can be activated. For the purposes of this article we will present two items regarding the transformations from symbolic to graphical, as well as from symbolic to verbal.

### Item Sample

Figure 1 shows two of the three open-ended questions (items A2 and A3), in which the diagnostic potential of individual mental models becomes evident. With them, we can explore the ideas that are prevalent in learners' minds about their conceptual understanding of power expressions and their connection to everyday life situations.

**A2.** Draw a picture representing the expression  $2^3$ . Explain your picture briefly.

**A3.** Try to come up with a situation from your everyday life, that can be described with the expression  $3^2$ .

**Figure 1: Test items A2 and A3**

Item A2 requires the translation from symbolic to graphical and we expect that mainly Grundvorstellung RM-s will be activated. By requiring a brief explanation, we add a second transformation that students must perform, namely graphical to verbal. Since practically none of the test subjects' answers includes an explanation, we will consider item A2 to address only the transformation symbolic to graphical. Item A3 requires the translation from symbolic to verbal and

<sup>3</sup> One comprehensive school (Gesamtschule) and one secondary school (Realschule).

the Grundvorstellungen RM-d, CC and SF are expected to be activated. In case RM-s is activated, the translation should still be considered to be under symbolic to verbal, not symbolic to graphical, since the task requires a verbalization of the situation, regardless of the fact that the given situation could describe a spatial arrangement.

### Some results

Our assumption concerning the results is the following: if an appropriate GV is activated, then there will be a plausible answer given. We make no claims to the opposite, namely, if no reasonable answer is given, as to whether the corresponding GV is present in the student's mind or not. We analyzed the data by categorizing each response to a corresponding pattern, within a small expert group to ensure interrater agreement. In Table 1, the results to item A2 are presented together with the respective response frequencies and in each case an example is given, followed by the relevant GV that most likely could be supported due to the proximity to an individual model. Only a total of 51 Grade 10 students answered this question, including isolated cases with answers that are not hereby listed, because we could not diagnose the structure of those responses. In these drawings we often encountered indications of repeated multiplication (RM), with correct answers as well as misconceptions. 16 answers corresponded to a more static view (RM-s, 1<sup>st</sup> row), where  $2^3$  is misunderstood as multiplication, presented in a spatial-simultaneous arrangement. We also saw substantial dynamic versions, for example a sequence (2<sup>nd</sup> row), which we see either as figured numbers or just as cardinality of the relevant numbers. We also attributed RM-d, when the variables were given as symbols, where we can say that the calculation is perceived correctly, but without any hints as to whether the meaning can be properly elaborated (3<sup>rd</sup> row).

Response pattern	N	Example	GV
Type of calculation misconception (multiplication)	16		RM-s
Cardinal numbers as symbolic sequence	7		RM-d
Repeated multiplication with symbolic variables	7		RM-d

**Table 1: Results and response frequencies to test item A2**

What can be extracted from these results is that learners have not yet adequately shown that they can activate and use the necessary GVs to deal with the given task. However, their individual models, albeit not wrong, remain confined within the world of mathematics and symbols, rather than extending to real-life applications. Table 2 shows the answers given to test item A3, with a total of 46 Grade 10 students answering this question. Some isolated cases have not been listed under the response patterns, showing—again—no structure or diagnostic value. The last column shows, as previously in Table 1, the GV that in our opinion has to be activated, in order for the initial presented idea to make sense in the context of the given power expression.

Here we encountered cases where  $3^2$  is misunderstood as multiplication, presented in a temporal-successive way (1<sup>st</sup> row). The most common given response that can be considered feasible is shown in the 2<sup>nd</sup> row, where the power expression is viewed as a 3-by-3 spatial-simultaneous arrangement. Very few students (3) tried to present a situation, such that the Combinatory Conception could be identified, but failed to present it accurately (3<sup>rd</sup> row).

Response pattern	N	Example	GV
Type of calculation misconception (multiplication)	17	I am ill. I have to take pills. Two in the morning, two at noon and two in the evening.	<i>RM-d</i>
Area	7	I want to find out the area of a square-shaped room to lay a new carpet. Each side of the room has a length of 3m. I calculate $3^2 = 9$ , then I know that I need a 9m <sup>2</sup> carpet.	<i>RM-s</i>
Combinatorics	3	I own 3 dresses, 3 handbags and 3 pairs of shoes that I can combine.	<i>CC</i>

**Table 2: Results and response frequencies to test item A3**

Looking at the first row of Table 2, we can identify a misconception that could be used as an opportunity for supporting learning. Further support, e.g. interviews, could be structured in a way that students are asked to compare the result of  $3^2$  with their own result (six), leading to a cognitive dissonance. This, in turn, could be the starting point of a conceptual change within their individual images to fit into the normatively set mental models.

## Discussion

In all presented cases, we can observe that multiplicative thinking is predominant, with more than 50% of given answers showing that the two variables in question are combined in a multiplicative fashion, mostly assuming commutativity<sup>4</sup>. That can be seen in the first example of Table 2, where the numbers 2 and 3 of the expression are combined in a way that results in a multiplication context. After categorizing the response patterns for items A2 and A3 we identify the main problem to be a fixation on previous arithmetic operations of a lower level (multiplication). This problem encompasses depicting a number raised to the third power (see Table 1, first example given) as an array or a two-dimensional area, rather than a three-dimensional object, for example a cube.

Looking at the results of items A2 and A3 we can assume, that the main problem overall is a misconception of the mathematical object of exponents and powers. Confusing multiplication with exponentiation seems to be a principal reason for the demonstrated findings. A possible explanation for these findings is the lack of context variety offered to students when introducing the concept,

---

<sup>4</sup> Responses to item A3 included both cases, where 2 and 3 were the multiplier and the multiplicand, respectively, and vice versa.

leading to a false notion of what exponentiation is and when it can be applied, even if plain calculation tasks can be performed faultlessly.

Regarding this TWG, our contribution is twofold. First, by expanding the range of Grundvorstellungen to include the normative GVs for powers, as mentioned above. Second, with our example we have shown how the concept of GVs can help to bridge the gap between individual models in students' minds and the relevant mental models which are necessary for the specific conceptualization. The method of connecting and comparing preexisting ideas and misconceptions with the normative level of GVs shows promising prospects to adequately describe our results, potentially leading to an accurate diagnosis and treatment of these misconceptions.

*This paper aims to propose a methodological tool for comprehensively studying variables on teachers' design and analysis of their own lessons. Our theoretical base is the anthropological theory of the didactic, especially the notion of para-didactic system and the scale of levels of didactic co-determinacy. Fusing these constructs, we create a new ecological scale of factors on teachers' didactic activities outside didactic situations, which makes us more sensitive to the ecology and economy of teachers' working. The functionality of the model is put to the test by an ecological analysis of data from an international lesson study situation where an archetypal phenomenon appears—teachers' excessive concern with either microscopic mathematical topics or general teaching methods. Our analysis of conditions on this phenomenon with the new tool identifies two constraints on lesson study in relation to teachers' professional terminology and authority.*

### Introduction

The Japanese *lesson study* as an approach for improving the quality of lessons has attracted great interest as a promising opportunity for developing of the scholarship for the teaching. There are many challenges for transplanting lesson study worldwide outside Japan. Winsløw, Bahn & Rasmussen (2018) categorised two different directions of the research about lesson study: *descriptive* and *intervention*. The descriptive research investigates lesson study itself as a research object and the intervention research use it as a method for the professional development. Our approach in this paper is located in the descriptive direction. Lesson study is a complex and contingent entity, since it is originated from teachers' spontaneous effort, which deeply affected by the Japanese society and its schooling culture. Consequently, the development of theoretical and methodological tools for describing lesson study has been challenged within the research community. Our aim in this paper is to provide an additional contribution to this endeavour.

In this study, we try to expand the analytic range of lesson study research within the ATD, i.e. the *anthropological theory of the didactic* (cf. Chevallard, 2019), which was created and developed by Yves Chevallard and his colleagues over the last 40 years (if we count from the birthyear of the *didactic transposition theory*, which is the origin of ATD). ATD is well established in both French and Spanish speaking communities and is still actively developing around the world. A feature of ATD is the *ecological* way of problematising didactic reality, that is, the habit of questioning *conditions* and *constraints* of all kinds and origins. This reality is related to any *didactic fact* of all types regarding the diffusion of knowledge, e.g., explaining a proof of the Pythagorean theorem in a classroom, writing a mathematics textbook for elementary school students, and so on and so forth.

The ecological questioning in didactics is crucial for both the understanding of the didactic world and the intervening to it. It is because any specific teaching activity is definitely determined not only by student, teacher, and content at stake, but also by institutional, cultural, and historical variables. However, in our view, the ecological approach has not fully percolated through a relatively new research field of ATD: the *paradidactic field*. The adjective *paradidactic* was introduced into didactics by Winsløw (2011)—with a special focus on lesson study—for studying teachers’ didactic activities outside didactic situations: the planning and reflecting upon their lessons. In the *paradidactic field*, the *ecological analysis* is usually conducted by the notion of *paradidactic infrastructure* (ibid.), which is an application of the notion of *didactic infrastructure*. Within ATD, the noun *infrastructure* means the fundamental construction to make a certain human activity function—their nature, size, and materiality do not matter—e.g., the infrastructure of camping activity consists of a tent, cooking equipment, firewood, a camping car, a camping site, etc. Regarding teachers’ activities, lesson study is based on a *paradidactic infrastructure*, that is, a structured set of basic conditions for *paradidactic activities*, e.g., the *open lesson*—which is an opportunity for many teachers to observe a same lesson and discuss it—conditioned by a time table, an equipment of the school where the event is held, a theme of the conference, organisers and advisers in the discussion, the lesson itself, and so on (cf. Miyakawa & Winsløw, 2013). Indeed, the notion of *paradidactic infrastructure* allows us to study the ecology of *paradidactic activities*. However, this notion does not amply enlarge and indicate our scope of ecological analysis in the *paradidactic field*. In other words, following kinds of methodological questions cannot be answered clearly: what kinds of conditions have to be investigated in the analysis for understanding and explaining *paradidactic phenomena*? To what extent do we need to look for *paradidactic conditions*? Which conditions are uncontrollable for teachers? Which connections are there between different *paradidactic conditions*? In this paper, we will propose a new methodological tool for the ecological approach, adapting a well-known hierarchical model of types of conditions—the *scale of levels of didactic co-determinacy*—to the *paradidactic field*.

### **A methodological tool for questioning the ecology of the *paradidactic***

In this section, we would develop a methodological tool for analysing the ecology of lesson study. However, at first, let us tell beforehand for readability that our analysis consists of two phases. The first one is the *economic* (or classically didactic) phase which means the analysis of the dynamics of target systems, e.g., a lesson. In the *economic phase*, we will clarify some properties of teachers’ foci or interests in the lesson study, by using the original scale of levels of *didactic co-determinacy* (Fig. 1). Next, at the second phase—called the *ecological*—we will identify some constraints on the lesson study, by using our new model—the scale of levels of *paradidactic determinacy* (Fig. 2).

#### **The scale of levels of didactic co-determinacy: an *economic* tool for *paradidactic* research**

One of the main purposes of didactics is to investigate the ecology of *didactic systems*. Any didactic system is made of a group of students, one or more teachers, and a *didactic stake*, i.e., something to be learnt by the students. In didactic systems of mathematics, student’s mathematical activities are affected by the teacher’s didactic activities, and vice versa. Such dynamics of didactic systems are called the didactic co-determination, which works under conditions of different kinds and origins.

The *scale of levels of didactic co-determinacy* is a model of hierarchy of genres of such conditions on the functioning of the didactic system (Fig. 1). The level of *didactic system* is divided into five sub-levels depending on degrees of taxonomical generality of didactic stakes—*discipline*, *domain*, *sector*, *theme*, and *subject*. The level of *pedagogy* includes every condition about teaching methods, ideas, and approaches which are independent of the nature of each disciplinary field. Subsequently, a didactic system with a pedagogy functions within a *school* system, which in turn depends on a set of characteristics of a given *society*, *civilisation*, and ultimately *humankind*.

**Figure 1:**  
**Didactic ecological scale**

In any didactic system, the role of teachers is to make students study a certain didactic stake. This is a fundamental type of works of the teacher. However, there exists another important sort of activities of teachers outside didactic systems. It is to design, observe, and reflect upon didactic systems themselves. The role of such kinds is played in “institutional systems about didactic systems” which is called *paradidactic systems*. In the studying of such systems, we can use the didactic scale (Fig. 1) in the economic way—e.g., the assorting of teachers’ foci—rather than the ecological way. In other words, it cannot work well as a tool for investigating conditions on paradidactic systems. Then, we need some new model for the paradidactic ecological analysis.

### The scale of levels of paradidactic determinacy: an *ecological* tool for paradidactic research

**Figure 2: Paradidactic ecological scale**

Let us describe here any paradidactic system by a nested system—an institutional system containing *its participants* and a *didactic system as its object of study* which we call a *paradidactic stake*. Then, similar to the case of didactic systems, we can think of a determinative mechanism inherent in paradidactic systems. Since the didactic system and the paradidactic system live in different types of institutional environments, let us propose a new hierarchical model of levels of conditions and constraints for studying the ecology of paradidactic systems (Fig. 2).

The paradidactic determination acts on different groups of conditions starting from the first level of *paradidactic system*. Principal conditions at this level mean properties of each item of the paradidactic system. In addition, as portions of conditions at the paradidactic system level, let us indicate the set of local clauses of paradidactic systems as what we name the *paradidactic contract*—*implicit* rules, e.g., avoiding negative comments about students’ abilities or attributing every failure in the lesson to the teacher’s didactic acts—applying the notion of *didactic contract* in the theory of didactic situations led by Guy Brousseau. The second level is the *paradidactic profession*—about the notion of *profession*, see also Chevallard (1992a)—professions more or less *acting* paradidactic activities. In this paper, we would focus on the profession of *teacher*, but there exist other kinds of professions which could be involved in different paradidactic systems: governmental official, teacher educator, mathematician, and so on. The third level is the *didactic noosphere*. Roughly speaking, the noosphere is the institution related to designing and evaluating school systems in some way (cf. Chevallard, 1992a, b). Noospheres are usually fuzzy and

heterogeneous institutions which consist of *professionals* within professions of different kinds. Simply illustrating, a meeting responsible for developing a national mathematics curriculum could be an epitome or miniature of the noosphere. In any noosphere, an institutional worldview consisting of visions of different types—e.g., transformative, pedagogical, ethical—implicitly integrates professionals of different kinds—politician, teacher, mathematician, and so on—into a noosphere. Higher levels than the *society* are similar to the original didactic scale.

## **An economic analysis: The case study of an international lesson study**

### **Context of the open lesson**

The demonstration lesson and the post lesson reflection—of which the open lesson consists—under investigation in this article was part of a one-day conference at an ordinary public school, situated to the North of Copenhagen, Denmark. The content of the conference included two open lessons and a number of 30 minutes workshops on the function and usage of specific teaching materials. Conducting open lessons is not an ordinary practice in Denmark, but in the image of Japanese lesson study conferences (*jugyō kenkyū kai*), teachers and school leaders from several primary and secondary schools in and outside the municipality, municipality officials, teacher educators, researchers etc. observed and discussed the teaching of ordinary classes. While the classes were ordinary, the situation was extraordinary for the participants, though the class being taught in the open lesson under scrutiny here had tried a similar situation once before: one year earlier, Hiroshi Tanaka of the Attached School of the University of Tsukuba taught that same class in the first open lesson. A large number of the participating observers had joined the (single) open lesson of the first Danish *jugyō kenkyū kai*. The open lesson includes three different languages (Japanese, Danish and English) with several types of translations. During the demonstration lesson, the Japanese teacher used mainly Japanese and the third author mediated between the teacher and the Danish students. The post lesson reflection session was conducted in both English and Japanese, where the second and third authors interpreted every Japanese comment and question into English and vice versa.

### **The paradidactic bipolarisation in the post lesson discussion**

The teachers at the Attached School of the University of Tsukuba play a leading role in the community of Japanese mathematics teachers at elementary level by publishing a number of educational books and performing lectures about teaching practice. Seiyama, who designed and implemented the demonstration lesson, is an experienced mathematics teacher in elementary school and has demonstrated several lessons in foreign countries. The participants were given his lesson plan beforehand. In this Seiyama describes the goal and the intended lesson process. The demonstration lesson is about considering how the total number of a fold lines on a paper changes when one repeats folding it in half. This was followed by a post lesson reflection session, where teachers from different schools in the region participated. Also, teacher educators from different universities in Copenhagen, as well as, a professor of the University of Copenhagen who specialises in didactics of mathematics were invited to give the participants some feedback regarding the observed lesson. The number of participants was approximately 180.

The discussion was organised in three phases: the Japanese teachers', the first group's and the second group's. The division of the Danish participants depended on their experience of post lesson

reflection: the first group consisted of the teachers and researchers who had experienced some post lesson reflections before, and the members of the second group did not have such experiences at all. Below, we describe a representative phenomenon, from the paradidactic situations described above, that we call the *paradidactic bipolarisation*, i.e., the shortage of *didactic* viewpoints in teachers' interests. This phenomenon is observed as the *thematic confinement* (cf. Barbé, Bosch, Espinoza, & Gascón, 2005) and the *pedagogical generalism* (cf. Florensa, Bosch, Cuadros, & Gascón, 2018)—it has two opposite *poles*. Teachers could usually focus on the level of specific topics (at the pole of thematic confinement) or the level of generic educational matters (at the pole of pedagogical generalism) *without* questioning interlevel intermediates between the both levels, e.g., the entire design of a course in a school discipline (for example, a geometry course in secondary school mathematics). Let us illustrate each of the two poles with data from the international open lesson.

*Thematic confinement: teachers' exclusive concern on specific matters in the demonstration lesson*

Generally speaking, teachers' discussion of the teaching tends to focus on the piece of knowledge taught in the lesson itself under the predetermined body of knowledge-to-be-taught. As a result, teachers usually talk about not the domain of the subject matter, but its topic, e.g., not treating Euclidian geometry but considering the Pythagorean theorem. Let us note that the analysis has the neutral nature, that is to say, we are not evaluating in any way. As we discuss in the next section, this focus of the teachers is systemically produced. The discussion of the first group including several Japanese teachers was not an exception (Hereafter, "DP" and "JP" means a Danish participant and Japanese participant respectively; these comments are not from a dialogue.):

DP 1: (...) regarding the girl who answered 5. She could reason  $1 + 2 + 2$  using preceding numbers. It could express the richness of the task? What is your idea of (helping the students) finding out the next number by adding some of the preceding numbers of the folds (when you constructed this task)?

JP 1: Seiyama should have let the pupils observe the figure more consciously. If I were him, I would use the paper more effectively when I let the pupils guess the answer. There were so many different conjectures by 3 folds, so, before I let them to fold paper I would let them look at the paper (individually) and let them guess again. Therefore, if they guess the number of lines at the same time they fold the paper, they could have understood the relation between the rule of the increasing of the lines and the figure much better. Thus, he should have used the figure more not only they control the answer but even when they guessed.

From the scale of levels of didactic co-determinacy, these comments are exclusively related to the levels of theme and subject—a specific issue of school (early) algebra. The absence of the concerns on broader organisations of mathematics—discipline, domain and sector—indicates that it is difficult for teachers to deal with lessons beyond the thematic level: the thematic confinement.

*Pedagogical generalism: teachers' exclusive concern on generic matters in the demonstration lesson*

Indeed, didactic facts beyond the thematic level usually disappear from teachers' eyes, but it does not mean that teachers always ignore all other levels higher than the theme. Factors at the pedagogical

level—out of the levels within a certain discipline—may become visible for teachers as is the case of the thematic confinement. In our case, such tendency is distinct in the second group:

- DP 4: How do you instruct the students who think fast and find the answer quickly? How do you give them more difficult task so that they do not get bored? I think this is the weakness of this kind of lesson that very talented students get bored if they found the pattern very fast.
- DP 6: There are other students who do not see the pattern. (...) If you implement this kind of teaching method, can you see even those weak students can find those patterns easily? Can you actually train their ability to see the pattern?

The issue they are problematizing exclusively concerns about generic teaching methods, which are not related to any specific contents: the pedagogical generalism.

### **An ecological analysis: constraints on post lesson discussion in lesson study**

In the previous section, we have analysed data coming from the participants' comments in a paradidactic system regarding a didactic system. This analysis conducted by the *original* didactic scale (Fig. 1) has been a clarification of a law regulating teachers' activities—the paradidactic bipolarisation—at the paradidactic system level within the *new* paradidactic scale (Fig. 2). In this section, we will discuss some constraints, which bring about the law, using our new model.

#### **The lack of didactic notions: a constraint at the levels of society and noosphere**

The history of didactics is relatively young. The motion initiated by some pioneers, e.g., Guy Brousseau, emphasized the existence of *didactic* phenomena, which are irreducible to as cognitive, semiotic, pedagogical and so forth (Bosch & Gascón, 2006). Since then, didacticians have been producing a number of theoretical constructs, *didactic contract*, *praxeology*, etc. However, these notions have not permeated into the community of teachers. Florensa et al. (2018) reported the result from interviews of university teachers, where they were asked about questions or difficulties in the beginning of their educational courses for preparing teaching at universities. The study showed that the participants' concerns are fulfilled with general issues and detached from the target content, i.e. the didactic stake: the pole of pedagogical generalism. Through reflecting upon the teachers' responses, the authors indicate the problem of the *lack of didactic notions* within the university teacher education, which could be identified as a condition at the society and noosphere levels. Commonly, the teachers do not have words to talk about how to connect between the target content and the way of teaching it. Thus, even if they can think about the didactic stake, their foci are limited at very specific ecological levels: the pole of thematic confinement. As a consequence, it becomes difficult for them to recognise and overcome the paradidactic bipolarisation phenomenon.

Generally, one cannot inquire the target content fully without using didactic notions. It is because “knowledge” tends to be regarded as an unchanging reality. This commonsensical belief is based on a prospering epistemology which is possibly set at the civilisation and society levels: the *epistemological absolutism*. This absolutism often gives a privileged authority to scholarly knowledge, regarding knowledge at school as some deficient form of it. In other words, absolutists consider that scholarly knowledge has universality. They cannot accept the principle of *institutional*

*relativity of knowledge*—as the historian emphasizes the importance of the historical analysis from *not* current perspective but from the analysed period's, the ATD-didactician insists that *school mathematics* exists in its own right. Then, knowledge-to-be-taught easily becomes unquestionable for teachers (see also Chevallard, 2007). Consequently, the pedagogical generalism as one pole of the paradidactic bipolarisation—focusing on wide-ranging teaching methods and purposes—flourishes in many paradidactic systems including the one in our case. At the same time, controllable conditions among the didactic levels from the discipline to the subject are limited for teachers, i.e. the thematic confinement as the other pole of the paradidactic bipolarisation. In both cases, there exists passivity towards bodies or organisations of knowledge.

### **The teachers' developmental byplay: A constraint at the levels of noosphere and profession**

So far, we have used the word *teacher* with twofold meaning, that is, as a professional institution—i.e. profession—in our societies, and as a general position of players in all kinds of didactic systems. However, let us focus here on the teacher as a profession by the notion of *schoolteacher*. The relatively restricted nature of the profession of schoolteacher is a frequently observed social fact, which is a main topic of ATD. For example, the schoolteacher has often been regarded as an occupation with limited autonomy in decision-making on its working process, compared with e.g., doctor and lawyer. This *semiprofessional* feature is typically visible in the work arranging knowledge-to-be-taught at school. In many countries, the national curriculum is more or less made by some kind of governmental paradidactic system. In the case of modern Japan, the committee organised by the ministry of education decides school disciplines, their domains and their sectors. In short, the type of tasks of curriculum development is generally not a main role of schoolteachers but of governmental curriculum-makers.

The supporting role of the schoolteacher in the process of development of curriculum—we call it the *schoolteachers' developmental byplay*, at the noosphere and profession levels—affects the different poles of the paradidactic bipolarisation phenomenon. Schoolteachers cannot freely decide sectors, domains, and disciplines, because the arrangement of knowledge-to-be-taught at these three levels is not their prerogative. This distribution of responsibility between schoolteachers and curriculum developers could percolate spontaneously through to most schoolteachers as a natural part of their professional common sense. For example, in the Japanese case, this tendency clearly appears as a paradidactic methodology of lesson study, which could be a condition at the profession and paradidactic system levels. Lesson study is usually conducted around a subject and a theme, applying some general pedagogy, e.g., competency-based education. As a consequence, the schoolteachers' developmental byplay tends to produce an implicit rule “the schoolteacher should focus on the thematic level when they talk about the target knowledge—not about the general matter”. It is a clause in the paradidactic contract at the profession and paradidactic system levels.

### **Final remarks**

We think that our new scale has dual value in didactic research. As the first, it allows us to study the ecology of the paradidactic. The second and rather indirect function is to invoke sensitivity to the boundary between the purely didactic and the para-didactic realities, since such a demarcation is difficult to recognise for most educators and researchers. In further research, we need to examine the

functionality of our tool by explaining more various cases of lesson study, since our data was one specific and rather unique case. We consider that such examination of the tool should not limit its scope within lesson study. In addition, there are possibilities of application to teacher education research, research of curriculum and/or textbook development, and meta-research of didactics. It is because such domains have objects of study with the nested structure similar to the teachers' paradidactic system. We believe that the scale can cast new light on the various objects of didactics.

### Acknowledgments

The authors would like to thank Carl Winsløw and Klaus Rasmussen for useful comments. This work is supported by JSPS KAKENHI (JP16K17433).

# TWG18: Mathematics teacher education and professional development

## **International perspectives on mathematics teacher professional development**

Stefan Zehetmeier (Austria), João Pedro da Ponte (Portugal), Laurinda Brown (United Kingdom), Àngela Bufo (Spain), Janne Fauskanger (Norway), Marita Friesen (Germany), Maria Mellone (Italy), Libuse Samkova (Czech Republic)

### **Rationale**

The study of mathematics teacher education and professional development has been a central focus of research over recent decades. Also, during previous ERME conferences, various research activities regarding this topic have been presented and discussed. Within CERME 11 TWG 18, we focus on mathematics teacher education (pre-service and in-service), professional development and teachers' professional growth, teachers' professional development practices, models and programmes of professional development (contents, methods and impacts) and the professional development of teacher educators and academic researchers. TWG 18 offers a communicative, collegial and critical forum for the discussion of these and other related issues, which allows diverse perspectives and theoretical approaches and which contributes to the development of our knowledge and understanding as researchers, educators and practitioners.

### **Participants**

53 papers were originally submitted to TWG18 and underwent a peer review process. All papers were revised by authors, according to reviewers' remarks. 43 papers were accepted as paper presentations, 10 were re-submitted for a poster presentation. Two of the accepted papers were withdrawn and one was re-assigned from another TWG. Finally, 42 papers were to be presented during the TWG sessions.

This led to the decision (according to ERME rules) to split the TWG into two sub-groups: TWG18a (with a particular focus on teachers and teacher educators) and TWG18b (with a particular focus on professional development settings).

10 posters were originally submitted and underwent a peer review process in TWG18: all authors revised their posters, according to the reviewers' remarks and all posters were accepted. Together with the re-submitted posters (see above), and 7 withdrawals, finally, 13 posters were presented during the conference poster session.

### **Organisation**

TWG sessions 18a and 18b comprised both plenary and sub-group working phases. During the plenary phases, two (or three) papers were presented for a maximum of five minutes each, in which the authors provided their paper's central message(s) and challenging questions for discussion. These plenaries were followed by parallel sub-groups, which were each managed by one of the presenting authors. Participants were free to choose and join one sub-group, where they discussed the paper for 30-40 minutes. Afterwards, the TWG's participants met in plenary to listen to and to discuss reports of each sub-groups' central topics and to summarise emerging issues. In addition, in 18b, the five-minute presentation of papers was followed by a brief commentary to the set of papers by one of the TWG leaders.

## Topics

The presentations in TWG18a and TWG18b were categorised into 13 main topics:

- Beliefs
- Educators
- Knowledge
- Noticing
- Particular Mathematics Topics
- Tools
- Curriculum Innovation and Professional Practices in Professional Development
- Evaluation of Professional Development Programs
- Collaboration and Communities in Teacher Professional Development
- Lesson Study
- Use of Video for Professional Development
- Use of ICT for Professional Development
- Initial Teacher Education

## Open questions and emerging issues

This section provides several key questions and issues, which emerged during the sessions of TWG18a and TWG18b:

### Beliefs

Open questions: What gets pre-service teachers into teacher education? How do we change pre-service teachers who do not want to be changed? How to support pre-service teachers to be exploratory in their teaching? What motivates mathematicians to be involved in projects with mathematics teacher educators?

Emerging issues: The potential of investigating the effect of ‘Missions’ on pre-service teachers’ thinking (e.g., getting into the habit of looking at their own experiences to make sense of the theoretical input of the course) and practices (in school placement or in their practice after graduation).

### Educators

Open questions: How do educators’ theoretical perspectives change over time? Parallels between mathematics teacher educators and mathematics teachers – what makes teachers confident teaching mathematics and what makes students in classrooms confident doing mathematics?

Emerging issues: Questioning our own assumptions of what we take for granted about how mathematics could be taught and shifting those assumptions by working across boundaries of contexts and countries.

### Knowledge

Open questions: What is our knowledge of the rationale that pre-service teachers have for what they do? How do we support pre-service teachers in developing through video analysis experiences?

Emerging issues: We need to have a national comparison of teachers' knowledge. Validity of simulations for measuring teaching practice.

### **Noticing**

Open questions: How to change beliefs so that students' errors can be analysed more productively? Changing beliefs from when pre-service teachers were students themselves? Do different types of critical events influence the way the pre-service teacher interprets?

Emerging issues: Different uses of critical events and reflections across the different countries. Safe place inside the university where pre-service teachers can make errors and reflect on them.

### **Particular Mathematical Topics**

Open questions: What about combining things that are shared between different subjects such as problem solving, e.g., mathematics and science modelling? Is it important that pre-service teachers struggle in terms of mathematical content and also struggle in the classroom?

Emerging issues: Differences in our countries producing generalist teachers (5 taught subjects) or specialist teachers (2 taught subjects).

### **Tools**

Open questions: Action research: takes too much time for pre-service teachers to do? In different situations, do the pre-service teachers move between different roles, such as teacher and researcher?

Emerging issues: The school community as a community of practice that pre-service teachers have to enter. Action research – different experiences across countries – pre-service and in-service teachers have different experiences. Being systematic from the very beginning, thinking about quality.

### **Curriculum Innovation and Professional Practices in Professional Development**

Open questions: How to use curriculum innovation and aim of improving student achievement for professional development? In large-scale professional development programmes, how can results similar to those that arise in small-scale programmes be achieved?

Emerging issues: Potential and limitations of practice-based professional development programs.

### **Evaluation of Professional Development Programs**

Open questions: How to research and how to measure the impact of professional development?

Emerging issues: Relating teachers' learning to quality of instruction and students' achievement.

### **Collaboration and Communities in Teacher Professional Development**

Open questions: What settings are successful in combining collective and collegial work with space for individual growth?

Emerging issues: The crucial role of the teacher educator/mediator/facilitator and how he/she may be trained.

## **Lesson Study**

Open questions: Teachers' dispositions regarding personal investment in professional development are a crucial factor for the success of lesson study. What steps may be taken to improve them?

Emerging issues: Need to have a theoretical orientation regarding pre-service and in-service teachers' learning. The crucial role of the Lesson Study (LS) facilitator and how he/she may be trained. LS is complex, in particular if it is not part of the culture. There is a need for future research on how to build collaborative trust among participants.

## **Use of Video for Professional Development**

Open questions: In observing videos, how to identify a "productive" discussion and how to measure the extent of the "productivity"?

Emerging issues: The key role of theories regarding teacher learning and of practical questions regarding working contexts in research in the use of videos in professional development.

## **Use of ICT for Professional Development**

Open questions: How can ICT elements be used to enhance and inform teacher education and professional development? How can the implementation of ICT elements be facilitated?

Emerging issues: Role of specific facilitation and monitoring, importance of collaboration with colleagues and need for quality control / standards.

## **Initial Teacher Education**

Open questions: What are appropriate learning and identity development aims for pre-service teachers (both primary and secondary) in different national contexts?

Emerging issues: Combining attention to didactical, cognitive, affective and social issues in Initial Teacher Education.

## **Summary**

There is a common agreement in TWG18 on the principles leading to more effective professional development of teachers that emerged across the 13 topics: bringing new elements to the teachers' work while keeping connected to the teachers' reality; clarifying these new elements in relation to existing frameworks and practices; combining collective and collegial work with space for individual growth; and supporting teachers in introducing new elements in their practice and reflecting on their consequences and possible constraints.

# Working with example sets: A productive focus in Lesson Study

Jill Adler<sup>1</sup> and Jehad Alshwaikh<sup>2</sup>

*The Wits Maths Connect Secondary Project, a research linked professional development project, included Lesson Study with teachers in school clusters. Planning and reflection is carried out using a Mathematics Teaching Framework, a key aspect of which is exemplification. We illustrate that and how working on example sets in a lesson has been productive in our (LS) work. Through this we build a case for a focus on exemplification when studying and working on mathematics teaching, and for support at a more general level for theoretically informed Lesson Study.*

*Keywords: Lesson study, mathematics, secondary, exemplification, South Africa*

## Introduction

The Wits Maths Connect Secondary Project (WMCS) is a research linked professional development (PD) project that has included Lesson Study (LS). Based on a view of professional learning as a collaborative practice, and thus with some similarities to the Japanese model, the LS model developed in the WMCS project has two distinct features. It is framed by a theoretically driven and empirically elaborated framework for mathematics teaching that includes an emphasis on exemplification; it has been shaped by conditions of learning and teaching in the WMCS project schools, and thus by constraints typical of low-income schooling contexts (Adler, 2017).

Lesson study has become widely used in PD globally and differently interpreted across contexts (e.g. Quaresma et al., 2018). Adaptations of Japanese LS have taken root in the US, the UK, and Australia (Wood, 2018; Huang et al., 2017), and spread across countries in Asia and Africa. Fujii (2014) reported on a project where LS was promoted in countries such as Malawi and Uganda and argued that cultural practices in Japanese schools were not ‘transferred’ together with doing LS. In South Africa, while there is recognition of the benefits of LS, Jita et al. (2008) state many challenges, in particular time for running the training and enacting the process and more critically the role of knowledgeable others which was undermined through a cascade model of expanding the reach of LS. The difference with practices in Japan is apparent, particularly in relation to LS in Japan being an in-school practice, where experienced and knowledgeable others are part of the systemic culture.

It is precisely these conditions that inspired the WMCS to (re)design lesson study in ways that both supported the goals of the wider project (see below), and the conditions of teachers’ work in South Africa. Hence the key design features of the WMCS model mentioned earlier – it takes constraints on time into account, and it focuses on current teaching practices like exemplification.

## Exemplification and variation

There is an extensive literature on the significance of exemplification in mathematics teaching (e.g. Antonini et al. 2011; Watson & Mason 2006). Bills & Watson (2008) and Sinclair et al. (2011) argued the need not only for deliberate and careful selection and sequencing of examples, but that teaching needs to bring learners’ attention to connections between selected examples, and to the underlying

patterns of variance amidst invariance that enable generalisation and/or appreciation of structure. This linked work on examples and variation in and for mathematics teaching has inspired and influenced our attention to exemplification in our research and PD work.

Zaslavsky's research has focused on teachers' awareness of their example use in their teaching and students' use of examples in their thinking (Ellis et al., 2017). Teachers' were not necessarily aware of how they were using examples. Teachers' thus can be supported in this work. For Kullberg et al. (2017), the application of variation theory in teaching enables critical features of the object of learning to come into focus. They argued further that multiple examples are not simply cumulative. Their ordering, simultaneous presentation, and the teacher drawing attention to similarities and differences are critical. We agree and have thus worked with teachers on their use of examples. In order to bring the object of learning into focus and enable learners to generalise through the use of examples, we have highlighted two necessary aspects for a sequence of examples, and the accumulating example set in a lesson. There needs to be *similarity* from one example to the next - where a feature is kept *invariant* while other features vary. In addition, there need to be *contrasting* examples that can draw attention to difference between key features. With a focus on variance amidst invariance, and contrast, it is possible to build generality and create possibilities for appreciating the critical features and structure of particular mathematical objects.

Of course, examples are always embedded in a task. While examples are selected as particular instances of the general case, tasks are designed to bring particular capabilities to the fore (Marton & Tsui 2004). In our LS work, constructing an example set across a lesson includes attention to tasks, and as we will show this was the collective work of the LS group – teachers and researchers.

### **The WMCS, framework of mathematics teaching and model of Lesson Study**

WMCS has aimed at improving mathematics teaching in disadvantaged schools in one province in South Africa. With a sociocultural orientation to learning as mediated, and to mathematics as a network of scientific, connected and hierarchic concepts (Vygotsky, 1978), we zoomed in on exemplification and explanatory talk in the lesson, viewing these as key mediational means in instruction. We developed an analytic framework, detailed in Adler & Ronda (2015), for describing and interpreting shifts in mathematics made available in teaching. It focuses on four key elements of a mathematics lesson: First is the *object of learning*, the 'what' of learning or lesson goal, and what students are expected to know and be able to do at the end of a lesson. This leads to *exemplification* - to the sequence of examples, with their associated tasks and representations, that can be used to bring the object of learning into focus with learners. As reflected in our discussion on exemplification, attention is on how to work with variance amidst invariance, to build generality and illuminate structure. We also focus on *Explanatory communication*, and *Learner participation* but these are not in focus in this paper.

Between 2013 and 2016 we explored a model of LS in the project. We worked in a school after school hours in small collaborating groups of teachers from clusters of schools. We used the framework above as structuring device to guide lesson planning and reflection, adapting it into a teaching framework referred to in the project as a Mathematical Teaching Framework – MTF, and illustrated in Figure 1 below. The MTF includes all the components of the analytic framework mentioned above

and is intended to assist teachers in planning and then as an observation/reflection tool on the ‘quality’ of mathematics offered in their teaching in LS. In this paper we focus on exemplification in the MTF framework in our LS work.

Lesson goal		
<b>Exemplification</b>	<b>Learner Participation</b>	<b>Explanatory communication</b>
Examples, tasks and representations	Doing maths and talking maths	Word use and justifications
Coherence and connections to the lesson goal		

**Figure 1** WMCS Mathematics Teaching Framework

### Our Lesson Study model

While our cycle follows mainstream practice of LS, differences, particularly in relation to time and place, are a function of resource constraints. Our LS cycle takes place one afternoon a week after school hours for three consecutive weeks, and involves teachers from a cluster of neighbouring schools. In week 1, the LS group plan a one hour lesson on a topic agreed by the teachers. In week 2, one teacher teaches the lesson to a class of learners who agree to remain after school for the lesson. After the learners leave, the LS group spends the following hour reflecting on the enacted lesson and planning the second lesson which is taught in the third week, to a different class, but the same grade. *A Lesson Study cycle thus involves six hours* of face to face collaboration, an evolving lesson plan, and reflection on both taught lessons. In our model, a LS cycle takes place over a relatively short time, outside of normal class teaching.

### The study: data and method

While we carried out LS in three clusters of schools, in 2016 we undertook a systematic study of our most participative and sustained LS cluster. A specific question in the study was on the evolution of the example set and in particular:

- What changes occur in the example set across the lesson plans over a cycle?
- How do these changes evolve?

We focus on one LS cycle where four teachers (Thembi, Lerato, Thabi and Sipho) from three different schools in the cluster, and four researchers (Frank, Linda, Jehad and Jill) from the project met in May to plan the first teaching. The teachers chose to work on “simplifying algebraic expressions with brackets in different positions” in Grade 10 because of persistent errors they observed with their learners’ manipulation of algebraic expressions when these included brackets in various positions. In order to systematically research our co-learning, we collected all relevant information: written lesson plans; audio and/or video-recordings of all LS sessions. We draw particularly from the lesson plans, post lesson reflective discussions and teacher reflections to engage with our research questions.

Our analysis proceeded with a description of the exemplification in the first lesson plan in terms of the MTF framework, and so our interpretation of variance amidst invariance, and similarity and

contrast in the accumulating example set. We identified examples that were removed/added, where this occurred, and how this linked with changing representations and tasks in Plans 2 and 3. Our analysis of the reflective discussions after each lesson included the identification of “example change moments” – moments in the reflective discussion where there was specific attention to exemplification, *and* the discussion led to some change. We described by whom and how the discussion was initiated, and how it evolved.

### The lesson plans and evolving example sets

In Table 1 below, we present the example sets for the Introductory and Activity 3 in each lesson plan produced: the initial plan (P1), the revised plan (P2), and then a re-revised plan (P3). The substantial changes are highlighted, and we now use these to illustrate the collective work of the LS group.

P1	P2	P3
<u>Introduction:</u> Calculate the following: a) $4 + 3(4 + 5) =$ b) $(4 + 3)4 + 5 =$ c) $(4 + 3)(4 + 5) =$	<u>Introduction:</u> simplify the following expressions: a) $4 + 3(4 + 5) =$ b) $(4 + 3)4 + 5 =$ c) $(4 + 3)(4 + 5) =$	<u>Introduction:</u> simplify the following expressions: a) $4 + 3(4 + 5) =$ b) $(4 + 3)4 + 5 =$ c) $(4 + 3)(4 + 5) =$ d) $(4 + 3) - (4 + 5) =$ Insert brackets in the left side to result in the given sum e) $4 - 3 + 5 = -4$ f) $4 + 3 - 5 = -35$
<u>Activity 3: Simplify</u> a) $(x - 3x) + 5 =$ b) $(x - 3)x + 5 =$ c) $x(-3x + 5) =$ d) $x - (3x + 5)$	<u>Activity 3: insert bracket(s) in the expressions on the left side so that the two sides are equal</u> a) $x - 3x + 5 = -3x^2 + 5x$ b) $x - 3x + 5 = -2x - 5$ c) $x - 3x + 5 = x^2 - 3x + 5$	<u>Activity 3: insert bracket(s) in the expressions on the left side so that the two sides are equal</u> 1. $x - 3x + 5 = -3x^2 + 5x$ 2. $x - 3x + 5 = -2x - 5$ 3. $x - 3x + 5 = x^2 - 3x + 5$

**Table 1 Examples in the introductory activity and activity 3 across the three plans**

With respect to the examples, the LS group agreed to introduce the lesson with numerical expressions. This representation of expressions with brackets would have meaning for learners and provide a semantic basis for moving on to algebraic expressions, and so more abstract symbolic forms. The numbers 4, 3, 4 and 5 and the + operation in each expression were invariant. Only the position of the brackets changed from one example to the next. The task was to calculate the value of these expressions. Communication with learners was to focus on ‘what was the same and what was different’ across the examples, thus bringing into focus the impact of the changing position of the brackets. The examples of algebraic expressions that followed in Activity 1 and 2 were similarly structured with  $x$ , 3,  $x$  and 5 and the + operation invariant while the position of the brackets changed with each subsequent example. Activity 3 included the operation of subtraction/negative terms and if time there was a 4<sup>th</sup> activity prepared. The accumulating example set reflects the group’s interpretation of variation for this lesson where similarity first within each activity example set and then across these could build generality in relation to the application of the distributive law and the more visible form of the changing position of brackets the expression. Contrast was introduced in

Activity 2 where two binomials were now added, and thus potentially bringing attention to the operation between brackets.

### **The changes made to the examples in P2 and P3**

Changes from P1 to P2 can be seen in Activity 3. There are now equations, with the expressions on the left retaining the same numbers and variables as in P1. Brackets now need to be inserted to produce an identity. The task for learners thus changed. Further changes appear from P2 to P3. There are additional examples of numerical expressions in the Introduction. It appears that the change in Activity 3 in P2 led to a change in the Introduction in P3. Across the three plans the accumulating example sets expanded. This was accompanied by a movement between the numerical and algebraic representations of expressions and changes in task demand. How then, did these changes in exemplification come about? What reflective processes provoked and produced these?

### **How did the change in plans evolve?**

We identified key ‘example change moments’ in the reflective discussion where there was specific attention to exemplification, *and* the ensuing discussion led to a change in the lesson plan. The vignette below, from the reflection after Lesson 1, takes us into the discussion, allowing us to see when the selected change moment occurred, who initiated it, how it was taken up by others and then evolved into a change in the example set.

#### **Vignette - when the exemplification is “not enough”**

Thembi taught Lesson 1, and closely followed the joint plan (P1). The hour long reflective discussion began, as was the practice in the WMCS LS, with the teacher herself reflecting on the lesson. After twenty minutes of general reflection, Frank asked the group to reflect on the example sets. It was at this point that Thembi voiced a key concern with her learners’ responses to Activity 3.

Thembi: Remember ... activity three ... they all answered “yes it will make a difference” ... already they picked up from activity one and two that ... if the bracket is put in a different place it changes the solution. ... But for me ... that was not enough ...

It was not immediately apparent to others what Thembi meant by “not enough”. Some thought she felt that Activity 3 was “too easy”. Following further discussion on how to ‘change’ activity 3, Linda made a suggestion that caught Thembi’s attention (“that’s brilliant”), and resulted in a change to the example set:

Linda: I had another suggestion ... what if you ... gave them the answer and then said: where must I put the brackets to get this answer?

Thembi: ...where you give them  $x$  minus three  $x$  plus five but then give them the solution and ask them where should we put the brackets? That will be, yes I think that’s brilliant. ....

Attention moved to collectively generating the example set that appears in Activity 3, P2 above. Staying with the expressions in b, c, and d in P1, the task now was to “insert brackets on the left expression “so that the two sides are equal”. Thabi expressed concern that this would be too much of a “jump” for learners. All agreed that as he was to teach the next lesson, he could give more time to the activity, and then perhaps not complete all of the other activities in the lesson.

This vignette evidences that the moment of explicit attention to examples was initiated by Frank (WMCS), and thus by the project interest supporting teachers to use the MTF to frame and steer reflection. Significantly, it was Thembi (teacher) who responded to this initiative with a teaching/learning concern in her enactment that unsettled her. In this way, Activity 3 came into focus. It took some time for the group to understand Thembi's concern and to offer productive suggestions. Finally, the suggestion from Linda (WMCS) satisfied Thembi, and despite Thabi's concerns, it was accepted, and the example set changed. Interestingly, there were difficulties in Lesson 2, and reflection that again co-produced the changes to the introductory activity highlighted in Table 1. We do not include more detail here due to space limitations. Briefly, discussion focused on how to scaffold the more demanding task, resulting in the suggestion that numerical examples be done first<sup>1</sup>.

## Discussion

The vignette shows how changes were initiated through “example change moments”. Here, as in other instances, the initiation was by a project member/researcher, reflecting the structuring of the reflection by the elements of the MTF framework, in particular by attention to exemplification. However, it was the teachers' engagement with these initiations that directed the discussion in relation to their learners and their teaching/learning concerns. It was possible to trace the substance of these discussions, as we elaborate below. Together this leads us to posit two main themes that emerge from vignette and that illustrate exemplification as an explicit focus in our LS and as powerful for teachers.

### Theme 1: Changes are a collective accomplishment

The vignette above illustrates how the initiation and evolution of change to the example set across the lesson, and particularly in the Introduction and Activity 3, was a *collective accomplishment* of both the teachers and the WMCS teacher educators/researchers. While a researcher initiated an explicit focus on the example set, the change was evidently a function of the driving concern of the teacher and the suggestions and additional instructional resources offered by teachers and particularly researchers together. Our evidence here reinforces the emphasis on the role of “knowledgeable others” in other models of LS (cf Takahashi & McDougal, 2014). We suggest that this role is crucial and has significant implications for any attempt to “cascade” the implementation of LS in contexts where experience with professional collaboration on the one hand, and focused lesson engagement on the other, are new. Cascading down, inevitably dilutes such roles. The important implication for the practice of LS in ‘less resourced’ contexts is that the human resources of knowledgeable others should not be side-stepped nor undervalued. This is a learned role. It is not a role that officials in a system can necessarily carry out without being inducted into LS activity over time (cf. Jita et al., 2008).

### Theme 2: Changes are a function of the MTF framework and so theoretically informed

The vignette also shows how discussion was shaped by attention being drawn to the MTF framework, and particularly the example set. The example set was initially informed and shaped by principles of

---

<sup>1</sup> A detailed and in-depth report on this research can be found in “A case of Lesson Study in South Africa”, Adler & Alshwaikh (in press).

variation, as were the changes. The additional examples in the example set kept the numbers and/or terms in all the examples invariant while the signs were changed, or the task was shifted from expansion to insertion of brackets. Here we see the deep inter-relation between theory and practice constituted in LS reflection. It was the teachers' practice-based concerns that influenced the ultimate joint decisions. As in Kullberg's (2017) learning study, the role of variation was a theoretical resource in the LS work.

## **Concluding remarks**

In this paper we have illustrated part of a LS cycle on "simplifying algebraic expressions with brackets in different positions" with Grade 10 learners in the context of a professional development project in South Africa. Structured by a framework developed in the project to support lesson planning and reflection, we described a key change moment in the reflection following the first enactment of the plan where Thembi expressed her concern with the example set in Activity 3; and how this shaped the subsequent lesson plan, its enactment and the reflection following. Through this we have made a case for explicit focus on exemplification and example sets in LS. Examples are critical for mathematics teaching and learning. Deliberate attention to how they are selected and sequenced and embedded in appropriate tasks is important in professional activity like LS. We zoomed in on one LS cycle with one LS cluster, indeed our most sustained and participative cluster. This was to illustrate the possible, which of course then could have broader purchase.

A related concern here could be that our focus on example sets and what they offer for teacher learning might be relevant to SA but not extend to lessons that are more problem based. We suggest (following Wood (2018)) that different solutions or strategies to a set of problems are themselves examples. How and what is variant and invariant in these would shape what is possible to learn. Attention in LS reflection to the different examples of possible solutions would hold similar possibilities and particularly if framed by principles of variation.

Furthermore, changes to the example set, and so exemplification – the additions, deletions, changing representations, and changing task demands – evolved as a function of the collective enterprise of the LS group - teachers and teachers educators or knowledgeable others. The implications for this in LS across contexts are serious. There are cost implications if knowledgeable others are to be included in any expanded form. Without this, however, LS will not function optimally, whatever the context.

Finally, we have pointed to the impact and the value of structured and theoretically informed observation and reflection. Planning, teaching and reflection were structured and shaped by the WMCS theoretical approach, the MTF tool used with teachers in our LS. Our work thus adds impetus to arguments for theoretically informed LS, and can hopefully stimulate further research along these lines.

# Reflections upon a research project seen as a means for teachers' professional development <sup>1</sup>

Mette Andresen

Department of Mathematics, University of Bergen, Norway; mette.andresen@uib.no

*Keywords: Secondary school teachers, teacher empowerment, educational development.*

## Focus of the study presented in this poster

The term 'research-and-development projects' reflects multiple goals of a certain type of design research project in mathematics, which includes teaching experiments like by Cobb (1999). Such goals are: i) Students' learning, and change of their beliefs ii) Change of norms, roles and relations between students and the teacher iii) Teachers' professional development iv) Researchers' experiences from actual classrooms v) Theoretical knowledge about i), ii) and iii). This study aims to contribute with theoretical knowledge about teachers' professional development.

## Theoretical foundation for the study

Main heuristics are from a) an interpretative framework for analyzing individual and collective activity in classrooms (Yackel & Rasmussen 2002), and b) A research based theoretical foundation for the study of educational development projects (Sowder 2007). The study reflected upon a research-and-development project involving eight upper secondary mathematics teachers who designed and completed teaching experiments in their own classrooms, focusing on students' strategies for inquiry and problem solving and based on discussions of problem-solving behavior by Schoenfeld (2011), and Pólya (1985). The participants shared a wish to find ways to support and stimulate students' creativity and students' ability to think mathematically in an intellectually independent way. The study's reflections were centered on the question: *How can teachers' ideas and visions about a change towards more inquiry and intellectual independence in problem solving be realized by the means of a research project?*

## The research project

The hypothesis underlying the research project's setup was a need for coherence between the norms and values realized by the teacher and those requested of the students. Therefore, the teachers had to develop and share their ideas about, and materials for, the teaching experiment with the peer group, based on their own experiences and visions, supported by the project activities and taking an inquiry approach. The research project is described in Andresen (2015).

## Data

Data for this study was in the form of: i) Notes and video recordings of students' work and classroom activities in all eight classes ii) Notes and materials from meetings in the project group iii) Two group interviews with all the teachers in October 2013 and in May 2014.

---

<sup>1</sup> This poster is a short version of the author's paper: *A research project seen as a means for teachers' professional development* which was accepted but never presented at CERME 9, TWG18.

## Results

The research project has served as a means for the teachers to get experiences with teaching according to their own, shared, desire with respect to students' inquiry and intellectual independence in problem solving. All the teachers were engaged with the project and all of them wanted to continue the project. They had tried out experiments that could realize their ideas and visions. All the teachers had a high degree of ownership of the teaching experiments. Nevertheless, elements of disappointment were revealed in the teachers' reports. Some teachers reported a lack of clear results of the experiments, which was explained mainly with reference to i) the period of time spent on the experiments, ii) the students' differing expectations and iii) students' earlier experiences with mathematics. The teachers expressed a common wish to continue the experiments.

## Conclusion

This study has shown that a research project can be suitable to frame teachers' development by enactment of their visions and beliefs about mathematics teaching. There is no guarantee, though, that the desired goals and learning outcomes for the students will be reached. One possibility for improvement would be a prolongation in time of the project. As the main conclusion, this study points to stressing the importance of the teachers' visions about desirable teaching. This is in accordance with the study's theoretical foundation, and even goes further: It is well known (Sowder 2007) that a research-and-development project can succeed only if the teachers' beliefs are in line with its overall goals. Partly based on this study, a framework was outlined by Andresen (2018) for analysis of the role of the teachers' visions about desirable teaching for successful professional development, and for analysis of the impact of taking the visions into account already in the initial design phase. A large potential for professional development may, seemingly, be realized in projects which include the teachers' visions about desirable teaching in their starting point.

# Portfolios as a way of documenting and reflecting learning processes in a mathematics teachers' professional development program

Jennifer Bertram<sup>1</sup>

<sup>1</sup>Ruhr University Bochum, Faculty of Mathematics, Germany; [jennifer.bertram@rub.de](mailto:jennifer.bertram@rub.de)

*Keywords: Portfolio, learning processes, self-regulated learning, professional development, mathematics teacher.*

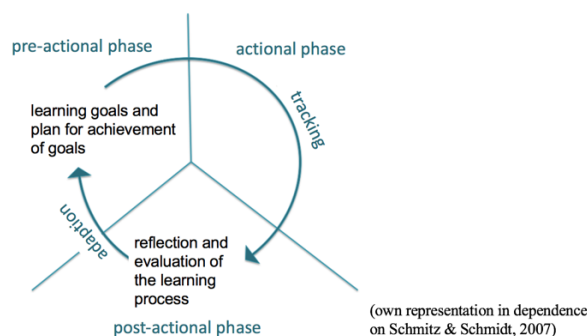

## Theoretical framework

Inclusion is one of the current challenges in the education system. Because of its complexity, inclusion in secondary education increases the need for subject-specific teaching development and corresponding measures for teacher professionalization, e.g. in form of teacher professional development (PD) programs. The knowledge about individual learning processes of teachers participating in a PD program is fundamental to organize a professional learning development systematically and effectively (Prediger, Leuders, & Rösken-Winter, 2017). Therefore, we are interested in what and how teachers learn when participating in a PD program on inclusive mathematics classes.

## How to make teachers' learning processes visible within a PD program?

In general, only a few studies focused on the processes of teachers' learning (Goldsmith, Doerr, & Lewis, 2014). First of all, the question "How to make learning processes visible?" aroused our interest. Schunk (2012) specifies different methods of investigating learning, for example with the help of a self-report. Portfolios can be used as one method of documenting and structuring self-reports. Learners can use portfolios to observe, document and reflect their learning progresses as well as to plan further learning steps (Gläser-Zikuda, Fendler, Noack, & Ziegelbauer, 2011).

In this study we based our considerations on the extended process-model of self-regulation (Schmitz & Schmidt, 2007). This model uses the basic assumption that self-regulation "refers to self-generated thoughts, feelings and actions that are planned and cyclically adapted to personal goals" (Zimmerman, 2000, p. 16 as cited in Schmitz & Schmidt, 2007, p. 11). One important element of this idea is the pursuit of goals during three learning phases: pre-actional, actional and post-actional (see Figure 1).

**Figure 1: Extended process model of self-regulated learning**

During the pre-actional phase the learner compares his situation with the desired goal and defines steps for achieving the goal (Gläser-Zikuda et al., 2011; Schmitz & Schmidt, 2007). In the actional

phase the learner tracks his goals and in the post-actional phase he reflects his learning process and evaluates it by comparing the actualized status with his expectations at the beginning (ibid.).

## Method

In order to uncover teachers' learning processes within a PD program, we understand self-regulated learning as a tool for developing reflection tasks as a basis for the work with portfolios. The creation of the reflection tasks is based on the PD program content and refer to the cyclic interplay of pre-actional and post-actional phase as explained above. At the moment we can rely our research on three portfolios, which were filled out at distance of six to eight weeks each. In the first portfolio (PF1), teachers wrote down a personal learning goal, which they want to achieve through the whole PD program, and formulated planning steps for achieving it (pre-actional). Within the second portfolio (PF2) they wrote down, which steps they made and how they evaluate their learning process (post-actional). In this context the teachers also looked back to what experiences they made in their inclusive mathematics classes (post-actional). Afterwards, they planned further steps for getting closer to their desired goal (pre-actional). In portfolio three (PF3) the teachers were asked to formulate their personal learning goal again, with or without a modification based on their previous experiences (post-actional). Finally, they planned again how to pursuit their learning goal (pre-actional).

## Results

With the help of case examples, typical teachers' answers are going to be introduced aiming at the discussion of further development and reflection of our portfolios as a research method. For example one teacher formulates the personal learning goal that she wants to prepare lessons at different levels of learning. She plans to reach her goal within the topic of percentage calculation (PF1, pre-actional). Later on she writes that she had used different methods with her pupils and she describes her learning process as being in flow (PF2, post-actional). She still wants to prepare a lesson in cooperation with a colleague (PF2, pre-actional). At last, she describes which aspects of lesson preparation she wants to improve (PF3, post-actional) and in which aspects she wants to work on collaboratively (PF3, pre-actional). All in all, we would like to discuss our portfolios, based on the self-regulated learning model, used as a possibility for making teachers' learning processes within a PD program visible.

# The story of Maia: I will try to survive!

Annette Hessen Bjerke

OsloMet – Oslo Metropolitan University, Oslo; [annette.hessen@oslomet.no](mailto:annette.hessen@oslomet.no)

*Two major concerns in mathematics teacher education research are the role of subject matter knowledge and the development of self-efficacy in teaching mathematics (SETM) in pre-service teachers (PSTs). These two bodies of research are normally not brought together, but I do so by investigating PSTs' SETM using an instrument developed with Skemp's two ways of understanding mathematics as the point of departure, and by exploring the sources of SETM through longitudinally conducted semi-structured interviews over a period of nearly two years. A focus on how one PST, Maia, drew on different sources of SETM, contributing to a new understanding of the agency of those PSTs that are recognised as "weak" because "they don't know any maths".*

*Keywords: Pre-service teachers, mathematics teacher education, self-efficacy, subject matter knowledge*

## Introduction

There is an ever-growing body of research investigating what teachers need to know in order to teach (Adler & Sfard, 2016). Unlike most research on subject matter knowledge (SMK) in the context of teaching mathematics, rather than investigating *what* knowledge is needed, this paper gives one particular pre-service teacher (PST) a voice in the matter, allowing an exploration of how *she* perceives the role of, and the need for, SMK as she develops her ideas about the teacher she not only *wants* to be, but *can* be. The importance of such a perspective is supported by Kagan (1992), who noted that PSTs' perceptions lie at the heart of teaching, and Pajares' (1992) comparison of 16 studies, concluding that PSTs' perceptions play a pivotal role in the way they acquire knowledge during pedagogical training.

One way of studying PSTs' perceptions of their own SMK and its role in teaching, is by paying attention to their self-efficacy in teaching mathematics (SETM). Teacher efficacy is considered one of the key motivation beliefs influencing teachers' professional behaviours and pupil learning (Klassen, Tze, Betts, & Gordon, 2011). Because of the situatedness of teacher efficacy, there is a need for more attention to domain-specific explorations (Klassen et al., 2011). Mathematics is an especially interesting context, since PSTs often express doubt about their own self-efficacy in mathematics (Gresham, 2007). Moreover, research indicating that teacher efficacy develops mainly during teacher education (Hoy & Spero, 2005) underlines the importance of investigating how and to what extent SETM develops in PSTs. In this paper, this is done in two ways, by a quantification of SETM through instrumentation, and through interviews focusing on one PST's perception of her own SMK and the need for such.

## Theory

Bandura's social-cognitive construct of self-efficacy is concerned with judgements of personal capability (Bandura, 1997). Self-efficacy is defined as a person's judgement of his or her abilities to execute successfully a course of action (Bandura, 1997), a future-oriented belief about the level of competence one expects to show in a specific situation. It has two

components: a personal belief about one's own ability to cope with a task, a personal self-efficacy, and judgments about the outcomes that are likely to flow from such performances, an outcome expectancy (Bandura, 2006, p. 309). In this paper, teacher efficacy is understood as a measure of "the extent to which teachers believe their efforts will have a positive effect on student achievement" (Ross, 1994, p. 4), the 'personal self-efficacy' component of Bandura's theory. Moreover, SETM is understood to be the component of teacher efficacy corresponding to Bandura's concept of personal self-efficacy, seen in the subject-specific situation of teaching mathematics.

Bandura (1997) describes four sources of information that may contribute to the formation of efficacy beliefs: *mastery experiences*, *vicarious experiences*, *verbal persuasion*, and *physiological responses*. *Mastery experiences* are constituted by previous perceived success in performing a particular task, such as actual classroom teaching, and are seen by Bandura as the most powerful source of efficacy information (Bandura, 1997). Because teaching lacks absolute measures of adequacy, teachers can appraise their capabilities in relation to the performance of others (Bandura, 1997). *Vicarious experiences* are situations in which one watches another person successfully perform or the behaviour one is contemplating (Bandura, 1997). *Verbal persuasion* involves verbal input from others with the intention of enhancing a person's belief that they have the capability to perform a given task at a certain level. It "is likely to be effective when it is received from a highly competent individual who is perceived as an expert in the field" (Palmer, 2011, p. 580), such as a PST's mentor in school placement. Verbal persuasion alone may be limited in its power to create an enduring increase in teacher efficacy, but may work together with other sources to provide teachers with encouragement to strengthen their teaching skills (Tschannen-Moran & McMaster, 2009). Bandura (1997) viewed verbal persuasion as a comparatively weak source. *Physiological responses* can be a source of efficacy information, providing indirect information about capability to deal with challenging situations (Palmer, 2011). Bandura (1997) viewed this source as the least effective source as they were not reliably diagnostic of one's capability.

Following his review of teacher efficacy research, Wyatt (2014) argued that poor conceptualisations of the role of knowledge have obscured understandings of how teachers' self-efficacy beliefs develop. Moreover, Morris, Usher, and Chen (2017), add that it is clear that teachers' knowledge, and their beliefs about that knowledge, can play an important role in their development of self-efficacy. There is a need to better understand the role of knowledge in the development of teacher efficacy (Klassen et al., 2011). I follow Bandura (1997) and Wyatt (2014), who noted that knowledge is not a source of self-efficacy in itself.

In discussing SMK, Shulman (1986) emphasises that a teacher should not only understand *that* something is so, but also understand *why* it is so. This distinction is related to Skemp's (1976) *instrumental understanding* - 'rules without reasoning', and *relational understanding*, requiring "knowing both what to do and why" (Skemp, 1976, p. 20). Even though Skemp (1976) underlines that to have strong knowledge of mathematics does not guarantee 'success' as a mathematics teacher, he adds that teachers who do not possess such knowledge are likely to be limited in their ability to help students develop relational understanding, which is the goal in mathematics teaching, and therefor in mathematics teacher education, where theoretical

perspectives are often related to reform teaching (Grossman et al., 2009) focusing on relational understanding.

In my work, the emphasis is on how PSTs perceive the role of SMK, how they perceive the need for such knowledge and how such knowledge (or lack of it) influences them and colours their interpretation of their experiences as they progress through teacher education. SMK is central both in the instrument used on cohort-level (reported in Bjerke and Eriksen (2016)), and in the way in which the sources that PSTs draw upon in order to develop SETM are closely related to their perceptions of their own SMK and its role in teaching.

## Methodology

This paper reports on data collected for a larger research project within a generalist primary teacher education programme for grades 1 – 7 (ages 6 – 13). Data were collected from a cohort of 191 PSTs admitted to a University College (UC) in Norway. At this UC, PSTs must take a minimum of 30 ECTS in mathematics, where the compulsory course spans the first two of a four-year programme, with 3 – 5 weeks school placement in each semester.

### The instrument

SETM was investigated on cohort level through instrumentation. The instrument consists of 20 items, given to the cohort of PSTs at the beginning (pre-test) and the end (post-test) of their compulsory mathematics methods course (at the end of their second year). Each item asks of the respondent how confident they are helping a child to solve a mathematics task, 10 strictly algorithmic tasks focusing on rules and procedures in mathematics as in knowing *that* (i.e. “Calculate  $-17 + 5$ ”), and 10 focusing on reasoning as in knowing *why* (i.e. “Explain why division doesn’t always make a number smaller”). In this way, the instrument asks of the respondents to consider their own SMK (see Bjerke and Eriksen (2016) for a description of the instrument’s content and validation).

Through Rasch analysis, items and persons are measured on the same interval scale, in logits, that allows us to avoid using non-equal interval values in parametric analyses that assume linearity (Boone & Scantlebury, 2006). The higher the person estimate, the more self-efficacious a person feels (Boone & Scantlebury, 2006). Selected findings from Rasch analysis of the data from the instrument implementation in Bjerke and Eriksen (2016) and Bjerke (2017a) are reported in this paper in order to place Maia amongst her peers.

### Semi-structured interviews

The sources of SETM were identified through analysis of interviews with 10 PSTs in the current cohort. The semi-structured interviews were conducted over a period of nearly two academic years. Interviews 1, 3 and 5 are conducted before three consecutive periods of school placement, while interviews 2, 4 and 6 are conducted after the same periods of placement, resulting in six individual interviews with 10 PSTs who volunteered to participate (by indicating this on their instrument response). The overall aim was for PSTs to tell their story, from their very first thoughts as novices, through two years of experience of repeated placements and the role of the UC in their preparation for teaching mathematics, up to the point where they had considerable

placement experience and were ready to look ahead and reflect on the mathematics teacher they can be. The semi-structured interviews were informed by their answers on the instrument.

To analyse the data, references to the role of SMK in UC and school placement contexts were identified, noting connections to experiences of success and failure as applied to accounts of being and becoming a mathematics teacher. In analysing accounts of success and failure, particular attention was given to Bandura's (1997) four sources of self-efficacy. A later, more contextually bounded, holistic case study approach, enabled me to note common trends across the group. More importantly for this paper, it enabled me to identify and explore one PST, Maia, who acted as a foil to the presentation of the data from the other nine participants (Bjerke, 2017a), and was for that reason selected as a case study. This paper gives Maia's story.

## Findings

As expected, there is a spread in novice PSTs' SETM (Bjerke & Eriksen, 2016), with Maia among those with lowest SETM within her cohort (with a measure of  $-.69$  logits in a cohort with mean  $0.55$  and  $SD = 1.16$  (Bjerke & Eriksen, 2016)). On cohort level, PSTs report being more confident helping a child to solve mathematics tasks focusing on rules and procedures in mathematics than tasks focusing on reasoning. Maia is representative of this trend, and a closer look reveals that Maia is 'Not confident' or 'Somewhat confident' on 15 of the 20 tasks in the instrument. She reports being 'Very confident' on one rules-task; she is very confident that she can help a child "Calculate  $342 - 238$ ". This stands in stark contrast to the thematically related reasoning-task, "Explain why, when subtracting, you can sometimes borrow from the place to the left", where she reports being 'Not confident' (Bjerke, 2017a). Holding Maia's responses to these two tasks up against each other highlights the impression the analysis gives of Maia: she is more confident when mathematics is limited to calculations following algorithmic procedures without questioning *why* these procedures work.

It is not first and foremost her placement amongst her peers that makes Maia an interesting case, but rather how she, during interviews, elaborates and explains her low SETM. A dominant theme in Maia's story is her own experience of mathematics, which she says she was 'OK at' in upper secondary school, where indeed she gained above average marks. In the first interview, Maia states that she likes mathematics when she is able to do it, but when she does not 'get it', she does not like it. This and related statements highlight the role of emotion in her novice story, looking back as well as looking forward: she does not know if she likes the thought of becoming a mathematics teacher, and she has few ideas and thoughts on what to expect from teacher education; she simply hopes that it 'fits' her way of doing mathematics. As it turned out, it did not 'fit' and Maia found it challenging at UC, because of the focus on a relational understanding.

Following her first school placement in her first semester, whereas other PSTs began to see the possibility that UC could support them in developing the kind of knowledge they need for teaching, Maia was hazy about what she might learn from the UC way of doing mathematics. Consistent with her response on the instrument, she expressed awareness of, and concern about, her inability to explain mathematics, but she did not see UC as a potential source of support. Instead, she relied heavily on her mastery experiences in placement learning:

Learning by doing ... it's totally different in school placement, it can't be compared to what is presented to us at UC (interview 2)

An issue of 'fit' between her way of learning mathematics (instrumental focus) and the teaching at UC (relational focus) persisted in her second semester, in interview 3. In the period immediately before the third interview, UC teaching had focused on 'The Family of Quadrilaterals'. The PSTs had investigated how the different classes of quadrilaterals connect to each other, and the fact that, for instance, a square meets all the requirements of a rectangle, and hence can be described as a rectangle. Maia expressed confusion about this inclusive definition, and was critical of the UC mathematics curriculum:

I'm getting more and more confused ... It's a bit uncomfortable to know that I have to teach things I didn't learn myself when I went to school ... It's hard to learn something that doesn't make sense. I don't want to talk about a square as a rectangle (interview 3)

While at the novice stage other PSTs took a generally positive emotional stance focusing on building their sense of development as mathematics teachers on the recognition that a different and more relational kind of SMK, focusing on knowing *why*, might be required and possible (Bjerke, 2017a), Maia's account of the teacher she would like to be reflected her new negativity about mathematics. The sense of building relational understanding based on underlying principles was strikingly absent in Maia's sources of SETM. This appeared to contribute to her insecurity in general: She simply hoped to be able to make her pupils understand that

...it [mathematics] might be alright, there are worse subjects (interview 3)

After the second school placement, in interview 4, Maia's story was noticeably more positive: her narrative was far more grounded in her mastery experience in school placement, with major emphasis on the benefits in terms of *feeling* like a teacher:

I've learned so much that it's hard to put it into words. It's another world ... I felt we [the PSTs in her group] were one of the teachers (interview 4)

She described how she felt at home in school placement. She relied on verbal persuasion in the form of praise in order to gain a sense of SETM. Success in placement was crucial:

It was nice to get feedback after lessons, because [the mentor] pointed out positive things ... I need to show that I'm meant to be here ... (interview 4)

In her third semester, in the run-up to her third placement, she still doubted her ability to be a mathematics teacher:

A part of me wants to be [a mathematics teacher] ... but I don't know if I'm capable of teaching this subject ... I struggle so much myself (interview 5)

After the third placement, in interview 6, she felt more confident due to guidance from her mentor as a source of vicarious experience:

My mentor taught me how to show to children how to calculate and why [the mentor] did it this way (interview 6)

She gave several examples of what she meant by this: "when to say 'digit', when to say 'number', when to say 'decimal' rather than 'decimal number'". Instead of dealing with these

issues in the UC-context, she relied on copying her mentor, trying to remember ‘when to say what’, as a vicarious source of self-efficacy. In this way, Maia’s account of how she learned to be a mathematics teacher remained heavily dependent on her learning in school placement, copying her mentor, building on vicarious experiences against a background of insecurity in her mathematics knowledge:

That’s where I learn everything; that’s where I learn to become a teacher (interview 6)

However, the decontextualized nature of this source of self-efficacy and the role of SMK in it, meant that Maia had to employ a particular strategy in order to manage her mathematics teaching, involving preparing which calculations to do on the blackboard, doing them herself before the lesson and thinking through how to explain every step in a way that pupils would understand. She worried about the demands of this strategy:

I’m afraid it will be too tough, that I’ll fall badly behind and almost drown (...) I’ll try to survive the last years in teacher education and get through it (interview 6)

While both pre- and post-test analysis on cohort-level places Maia amongst those with lowest SETM, it is important to notice that, despite the negative outlook of her developmental story, Maia is closer to the mean by the end of her 2<sup>nd</sup> year than she was as a novice (Bjerke, 2017a), revealing that her SETM has developed more during these two years compared to the average PST. During the mathematics method course, spanning the two first years of teacher education, Maia’s responses on the pre- and post-test show that she has gained confidence in all items in the instrument that are comparable (five are not comparable due to how they are interpreted differently by the students as novices and as 2<sup>nd</sup> year PSTs (Bjerke, 2017b)). She is no longer ‘Not confident’ on any tasks, and on all comparable tasks, she has ticked one confidence-level higher on the post-test compared to what she did on the pre-test. From this we can read that the difference in confidence-level between rules- and reasoning-items is still an issue towards the end of the course.

## **Discussion and concluding remarks**

The analysis reveals that SMK is indeed an issue in Maia’s developmental story: she finds mathematics challenging at UC, much due to the focus on relational understanding. She looks upon teacher education as something to be ‘survived’. While her perception of her own SMK and the role of such is indeed an issue, her reflection of this situation, and how she dealt with it, is equally important. She expresses awareness of, and concern about, her inability to explain mathematics, but she does not see UC as a potential source of support. The role of SMK in sources of SETM in the sense of understanding connections and underlying principles is strikingly absent, and it appears to contribute to her insecurity in general. But still, we see that her strategy of over-preparing in exhaustive and rigid details in order to manage her mathematics teaching. Drawing on her placement as a strong source of mastery has resulted in positive development in her SETM.

In line with Bandura’s (1997) understanding that mastery experience generally has the strongest effect, Maia’s story of her development as a mathematics teacher is dominated by a strong emphasis on mastery. She deals with the demands of teaching by focusing her learning in school placement, drawing on vicarious experiences when trying to copy her mentor. A longitudinal

reading of her interviews reveals a repeated negativity in her story after periods of lectures at UC (in interviews 1, 3 and 5), and a positivity after each period of school placement (in interviews 2, 4 and 6). In the interviews where she talks about UC-teaching, there are not many signs of sources of SETM. She focuses on experiences of failure and what she finds hard, and the fact that UC teaching in mathematics does not seem to “fit” her way of doing mathematics. Meanwhile, in the interviews taking place after periods of school placements, she points to both mastery experience, verbal persuasion and vicarious experiences as sources of her SETM. She notices the role of her own SMK in these sources, tending to avoid the difficulties arising due to the UC’s focus on relational understanding and instead focusing on praise from her mentor, strategies of copying her mentor, and over-preparation with an overall instrumental focus. She appears to find a strong source of SETM in her placement relaying heavily on praise, which in turn might prevent her from further development, given that verbal persuasion is found to be a comparatively weak source (Bandura, 1997) and on its own may be limited in its power to create an enduring increase in teacher efficacy (Tschannen-Moran & McMaster, 2009).

Bringing together research on SMK and on teacher efficacy enabled me to explain in more detail the complex role of SMK in Maia’s story. Bandura (1997) argues that self-efficacy is central to the exercise of human agency. My investigation of this construct, in PSTs from novice to more experienced, offers a new way of recognising the agency of “weak” PSTs. The story of Maia is an example of someone with low SETM, who seems unwilling to reflect on the role of SMK, and unwilling to engage in the ‘new dimension’ of mathematics - the focus on relational understanding and the ability to *explain* mathematics - and who sees teacher education as something to survive; she is easy to describe as a “lost cause”.

Based on my own experience as a teacher educator, I suspect that there are many PSTs like Maia in different teacher education programmes, struggling with the focus. Maia wants mathematics to be like it was in upper secondary school, which she saw as a set of rules to learn and use, requiring a purely instrumental understanding. Teacher education demands that she engage in knowing *why*, being able to explain *why* it makes sense to use rules, not only *how* to use them. My findings suggest that such “hopeless cases” are not solely “those who cannot do any maths”, but rather, might be someone who has a hesitation to engage with SMK in a new way.

Applying these insights, building on the recognition of Maia’s positivity after each school placement where she finds strong sources of SETM, I suggest there is a need to bring in new pedagogies of practice in teacher education that focuses on mastery of reform teaching where relational understanding is considered a key to success. Building on Grossman et al.’s (2009) suggestions, teacher education should seek to offer PSTs opportunities to experience alternative ways of teaching through *representations of practice* (e.g. by participating in reform teaching led by the course instructor), *decompositions of practice* (e.g. by using videos and analysing those based on theoretical frameworks such as Skemp (1976) on relational understanding), or through opportunities where PSTs are enacting teaching practices, rather than contemplating them as in *approximations of practice* (lesson planning, rehearsals, co-teaching with experienced teachers where SMK is focused).

*Research suggests that mathematical knowledge is likely to influence how mathematics is taught. In turn, how mathematics is taught impacts students' opportunities to learn mathematics. We report on a study examining the connection between preservice teachers' mathematical knowledge and the nature of their eliciting and interpreting of student thinking. Our findings suggest that preservice teachers elicit and interpret student thinking with more emphasis on student understanding in situations in which they have strong mathematical knowledge of an algorithm used by the student compared to situations in which they have weaker mathematical knowledge about the algorithm used.*

## Mathematical knowledge, dispositions, and pedagogical skill

Mathematical knowledge and pedagogical skill are crucial to effective teaching. Studies show teachers with substantial mathematical knowledge (Hill, Rowan, & Ball, 2005) and command of core teaching practices like formative assessment (Black, & Wiliam, 1998) have a greater impact on student learning of content. In the United States (US), mathematical knowledge and pedagogical skill are assets delineated in standards used to appraise both accomplished teachers (NBPTS, 2012) and beginning teachers (CCSSO, 2013). That mathematical knowledge and pedagogical skill are important in mathematics teaching is seldom questioned, but this does not mean that the field has determined the nature of the relationship between them. Mathematics teaching is a complex professional activity involving teachers in interaction with students, content, and context (Cohen, Raudenbush, & Ball, 2003). It is easy to imagine a multitude of ways in which mathematical knowledge and pedagogical skill are mutually influencing, if not mutually defining. For example, mathematical knowledge impacts the content and characteristics of questions that teachers ask during a lesson. Oriented in the other direction, pedagogical skill impacts the extent to which a teacher has access to student thinking that can be a substantial driver of a teachers' own mathematical development. This paper focuses on understanding the interrelations between mathematical knowledge and pedagogical skill empirically with respect to preservice teachers who are enrolled in a teacher preparation program.

Prior studies on teacher effectiveness connect teachers' mathematical knowledge with the achievement of their students. Often these studies examine the number and type of professional development experiences (Blank, & Atlas, 2009) or teachers' performance on mathematics content tests. When mathematics content tests are used, they tend to focus on general mathematical knowledge or mathematical knowledge identified as central to mathematics teaching (Hill, Rowan, & Ball, 2005). Such studies provide a connection between the mathematics that teachers know and the achievement of their students. What these studies do not explain is the way in which teaching is shaped by mathematical knowledge in ways that generate enhanced achievement for students. In a comparative study of Chinese and US mathematics teachers, Ma (1999) advanced the notion that the

way that teachers hold mathematical knowledge (e.g. the depth of understanding of foundational ideas interwoven with knowledge of how those ideas are shown across the breadth of mathematical topics) supports their engagement in teaching. Some examples of engagement in teaching are the questions teachers are able to ask students, the examples they create, and their analyses of student work. Among other mathematical foci, Ma explored differences in teachers' understanding of subtraction algorithms. Her findings illustrate the potential impact of the teachers' understanding and the ways in which different types of understanding might provide the basis for teaching that would support students' learning about subtraction. Needed are studies that can show connections between teachers' knowledge and the ways in which they engage in teaching practices. This would especially support teacher preparation, where resources are most plentiful, to scaffold improvement.

Since mathematical knowledge is likely to impact/influence mathematics teaching, it is important to understand how those resources impact teaching. To enhance the utility of what is learned, it will be important to focus studies on practices of teaching that are routine and crucial to students' learning of mathematics. Two such practices are eliciting student thinking and interpreting student thinking. Teachers use these practices to encourage students to share their thinking about specific academic content in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students (TeachingWorks, 2016). Research on learning supports the use of teaching practices that enable teachers to know about and build on students' ideas. It also shows that teachers who know about their students' thinking and use that knowledge to influence their instruction have a significantly greater impact on student achievement (Black, & Wiliam, 1998). Hence, understanding the connection between mathematical knowledge and preservice teachers' engagement in the teaching practices of eliciting and interpreting student thinking is likely to be use to the wider field.

In this context, this paper reports on research driven by a desire to better understand the ways in which mathematical knowledge influences preservice teachers' engagement in eliciting and interpreting student thinking. We studied these teaching practices of preservice teachers within a mathematical content strand that dominates the primary grades – number and operation – zooming in on the operation of subtraction. Within subtraction, we focus on the use and understanding of different algorithms to solve problems, an area in which preservice teachers experience difficulty connecting their knowledge of traditional algorithms to alternative approaches (Son, 2016). Our research was guided by the question: What is the relationship between preservice teachers' mathematical knowledge of particular mathematical algorithms and the ways in which they approach eliciting and interpreting student thinking about those algorithms?

### **Using simulations to learn about preservice teachers' engagement in eliciting and interpreting student thinking**

A practical problem that arises is how to study the ways in which preservice teachers' mathematical knowledge of particular mathematical algorithms impact their eliciting and interpreting of student thinking. We chose to design and use simulations in which preservice teachers engage in eliciting and interpreting a student's thinking about the use of a particular subtraction algorithm. Simulations are approximations of teaching that place authentic, practice-based demands on a participant while purposefully suspending or standardizing some elements of a teaching situation (Shaughnessy &

Boerst, 2018). For each simulation, we developed a piece of student work and then designed an elaborate protocol detailing how a student would: complete the process shown in the work; reason about the process used; talk and act when questioned about the process. Those taking on the role of the student (teacher educators) were trained so that they could use information from the protocol as the basis for engaging in the situation and so that they could respond in ways that aligned with the profile of student thinking and acting.

Our decision to use simulations was driven by four factors. First, simulations of practice have proven to be usable in many professions to gauge clinical knowledge and skills (e.g. Boulet et al., 2009). Second, simulations provide reliable access to teaching situations that other methods, such as interviewing real children or interviewing in school contexts, could not. Third, simulations allow for the standardization of the assessment context (Shaughnessy, Boerst, & Farmer, 2018). Fourth, our goal required a design that would purposefully put preservice teachers in situations where their mathematical knowledge was low. The use of simulations allowed us to accomplish this while preserving our own ethical commitments to educating children and consistently positioning preservice teachers to work productively with children.

## **Methods**

We collected information about the mathematical knowledge of preservice teachers and used that information to assign them to three teaching simulations that each strategically positioned preservice teachers to elicit a student's thinking about a particular algorithm that had been used to compute an answer to a subtraction problem. Specifically, the simulations were designed to present opportunities to elicit a student's thinking about algorithms about which the preservice teachers had different degrees (known to the researchers) of mathematical knowledge. Twenty-four elementary preservice teachers from one teacher preparation program participated. Because our goal was not to bound our analysis to any point in time during a teacher education program, we purposefully recruited preservice teachers who were at different points in the program. Specifically, two were at the beginning of the teacher education program, eight were at the midpoint of the teacher education program, and 14 were at the end of the program. Next, we describe the pre-assessment, the assignment of preservice teachers to specific simulations, and the administration of the teaching simulations.

### **Pre-assessment of mathematical knowledge**

We designed an assessment of mathematical knowledge inclusive of four subtraction algorithms that could be encountered in a subsequent teaching simulation. These algorithms, shown in Figure 1, include: A) the US traditional algorithm for subtraction; B) adding up subtraction; C) subtracting from the base; and D) expand and trade subtraction. Largely, these algorithms represent processes that are either directly taught through common US mathematics curriculum materials or are likely to surface in some form during mathematics work in US classrooms. One was deliberately picked to represent an algorithm that would likely be unknown to preservice teachers.

Figure 1 displays four examples of subtraction algorithms used by students in a pre-assessment:

- A:** Standard subtraction:  $619 - 235 = 484$ .
- B:** Decomposition method:  $435 - 261 = 174$ . The student breaks down 435 into 400 + 30 + 5 and 261 into 200 + 60 + 1, then subtracts:  $400 - 200 = 200$ ,  $30 - 60 = -30$ , and  $5 - 1 = 4$ . The final result is  $200 - 30 + 4 = 174$ .
- C:** Standard subtraction:  $593 - 306 = 287$ .
- D:** Decomposition method:  $697 - 428 = 269$ . The student breaks down 697 into 600 + 90 + 7 and 428 into 400 + 20 + 8, then subtracts:  $600 - 400 = 200$ ,  $90 - 20 = 70$ , and  $7 - 8 = -1$ . The final result is  $200 + 70 - 1 = 269$ .

**Figure 1. Pre-assessment subtraction algorithm examples**

Preservice teachers were shown two examples of students' use of each of the subtraction algorithms, resulting in eight total examples to analyze. Half of the examples showed how the algorithms could result in correct answers and the other half of the examples showed how the algorithms could result in incorrect answers. This was done because of the potential for inaccuracy to influence preservice teachers' understanding of the different algorithms. For each example, preservice teachers were asked to determine accuracy of the answer, describe the steps that the student likely used to arrive at the answer, provide an explanation about the mathematical validity of the student's method, and apply the student's approach to another problem. The intent was to capture information that would allow us to categorize each preservice teacher's mathematical knowledge of each algorithm as "strong", "moderate", or "weak" relative to the mathematical knowledge shown across the algorithms. For each preservice teacher, the subtraction algorithm about which they demonstrated the most understanding was designated as "strong" and the subtraction algorithm about which they demonstrated the least understanding was designated as "weak. Those algorithms that were neither strong nor weak were designated as "moderate."

### **Assignment of preservice teachers to particular simulations**

We used information from these pre-assessments to assign preservice teachers to three simulations. One simulation involved a "student" using an algorithm for which the preservice teacher was characterized as having strong mathematical knowledge (relative to the other algorithms). Another simulation involved a "student" using an algorithm for which the preservice teacher was characterized as having weak mathematical knowledge (relative to the other algorithms). An additional simulation involved a "student" using an algorithm for which the preservice teacher was characterized as having moderate mathematical knowledge (relative to the other algorithms).

### **Administration of the teaching simulations**

All simulations were facilitated through the same sequence of stages. First, the preservice teacher prepared for an interaction with one simulated student (i.e., a teacher educator taking on the role of the student) by reviewing a specific piece of student work and considering what would be relevant to ask the student. For each simulation, they had 10 minutes for this preparation work. Second, the preservice teacher elicited and probed the simulated student's thinking to understand the steps she took, why she performed particular steps, and her understanding of the key mathematical ideas involved. Preservice teachers had five minutes to interact with the student. All preservice teachers finished their interactions within this time frame. All simulations were video recorded to support

scoring and research purposes. Third, following the simulation, the preservice teacher responded to questions about their interpretation of the student's process and understanding and their prediction about the student's performance on a similar problem. Interviewers followed up on the preservice teachers' responses as needed.

## Methods of analysis

We analyzed the simulation performances in which the preservice teachers elicited student thinking and the follow up interview in which the preservice teachers interpreted student thinking. Because the simulations made use of highly specified protocols for the student's processes, understandings, and ways of being, we were able to use checklists to track on the absence or presence of particular moves (Shaughnessy, & Boerst, 2018). Our checklists for the eliciting portion of the teaching simulations are based on an articulation of "high-quality" eliciting of student thinking. For example, high-quality eliciting student of thinking includes: eliciting the process/steps involved in using the algorithm and probing understanding of the algorithm and ideas underlying the algorithm. The checklist includes specific things that the preservice teacher might do in the context of each teaching simulation (e.g., probes why borrowing works) and specific responses that the student provides based on their preparation and training (e.g., "When you borrow, you're not changing the problem. You're just moving the same amount to a different place) when prompted by the preservice teacher. The practice of interpreting student thinking includes describing the components of the algorithm used by the student, making claims about the student's understanding of the algorithm, and substantiating claims by drawing on evidence from a larger body of data gathered from the eliciting. The checklist includes specific things that the preservice teacher might do in the context of each teaching simulation (e.g., describes the student's understanding of why borrowing works). For interpreting, we also cross-check any evidence that a preservice teacher cited with the information gathered during the interaction with the student to ensure that they had the evidence that they cited. For each situation, we further specified crucial "core" components of the process and understandings that were at the heart of the student's algorithm, ones that would be particularly important to attend to in the interpretation.

Each performance was appraised by two members of the research team. Disagreements were resolved through review of the data and remediating differences of interpretation by developing and refining a codebook.

## Findings: Connecting the preservice teachers' eliciting with their mathematical knowledge and disposition

As noted previously, we analyzed the quality of each preservice teacher's eliciting performance in a context in which the preservice had "*strong mathematical knowledge*" of the subtraction algorithm versus their performance in which they had "*weak mathematical knowledge*" of the subtraction algorithm. We next turn to findings related to their eliciting and interpreting of student thinking.

### Eliciting practice

For each teacher, we compared their eliciting performances in the strong mathematical knowledge simulation context (SM) and the weak mathematical knowledge simulation contexts (WM). There were no differences across the two conditions with respect to the preservice teachers' eliciting of the student's procedural steps to solve the problem. However, preservice teachers probed for the students' understanding of the process more frequently in the SM simulation ( $M = .792$ ,  $SD = .2518$ ) than in

the WM simulation ( $M = .313$ ,  $SD = .3848$ ),  $t(23) = 5.468$ ,  $p < .001$ . In other words, when preservice teachers had stronger understanding of mathematics of the student's algorithm (relative to the second algorithm), they more frequently elicited the student's understanding about core ideas.

### **Interpreting practice**

For each preservice teacher, we compared their interpreting performances in the SM simulation context and the LM simulation context. Preservice teachers did not differ in their skills in interpreting the procedural steps of the algorithm used by the student in the two contexts. Almost all of the preservice teachers named all of the student's steps in both contexts. However, the quality of their interpretation of the student's understanding of the process that was used was significantly higher in the SM simulation ( $M = .500$ ,  $SD = .3612$ ) than in the WM simulation ( $M = .188$ ,  $SD = .3234$ ),  $t(23) = 3.498$ ,  $p < .002$ . In other words, preservice teachers were better at interpreting the students' understanding in situations in which they had strong mathematical knowledge of the algorithm compared to a situation in which their mathematical knowledge was comparatively weaker.

### **Implications and next steps**

Preservice teachers demonstrated different eliciting and interpreting skills across two situations – one in which they had relatively high mathematical knowledge of a particular subtraction algorithm being used by a “student” and one in which they had relatively weak mathematical knowledge of a different subtraction algorithm. Preservice teachers focused their eliciting and interpreting practices more on student understanding when they had relatively strong mathematical knowledge. In some ways this finding is not surprising. Strong mathematical knowledge of an algorithm may enable preservice teachers to know what to ask about in terms of understanding. Further, in interpreting student thinking, mathematical knowledge of an algorithm may impact preservice teachers' abilities to identify the mathematical understanding that are worth naming. To be clear, in our work with preservice teachers we have seen cases where preservice teachers with strong mathematical knowledge of a situation did not elicit much thinking from the student, but instead made assumptions about the process and the students' understanding based on a combination of the student's written work and their own understanding of the algorithm. A contribution of the study was gain a better sense of the degree to which such engagement was common (or not) in our context. While this study does not provide insight into the reason(s) behind the differences in the practices, this outcome is useful because it shows concretely that differences in practice predicted by researchers like Ma (1999) who had theorized that greater mathematical knowledge would enable engagement in teaching practices that support student understanding of mathematics.

Some elements of the preservice teachers' eliciting and interpreting were not significantly different across the two situations. Notably, there were not marked differences in the extent to which preservice teachers elicited procedural aspects of the student's algorithm. Likewise, there were not marked differences in preservice teachers' interpretations of procedural aspects across the different algorithms. When coupled with the previous analysis, this indicates a nuanced relationship between knowledge and teaching practice. The degree to which mathematical knowledge impacts the focus of teaching practices with respect to some facets of mathematics (understanding) more than others (procedural) is interesting. It is plausible that differences were not seen due to the fact that eliciting information about steps in a mathematical process, like an algorithm, may be more straight forward than eliciting information about understanding and thereby are not as heavily impacted by the degree

of mathematical knowledge one has about an algorithm. The similarity of eliciting and interpreting with respect to the steps in an algorithm is notable for the questions it suggests. What enables preservice teachers to elicit and interpret student thinking about the procedural aspects of an algorithm irrespective of the depth of their mathematical knowledge about the algorithm? What compels preservice teachers to elicit student thinking about the procedural aspect of an algorithm and to attend enough to the procedural aspects to be able later to produce accurate evidence-based interpretations?

A clear limitation of the study findings presented here is consideration of other factors that might be contributing to the differences in eliciting and interpreting practices. For instance, a teacher's mathematical dispositions may shape teaching practices in ways that impact students' opportunities to learn mathematics (Thompson, 1992; Philipp, 2007). As an example, in our own work with preservice teachers, we frequently hear differing, and often strongly expressed, dispositions toward particular computational algorithms. These dispositions influence and give structure to how teachers perceive students' engagement in mathematics. Studies have illustrated ways in which dispositions can impact the classroom practices of teachers (e.g., Fennema et al., 1996). Some of the connections between teaching practice and content knowledge that we have shared in this paper could be explained by the influence of mathematical disposition. For instance, it is just as plausible that a positive mathematical disposition may result in preservice teachers believing that it is worth asking questions about understanding because they personally know that the algorithm can be understood as it is that strong mathematical knowledge is the resource driving that approach to the practice. Given the potential for mathematical knowledge and mathematical dispositions to be mutually influencing (e.g. the more robust the mathematical knowledge of the teacher about an algorithm the more favorable the disposition to engage in and with the algorithm), in current work, we are teasing apart their influences with respect to engagement in teaching practices.

Keywords: *Teacher education, Teacher professional development, Teaching methods, Interdisciplinarity, Mathematics Teacher's Specialized Knowledge*

## The project *Liceo Matematico* and the issue of teacher training

In this work, we deal with a challenging research question: what teacher training activities are effective to train mathematics high school teachers to teach properly interdisciplinary modules involving Mathematics? The context of the research is an Italian national project for high schools, named *Liceo Matematico* (Capone *et al.*, 2016), that aims at turning Mathematics, hard subject to learn, into a tool to connect disciplines and deal with current social challenges. To make this possible, it is necessary first to deepen into the epistemology of disciplines and to look for fruitful connections between them, then to design suitable modules for high school students. Operationally, the project consists in additional activities for high school students (40 hours per year), carried out by voluntary mathematics high school teachers, trained by university teachers. University teachers identify topics, epistemological issues and interdisciplinary connections (Frodeman, Thompson Klein and Mitcham, 2010) relevant in order to pursue the general goal of the project, and then propose possible classroom activities. Each module is proposed in 2 steps: in the first the contents are presented with a frontal lesson, while in the second step the didactical activities are before proposed to the teachers and then discussed with them in terms of potential students' difficulties and connections with the curriculum. After the course, the high school teachers have to choose some modules and adapt them for their students, consistently with the school institutional constraints and goals. We focus our attention on the teachers' choices and adaptations of the modules proposed in the training course.

## Research framework: Mathematics Teachers Specialized Knowledge

To describe the aspects of teachers' knowledge considered in the training course, we chose to use the Mathematics Teacher's Specialized Knowledge (MTSK) model elaborated by Carrillo-Yañez, Climent, Montes, Contreras, Flores-Medrano, Escudero-Ávila, Vasco, Rojas, Flores, Aguilar-González, Ribeiro and Muñoz-Catalán (2018). Such model is focused on "the specialized components of mathematics teachers' knowledge, that is, their knowledge of mathematics as the object of teaching and learning" (ibid. 2018, p. 14). It includes three sub-domains of Mathematical Knowledge: mathematics content itself (*Knowledge of Topics, KoT*); the interlinking systems which bind the subject (*Knowledge of the Structure of Mathematics, KSM*); how one proceeds in mathematics (*Knowledge of Practices in Mathematics, KPM*). For what concern the pedagogical content knowledge (PCK), two sub-domains concerned teaching and learning (Ball *et al.*, 2008), *Knowledge of Mathematics Teaching (KMT)* and *Knowledge of Features of Learning Mathematics (KFLM)*, while the last sub-domain of PCK is *Knowledge of Mathematics Learning Standards (KMLS)*.

## Methodology of the research

We carried out a preliminary study after the first year of teacher training to investigate whether and how the course had provided teachers with the suitable knowledge that could allow them to adapt the trainers' proposals without transforming them so much to lose their most important aspects. We analyzed the modules proposed by university teachers using the model MTSK and then we used the same model to analyze the teachers' choices and adapted modules. Finally, we analyzed the teachers' adaptations in terms of differences and similarities with the original proposals, identifying the sub-domains of MSKT that were more considered by the teachers to adapt the modules.

## Data analyses

For the first year the modules proposed by university teachers were: theorems with Origami; programming languages; congruence and divisibility; the language of Physics; From frescoes to videogames. The modules addressed merely the following domains: KoT (5/5), KSM and KPM (3/5); the only modules including interdisciplinary aspects explicitly were Languages of Physics and Art & Science. Looking at patterns in teachers' choices and adaptations, it emerged that the interdisciplinary modules were the less considered and, in these cases, the teachers felt the necessity to modify them a lot, separating and juxtaposing Mathematics and the other disciplines, using merely the epistemological perspective of Mathematics and using the other disciplines just to engage students and act on motivation, without really integrating the two as it was proposed in the modules.

## Discussion and conclusions

One of the main aspects of the *Liceo Matematico* project is interdisciplinarity. This preliminary analysis showed that the interdisciplinary activities were the most problematic to adapt for the teachers and the less chosen, so we realized that another kind of specialized knowledge is necessary for the teachers to carry out meaningful interdisciplinary activities, that we name *Mathematics Interdisciplinary Knowledge (MIK)*, i.e. the awareness of the different epistemological status of the disciplines, fruitful connections and critical issues emerging when mathematics is integrated with other disciplines, both sciences and humanities. Without a specific meta-reflection on these aspects the teachers fail in identifying the crucial points of interdisciplinary activities. In the second year we are interacting with the teachers addressing explicitly this point and looking for activities in the course that potentiate the MIK domain. As a general aim, we will try to characterize explicitly this domain providing examples and clarifying its specificity, according to our a priori analysis and results.

# Researching as a mathematics teacher educator: analysing mathematics teachers' detailed descriptions of first lessons

Laurinda Brown

University of Bristol, School of Education, Bristol, UK; [Laurinda.Brown@bristol.ac.uk](mailto:Laurinda.Brown@bristol.ac.uk)

*As a mathematics teacher educator, researching classroom environments and practices has supported me in linking theory and practice so that awarenesses developed support the prospective teachers with whom I work. The research has built a belief that there is not one way to teach mathematics. How do experienced mathematics teachers create the environment in which they teach? What do they consistently do from their first lessons with a group? This paper reports on interviews with effective teachers of mathematics in the UK where they stay with the detail of what happened in recent first lessons with a group new to them to illuminate their decision-making processes as they establish the culture of their classrooms. Energetic statements arising out of the detail, such as “I like to give things a story” can be used to support novice prospective teachers, like with Alf Coles, to find the teacher they can be when faced with not knowing what to do when teaching their first lessons.*

*Keywords: Mathematics teacher educator research, classroom environment, interviewing.*

## Background

Over my career as a mathematics teacher educator (MTE), I have interviewed many experienced teachers of mathematics. As I accepted the post of lecturer in mathematics education, in 1990, I left the classroom and my then role as a curriculum developer. I became fascinated by the mathematics teaching of others that seemed so different from my own. This paper explores stories from experienced mathematics teachers related to the detail, elicited using an interview, of their first lessons with a new group of students, investigating the questions: How do experienced mathematics teachers create the environment in which they teach? and What do they consistently do from their first lessons with a group? The first set of interviews explored the first lessons of experienced teachers because my prospective teachers did not have access to these and did not know what to do in their own first lessons. They may have had ideals of what they wanted to be as a teacher, with a view of what a classroom in which learning mathematics takes place might be like, but they did not have the experience to have honed the skills that would allow this vision to exist.

I have continued to interview practising teachers as part of my research to extend my awarenesses of possible practices, rather than come to some fixed view of what mathematics teaching looks like. Over time, my interviewing practices have changed and these interviewing practices have also influenced my practice as an MTE. In what follows, I will first discuss my interviewing practices and how these link to my practices as an MTE and will then move on to discuss cases of interviews.

## On interviewing

The original “first lesson” interviews were designed using Bruner’s (1990) ideas of a “culturally sensitive psychology”:

[which] is and must be based not only upon what people actually do but what they say they do [...] how curious that there are so few studies that [ask]: how does what one does reveal what one thinks and believes. (pp. 16–17)

I will be reporting on what the teachers actually do and what they each say they do in their mathematics teaching to illuminate their decision making in the next section. It was the access to the decision making that was supportive of the developing prospective teachers because I had a range of anecdotes available in group and individual discussions in those early days. However, as my interviewing skills developed, especially through Claire Petitmengin's writing and protocol, the process of interviewing became part of the structures of the course.

### **First lesson interviews**

First lessons with a new group of students were important to teachers in establishing their ways of working, but were often times where observers of the lessons were not so welcome. This included having a video-recorder in the classroom because it might cause a distraction in an important lesson or sequence of lessons. As a new mathematics teacher educator, I was fascinated by observing different mathematics teachers and their students interacting. The nearest I could come to observing first lessons was to interview teachers as soon after the lesson as possible.

At the time, I designed an interview protocol where each teacher interviewed was invited to tell me in detail about a first lesson or sequence of lessons with a group of students who had not been taught by them before. I wanted to focus on what happened in some detail as the teacher established their ways of working with the class. In looking at the transcripts again, I was struck by how similar my current interviewing protocol is and was moved to listen again to the tape-recordings (having found a player!) listening this time for when each teacher's voice was more energetic. This energetic voice was heard at times when they were talking *about* the detail, seeming to discover meaning in what they had been doing. The first-lesson interviews were an important critical incident in my own development as a mathematics teacher educator. I started to listen for energetic comments from my prospective teachers, as evidence of their learning, articulations of what previously had been implicit.

### **Claire Petitmengin's interview protocol**

The protocol for interviewing I currently use is adapted from the work of Petitmengin (2006) and has strong similarities with those early interviews. Petitmengin designed the protocol for her doctoral study, related to supporting epileptics to identify internal changes prior to having a fit. The design of the study linked the third-person neuroscience that had shown the changes in mappings of the brain, with a phenomenological first-person protocol redesigned as a second-person interview. The behaviours for the interviewer were the focus of Petitmengin's protocol and are as follows:

*Stabilising attention.* A regular reformulation by the interviewer of what the subject has said, asking for a recheck of accuracy (often in response to a digression or judgement). Asking a question that brings the attention back to the experience, such as, "How did you do that?"

*Turning attention from "what" to "how" (never "why").*

*Moving from a general representation to a singular experience,* a re-enactment, reliving the past as if it were present. Talking out of their experience, not from their beliefs or judgements of what

happened, often involves a move to the present tense. Staying with the detail is important, a maximal exhaustivity of description that allows access to the implicit. (adapted from pp. 239–240)

One of the changes in my own behaviour as an interviewer over the years has been to let go of “why” questions, whilst still supporting interviewees “talking out of their experience, not from their beliefs or judgements” (Petitmengin) to focus on “what people actually do [and] say they do” (Bruner). The changes in my behaviour as interviewer also led to changes in my behaviour as MTE. There was a realisation that the actions in the protocol were useful for supporting any learning, which could be described as “access to the implicit”. So, using these strategies could support the prospective teachers in supporting the learning of the students in their classrooms, getting them to talk through what they were doing when stuck on a problem say, and asking for evidence or examples when faced with an assertion. I developed an activity under the label of “diagnostic questioning” for prospective teachers to listen in pairs to each other solve a mathematical problem whilst the “interviewer” used strategies to draw out the other rather than get involved in the mathematics themselves. Over time, Alf Coles and I, who were colleagues teaching the prospective teachers together, extended the protocol for what we call narrative interviewing to a fourth point:

*Getting to new category labels.* After dwelling in the detail, telling stories and exploring without judgement or digressions, invite statements of what is being worked on. In this way, new category labels might be identified [...] that will link to learning new actions. (adapted from Brown & Coles, 2018, p. 178)

The prospective teachers need to act in the classroom even when they have no experience to draw on. In a small group, led by one of the MTEs acting as facilitator, the prospective teachers are asked to think of a story when they were feeling uncomfortable in their recent classroom experience. One person tells their story, without judgements or digressions, minimally and this is followed by others in the group telling stories that seem similar to them in some way (see The Mathematical Association, 1991, working group chaired by Barbara Jaworski). At some point, a discussion about what is similar about the stories happens and these statements might be different for different students. This discussion might give a range of “new category labels”, for example, “How do I know what they know?”; “How do I know that they know?” that can be worked on by those prospective students who find them meaningful by trying out a range of actions in their classrooms that can be used flexibly to support the classroom environment. In this way, developing my skills as an interviewer impinged directly on my practice as an MTE.

## **Cases from the original first-lesson interviews**

The teachers (10 in all from which I will illustrate two) were chosen by the three local advisory mathematics teachers who had observed them in their classrooms as being particularly effective (deliberately not defined because I wanted a range). The teachers were encouraged to stay with the detail of their first lesson with a new group of students and, in so doing, they also commented *about* the detail, without being prompted to by me. This might mean comments about their images of teaching and learning mathematics or about what mathematics was to them. These comments were said energetically, often quickly and explosively. In Petitmengin’s terms, I would now read these

comments as giving “access to the implicit”. In listening back to the original tape-recordings, for analysis, I paid attention to these energetic comments.

### Case 1: “I like to give things a story”

One teacher in his first lesson with a new group described using the following problem:

I had a dream last night and, in that dream, this is what I heard. You must build a tower and from the top of the tower, sort of like a plus sign from the side, it should look like two staircases meeting. We haven’t decided yet how big the tower should be but when we decide, you must be able to build it and organise the building of it.

After telling the problem, the following exchange occurred where there was a shift in the teacher’s comments to be *about* what he had described, giving access to his thinking and beliefs:

Teacher: I like to give things a story because I like to give the children a natural language as a parallel to the mathematical language.

Laurinda: So, a story for you would apply basic language, not mathematical language. Any other things that you would say in the story?

Teacher: I think it allows enabling people to enter the world of maths you are talking about then if you have got a story if it’s amusing or catchy in any way they might get interested in the first place, but it does provide short simple language with which they can converse with one another. So, it allows for group work which is something else I think.

In this extract, my contribution is stabilising attention, repeating back what I have heard said and returning the focus to the story, to the detail of what happened. This comment is followed by the teacher saying more *about* the thinking behind his decisions, giving insight into his vision of how the lesson will develop, what will be done over a sequence of lessons before returning to the detail of what happened:

By the end of two days’ work we were going to have posters of this and I wanted the posters to be different and I wanted people to have things to look at which would be new for them and interesting, and I wanted different people to have different problems that they would be solving [...] just to show that a huge range of possibilities can come out of story anyway. There is not one right answer, there are lots of answers [...] I then asked them in groups again, individually, to write down the task and everything and the story and then in groups giving them five minutes to do that, in their groups to decide what kind of questions or concerns or worries the architect has.

### Thoughts on Case 1

The word “story” is part of a rich set of interconnected images for this teacher. There are reasons such as using natural language alongside the mathematical language and also criteria for choosing a story, given that the children will do different things so that the children can see a “huge range of possibilities” emerging. Story is also linked to metacomments, where the students are asked to review each other’s design and come up with questions for the architect. The element of role play makes the learning student-centred, in that they have to make decisions. The teacher sets up the environment of

the classroom and comments on the students' actions, whilst the students themselves are given the responsibility of doing the mathematics. Mathematics teaching and learning being about story is closely linked to this teachers' and their students' behaviours.

### **Case 2: “Mathematics is a study of pattern”**

The teacher begins the mathematical part of his first lesson with:

So, on the board I write mathematics is a study of pattern. Basically, in a sentence I would say it is and then I draw little arrows and say there are two basic big areas of maths, one is numbers and the other is shape. I give them all this philosophical stuff. Today we are going to do an activity that is going to combine between these two things.

Quite soon after the description of what happened above, the teacher energetically, talking about what he does, revealing his passion, says:

What I find with children is they all think that maths is just numbers [...] I always try to emphasise how the two areas really do link because I think apart from anything else, anybody using the creative side of their brain, geometry can help a lot in understanding power in the numbers [...] bad experience with number work seems to block their whole mathematical enjoyment and I try to emphasise that maths is lots of things and not just knowing your times tables.

The teacher is clear what he wants students to be doing sitting them in groups to work together:

Well I'm looking for the children to be confident enough to be able to take an original idea and then move it on themselves into different areas.

### **Thoughts on Case 2**

The teacher in Case 2 sees mathematics as pattern, linking to a passion for overcoming students' previous bad experience with number. All his interactions with students supported this. The problem, given to students first, is one that he has used before, many times and has confidence in. Initially, the teacher reports that, when asked what mathematics is at the start of the lesson, no-one responds, whereas, twenty minutes in to exploring a problem, that links number and shape, students are describing patterns and asking questions. The teacher is able to comment, about their work, to students that they are doing mathematics.

What follows is a report of using the interview protocol over four years, with the same teacher, Alf Coles, initially new to the profession, showing how the interviews change over time.

### **Alf Coles's first-lesson interviews**

I first started working with Alf Coles in 1995. In the early days of working with him, he was a new teacher and I interviewed him at the beginning of his second year of teaching. I will use the first-lesson interview of 1995 to give some background to where the fourth protocol item developed and discuss differences with the interviews with experienced teachers.

### **Getting to new category labels**

When I first met Alf, he was in his first year of teaching and did not have the experience to link his teaching practice with his beliefs. The protocol of asking for details of his first lessons gave us an

opportunity to see what underpinned his practice. There seemed, however, to be no energetic comments *about* his teaching occurring within the interview linked to what he does as a teacher. The following interchange from 1995 shows how Alf is finding some actions that support his ideal image of teaching mathematics as opposed to actually being able to achieve that ideal in his practice:

AC: With my year 9 class who I had in year 8 one of the things that I said to them at the beginning is that one of my aims this year is to try to make you independent thinkers, although who knows what independent means. That felt quite nice because I could come back to that.

LB: That was in a first lesson?

AC: Yes. That gave some power to when they said, “Can you tell us how to do this?” that I could say, “I’m wanting you to do this independently.”

Compared to how the teachers in the original first-lesson interviews talk about their teaching, in the 1995 interview, when reliving the first lessons with a new year 7 (11–12 years old) group, there were no comments from Alf about the details of his teaching and no energetic comments. It was in our conversation after the interview, when I reported back to him about this, that the comment above about the year 9 (13–14 years old) group emerged. This was an energised statement and evidence, to me, that he had begun his journey to be able to act in a way consonant with his beliefs. The interview was at the start of our work together and also developed into a conversation about what we might work on and what it was I was interested in. Some of my comments were linked to what he was saying. My comment, out of my experience of other first lesson interviews, was a response to Alf talking about his vision of teaching mathematics:

AC: A sense of what it’s like to create a space for students to work on their own images. A sense of how that could be maintained. Picking up from what students have said at the beginning of class [...] by some people giving their method or explaining what they’re doing it’s not that you’re taking away the journey from the others it’s helping them along.

LB: [A] description of you at the moment is that you have no metacommenting. Some teachers when they are teaching are metacommenting. Some people think of this as patter - [...] “remember to reflect on what you’re doing as well as do it.” [...] I don’t think I’ve spotted any. [I]t’s not good or bad. I think what happens to [experienced] teachers is that they become very clear about what they’re trying to do, so all those metacomments become completely standardised and in a sense they become close to their behaviours - it’s a sort of autopilot. Right down to a [child] comes up and says, “I’ve got a problem with this” gets a reply, “OK, you tell me.” It’s a metacomment because it’s saying, “I’m not going to engage with this until you tell me.”

As we continued to work together, each year I did another first-lesson interview at the start of a new academic year until, by 1999, a pattern had become established and the interviews were similar, with similar comments about what was happening. At this point, we wrote up our research in a book

(Brown & Coles, 2008). The 1999 interview illustrates the way in which the interview shows what Alf did and what he said he did. Alf states, near the start of the lesson,

AC: And I said welcome to mathematics at secondary school. [A]s well as all the skills and techniques like adding or multiplying or taking away that they will have learnt and they will continue to learn it's also about learning to become a mathematician [...] and learning to think mathematically [...] [I]f you're thinking mathematically then it's about noticing things about what's around you and it's about writing things down about what you notice [...] a question about something [...] maybe they've seen a pattern and a question that mathematicians often ask is "Why?" Make a prediction maybe based on that pattern. Say why they think that pattern will continue.

This purpose of the year "about learning to become a mathematician", was linked to behaviours for the students like asking questions and making predictions. There were also metacomments about the students' ways of working that Alf made, such as, "That's a really nice example of how working together mathematically as a group that in talking about how you're doing something you can recognise where you've gone wrong." These comments are not pre-planned. In the complex decision-making, moment-by-moment in his classroom, Alf's comments about what his teaching is about are underpinned by metacomments close to his and his students' behaviours in doing mathematics.

In working with Alf for the last twenty years, we have come to see staying with the detail, dwelling in it, as a mechanism for finding the images of teaching, new category labels, that can be linked closely to actions as teaching strategies emerge that support students. This is particularly important for working with prospective teachers of mathematics, who are in the position that Alf was in in 1995. Ideals, such as independence or autonomy, of what they want to be as a teacher, are not linked with a view of what a classroom in which learning mathematics like that might take place, nor to teaching strategies. They simply do not have the experience to have honed the skills that would allow this vision to exist.

Novice and expert teachers can learn in the same way, staying with the detail of what happens and dwelling in it, what Varela (1999) calls "deliberate analysis",

Indeed, even the beginner can use this sort of deliberate analysis to acquire sufficient intelligent awareness to [...] become an expert. (p. 32)

For an expert teacher, this could be creating a new label linked to a behaviour to solve an issue arising in their classroom. Intelligent awareness "allows experts to unpick, if necessary, the reasons an action was taken, and hence open themselves up to alternative possibilities in the future" (Brown & Coles, 2011, p. 862). This again, for us, is Petitmengin's "access to the implicit", bringing to conscious attention the behaviours that support the ideal images of teaching to be put into practice.

The first-lesson interviews with experienced teachers were not designed to change what the teachers were doing. These teachers were experienced and effective according to local mathematics advisory teachers. I was interested in how they did what they did.

## Conclusions

So, how do experienced mathematics teachers create the environment in which they teach? From their first lessons, they are able to comment to students about their behaviours, for example, “you’re doing mathematics” (Case 2) and give them activities related to their beliefs about what mathematics is, such as the story problem (Case 1). In cases 1 and 2, the teachers use problems they have confidence in to achieve their clear images of what their classrooms can look like with their students, “describing patterns and asking questions” (Case 2) or “different people having different problems they would be solving” (Case 1). What do they consistently do from their first lessons with a group? What does seem to be the case is that for all these teachers their beliefs are closely linked to their and their students’ actions in their mathematics classrooms. Their different beliefs lead to different actions but, through the teachers metacommenting about actions they see as fitting their image of their mathematics classroom, the students know how to do mathematics in this teacher’s classroom. Even though the practices vary with the images of mathematics and mathematics teaching and learning of the students, what seems important is the students knowing what to do. Prospective teachers, similarly to Alf Coles, can use this same process of staying with the detail to raise new possibilities for action. Paying attention to the variety of practices that could lead to effective mathematics teaching and learning supported my own development as an MTE, in that I came to see my role as not replicating my own classroom practices. As an MTE I gained conviction in there not being one way to teach or learn mathematics.

# Using mixed-assessments to evaluate opportunities to learn in mathematics teacher education

*Keywords: Summative assessment, formative assessment, e-portfolio, opportunities to learn, mixed methods.*

## Focus and rationale

Many teacher education programs require practical activities, like internships in schools or teaching experiments. Our task as teacher educators is to evaluate these activities and to assess performance-related achievements, either for certification reasons or for program development. However, the assessment of the development of teaching competence of pre-service teachers in practical teaching activities is methodically challenging. In our study, we wanted to overcome current challenges with this issue by using an innovative methodological approach. In our evaluation study on mathematics pre-service teachers' opportunities to learn (Buchholtz et al., 2018), a mixed-assessment was applied, consisting of a summative assessment (SA) of pre-service teachers' perceived study content and a formative assessment (FA) on situation-specific learning opportunities during internships in schools.

## Theoretical background

In their review of research on the assessment of competencies in higher education, Blömeke, Gustafsson, and Shavelson (2015) model competence as a continuum that comprises dispositions, situation-specific skills, and performance. They also point to the challenges of an appropriate assessment: Pure cognitive-analytical approaches (like knowledge tests) lack sufficient validity because relevant parts, like the situational or contextual facets, can be underrepresented, and pure performance-based assessments might neglect the contribution of dispositional resources. Assuming that “the whole is greater than its parts” (p. 9), Kaiser et al. (2017) recommend working with a broader range of combined and situated assessment formats that are able to cover processes mediating the transformation of dispositions into performance. Other authors such as Carr and Claxton (2002) also understand learning as a situated activity; these authors point to the situatedness of what they call learning dispositions. Accordingly, they favour formative assessment (FA) approaches such as interviews and self-reports like those that appear in portfolios when it comes to the assessment of performance-related competence. However, unlike in summative assessment (SA) forms, FA forms presuppose that we have to give up the idea of comparing the achievements of pre-service teachers in a standardised way.

## Methodology and corresponding research design

Against this background, two basic ideas of the mixed methods methodology can be transferred to the level of assessment (Kelle & Buchholtz, 2015). Using a *combination* of SA and FA can extend the scope of the assessment, i.e., both widen and deepen the assessment by gathering as much

information as possible on multiple components of the assessed phenomenon or different, but closely related phenomena. The basic idea of an *integration* of SA and FA is to assess one phenomenon with different assessment forms, for example by using SA in a formative way for giving feedback, or integrating FA as a part of an overall SA (Buchholtz, Krosanke, Orschulik et al., 2018).

Respectively, in our study, a panel-survey measuring the professional knowledge and learning opportunities of 187 pre-service teachers was *combined* with the analysis of 30 individual e-portfolios from internships in order to holistically address both dispositional and situation-specific aspects of learning opportunities to develop teaching competence. In particular, the FA during the internship was composed of 18 predetermined tasks affording situation-specific skills. The pre-service teachers had to address the tasks during their observations of other teachers or their own teaching in school, and to work on them as a written contribution to their personal e-portfolio. In favour of an increased interpretability of assessment results, a mutual complementation of the collective findings from the panel study with the findings from individual FA was sought (e.g. when identifying evidence for learning opportunities in FA). This approach might also partly overcome the challenge posed by the inability to standardize FA in teacher education.

## Results

With SA data, we were able to determine comparatively that the analysed pre-service teachers had significantly higher perceptions of the number of learning opportunities regarding heterogeneity and research in mathematics education. Additionally, we used the data from the FA to identify pre-service teachers' situation-specific skills and to link the individual learning opportunities of the pre-service teachers with specific situational aspects of the school internships. With this combination, we were able to make detailed statements about the types of learning opportunities the pre-service teachers had, for example when dealing with errors in the classroom or differentiating instruction.

*This study examined mathematical knowledge for teaching of a prospective teacher having a PIP, Alin, and it revealed the relationship between PIP and mathematical knowledge for teaching. The case study design was used and the participant was selected by criterion sampling. Data were gathered from Alin's lesson plans, transcripts of her practicum-teachings, interviews done before and after her teachings, and self-reflections on her teaching. Results showed that Alin having a PIP demonstrated all the codes in the Knowledge Quartet. Results also showed that knowing the perspective a prospective teacher has allows to draw on the basis of her mathematical knowledge for teaching. This indicates that the perspective a prospective teacher has might induce her mathematical knowledge for teaching. We suggest ways to promote the development of a PIP on the part of prospective teachers during methods courses.*

*Keywords: Progressive incorporation perspective, Knowledge quartet, Prospective teachers.*

### Introduction

The perspectives prospective mathematics teachers have on mathematics, mathematics learning and mathematics teaching have affordances and limitations on their teaching (Jin & Tzur, 2011). Mathematics teacher education is not an easy task because of the traditional views prospective mathematics teachers hold (Ball & Cohen, 1999; Lloyd & Wilson, 1998). Therefore, researchers suggested that to develop mathematical knowledge for teaching on the part of prospective teachers, their learning to teach should be highlighted instead of giving them certain skills during methods and practice-teaching courses (Ebby, 2000; Hiebert, Glad, & Morris, 2003; Shulman, 1986; Simon, 1995).

Based on a series of research with in-service teachers, some researchers have come to the conclusion that (prospective) mathematics teachers might have a continuum between traditional perspective, perception-based perspective (PBP) and conception-based perspective (CBP) on mathematics, mathematics learning and mathematics teaching (Simon, Tzur, Heinz, & Kinzel, 2000; Heinz, Kinzel, Simon, & Tzur, 2000; Tzur, Simon, Heinz, & Kinzel, 2001). Jin and Tzur (2011), in their work with a group of mathematics teachers in China, have placed an intermediate category in this continuum between the perception-based perspective and the conception-based perspective: the Progressive Incorporation Perspective (PIP) (see Table 1).

Perspectives	View of knowing	View of learning	View of teaching
<b>Traditional Perspective (TP)</b>	Independent of the knower, out there	Learning is passive reception	Transmission, lecturing instructor
<b>Perception-Based Perspective (PB)</b>	Independent of the knower, out there	Learning is discovery via active perception	Teachers as explainer (points out)
<b>PIP (PIP)</b>	Dialectically independent and dependent on the knower	Learning is active (mentally); focus on the known required as start, new is incorporated in to known	Teacher as guide and engineer of learning conducive conditions
<b>Conception-based Perspective (CBP)</b>	Dynamic; depends on the knower's assimilatory schemes	Active construction of the new as transformation in the known (via reflection)	Engaging students in problem solving; Orienting reflection; facilitator

**Table 1: Placing PIP within teacher perspectives (Jin & Tzur, 2011, p. 20)**

They used the term “perspectives” to refer to both the knowledge and beliefs teachers might hold regarding the nature of mathematics, mathematics learning and mathematics teaching and also the practices they might engage in based on such acknowledgment. Tzur and his colleagues proposed that teachers holding CBP would act accordingly with the views of radical constructivist epistemology. They proposed that PIP would be a more realistic target for the teacher education since “a PIP-rooted teacher’s practice can engender students’ learning processes envisioned by CBP without requiring the teacher’s explicit awareness of such view...”. They argued that providing ways for prospective teachers to develop a PIP during methods and practice teaching courses will contribute greatly to the field of mathematics education. In this respect, in the larger study, during the methods and the practice-teaching courses, our purpose was to examine prospective secondary mathematics teachers’ development of PIP to teach mathematics effectively. In this paper, we report on the “mathematical knowledge for teaching (MKT)” of a prospective mathematics teacher who has been educated through these courses and has a PIP. Therefore, for this part of the study, investigating prospective teachers’ MKT once they have a PIP, we prepared a chart showing the list of characteristics a teacher would show in practice before, during and after the teaching. Also, when investigating MKT, we used the Knowledge Quartet (KQ) framework (see Table 2) (Rowland, Huckstep, & Thwaites, 2005).

Dimension	Contributory Codes
<b>Foundation</b>	(a) theoretical underpinning of pedagogy, (b) awareness of purpose, (c) identifying pupil errors, (d) overt display of subject knowledge, (e) use of mathematical terminology, (f) adherence to textbook, (g) concentration on procedures
<b>Transformation</b>	(a) teacher demonstration, (b) use of instructional materials (c) choice of representations, (d) choice of examples
<b>Connection</b>	(a) making connections between procedures, (b) making connections between concepts, (c) anticipation of complexity, (d) decisions about sequencing, (e) recognition of conceptual appropriateness
<b>Contingency</b>	(a) responding to students' ideas, (b) deviation from lesson agenda, (c) teacher insight, (d) responding to the (un)availability of tools and resources

**Table 2: The Knowledge Quartet: dimensions and contributory codes (Thwaites, Jared & Rowland, 2010, p. 86)**

The reasons we chose to use KQ in juxtaposition with the teacher perspectives framework was the following: First, we hypothesized that the framework corresponds to the three dimensions, nature of mathematics, mathematics learning and mathematics teaching, expressed in the perspectives. This is because as well the theoretical knowledge and beliefs related to mathematics and mathematics

education are handled in KQ, the theoretical knowledge possessed by teachers is transformed into teaching through connections and the existence of contingency moments revealing students' thoughts, mistakes and difficulties. Thus, student knowledge is also an important component of MKT. Secondly, we hypothesized that prospective teachers holding different perspectives regarding the nature of mathematics, mathematics learning and mathematics teaching might depict different MKT (Karagoz Akar, 2016). By the same token, even if prospective teachers depict the same MKT they might do so with having different reasons. For instance, prospective teachers with a PBP might not be able to anticipate students' difficulties and respond to their ideas in spite of the fact that they might specifically know the 'why' behind the concepts since they are not able to think from their students' point of view (e.g., Tzur et al., 2001). On the other hand, prospective teachers with a PIP might anticipate students' difficulty and deviate from the agenda because they purposefully take every opportunity to expose and discuss students' mistakes (Jin & Tzur, 2011). In this regard, scrutinizing the coherency between teacher perspectives and the domains in the Knowledge Quartet might help to uncover the reasoning behind (prospective) teachers' MKT. In other words, we conjectured that once prospective teachers had the PIP perspective, their MKT would reveal itself during their teaching. We chose the Knowledge Quartet framework for evaluating MKT of prospective teachers since it allows to depict the MKT of teachers' during their teaching qualitatively. Therefore with this study, we planned to make three main contributions to the field. First, how the practices of a prospective mathematics teacher with PIP before, during, and after teaching will be examined. Secondly, how such practices comprehensively revealing the relation between the characteristics of the PIP and the codes of KQ through empirical data, including before-during-after teachings and interviews, will be depicted. Third, and most importantly, how this correspondence presents evidences that a prospective teacher with a PIP is able to perform effective mathematics teaching will be explored. Diagnosing the reasons might provide teacher educators with particular steps to follow towards establishing more sophisticated perspectives and a full grasp of mathematical knowledge for teaching on part of prospective teachers. It is in this respect that the purpose of this study was to examine the MKT of a prospective mathematics teacher (Alin) who has a PIP and to reveal the relation between PIP and MKT. In light of our goal, the research questions were: "What are the indicators that Alin has the PIP?"; "How is Alin's MKT while examining the codes of KQ?"; "How is Alin's perspective reflected in MKT?"

## **Methodology**

### **Participants**

In the larger study, the participants were seven prospective secondary mathematics teachers who were in their fifth year of study at one of the universities, in which the medium of language is English, in Turkey. For the report in this paper, we chose one prospective teacher, Alin, having the highest GPA (Grand Point Average) (3,44). Based on the first week of the classes during the methods course, we observed her as a verbal individual. Also, she volunteered to participate in the continuing set of interviews and the teaching sessions till the end of the study. We used the data from her because the data were representative providing context that allowed us to examine the relationship between PIP and MKT.

## Data Collection

For this study, Alin's practice teachings were videotaped and transcribed. Also, we conducted interviews with Alin to talk about her lesson plans prior to the teachings, observed her teachings and conducted interviews upon completion of the teachings within the same week. In this regard, we used a modification of account of practice methodology (Simon & Tzur, 1999). Therefore, we conducted an interview prior to and after the practice teachings and we also observed the lessons. In addition, Alin wrote self-reflection papers after watching her videotaped lessons based on reflection tasks (Öner & Adadan, 2011). For instance, in the interviews, we asked the rationale behind Alin's choice of the learning goal(s), the tasks and how she thought that the tasks she has chosen would allow students to learn meaningfully. We also asked what evidences of learning and difficulties of students she observed during teaching. In this paper, we report on one of Alin's practice teaching. She taught an 80 minute lesson to the 10<sup>th</sup> grade students in a private high school.

## Data Analysis

First, each researcher analyzed Alin's perspective on mathematics, mathematics learning, and mathematics teaching and then analyzed her MKT through the Knowledge Quartet framework. We used coded analysis (Clement, 2000) for both frameworks. We analyzed the data to support theoretical hypotheses generated by the two frameworks and provided empirical data to show the coherence between these two frameworks that might yield to hypothesis generation, in the following way: First, each researcher read the lesson plans and transcripts from the practice teachings line by line, looking for Alin's explanations regarding her perspective. Using the characteristics of teacher perspectives taking into consideration of previous research, we looked for her existing meanings. Once we spotted a line of explanation regarding her meanings in any of the data sources, we also checked her reflection papers that could possibly provide further evidence of such meaning. Based on the conjectures, we continued to examine the rest of the data. Then, we came together to have a consensus on the data set and our analyses and went back to the whole data set to challenge our conjectures. After determining Alin's teaching perspective on mathematics, mathematics learning and mathematics teaching, secondly, using the codes from the Knowledge Quartet (see Table 2), we examined both this same data set and read further each of the data sources line by line to determine Alin's MKT. Then we came together to have a consensus on the whole data set to challenge our conjectures. Finally, we wrote the narrative regarding the relationship between Alin's perspective and her MKT.

## Results

In this section, we share data showing Alin's perspective on mathematics, mathematics learning, and mathematics teaching and her MKT in relation to her perspective. Alin modified a task for her students to make sense of the function  $f(x) = ax^2 + bx + c$  and the meaning of the coefficients  $a$ ,  $b$ , and  $c$  on the graph of the function. During the pre-teaching interview, Alin stated that students could construct mathematical meanings by performing the mental operations required for the concept. Moreover, she said that her lesson plan would promote such learning.

Researcher: What do you want the students to learn as a concept?

- Alin: ... we need to observe the change of “ $a$ ” one by one, and keep “ $b$ ” and “ $c$ ” constant so that we can only be aware of the change in “ $a$ ” ... Let me say the amount of change in  $y$  in terms of  $x$ , rather than amount of increase, because “ $a$ ” can be negative too. It is necessary for students to observe how the amount of change in  $y$  is changing. When “ $a$ ” changed and  $x$  changed as one unit, they can compare the amount of change corresponding to  $y$ , so that they can have an idea about the shape of the graph, I mean the arms (referring to the parts of the parabola)... Actually, what I am learning is to compare the amount of change in  $y$  with respect to change in  $x$  as one unit for different “ $a$ ” values.
- Researcher: Why do you think this [lesson] plan will promote your students’ learning?
- Alin: ...I’m starting with the amount of change in  $y = x^2$ ; therefore, students need to recognize the arms of the graph gets open and there is a decrease, I mean, there is a change in slope... Starting always with  $y = x^2$ , how this change is formed and how this change affects the graph, so thinking this point... I mean, my activity provides quantitative operations by playing with something existing in their mind that they know.
- Researcher: You said playing with something they know, what do they know? Like could you explain one more time what is quantitative operations?
- Alin: They know what  $y = x^2$  is, what its roots are, how the change occurs in  $y = x^2$ , I mean, how the slope is changing and how it looks in the graph. However, they don’t have any idea about what happens to the graph when “ $a$ ” changes, because they don’t observe  $ax^2 + bx + c$  for changing “ $a$ ” values. Therefore, the quantitative operations formed in their mind when they changed “ $a$ ”, I mean the thing they know in their mind, is like how the slope in  $y = x^2$  is, how the amount of increase is, and drawing the graph.

Alin expressed that students need to compare the amount of change and examine how the change in the dependent variable occurs when the independent variable changes one unit, in order to construct the meaning of the coefficient “ $a$ ” for a quadratic function. For Alin, students might create an idea about the graph and its structure by only performing these mental operations—comparing the amount of change. This suggests that for Alin mathematics is constructed depending on the learner’s mind. Also, Alin planned her lesson hypothetically depending on her students’ mental operations and actions. We propose that this could be considered as an additional characteristic for the PIP. When we consider the MKT, data showed that Alin had awareness of the purpose for her teaching, and concentrated on the ways to reach that purpose. She effectively analyzed which mental operations students need to perform to make sense of the meaning of “ $a$ ”. Her analyses revealed that she has a strong subject knowledge and theoretical background about coefficient “ $a$ ” for quadratic functions. Moreover, her expressions about mathematical structure of the concept and her use of mathematical terminology supported that she has a strong subject knowledge. Also, she anticipated the complexity of the concept: She planned her lesson in such a way that by keeping “ $b$ ” and “ $c$ ” constant, students’ examining the change of “ $a$ ” would be more efficient. Moreover, she gave priority to students’ mental processes and planned her lesson depending on students’ ideas rather than adhering the textbook or planning randomly. Her consideration of graphical demonstrations while students were examining the coefficient “ $a$ ” showed that Alin has knowledge about different representations and she could integrate these representations into her lesson with relations to each other, too. Alin also stated that she planned to focus on students’ mental processes throughout the teaching so that students could

create concepts and structures of quadratic functions relating with their prior knowledge. She leaned on her choice of examples to this.

Researcher: You said you are starting with  $y = x^2$ . Why do you start with this?

Alin: Because  $y = x^2$  is easy for students to understand and play on it, I mean they can use it to examine others... They know it very well, also they won't work away to find roots, but they will examine the change in " $a$ " directly.

Data indicated that Alin chose  $y = x^2$  as an example because students already knew this function. This suggested that she wanted to re-activated their prior knowledge: Alin believed that students learn new mathematical concepts by forming relationships between the new and old knowledge in the process. While planning her lesson, Alin's consideration of possible students thoughts' on examining the amount of change in the  $y = x^2$  revealed that Alin took teaching process into consideration before she executed teaching. All these approaches Alin has taken in the process of before teaching displayed the first three dimensions of the knowledge quartet. In addition, data showed that Alin is aware that there might be unexpected events in the class:

Researcher: ... What is the purpose of your questions? I mean why did you plan to ask these questions?

Alin: I will ask (questions) so that they can make relations. Some students could go faster but some could not. I can change my questions in a way to make them more understandable by the students. I can ask questions to fix their misunderstandings. I mean I will react regarding to students' thinking.

She explained that she prepared questions in her lesson plan to enable students to form connections and she is willing to make differences in classroom context depending on students' approaches because students could make connections in different ways. She also thinks that her plan could undergo some changes depending on the teaching process. Therefore, it can be interpreted that the contingency dimension is present in Alin's actions even prior to teaching.

This was also evident in her teaching: During teaching, she realized that students faced some difficulties. So, she deviated from her plan by presenting an example that was not in her lesson plan.

Alin: ...how does y values change when  $y = x^2$  as x increases one by one, so when you consider the change of  $x$ ... When you consider the change of it from 0 to 1, how does my y values change? From 1 to 2, how does y values change? (Waiting for several seconds)...

Okay, let's consider linear functions; like  $y = 2x$ . (Drawing on the board) In the linear function like this, when x goes through 1 to 2. When x is 1; y is 2. and x is 2 which value of y do you get?

When the students faced some difficulties to make sense of the change in y corresponding the one unit change in x, Alin tried to overcome such difficulty by providing an example not given in her lesson plan. She gave a linear function example of  $y = 2x$  and wanted students to examine the amount of change in y given x. This approach revealed the codes of responding to students' ideas, deviation from agenda, and teacher insight during instruction presented in the contingency unit of the Knowledge Quartet. With this example and her questioning, Alin further allowed the students to overcome the difficulty and examine the amounts of change in the quadratic function. This showed that Alin provided opportunities for her students to reflect on their prior knowledge and connect it to

the new knowledge. Alin's approach also showed that she possessed the PIP's characteristic features: mathematics is both independent and dependent of the learner. That is, for her both linear and quadratic functions had qualities –the amount of change in the dependent variable given the change in the independent variable—out of the learner. Yet, the learners needed to make sense of such relationship on their own. She further explained her reasons about her choice of this example during the interview after teaching:

Alin: ....I did not give  $y = x$  as an example because it goes as one to one, so I gave  $2x$  as an example.... We talked on the board to look at  $x^2$ . When we look at it, after the things between  $x$  values, when we draw the  $y$  values with arrows, students said that  $y$  values are increasing... In terms of their answers; whether they learned by heart or understood the rate of change. (I asked) Are you sure? Why? Re-express what your friend said... I was like pushing them like that...

Alin explained that she chose the example,  $y = 2x$  rather than  $y = x$  since the function  $y = 2x$  could have triggered them to focus on the amount of change. Her insight during her instruction was strong enough that she realized her students' difficulties. She aimed at triggering their mental processes to form the concept by using the common features of linear and quadratic functions.

## Discussion and Implementation

This study investigated mathematical knowledge for teaching of a prospective teacher having a PIP and revealed the relationship between PIP and mathematical knowledge for teaching. Results showed that the teaching of a prospective teacher having a PIP was effective because she planned her lesson with a view on mathematics as depending on learners' minds and revised her hypothetical plan for her teaching by considering both the learners' actions and reasoning. We might link the revisions of a hypothetical plan with contingency situations presented in the KQ, too. For instance, Alin considered her students' thoughts and deviated from her plan when she determined that her students had some difficulties during teaching. This is important because hypothetically determining the teaching process envisioning students' reasoning prior to the teaching is suggested to be an important part of MKT (Silverman & Thompson, 2008). This is also important in terms of noticing skills prospective teachers need to acquire (Jacobs, Lamb, & Philipp, 2010). Results of the study also suggest that if prospective teachers are trained to have a PIP, the strong MKT arises by itself. Particularly, the effects of Alin's perspective are seen precisely in the deep examination of data done with respect to the KQ framework before, during and after teaching. For example, Alin was aware of her students' having a different mathematics than hers. That is, she did not adhere to the textbooks, rather she focused on her students' mental actions and prior knowledge while she was deciding and arranging the lesson activities. Also, she always took into consideration her students' prior knowledge, even during teaching, and reactivated their prior knowledge to connect it to the newly established knowledge. So these were related with the connection, transformation and foundation dimensions in the KQ as well as her perspective on teaching. Based on these results, we suggest examining which codes of the KQ are activated before, during and after teaching and examining MKT of prospective teachers having different perspectives. Finally, we suggest to promote the development of a PIP on the part of prospective teachers during methods courses.

*We aim to understand how primary teachers who participated in a lesson study developed their collaboration relationships. The research is qualitative and interpretive with a case study design. The results show that the involvement in moments of planning and analysis of the students' work, where teachers reflected on practice and for practice helped them to develop collaborative relationships, moving from storytelling and scanning to joint work. The teachers were encouraged to express their voices regarding their participation in the lesson study and this led to an increasing involvement in the group, favoring the development of their reflection and knowledge of mathematics teaching.*

## Introduction

Lesson study is a professional development process widely practiced in many countries around the world. Teachers work in a collaborative way on a curriculum topic or issue related to students' learning, study curriculum documents and teaching materials, and plan and teach a research lesson which is then object of reflection (Fujii, 2016; Lewis, 2016; Takahashi & McDougal, 2018). During the lesson, taught by one of the teachers, the participants observe the events and afterwards analyze students' learning, emerging difficulties, and possible alternatives to consider. In lesson study, the discussions held by the group elicit, challenge and question the conceptions and practices of teachers (Cajkler, Wood, Norton, Pedder & Xu, 2014; Fujii, 2016). This collaboration provides teachers opportunities to run risks in their practice and to try new ideas in a structured and supported way, with focus on students' learning (Fujii, 2016).

Collaboration is central in discussions about teachers' professional development. According to Fullan and Hargreaves (1992), for change to occur in the classroom, teachers must be encouraged to collaborate with their colleagues in a learning community. Ponte (2012) suggests that teachers learn through their activity and the reflection that they make on that activity and such learning depends both on their personal commitment and collective support. However, a recent survey on collaboration made for ICME 13 (Robutti et al., 2016), showed that very little is known about the dynamics that take place in collaborative processes. Therefore, the aim of this paper is to understand how collaborative relationships among teachers may develop in a lesson study.

## Collaboration

In collaboration, teachers work together aiming to achieve a common goal, negotiating working processes and making decisions together (Boavida & Ponte, 2002; Menezes & Ponte, 2009; Robutti et al., 2016). Research on teachers' professional development has pointed out the benefits of joining teachers and researchers in collaborative processes (Boavida & Ponte, 2002; Hollingsworth &

Clarke, 2017). The role of participants may be distinct, as the important point is that they work in horizontal relationships so that there is mutual support to achieve the common goals of the group (Boavida & Ponte, 2002). When involved in collaborative processes focused on their own practices, teachers work with more experienced colleagues and with researchers, they may develop new knowledge, which is in their zone of proximal development (Blanton, Westbrook & Carter, 2005).

Little (1990) distinguishes four kind of professional relationships among teachers, with different nature and potential: (i) storytelling and scanning for ideas; (ii) aid and assistance; (iii) sharing; and (iv) joint work. Storytelling and scanning for ideas corresponds to interactions among teachers that are occasional and stand on opportunity, where teachers seek to obtain specific ideas, solutions, or confirmations in brief exchanges of experiences in informal settings. In aid and assistance, teachers expect to get support from their colleagues in solving problematic situations. This relation is unidirectional and unequal and keeps the individual teacher as the sole decision maker. Sharing takes place by the exchange of resources, methods, ideas and opinions, and necessarily involves some level of exposition of the teacher regarding his/her colleagues. Finally, joint work occurs “among teachers that rest on shared responsibility for the work of teaching (interdependence), collective conceptions of autonomy, support for teachers’ initiatives and leadership with regard to professional practice, and group affiliation grounded in professional work” (Little, 1990, p. 519). This form of collaboration requires much responsibility, commitment, and time from the participants but has stronger potential for solving problems and developing knowledge in a group that seeks to improve teaching practice. The work developed in the lesson study is intended to be collaborative and, in this way, in this research we analyze the interaction of the group according to the four kinds of relationships stated by Little (1990).

## Methodology

This research is qualitative and interpretative (Erickson, 1986), based on a group of teachers who participated in a lesson study in 2013-14, in a school in Lisbon. This lesson study originated in a request from the school principal to support a project to improve students’ results in mathematics. Seven teachers were appointed by the principal but, after five sessions, only three (Irina, Manuela, Antónia, fictitious names) remained in the group. Several teachers gave up indicating little interest in the activity or other personal reasons. The three participating teachers had between 10 and 15 years of experience and all had initial teacher education as primary teachers. However, Irina had a specialization in teaching Mathematics and Science and Manuela in teaching Portuguese and French. Our team included the two authors, another researcher and an assistant for data collection. We directed all sessions, leading the planing and assuming the role of experts in the post-lesson reflection. We sought, essentially, to center the work of the group in the exploratory approach (Ponte & Quaresma, 2016), with special attention to the tasks to propose to students, students’ reasoning, and classroom communication processes.

The lesson study had twelve sessions. Session 1 included the introduction of participants, the establishment of the general work program and the definition of the topic to address. Sessions 2 to 4 were dedicated to study the topic and the exploratory approach and sessions 5 and 6 to the planning of the research lesson. Session 8 was the research lesson and session 9 the post-lesson reflection. In sessions 10, 11 and 12, which we called “follow-up”, the teachers planned, carried out and reflected on

two lessons that they made, as a way to deepen the work undertaken before. After the post-lesson reflection, we made an individual semi-structured interview to each teacher and in the last session we made a focus group interview, asking the teachers to reflect on the lesson study and the work developed, on the various aspects of the exploratory approach and on the work of students. Two main adaptations from the usual Japanese model were made in this process: (i) setting up a collaborative environment, including teachers and researchers, from the beginning to the end of the lesson study; and (ii) follow-up sessions, that allowed teachers plan new lessons together, addressing new topics, putting into practice what they learnt in previous sessions, and reflecting on the results. Data were gathered by participant observation through the undertaking of a research journal (elaborated by a researcher and completed by the others), audio recording of working sessions (designated as  $Sx$ ), with transcriptions, and video recording of the research lesson, and individual interviews to participant teachers (E). Data were analyzed in an inductive way, taking into account the four teachers' forms of interaction indicated by Little (1990): (i) storytelling and scanning for ideas; (ii) aid and assistance; (iii) sharing; and (iv) joint work.

## **First part of the lesson study**

### **Study of the topic and of the exploratory approach**

In session 1, taking into account students' difficulties, it was decided that the topic to study would be addition and subtraction of fractions by juxtaposing of line segments. Sessions 2 to 5 addressed mathematical and didactical issues relevant to teaching and learning this topic. Therefore, in session 2, the group solved tasks and identified students' difficulties. In session 3, there was a discussion about students' current knowledge and a diagnostic worksheet for the teachers to carry out in their classes was elaborated. In session 4, the responses of the students were analyzed, taking into account the nature of tasks, seeking to identify generalizations and justifications and surprising features in students' responses. In session 5, possible generalizations in addition and subtraction of rational numbers were identified. The main ideas related to the exploratory approach were discussed in depth: using challenging tasks, supporting students' reasoning, figuring out strategies to solve problems and making generalization and justifications, and promoting students' communication of their ideas with particular attention to whole class discussions. During these sessions, Irina had a very active participation working jointly with the researchers but Manuela and Antónia participated very little, interacting in aid and assistance way with the group. One perturbing factor of the group dynamic in this phase of the work was the reluctance of all teachers to assume the role of teaching the research lesson. This situation was finally overcome in session 5, when it was decided that Irina would take that role. She made the initial draft of the lesson plan that was discussed in session 6.

### **Post-lesson reflection and interviews**

The post lesson reflection was carried out in session 9 as a reflection on practice. The group agreed that Irina prepared well the research lesson and its enactment corresponded very well to the planning. Some video excerpts from the lesson, representing students' strategies and difficulties, were analyzed. We made several challenges to the teachers, but only Irina sought to respond to them. When questioned, Antónia and Manuela, only described the events to support the judgments made by other participants. In a quite reserved stance, they narrated observations that they made during the lesson and supported the group in forming a general idea about the lesson participating in

an aid and assistance way and storytelling and scanning for ideas. In contrast, Irina shared with the group her ideas and opinions (joint work). However, during this analysis of students' difficulties, she seemed to feel unease, assuming that her work was being criticized.

After this post-lesson reflection we made individual interviews to the teachers. Surprisingly, these interviews turned out to be quite deep reflections about the work previously carried out in the lesson study. Irina made a deep reflection of the activity carried out in the former sessions, including the research lesson. Manuela and Antónia, indicated the reasons why they were not much involved in the sessions: Manuela felt difficulty in understanding much of the mathematical discussions that went on and felt insecure in participating and Antónia found the analysis of students' strategies and difficulties too detailed. The expression of feelings and difficulties by the teachers, in a relationship of great confidence with the researchers, created a completely new working environment.

## Follow up

### Planning

In session 10, we asked teachers to plan a lesson that they would be teaching, taking into account the work carried out before. Manuela suggested that they could plan a lesson together and that she and Antónia could teach it, instead of Irina that had made much work previously.

And why we do not the following: we give Irina a break, we plan [together with Marisa], I and Antónia [make the tasks in our classes] and present them [in the next session]? And you [Irina] may use them later in your class. (S10).

In this way, Manuela recognized that she and Antónia were not much active in their participation in the previous phase of the lesson study. Now, she was willing to assume an active role. This shows that she felt more confident with what she learnt in the previous sessions. It was then decided that both teachers would use the tasks in their classes and Irina would support them in reflecting about the results to present and discuss in the next session. In this way, the three teachers prepared a lesson about the relationship between fractions and decimals in a setting of shared responsibility of planning a lesson in joint work.

However, Antónia and Manuela begun their planning quite insecure. They opened the textbook and began to scan different pages. It was noticeable that they were uncomfortable with the perspective of picking tasks from the textbook, perhaps as they thought that we would not find that much appropriate. Taking into account the struggle of the teachers, Marisa suggested that, instead of selecting a task, they could adapt it. Manuela agreed: "I think so, increasing the difficulty, isn't it? Because that one is very basic. But I think yes, mixing up tenths, hundredths and thousandths, with different denominators" (S10). At that point, Antónia and Irina also began giving suggestions and registering more ideas to elaborate the task:

Antónia: Or A, B and C, in order to have two equivalent and one different.

Irina: Ah, yes.

Antónia: For example, to have two equivalent fractions. They understand that . . . Are equivalent fractions, albeit having different denominators.

- Manuela: Why we do not give a hypothesis here... That is, why do not give equivalent fractions?
- Marisa: Ah, one of these being as a fraction. Yes, instead of all being as decimals . . .
- Manuela: For example, here are four as decimals, isn't? And one in words. Why we do not take out that is in decimal and put it in fraction?
- Irina: Exact.
- Marisa: May be.
- Irina: And then, during the discussion, we can ask them to write this also as a fraction. (S10)

So, in joint work, the teachers constructed the first question of the task (Figure 1):

---

1. In the squared paper, paint 0.4 in green;  $40/100$  in blue and “four hundredths” in yellow.

---

**Figure 1: Task elaborated by the teachers in session 10**

Irina went on providing suggestions, Manuela was much more participative and engaged than usual, and Antónia, albeit less participative than the colleagues, was also involved, contrarily to what happened in former sessions. This session witnessed two important aspects. The first is the change in attitude of Manuela and Antónia that began to assume strong participation in the common activity. This change seemed to result from the confidence that was established in the group after the interviews. The second aspect is the difficulty of the teachers in assuming an authorship role and a critical stance regarding tasks. This difficulty, however, was overcome with our suggestion of adapting tasks. It seems that the work carried out in the lesson study brought the teachers towards a point in which they were ready to assume this way of working, only with minimal support of a more experienced partner.

### Reflection

In session 11, the three teachers reflected on their classroom experience in carrying out the task prepared in session 10. Antónia reported that her students had many difficulties in solving the first question:

Mine, I only had one that was able to make everything right. A group. Then, I had three more that could make one part right and another wrong, they made well the four tenths, but then the forty hundredths, which corresponded to the same thing, they did not. And that is it. I think that they had here several squared that confused them. (S11)

Antónia tried to understand the difficulty of the students and suggested that they could get confused by having squared paper to represent the numbers indicated. She suggested that may have led the students to “not understand what the unit was” (S11). She showed surprise and frustration with the difficulties of her students: “they already know this well . . . They know how to transform decimals in fractions and fractions in decimals” (S11). The other teachers tried to find an explanation for the difficulty of her colleague: “I think that the fact that this looks visually different, it is only enough

that one is as a decimal and the other as a fraction, this is enough to prevent them of seeing something that is equivalent” (S11). Seeking to find reasons for the students’ difficulties, still in a superficial way, Antónia referred that they forgot what they knew, whereas Manuela focused in the differences between fraction and decimal representations.

In the sequence, Manuela also presented her analysis of the work of her class. All students had the question on the painting of 0.4 correct but failed the next questions. In response, Antónia pointed out some similarity in the results of the two classes: “Here, there is something more or less similar. My [students] that got some [questions] right, the green [0,4], which was first. After that...” (S11)

Irina also tried to find a reason for the difficulties of the students, referring that “from the moment in which we begun to work with decimals, fractions become in trouble” (S11). She considered that the work with decimals led the students to forget about fractions. Up to this point, the teachers were still scratching the superficial features of the issue.

Taking into account that most students failed in representing the hundredth part of the unit, Manuela suggested that this mistake was related to visualizing the hundredth part of the picture that they were shown, in contrast with the visualization of tenths: “Here they visualize very well the tenth parts” (S11). Irina agreed, saying: “the hundredth is not easy for them to see. It is not intuitive” (S11). That is, Manuela began to base her analysis of the strategies of the students noting an important constrain related to the material that they received, which is a quite interesting reflection.

As the difficulty of the students was identified, Irina reflected on her own practice, notably on the work that she usually does concerning the representation of decimals:

When we speak of the tenth, usually we use a bar divided in ten. Then, suddenly, we start speaking of the hundredth, and the unit instead of being the bar with ten, becomes a square with one hundredth. And, suddenly, we begin to speak of the thousandth, and we get this. Therefore, the unit that is always one, change its form. And that messes up the students in an extraordinary way. (S11)

Irina identified a problem of her practice as she considers that the way she presents the submultiples of the unit to the students does not facilitate their understanding of the unit and of that relationship with the submultiples. All participants agreed with Irina, that decided to take the discussion one step further, challenging the group to think in a solution for the problem: “But, and now? This is a reflection. What do we do?” (S11). She went on, pointing that the representation requires that students really understand the decimal number system and what the unit is.

In the sequence of the discussion, Antónia suggested to her colleagues that they could do the same way she did in the discussion of the task, cutting the rectangle in 10, 100, and 1000 parts and Irina agreed. In addition, Manuela referred the need of the students to have flexibility to interpret other representations. Irina concurred but underlined the importance of changing their practice making an initial work consistent with the rectangle representation, as a basis to later understand more simplified representations of the unit. This discussion was mediated by Marisa, who raised questions. But the teachers themselves developed a deep reflection about her own teaching practice, questioned the solutions and difficulties of the students and tried to find explanations for what happened, analyzing with much detail the origin of the difficulties. The teachers did not limit themselves to trying to

understand the problem, they sought to overcome it in a reflection for practice. Irina continued to show a strong inclination to carry out the reflection further, proposing well-grounded solutions, and Manuela and Antónia had a strong participation, with a great engagement in analyzing students' learning in relation to their practice. The change in attitude of Antónia and Manuela led the group to a joint work mode, in which all participants were involved in a common activity.

## Discussion

During the lesson study, we challenged the teachers in different ways. Irina, who taught the research lesson and was very confident in mathematics teaching, was always much involved in all activities. From very early, she worked jointly with us in constructing an exploratory task for the research lesson, in order to favor students' learning and understanding. The post-lesson reflection was carried out in a frame of joint work between Irina and the researchers. However, Manuela and Antónia were little involved in the activities remaining in the mode of storytelling and scanning for ideas.

In the follow-up sessions, all teachers were called to plan, teach and reflect about two lessons. Manuela and Antónia become very active and participating. They were going now to teach their classes with their own students and no observers. However, the main reason for this active participation was the reflection that they made in the interviews, in which they assumed a very personal voice regarding their development trajectories. This key importance of teachers' voice in collaborative processes is also underlined in Robutti et al. (2016). With the support from Irina, they felt confident to adapt tasks from the textbook and make them more challenging for their students. In the lesson study, they appeared to have developed new knowledge, which was in their zone of proximal development (Blanton, Westbrook & Carter, 2005). Therefore, from this point on, all group (teachers and researchers) begun to work jointly, sharing a common responsibility for the work.

## Conclusion

This lesson study, favored the development of joint work among the participants and that led them to get involved in reflecting about their own practice and the way students learn. Such reflections are important levers for professional development. During the follow-up, the work carried out favored the creation of an environment of integration of knowledge (Lewis, 2016), in which teachers constructed actively their knowledge by designing tasks and collecting data from their students, establishing connections among different data sources. This has largely resulted from the possibility that the teachers had to express their voice and individuality and the challenges and responsibilities that they progressively assumed, namely the responsibility for the decisions of the group, for the materials produced, in particular for the selection and elaboration of challenging tasks and the preparation of the lesson plans that all teach. With this, they identified problems in their practice and created solutions with strong rationales. This evolution only occurred when the teachers felt confident to question their conceptions and practices and to try out new ideas (Cajkler et al., 2016; Fujii, 2016; Ponte, 2012). The follow-up sessions were much important to bring together the members of the group. The fact that all teachers taught and reflected on two lessons at this phase led them to get more involved and with more responsibility in the development of the work, suggesting the value of all participants teach a lesson and share that experience with the group. Other modifications in the format of a lesson study, such as teaching and reflecting on a pilot lesson during the planning, may contribute to similar results.

This and other adaptations are to be experimented in order to take the most out of this professional development process, taking into account the local culture of the participating teachers.

# How to visualize classroom norms through social interaction

## A pilot study of two frameworks

Jonas Dahl<sup>1</sup>, Christina Svensson<sup>2</sup> and Richard Wester<sup>3</sup>

<sup>1</sup>Malmö University, Sweden; [jonas.dahl@mau.se](mailto:jonas.dahl@mau.se)

<sup>2</sup>Malmö University, Sweden; [christina.svensson@malmo.se](mailto:christina.svensson@malmo.se)

<sup>3</sup>Lunds kommun, Sweden; [rickard.wester@lund.se](mailto:rickard.wester@lund.se)

*Keywords: Classroom norms, interaction, mathematics education, professional development.*

In this pilot study we investigate if and how two different frameworks can be used to visualize classroom norms through classroom social interaction.

### Background

Between 2013-2016 the Swedish National Agency for Education launched a curriculum-based professional development project, the so-called Mathematics Boost (Swedish: Matematiklyftet) (Skolverket, 2016). The aim was to develop and improve mathematical classroom teaching with a focus on four different didactical dimensions: formative assessment, teachers' knowledge about competencies, social interaction and socio-mathematical norms (Skolverket, 2016).

Parts of the Mathematics Boost and the national evaluation afterwards is based on Cobb and Yackel's framework of classroom norms (Skolverket, 2016). Cobb and Yackel divide classroom norms into social norms (SN), socio-mathematical norms (SMN) and mathematical praxis (MP). According to Cobb and Yackel (1996), these classroom norms are reflexively connected. Our approach in this project is that for classroom norms to change or develop all three aspects above needs to be challenged, in this case, through the Mathematics Boost.

The national evaluation of the Mathematics Boost (Skolverket, 2016) showed development in some aspects of social interaction. A reasonable interpretation, based both on the national evaluation and on the writings of Cobb and Yackel, is that the SN hence is challenged and developed. According to the evaluation, it is impossible to state anything about SMN in regard to change or development but it is also stated the SMN will probably change over time (Skolverket, 2016).

Following the idea that classroom norms are reflexive and needs to be challenged simultaneously as mentioned above, another explanation for the lack of development could be that the SMN has not been challenged enough through the Mathematics Boost. As a complement to the national evaluation in 2016 we therefore pose the question for a coming study: Which classroom norms were challenged through the Mathematics Boost? But first we need to investigate how to visualize classroom norms through classroom social interaction.

### Pilot study

In order to do this, we put two different frameworks into a test, one developed by Kilhamn and Skodras (2018) and one suggested by the Swedish Institute for Educational Research (Fredriksson, Envall, Bergman, Fundell, Norén & Samuelsson 2017), originally a framework by Hufferd-Ackles,

Fuson and Sherin (2004). Both frameworks are hence in a Swedish context and they both focus on social interaction but in different ways. The former framework is created in order to analyze the analyze level of teacher questions with a focus on responses from students (Kilhamn & Skodras, 2018). The latter is focused on how discourse is moved from a teacher centered to a student centered discourse when it comes to who poses questions, the type of questions/answers, sources of mathematical ideas and responsibility for learning (Hufferd-Ackles, Fuson & Sherin, 2004). Neither of the frameworks are created for the purpose that we have in our project but we have connected different parts of the frameworks to SN and SMN respectively. Hence, in this poster presentation, we put these frameworks into a test in order to investigate if and how these connections is possible to make in order to help us visualize classroom norms through classroom social interaction.

## Method and initial results

Out of a total of 60 video-recorded classroom situations during the Mathematics Boost we have, in this pilot study, analyzed six classroom situations via transcriptions of what the teacher and students express. Our initial results using the two different frameworks show that they can help us visualize the level of social interaction. Our initial results also indicate that we can connect these different levels to SN and SMN. The first framework shows the potential for if and when SMN are challenged through social interaction. The second framework show if and when teachers and students are on the same level of social interaction, that is, if and when they agree on SN.

## The poster

On the poster we present the frameworks and how we connect SN and SMN to these. We also present our initial results that indicate that despite the potential relatively high level of social interaction, that is SN, the social learning stays on a low level. That is we show that the SMN are not challenged enough. In the long run this means, due to the reflexivity in the model, that there are limited chances for MP to develop.

# Understanding student teachers' professional development by looking beyond mathematics teacher education

Andreas Ebbelind

Linnaeus University, Department of Mathematics, Sweden; [andreas.ebbelind@lnu.se](mailto:andreas.ebbelind@lnu.se)

*The empirical material in this paper is from a multiple case study exploring the role, if any, that social practices related to teacher education and beyond teacher education play in primary student teachers' tales of themselves as teachers-to-be. The case of Lisa is used as an example to illustrate how different past and present social practices influence how she talks about competitive teaching during different phases of her teacher education. Of particular influence is her past school-related experiences as they in turn influence how she interprets other social practices. Thus, the case of Lisa illustrates the importance of widening our research interest beyond teacher education if we want to understand the process of becoming mathematics teachers.*

*Keywords: Professional development, teacher education, social practices.*

## Introduction

Student teachers' professional development is by many researchers considered as a rather complex process (Skott, Mosvold & Sakonidis, 2018). One concern is how student teachers' school-related experiences influence how they perceive teacher education and how they view their future profession. According to Forgasz and Leder (2008) prior experience impact student teachers becoming as teachers more than undergoing teacher education. To this, Scott (2005) concludes that student teachers are less sceptical to advice from others, "outside" teacher education, than from teacher educators in mathematics. Student teachers use educated teachers at the internship or from other settings or family and friends instead of teacher educators to conclude their vision of future teaching. For example, internship, which is often part of teacher education, is said to frame how student teachers perceive the content in mathematics education courses. Thus, the teaching of the internship supervisor during internship becomes important in student teachers' professional development (Mosvold & Bjuland, 2016).

To widen the perspective of the "outside" this paper reports parts of a multiple case study with the aim of contributing with insights about how experience from teacher education and other past and present social practices play for generalist student teachers' tales of themselves as primary mathematics teachers-to-be. This is in line with Morgan (2012) and Skott (2018) that mentions that we need to look outside the immediate social practice [teacher education in this case] if we want to view what the [student] teachers bring into the situation. To be interested in any data "that point to any practice [...] that appear to orient the [student] teachers' action or meaning making as they relate to the profession (Skott, 2018, p. 615)".

Thus, this paper aims to illustrate how different past and present social practices play for a primary generalist student teacher, tales as primary mathematics teacher-to-be. The empirical material used relate to how a student teacher, whom I will refer to as Lisa, talks about competitive teaching during different phases of her teacher education.

## **The process of becoming a mathematics teacher**

To enter teacher education and become a teacher is in this paper regarded as an emerging learning process. To follow the process of developing into a teacher is partly to follow how student teachers negotiate and re-negotiate their mathematical and pedagogical knowledge. In this process Hodges and Hodge (2017) recognise student teachers bringing together different perspectives on teaching and learning mathematics, often conflicting while creating their idea of teaching mathematics. While bringing different perspectives together student teachers can, for example, position themselves in relation to future pupils, relate their participation to different educational models, expand educational models through new experience and develop a critical positioning to either the teaching at internship or the pedagogy taught and used at teacher education (Bjuland, Cestari, & Borgersen, 2012).

Jong (2016), as an example, illustrate that teacher education in different ways impact student teachers' professional development. However, attention is on to the characteristics of their participation that draw on ideas from past teaching experience and their cultural, socioeconomically and linguistically background. Jong concludes that becoming a teacher starts the day when children enter school for the first time and meet different educational models. These models influence the idea of teaching that student teachers have. The main result in Jong's study is that any social practices related to teaching and learning mathematics might be critical in professional development, this because social practices, past and present, are used to negotiate and re-negotiate the meaning of teaching mathematics.

## **The conceptual framework Patterns of Participation**

The overall study and this paper start with an interest in professional development, a construct that elaborates within the conceptual framework of Patterns of Participation (PoP). Professional development can be viewed as "a process of flexibility, autonomy, and adaptation to the teaching context" (Hošpesová, Carrillo & Santos, 2018, p. 181). Learning and thus becoming a teacher is therefore considered from a situated perspective. Thus a perspective, that considers learning as participation in social practices take social, cultural and historical systems as well as prior experiences and present participation into consideration when studying professional development. A social practice as a collective way of being with a common endeavour where entities interact and reconcile/mould together.

PoP "seeks to understand how a [student] teacher's interpretations of and contributions to immediate social interaction relate dynamically to her prior engagement in a range of other social practices" (Skott, 2013, p. 549). Skott makes an important move, according to Lerman (2013), when focusing on the emergence of the situation, the process. "This dynamic process is studied through eliciting the teacher's interpretation of what she does in classrooms and how that relates to her prior engagement in other social practices (p. 625)". The intention with PoP is to disentangle shifts of participation in different social practices, and by doing so shed light on the role of the student teacher in the practices that emerge.

Through the conceptual framework Patterns of Participation, Skott tries to accomplish three things. First, he tries to reduce the emphasis on objectification in research about student teachers and teachers. Secondly, he tries to re-centre the student teacher and teacher in research. Finally, he tries to re-conceptualise what is known as beliefs, knowledge, and identity in participatory terms. In this

quest Skott (2018) point out that the conceptual framework PoP focuses on the pre-reified processes that precede, give rise to, what others term beliefs, knowledge, and identity.

Patterns of Participation draw on two main theoretical sources, symbolic interactionism and social practice theory. Symbolic interactionism views humans as actors and reactors in situations, and position meaning as something that one engages in when experiencing things in the situation, on the spot. Humans respond to the situation by interacting with others and with the self, and by taking [interpreting] the role of others (Skott, 2018). Social practice theory views social practices as ordered across time and space. They are linked historically to other social practices (Wenger, 1998). Social practices are stratified. Most important is that social practice theory stress that it is through the engagement with different or using different social practices within communication that individuals understand the world around them when they, for example, emerge into the teaching profession.

By considering that social practices are ordered, stratified, in time and space allow researching complex patterns in multiple social practices. To make visible and describe this plurality of relations lies in the core of PoP but also to make visible how these pluralities of relations change over time.

### **The overall study**

The overall study adopts a multi-sited ethnographic approach. Two primary student teachers were followed for two and a half years as cases during their teacher education with a focus on their education in mathematics. Often student teachers at primary school level are generalists with no specialisation or interest to the teaching of mathematics. However, that was not the case in this study. The student teachers in this study related strongly to the teaching of mathematics in the interview before entering teacher education and they were selected as critical cases (Flyvbjerg 2006) based on their commitment, their mathematical knowledge and interest. The choice of critical cases was based on the indicated research gap related to the lack of research related to primary student teachers that are interested in mathematics, mathematics teaching, mathematics learning and regard themselves as knowledgeable/proficient in mathematics.

In Sweden, the combined course in mathematics and mathematics education for primary school student teachers is a 30 ECTS point course in the four-year teacher education programme (240 ECTS). ECTS means European Credit Transfer System, where one year of studies is 60 ECTS (40 weeks). Student teachers have four internship periods, five weeks each, during their teacher education. Teacher education in Sweden does not have any pre-requisite of university studies before entering the education.

In this paper, only one of the student teachers is used as an example, Lisa. Lisa, who is in her early 20s, started teacher education directly after high school. Lisa's positive experiences of participating in a competitive mathematics classroom are expressed as her primary reason for entering teacher education. Lisa perceived herself as "good" at mathematics and had the highest possible grade in upper secondary school. It is also worth noticing and most important concerning this paper that Lisa described herself as extremely competitive both as a private person and as an athlete, playing soccer at a high national level.

## **The role of social practices in different phases**

The empirical material in this paper is interview transcripts, five in total, and field-notes from observations made during the internship and the mathematics education course. During the mathematics education course, I attended 31 lectures, seminars, examinations or study-group sessions. Based on the multi-sited ethnographic approach, considering social practices as ordered in time and space and considering the “outside”, persons related to Lisa were also interviewed, in this paper the internship supervisor whom I will refer to as Mr Higgins.

Lisa’s professional development is described, in this paper, in three different main phases related to how she re-negotiates the use of competitions in teaching mathematics. Each phase will start with excerpts in time spread over the actual phase. Then there will be a summary accentuating the role of social practices within the phase. This section set out to offer the reader a “virtual reality” to explore (Flyvbjerg, 2006), to provide the reader with situated aspects (Bjurland et al., 2012).

### **Phase one – The internship experience strengthens her experience of learning mathematics**

In phase one, Lisa re-engages in her prior school-related experience, the social practice of her upper secondary mathematics classroom. This experience is later in this phase re-negotiated with the social practice where her internship supervisor Mr Higgins is a part.

In the first interview, conducted before entering teacher education, Lisa talks a lot about how she, from an early age, developed a passion for mathematics as a subject. She credits this passion to the fact that she found mathematics easy and she recalls positive memories with the subject itself. During primary school, Lisa perceives herself as extremely good in mathematics. "Secondary school was okay, it became harder, but it was not hard [...] I chose a direction with as much mathematics as possible, so I thought it was fun." Lisa especially remembers two teachers. "Both were extremely interested... they taught playfully..." Lisa describes these teachers as knowledgeable and dedicated to their commitment as teachers. She also describes how they frequently used "competitive teaching" which increased Lisa's motivation: "this to get it a little more challenging and you got interested."

The first internship is conducted approximately eight months after Lisa enters teacher education. Lisa’s supervisor Mr Higgins "admits" in an interview two months before that he uses competitions when teaching mathematics, all the time. However, he emphasises that the main idea is for students to compete with themselves, but that there might be some competition among the pupils as well. One example is how the class "do multiplication every third week [...] we do it both on Mondays and on Fridays... on time... it might seem a little stressful and inconvenient, but they like it very much."

At the internship, Lisa is stunned after her initial participation in Higgins classroom.

I think he explains in a way that is very close to pupils thoughts... it is very close to pupils, and it is... it is at their level of understanding ... and it is very playful all the time [...] they [pupils] are involved in everything he does... then they have tests in mathematics where the competitive instinct comes into play... when he says something it becomes fascinating...

Lisa accentuates her admiration for the teaching that she participates in and relate the teaching to the use of competitions, "he has it all the time." Lisa concludes that "I am very impressed with him as a teacher and would I... I would be like him."

Two relevant social practices are visible in Lisa's tales. Lisa re-engages in the past social practice, upper secondary mathematics classroom, as a hugely successful pupil. The success was related to the competitive structure which increased her motivation. The common endeavour of participating in competitive teaching practices that she shared with some others is central in her positive experience of mathematics education. It is also central to her view of teaching. Lisa do not question her first internship. Her prior participation in the upper secondary mathematics classroom is instead reinforced as valid in the present school-related social practice.

These two social practices are closely related, there are many similarities. Lisa brings two different social practices together, her past and present participation moulds together while re-negotiating the role of competitions. By participating in a present educational model, the role of competitions is actualised from past participation to present experience.

### **Phase two – Questioning competitive teaching when teaching**

The second phase links to the 30 ECTS course in mathematics education and the common endeavours of the teacher educators. This paper stresses two different ways of participating, ways of being, within the mathematics education course. There are also other social practices of importance, for example, the study group containing three other student teachers.

During the mathematics education course, it became apparent, to Lisa, that most students did not enjoy mathematics at school and competitive teaching is filled with anxiety. She immediately starts to question her experience in mathematics classrooms and begins to align with the teaching in mathematics education. To understand this shift in her participation, the re-negotiation of her past participation, we need to enter lecture halls and seminar sessions that the mathematics education course provided during the first week.

Several different teacher educators indicate that the student teachers' bad experience of mathematics teaching might relate to competitive teaching. During the first week, it becomes clear to Lisa that her positive experience of competitive teaching is uncommon and she starts to question her past participation in mathematics classrooms. "Everyone is more or less competitive, and it is a huge strong feeling in all of us... or in me... it is [...] it suits them who are good and not those who have difficulties ... so I do not know how much one will use it ... you will have to think about the pros and cons... and then usually... well, the disadvantages take over ..." There are positive things with competitive teaching "everyone concentrates more and makes every effort to get ahead [of others] or to win... there will be more ... a bit more fight and quality ... sort of ..." However, the negative side takes over "it ruins the confidence and quality deteriorates because it usually goes on time and that it should go as quickly as possible ... instead of as good as possible. I think it is important that they compete against themselves, but I think it is difficult for students to grasp that ..."

However, when engaging in informal discussions in other social practices, she talks differently. For example, in her study-group, she several times during this course highlight that "competitions are excellent" and "to get ahead in the textbook is a great feeling."

During the course in mathematics education, Lisa starts to contrast her prior experience with the mathematics education course developing a critical stance against the kind of teaching that is promoted by the teachers. "You do not agree with everything they say."

At the beginning of the mathematics course, Lisa makes a shift concerning competitive teaching. By participating in the social practice set up by mathematics education, she tries to balance her past participation while re-negotiating the role of competitive teaching. The manifestation of the conflict, Lisa participates in, can be viewed between the prior experience of competitive teaching and the present experience of mathematics teacher education. Also relevant is the experience of the "other", those with negative experience from the past. The point is that Lisa re-engages and engage in two distinctly different themes that relate to different social practices, that do not relate to each other, trying to balance the role of competitive teaching during the mathematics education course. The teacher education course in mathematics education has a significant role in the shift describes, how Lisa use past and present experience. While trying to bring these different perspectives together, Lisa starts to develop a critical positioning to the promoted teaching presented at the mathematics education course.

### **Phase three – Competitions is positive for all learners**

The last phase starts before the end of the mathematics education course. She engages in an imagined, present or future, social practice and relates that social practice against the content promoted at the teacher education course.

Even though Lisa think that this has been the best course, so far in her teacher education experience, she does not align with the general promoted teaching of the teacher educators. Lisa concludes that she is still positive to competitions even though it is described as an insufficient teaching strategy by the teacher educators. She admits that she may "sound mean" but "everyone is competitive more or less... everyone wants to win, and no one likes to lose".

I do believe that competitions engage pupils... then one might not do it so outspoken that the one who wins gets a candy box ... but competitions are there... not that anyone gets knocked down because they never win... however, still there... something that engages them and makes them want to make an effort... and that...well... in that way, I do even believe that one can involve them who have it easy and those who find mathematics hard ... that they can applaud and encourage each other in this way... but then I do not know if competitions are the perfect teaching way, but I do think that it can be of importance to put it into teaching... and mathematics feels like a subject where it can be easily done.

Lisa also conducts her second internship with Mr Higgins as a supervisor. He still works in the same way, and Lisa is very comfortable in that classroom. She highlights that Higgins still uses competitions as a teaching strategy and in the final interview, two years and five months after the first one Lisa concludes that "Higgins is an excellent role-model at the moment... he is in my thoughts a splendid teacher... he is like the teachers I liked when I was young".

There is an apparent shift in Lisa's PoP. She is no longer obliged to participate in the collective way of being and share the common endeavour set by the teacher educators. She need not consider the

role of the mathematics education course and the way of participating in this social practice. While bringing different perspectives together Lisa positions herself concerning future pupils, expand her educational model related to competitive teaching and develop a critical positioning to the teaching promoted by teacher education.

## Discussion

This paper aimed to illustrate how different past and present social practices play for Lisa's, a generalist student teacher, tales of herself as primary mathematics teacher-to-be. In the result section, it has been illustrated what experiences from teacher education and other relevant social practices that are visible. PoP has offered a way to follow the re-negotiation of the meaning of teaching mathematics, how Lisa is using different social practices within communication to understand the world around her when emerging into the teaching profession.

Lisa's pathway through teacher education is viewed as "a process of flexibility, autonomy, and adaptation to the teaching context" (Hošpesová, Carrillo & Santos, 2018, p. 181). In her professional development, she has for example negotiated and re-negotiated her experience of competitions, upper secondary, internship, teacher education, and study-group work. She has first of all re-engaged positively in prior experience and in teachers teaching rather than teacher educators promoted teaching. The teaching of the teacher educators has been used as a discursive counterpart. Most important has been her own experience of being a pupil at school and how she re-negotiated that experience with Mr Higgins teaching practice. It can also be interpreted that her background as an athlete has contributed to her professional development.

Lisa draws on competitive classroom when entering teacher education and she still draws on competitive classrooms at the end of this study. In this sense, there is no shift in her participation. However, the third phase is no regression to the first phase, as Lisa brings in different perspectives and social practices in the different phases. Lisa uses other information in her argumentation and justification during different parts of her teacher education. Also notable is that teacher education promotes another teaching than the one Lisa draw on, and this evolves into the fact that Lisa questions some of her assumptions during her education. In this way, the mathematics education course has played a role, but in the end, not the role the teacher education community expects or wants.

The different phases in this paper are critical because we can interpret how social practices play a role in her tales of herself as teacher-to-be. We can interpret how past and present social practices influence how Lisa talks about competitive teaching during different parts in her teacher education. The point is, by looking closer to the process one can understand how and what students change or not. Many things happen during an education, both inside and "outside". While most others, for example, Hodges and Hodge (2017) focuses on social practices related to teacher education I suggest that there are other social practices of importance when student teachers become educated teachers. There is a need to be interested in any social practice when trying to understand student teachers as teachers-to-be.

*Many preservice teachers (PSTs) experience a tension between theoretical input from university and from school placement. What to do about this theory-practice divide is an ongoing debate. In this paper, when investigating the potential of a type of assignment, ‘Missions’, to reduce this divide in mathematics teacher education, we give PSTs a voice in the matter. Their statements connect specific features of the assignments to theory on mathematics pedagogy and to professional practice. Two factors emerge as central to ‘Missions’ bridging theory and practice: PSTs’ lack of familiarity with mathematical investigations and the synergies between several pedagogies of practice – both prior to and during the work on the assignments.*

*Keywords: Pedagogies of practice, missions, maths preservice teachers, theory-practice divide.*

### Introduction and background

Preservice teachers (PSTs) often experience a disconnect and tension between theoretical input from university and practice in school placement (Nolan, 2012). When in conflict, PSTs reject theoretical perspectives from university, which highlights that, in their eyes, practice is a highly valued component of teacher education, more important than the university input for their future as mathematics teachers (Solomon, Eriksen, Smestad, Rodal, & Bjerke, 2017).

Nolan (2012) notes that, in mathematics, tension between practice in schools and university’s theorisation of that practice mirrors the conflict between inquiry-based focus at university and instrumentalism in schools, where the PSTs’ habitus plays a pivotal role. Habitus is strongly rooted in experiences from early schooling, and is, for that reason, hard to change (Nolan, 2012). PSTs’ ideas of what mathematics teaching is and ought to be, is influenced by memories from their own years as students (Arvold, 2005). For alternative views to stand a chance, it is important to offer PSTs opportunities to reflect critically over their own experience as students, at the same time as they are offered support in experimenting with less familiar approaches to teaching mathematics (Leavy, & Hourigan, 2016).

As a response to this disconnect between theory and practice, in Norway, the practice component of teacher education is expanded. Researchers within the field are sceptical of such quantitative solutions for qualitative problems (McDonald et al., 2014): it is hard to see that such an expansion on its own can bridge the theory-practice divide, but what the alternative is, is an ongoing debate.

In this paper, we explore the potential of ‘Missions’, a type of assignment developed at our university, to be part of such a solution in mathematics teacher education. We do this through a two-pronged approach: first we analyse the text of the Missions in order to identify how they address theory and practice, and second, giving PSTs a voice in the matter, we investigate how they experience these assignments as part of their teacher education programme, which includes 100 days of school placement.

In the Missions, working in groups of 3 – 5 PSTs, the idea is for the PSTs either to observe and interpret students' strategies and methods within a topic, or plan and conduct an activity with students and holding a specific focus (mathematical or methodological). The chosen activity shall provide opportunities for investigative work (Skovsmose, 1999). In preparation, the PSTs must think through what kind of suggestions, solutions and prior conceptions the students might bring up - and how to meet their contributions. During implementation, the focus shall be on student thinking, communication of ideas, and how the PSTs manage to challenge the students and provide support. After implementation, the process shall result in a written report where, on the basis of theory, PSTs shall analyse and discuss their observations and the work produced by the students. Critical reflection on the process and their own role as mathematics teachers is a crucial part of the report.

## Theory

As teacher education is ultimately preparing PSTs for their professional practice, in recent years educational researchers have become increasingly preoccupied with how this is reflected in the design of the programmes. In mathematics teacher education, the inclusion of actual records of teaching, such as samples of student work and transcripts of classroom episodes, have become widespread, as they are seen as “extremely powerful sites for learning” (Boaler, & Humphreys, 2005, p. 4).

One particularly useful tool for analysing the design of teacher education programmes, in this respect, comes from Grossman et al. (2009), who have developed a framework for pedagogies of practice, pedagogies used in the education of professionals in order to connect to their future practice. They have identified three types of pedagogies: *representations*, *decompositions* and *approximations of practice*.

*Representations of practice* are activities that illustrate facets of practice that allow novices to develop images of professional practice and ways of participating in it, such as portrayals of decontextualized classroom dilemmas that teachers pursue in their ongoing work. *Decompositions of practice* are activities in which teaching is parsed into components that are named and explicated, such as when analysing videos of lessons by using a certain framework. Finally, *approximations of practice* are activities in which PSTs engage in experiences akin to real practice that reproduce some of the complexity of teaching.

In mathematics teacher education, theoretical perspectives are often related to reform teaching. The relative difficulty of reform teaching can cause the teacher to fall back on more traditional, teacher-centred approaches. One way of addressing this during university courses, is through opportunities to experience alternative ways of teaching through *representations of practice* (e.g., by participating in student-centred teaching led by the course instructor), *decomposition of practices* (e.g., by using videos and analysing those based on specific theoretical frameworks), or *approximations of practice* (lesson planning, rehearsals, co-teaching with experienced teachers). In *approximations of practice*, the PSTs are enacting teaching practices, rather than contemplating them (Grossman et al., 2009).

The idea behind the Missions is closely connected to an understanding of teacher competence as something dynamic and action-oriented that needs be developed in close interaction with the field of practice (Kværne, & Solem, 2012). If the goal is to educate mathematics teachers with such competence, we need to understand what this requires of the components we choose to incorporate

in programme designs, such as the Missions. Schoenfeld and Kilpatrick (2008) have developed a theoretical framework for *proficiency* in teaching mathematics that considers both knowledge of theoretical perspectives and competence in enacting teaching practices. The seven categories are: *knowing school mathematics in depth and breadth*; *knowing students as thinkers*; *knowing students as learners*; *crafting and managing learning environments*; *developing classroom norms and supporting classroom discourse as part of “teaching for understanding”*; *building relationships that support learning*; and *reflecting on one’s practice*. The names of the categories are relatively self-explanatory and, for lack of space, we refer the reader to the original source for details.

## Methods

This paper reports on a study with a generalist primary teacher education programme for grades 1 – 7 (ages 6 – 13) at a University in Norway. The participants are in their third year of a four-year programme, undertaking a specialization mathematics course that builds on the compulsory 30 ECTS in mathematics methods from the first two years. During each academic year, PSTs spend 30 days in school placement, leaving them with a minimum of 60 days in schools before their first Mission. All PSTs undertaking the course were invited to participate in the study, and ten volunteered.

The ten PSTs were interviewed in pairs. The questions raised in the semi-structured interviews focused on their ideas on two Missions’ purpose and function, PSTs’ perception of the use of theory, and their experiences with these two Missions. Considering their development as future mathematics teachers, we encouraged the pairs to discuss the role played by the Missions and by teaching mathematics in school placement.

The analysis of the two Missions is organised through a comparative perspective. Our analysis of the text of the two Missions is conducted in order to identify references to theory (operationalised through the syllabus of the course) and teaching practice (operationalised through tasks of teaching). Once these two Missions are identified as pedagogies of practice, we proceed to characterize them by means of the framework of Grossman et al. (2009), including an overview of constraints that are a means of reducing complexity.

In order to capture PSTs’ experiences with these two Missions as pedagogies of practice, for our analysis of the interview data, we developed coding categories close to Schoenfeld and Kilpatrick’s (2008) theoretical framework. This framework was chosen because it considers both theory and practice, and the seven aforementioned categories were operationalised in a way that enables PSTs’ statements to be immediately linked to one of the categories, or associated to a category due to the literature in the course syllabus. The authors conducted the coding individually, and coding categories were discussed until agreement was reached.

## Findings

To identify the two Missions’ traits as pedagogies of practice, we begin with an analysis of the text of the assignments, before proceeding with an analysis on how PSTs perceive these two Missions and the university instructors’ intentions in employing pedagogies of practice that both resemble normal teaching practice and reduce complexity.

## The two Missions

Both Missions are reform-oriented, mathematical investigations (Skovsmose, 1999) as presented in the course syllabus – and requiring PSTs in groups to bring to the classroom activities where the students are challenged to explore, explain and justify mathematical ideas. In both cases a written report was required, a *decomposition of practice* addressing the planning stage, the implementation and the reflection following the lesson. Table 1 displays a comparison of the two Missions.

	<b>Mission 1</b>	<b>Mission 2</b>
<b>Lesson type</b>	Investigation	Investigation
<b>Topic and activity</b>	Algebra - The Border Problem (Boaler & Humphreys, 2005)	Not set
<b>Grade, class size, timeframe</b>	Not set	Not set
<b>Methodical considerations</b>	Follow closely the model in Boaler & Humphreys (2005) or make different choices as long as the investigative nature is preserved	Lead the lesson so that the investigative nature of the task is preserved
<b>Collect documentation</b>	Proof of the students' inquiry processes. Focus: The emergence of important algebraic ideas, students' use of representations as theorised in Boaler & Humphreys (2005)	Proof of the lesson being a true investigation as defined in Skovsmose (1999). Focus: The nature of teacher-student and student-student communication as theorised in the course literature (i.e., Solem and Ulleberg (2013))

**Table 1: Comparison between the two Missions**

In both cases, work on the Missions was preceded by teaching sessions at the university. In addition to introducing theoretical input, these sessions included a sequence of a *representation of practice* and a *decomposition of practice* directly relevant for each of the two Missions. Specifically, the course instructor opened each session by conducting an investigation with the PSTs (“The Border Problem” prior to Mission 1, and a selection of different investigative activities prior to Mission 2), collecting artefacts – *representations of practice*. Next, the course instructor introduced a theoretical perspective and then presented the PSTs with opportunities to participate in a *decomposition of practice*, using theoretical perspectives in analysing artefacts from their own work, as well as from examples of implementations in primary and middle school classrooms. For Mission 1 an additional opportunity for the PSTs to engage with *representations* and *decompositions of practice* was provided. Boaler and Humphreys (2005) is compulsory reading and includes a video recording of a classroom implementation of The Border Problem, as well as an in-depth discussion of that session. In Mission 2, the PSTs were free to choose the activity; although they could choose one where *representations*

and *decompositions of practice* were available (e.g., the activities used by the course instructor), overall, support is reduced compared to Mission 1, and so the complexity is higher.

We argue that the two Missions ensure that the PSTs engage in *approximations of practice*. The assignments, as set by the course instructors, require planning and enacting a lesson, and are therefore proximal to the practice of teaching. At the same time, the complexity of the teaching situation is reduced by narrowing the scope to the specific traits of investigations, to the concept of variable introduced by translating between representations and to communication in the mathematics classroom, respectively. Additionally, complexity is reduced as the PSTs are only required to select some pivotal moments for discussion, and may simply ignore others. Rather than being evaluated based on how ‘successful’ the lesson has been in terms of learning goals for the students, the written report – a *decomposition of practice* – will be evaluated based on the manner in which PSTs connect observations from the classroom with the theoretical input from their course, as well as their reflections on the implementation. This gives room to experiment in a safe environment - reflections on ‘failures’ such as reducing a student’s opportunity for productive struggle, or on misinterpreting a student idea are welcome in the report, and will be regarded by the instructor as a positive learning experience for the PSTs. Finally, as the PSTs are required to work in groups, this provides them with a type of support unusual for the practice of teachers - at least in Norway.

### **PSTs’ reflections on the two Missions**

The rationale of using pedagogies of practice is that they are simultaneously proximal to actual practice, and have reduced complexity. In the eyes of the PSTs, the main reason why the course instructor has chosen to give these two Missions is because enactment makes theory meaningful: “...a very good opportunity to understand what is expected of us as teachers, the contrast [between theory and practice] is not so great when I can try out what I’d learn about” (PST1).

Specifically, the contrast between the analytical stance of a *decomposition of practice* in isolation and the combination of *approximation* and *decomposition of practice* emerges as the PSTs reflect on how the two Missions supported their understanding of the concept of mathematical investigations:

One could for sure just say: “Be careful, don’t deprive [the pupils] of this opportunity [to figure things out themselves]”, but this was something else entirely. It gave me a completely different awareness, by allowing me to experience it (PST2)

In both statements, the presence of the course instructor is noticeable - “what is expected”, “one could [...] say”, indicating they perceive the two Missions to be part of teacher education, pedagogies of practice rather than pure professional practice.

In other statements, however, the perspective of professional practice emerges, with its demand on the PSTs’ knowledge of the depth and the breath of mathematics: “you go deeper [in the mathematical ideas], and learn more about *why* it is like it is” (PST5).

Making sense of mathematics is an experience included even in *representations of practice*, such as the investigations led by the course instructor during the session at the university; however, planning for an actual lesson (i.e., an *approximation of practice*) is significantly different, forcing PSTs to consider not only themselves, but also the students:

It takes a lot - preparing for all possible answers that might come, and all possible questions. You end up pondering imaginable scenarios and preparing how you could explain it from there (PST8)

The theme of *knowing students as thinkers*, their possible ways of approaching the tasks, and their possible questions, as well as the theme of *knowing students as learners*, what might be a helpful way of meeting their contributions, recur again and again as central to the assignment:

Normally, if the students had given the wrong answer you would just think “OK, that’s wrong”. But as it is [in Missions], you have to think what might be the thought behind the answer (PST5)

PST7 relates her first-hand experience with the difference between *knowing students as learners*, and actually successfully *crafting and managing a learning environment* that aligns with that knowledge:

You had gone through [The Border Problem] quite thoroughly, you knew there were six ways [of thinking] and possible misconceptions and so on, you had seen quite a lot of examples [...] so you got started on Mission 1 from a position of strength. [...] But] how we prepared [for the lesson in Mission 1] and how we put it across to the students did not help them as we thought it would. When we left the classroom we were thinking “Damn, we should have done a lot better!” We knew what to do – we had been through it all [at uni] – but we haven’t dug deep enough (PST7)

As investigative work is at the heart of these assignments, the learning environment was often discussed in terms of characteristics of this approach:

I still remember the maths classes where you practiced algorithms and if you asked why it worked, the teacher said “It’s just the way it is”. I can see it’s tempting to say that... The Missions give us a chance - no, force us - outside the “It’s just how it is”- box, since they are made so that the tasks don’t work unless you actually understand. It’s probably [their] the most valuable quality (PST4)

The comparative freedom in Mission 2, got mixed receptions:

On the first assignment, you got very clear constraints on what to do. On the second one, my group chose to do several tasks, and then we didn’t get the depth we needed, we sailed more on the surface of what an investigation should be (PST4)

My group designed the activity [for Mission 2], and we found it gave us more ownership of the lesson. It was ours, and it was easier to learn from it. [Working with a given task in] Mission 1 was necessary to show us how to [investigate] (PST3)

Regardless of the risk of failure, the PSTs regard the two Missions as opportunities to think deeply about what happens in the interaction with the students:

When you plan a lesson, teach it and then write about it, you become more aware of how you react to what the students say - it’s not just that you ask them something, they say something in return and you don’t think too much about the answer. You actually reflect on the conversation! (PST10)

The *classroom discourse in mathematics* appears often in PSTs’ reflection. This could be in part due to the explicit focus on communication in Mission 2 (Table 1), that retrospectively spills over in what they remember from Mission 1, but could also be in part a direct consequence of having communicated with children, and being required to document it. *Establishing classroom norms* are

mentioned in connection with these assignments as well: “The assignments contributed [towards the awareness that] it’s not just what you teach, but how you teach it, too!” (PST1). However, this code appears less frequently, perhaps given that PSTs spent a short time with students during Missions.

In comparing the *approximations of practice* in Missions 1 and 2 with those of mentored teaching in school placement, some PSTs expressed the value they placed on school placement because it offered something unique: the teacher mentors’ insight in building relationships that support learning - “[the mentors] know the children, and know how they need to be taught” (PST9). One mentor made a lasting impression on PST1 because of her awareness of mathematics teaching as more than a collection of isolated moments: “My mentor wanted us to reflect on our role, what makes us teachers ... She wanted us to take a long term perspective, more than just the weeks we were there, or the year” (PST1). Except for this relational aspect, and the opportunity to develop norms over time, the value of teaching in school placement did not connect to mathematics specifically:

[In school placement] we were two in charge of a class - lots of teaching! There wasn’t much time for either seeking advice or getting feedback (...) So [teaching in school placement] is something else [than the Missions] entirely but now I feel much better prepared for lesson planning - at least in maths, after having done the Missions. You start thinking in another way than before (PST2)

Time creates a constraint on reflection in school placement. By contrast, as we have seen, PSTs valued the opportunities that Missions 1 and 2 give them to *reflect on their own practice* by requiring them to plan as a group, and to hand in *decompositions of practice*:

You get an opportunity to think things through - what shall we do? And why should we do that? And what do we want to achieve in the end? (PST2)

We could just as well had had three Missions and no school placement, if you are thinking in terms of mathematics. School placement is good practice, but you don’t get much of the subject-specific reflection, more about the organisational aspects...The subject specific ends up neglected (PST3)

## Discussion and concluding remarks

PSTs see the two Missions as *approximations* and *decompositions of practice* - close to teaching practice, enacting and analysing a practice of reduced complexity. As indicated in the introduction, the divide between theory and practice is an issue of great concern for researchers and teacher educators (Nolan, 2012); bringing theory into practice has proven difficult (Solomon *et al.*, 2017).

In this study, we explored the potential of the two Missions to bring together theoretical perspectives with teaching practice. The framework used for the analysis (Schoenfeld, & Kilpatrick, 2008), with its double orientation towards theory and practice, allowed us to examine the two Missions’ contribution to these two elements of mathematics teacher education in the PSTs’ retrospective reflections. PSTs consider the two Missions as contributing to both dimensions, and, furthermore, they complement the contribution of teaching in school placement. Both the two Missions and school placement are *approximations of practice*. While the two Missions provide the mathematics-specific focus lacking from the school placement, the long-term aspects, such as building relationships with the students, are mostly lacking from the two Missions, – although they provide at least an opportunity to appreciate that certain classroom norms are worth attempting to establish.

The PSTs' reflections highlight the synergies between several pedagogies of practice. The interaction with real children (*approximation of practice*) and a focus that - by their own account - forces PSTs outside their comfort zone mathematically, as well as in terms of teaching methods. PSTs value the requirement of group work, and of submitting a *decomposition of practice*, a written report including a reflection drawing on theory. The progression from Missions 1 to 2 gives an opportunity to develop further. Everyone appreciated the role of Mission 1: it allowed PSTs to enact an investigative lesson by 'imitating' Humphreys' video (Boaler, & Humphreys, 2005). The two Missions form a 'chain' of *approximations of practice* with an increasing degree of complexity from periods of mentored school placement, via a Mission 1, to a more open Mission 2. While some PSTs willingly took off the training wheels in Mission 2 and experimented with self-chosen activities, others stuck with the familiar examples from the class at the university (*representations of practice*). Habitus is strongly rooted and hard to change (Nolan, 2012), and these approaches to teaching mathematics are unfamiliar to many PSTs. However, if new approaches should stand a chance, these opportunities to try out less familiar investigative activities are of great importance (Leavy, & Hourigan, 2016).

## Abstract

*This study examines rehearsals embedded in cycles of enactment and investigation, and more specifically, the discussions the participants engage in when instruction is paused – Teacher Time-Outs (TTOs). The paper studies the ambitious teaching practices that are revealed in the discussions, as well as the aspects of these practices that the participants have the opportunity to learn. Approximately 60% of the rehearsal time was spent on teaching and 40% on TTOs. The use of representations was a key aspect in 28% of these discussions. It is particularly interesting that the discussions in the rehearsals make it possible for the participants to learn how to represent students' mathematical ideas in writing on the board while at the same time paying close attention to connections between student talk and mathematical correctness. Implications from these findings are also discussed.*

## Introduction

The aim of professional development (research) is to support in-service teachers (ISTs) in developing ambitious teaching practices (e.g. Lampert, Beasley, Ghouseini, Kazemi, & Franke, 2010; McDonald, Kazemi, & Kavanagh, 2013). Ambitious teaching entails mathematical meaning making, identity building and creating equitable access to learning experiences for all students. It requires that teachers know their students as learners and engage deeply with their thinking. Ambitious teaching practices enhance student learning of complex ideas and performances (Lampert et al., 2013, Ghouseini et al., 2015). Examples of ambitious practices are aiming toward goals, eliciting and responding to students' mathematical ideas and using representations (Lampert et al., 2010) (see more examples in Table 1).

Recently, teacher education and professional development (PD) have had more focus on teaching practices and pedagogies of enactment (cf. Grossman et al., 2009; Lambert et al., 2013; Gibbons, Kazemi, & Lewis, 2017). The focus of this paper is on *rehearsals*. These researchers emerging research indicates that the use of rehearsals contributes positively to the development of ISTs' ambitious teaching practices (Gibbons, Kazemi, Hintz, & Hartmann, 2017; Kazemi, Ghouseini, Cunard, & Turrou, 2016; Lampert et al., 2013; Valenta & Wæge, 2017), as well as to the development of mathematical knowledge for teaching (Ghouseini, 2017). Previous research highlights the need for more research on rehearsals (Kazemi et al., 2016; Lampert et al., 2013).

We report on findings from the PD project *Mastering ambitious mathematics teaching* (MAM). In the MAM project, ISTs are invited to collaborate in learning cycles of enactment and investigation where the overarching aim is to learn to enact the practices that constitute ambitious mathematics teaching. Rehearsals are an important element of these cycles, and we especially examine the use of teacher time-outs (TTOs) during them. The ISTs work on instructional activities (IAs) in the rehearsals. IAs are developed to highlight and support ISTs' learning of specific ambitious teaching practices and to focus on specific mathematical ideas. The IAs in the MAM project include choral counting, quick images, number strings, problem solving and games (cf. Lampert et al., 2010). The ISTs learn to teach IAs through cycles of enactment and investigation.

Lampert et al. (2013) explore what teacher educators and novice teachers do together during rehearsals so they can “learn to enact the principles, practices, and knowledge entailed in ambitious teaching” (Lampert et al., 2013, p. 226). They suggest that rehearsals provide room for novice teachers to open up their instructional decisions to one another. Kazemi et al. (2016, p. 16) suggest that rehearsals, as nested in learning cycles, provide repeated opportunities for novice teachers “to investigate, reflect on, and enact teaching through coached feedback”. Furthermore, rehearsals bring the student teachers “into interaction with one another around instructional decision making that is responsive to students’ contributions”, enabling them to “come in close contact with how their colleagues make sense of and take up the practices that are being learned” (Kazemi et al., 2016, p. 28). In the context of PD, Valenta and Wæge (2017) found that the interactions between the ISTs and the teacher educator during rehearsals were mainly discussions on using mathematical representations, using a mathematical goal, paying attention to student thinking and eliciting and responding to students’ mathematical ideas – all important principles and practices of ambitious mathematics teaching. They suggest that rehearsals offer ISTs “the environment and opportunity to work simultaneously on a variety of aspects of practice” (Valenta & Wæge, 2017, p. 3387).

The organisational TTO procedure has been highlighted as a promising way for ISTs to learn together in and through practice (Gibbons, Kazemi, Hintz et al., 2017). The participants can pause the instruction to think out loud together and share decision-making with one another before continuing with the enactment. For example, Fauskanger and Bjuland’s (in press) analyses suggest that TTOs enable ISTs to develop a better understanding of how to elicit students’ mathematical ideas by, for example, practising questions to ask. Research indicates that TTOs provide opportunities for ISTs to make changes and to shift the focus in the interactions “from one of judgment and evaluation to one of collective consideration and opportunistic experimentation in the midst of teaching mathematics” (Gibbons, Kazemi, Hintz et al., 2017, p. 29). Gibbons, Kazemi, Hintz et al. (2017, p. 48) hypothesize that TTOs support the ISTs’ “ability to be adept at moment-to-moment decision-making to engage students in rich discussions” and “to cultivate learning environments where everyone [is] positioned as capable of doing substantive mathematics” at the same time as ISTs become good at “at drawing on students’ multiple knowledge bases.” These researchers point out, for instance, that future research should attempt to understand more about how TTOs might support ISTs in developing their instructional practices. In this paper, we address the following research questions: (a) Which (if any) of the practices entailed in ambitious mathematics teaching are the focus of attention in the TTOs taken during rehearsals? and (b) Bearing the TTOs in mind, which aspects of the practice of using

representations do the ISTs have opportunities to learn to enact? The second research question is the main focus of this paper.

## Methodology

### Design, data material and participants

The ISTs learn to teach instructional activities (IAs) through cycles of enactment and investigation. Each cycle involves the following six steps:

1. The ISTs read an article and watch a video of a teacher's enactment of a particular IA.
2. The supervisor leads a discussion/analysis of the article and the observed video.
3. Groups of ISTs prepare to teach the IA to a group of students, guided by the supervisor.
4. One IST (the rehearsing IST) enacts the IA in a rehearsal, where the supervisor and the other ISTs act as students. During this rehearsal, all participants can ask for TTOs.
5. The IST enacts the activity with a group of students. All participants can ask for TTOs.
6. Each group of ISTs analyse the enactment, guided by the supervisor. This is followed by a guided analysis of the enactment with all the ISTs.

Thirty ISTs from 10 elementary schools participated in the project. The ISTs were divided into four groups. One group consisted of those teachers who did not want to take part in the research, whereas two out of the three remaining groups (groups 2 and 3) were randomly chosen to be part of the research reported on in this paper. The ISTs' teaching experience varies from one to 30 years. The ISTs participated in 12 sessions, which included nine cycles of enactment and investigation, over the course of two years. All the sessions were videotaped where one researcher observed each group and took notes. The data material from groups 2 and 3 consists of video recordings of the rehearsals (step 4 above) from the nine cycles of enactment, resulting in 18 recorded rehearsals.

### Analytical approach

A sociocultural view of ISTs' learning frames this research as the ISTs work together and learn ambitious teaching practices in a community of practice. We analysed the video recordings of the rehearsals, looking specifically for opportunities for ISTs' learning. First, all the TTOs in the rehearsals were identified according to the following definition of a TTO: The instances where the rehearsal is explicitly paused (often with a TTO hand signal) so the participants can better understand and/or act in relation to their colleagues' thinking, pedagogical choices and/or mathematical content (cf. Gibbons, Kazemi, Hintz et al., 2017). Second, we undertook a conventional content analysis (Hsieh & Shannon, 2005) of each of the TTO episodes, i.e. we used an inductive coding process with the aim of identifying aspects of ambitious teaching practices in the TTOs and which of these the ISTs have opportunities to discuss.

## Findings

In a previous study, we found that approximately 60% of the rehearsal time was spent on ISTs teaching the IAs and 40% on TTOs, showing the back-and-forth pattern between facilitating deliberate practice and posing questions (Wæge & Fauskanger, submitted). Moreover, we identified 175 TTOs and found five common dimensions of ambitious teaching practice that were addressed during them (Wæge & Fauskanger, submitted). An overview of these practices is given in Table 1.

Note that many of the TTOs involved simultaneous work on multiple aspects of practice, thus many of the TTOs involved more than one category.

Ambitious teaching practice	Example	Number of TTOs
Setting up a task, i.e. the TTOs consisted of questions and discussions on the practice of launching a problem.	The rehearsing IST has just posed a problem when one of the observing ISTs asks for a TTO: “There’s something I’m wondering about. Justification. Should she [the rehearsing IST] say something about that [invite the students to justify while presenting the task]?” (session eight, problem solving, group 3)	42
Using a goal to work towards, i.e. discussions on the practice of directing students’ attention on a learning goal for the lesson.	The rehearsing IST has just written the student solution “three times ten minus one” on the board: $3 \times 10 - 1$ . The supervisor intervenes by saying: “Now, the question about [the use of] parentheses becomes interesting [referring to the expression $3 \times 10 - 1$ ].” (session three, quick image, group 2)	35
Supporting mathematical discussions, e.g. using talk moves (cf. Kazemi & Hintz, 2014).	The rehearsing IST gives the ISTs (acting as students) some time to think about the problem 400 - 379, and then asks them to share their solutions when one of the observing ISTs asks: “Should we ask them [the students] to turn to each other and talk or should we let them think individually first?” (session six, strings, group 2)	23
Using representations, i.e. representing students’ mathematical ideas in writing (on the board), making connections between student talk and representations, and making connections between different kinds of representations (Lambert et al., 2010, Lambert et al., 2013).	The rehearsing IST, representing a student strategy on the board, pauses and asks: “Do I write in between (points on the number line)?” (session five, strings, group 3)	49
Organising the board, i.e. organisation on the smartboard and utilising space.	The rehearsing IST is representing a student solution on the open number line when the supervisor intervenes by saying: “I’m thinking of another thing right now and that is where to put the number line and the tasks.” (session six, strings, group 2)	27

**Table 1: An overview of the content of the 175 analysed TTOs (Wæge & Fauskanger, submitted)**

With Wæge and Fauskanger’s (in review) study as our point of departure, in this paper we focus on one dimension, namely the “use of representations”. Table 1 shows that this dimension is an important feature in many of the TTOs (shaded in Table 1).

### Use of representations

Using representations (Lampert et al., 2010) is one of the key practices in ambitious teaching. Representing students’ mathematical ideas in writing on the board, making connections between student talk and written representations, and making connections between different kinds of representations, such as the open number line, arrays and tables are important features in 28% of the TTOs. In many of these TTOs the participants discussed how to write student ideas or strategies on the board so they could represent the students’ thinking and at the same time keep mathematical

correctness in focus. For instance, they discussed the use of parentheses when representing students' ideas, the use of arrows instead of the equal sign and the degree to which they should focus on the convention related to the order of factors (in Norway, i.e.  $3 \times 4$  normally represents three groups of four). The importance of recording exactly what the students said was emphasised in several of these TTOs, however, this sometimes led to mathematical incorrectness and thus TTOs were requested.

To illustrate the TTOs in which the participants discussed how to represent the students' ideas or written representations, we provide an example from a rehearsal of a game where number sentences<sup>1</sup> presented by the students were written on the board. In this game, the students worked on finding number sentences using given numbers. Just prior to the coded exchange, the rehearsing teacher represented what one student said by writing the following two number sentences (all supposed to equal the given number 8):  $5 + 3 = 8$  and  $9 - 5 = 4 \times 3 = 12 : 6 = 2 \times 4 = 8$ . We join the rehearsal as one of the observing teachers intervenes:

- 1 OT1<sup>2</sup>: Then the question is/ (interrupted by OT2)  
 2 OT2: Then the question about [correct] notation is relevant.  
 3 S: Yes, and it can't be [written] like that (pointing to  $9 - 5 = 4 \times 3 = 12 : 6 = 2 \times 4 = 8$ )  
 4 RT: Ok, it can't be written like this? (...) <sup>3</sup> (session nine, game, group 3)

The use of the equal sign in the number sentence is not mathematically correct, and the observing ISTs suggested taking a closer look at the use of notation in the number sentences (Lines 1, 2). The supervisor supported their suggestions, pointing out that they needed to find another way to write the number sentences (Line 3). The use of arrows was introduced in the MAM project, but these ISTs do not appear to be used to writing an arrow instead of the equal sign when recording students' thinking. As the discussion continued, some of the ISTs suggested that the number sentence could be written the way it was because that was the way the student presented it. However, at the end of this TTO the participants concluded that they would replace the equal sign with arrows so the number sentences would be mathematically correct:  $9 - 5 \rightarrow 4 \times 3 \rightarrow 12 : 6 \rightarrow 2 \times 4 = 8$ .

A second representative example is taken from another group rehearsing the same IA, but now all the number sentences were to equal 6. The following was written on the board:  $5 + 1$ ,  $8 - 5 + 2 + 1$ ,  $10 - 8 + 2 + 5 + 1$  when one of the observing ISTs asked for a TTO (referring to  $10 - 8 + 2 + 5 + 1$ ):

- 1 OT1: Should we ask them [the students] what they are thinking as they do this?  
 2 RT: Yes.  
 3 OT1: Ask them to explain their thinking. (session nine, game, group 2)

In what followed, the participants discussed what to do when they wrote exactly what the students were saying and it turned out to be mathematically incorrect. After arguing back and forth whether to write exactly what the students were saying or to represent their ideas in a mathematically correct way, they agreed to use "circles" (e.g.  $10 - 8 + 2 + 5 + 1$ ). The rehearsal continued, but similar

<sup>1</sup> In their planning, the ISTs used the term equations. When analysing the rehearsals, however, we find that sometimes the "equations" are written as equality strings or false equations (e.g.  $9 - 5 = 4 \times 3 = 12 : 6 = 2 \times 4 = 8$ ) or without an equal sign (e.g.  $9 - 5$ ). For this reason we use the term "number sentence" (cf. Ghouseini, 2017).

<sup>2</sup> In the transcripts, OT represents one of the observing ISTs, RT is the rehearsing teacher and S is the supervisor.

<sup>3</sup> (...) indicates that the TTO continues.

examples were presented by ISTs acting as students (e.g.  $20 - 8 = 12 + 3 = 15$ ) when the supervisor requested a TTO to ask the ISTs what they would do if these examples were presented by students in the enactment phase. In the ensuing discussion, some of the ISTs pointed out the importance of writing exactly what the students were saying, whereas others pointed to the importance of writing what was mathematically correct. This group did not reach a conclusion on this matter before continuing the rehearsal.

The next example, taken from a rehearsal of a string, shows a discussion on how to represent students' ideas in writing. The first problem in the string was to focus on a run where four students were going to run equally long where the total distance was one hundred metres. One of the observing ISTs (acting as student) said that he knew that "they have to run 25 metres each" because "four times 25 equals one hundred". When representing this on an open number line on the board, the rehearsing IST started by dividing a line segment into two and then by dividing each of these parts into two again thus representing  $(100 : 2) : 2$  instead of  $4 \times 25$ . The supervisor asked for a TTO:

- 1 Supervisor: What is interesting here is that you have thought, you have explained that you were thinking four times 25 (referring to the observing IST who presented this idea). You just knew that, right. But, when you (referring to the rehearsing IST) were making the number line now, what did she do, do you recognise that [what she did represent] (looking at all the observing ISTs)?
- 2 OT1: She divided into two and then divided into two again.
- 3 S: Yes, you halved and then halved again.
- 4 RT: Ok.
- 5 S: It's important that we are aware of this [that this represents  $(100 : 2) : 2$  and not  $4 \times 25$ ]. (...) (session six, strings, group 2)

The supervisor wanted the rehearsing IST to represent exactly what the student was saying ( $4 \times 25$ , Lines 1, 5) and she invited the observing ISTs to recognise this (Line 1). One of the observing ISTs recognised that the rehearsing IST had represented  $(100 : 2) : 2$  instead of  $4 \times 25$  (Line 2). As the discussion continued, the rehearsing IST asked if she should present the strategy  $(100 : 2) : 2$ . This was followed by a short discussion on the pros and cons relating to ISTs presenting their own ideas. The supervisor advised the rehearsing IST to represent  $4 \times 25$  on the number line as "25 and 25 and 25 and 25" (showing the four "jumps" by pointing to the number line). They agreed that the rehearsing IST in the enactment should illustrate  $4 \times 25$  as four jumps of the length 25 and in addition writing 25 above each arch as illustrated in Figure 1.

**Figure 1:  $4 \times 25$  represented on a number line**

These three examples illustrate that the TTOs in the rehearsals could support the ISTs' learning of the practice of representing students' ideas or strategies and their paying close attention to connections between student talk and written representations. The ISTs could also learn more about

the balance between representing students' mathematical ideas or strategies as presented by the students and representing these ideas or strategies in a way that is mathematically correct.

## Concluding discussion

In this study we have identified and analysed ambitious teaching practices that are revealed in TTOs in rehearsals, exploring which practices the ISTs have opportunities to learn to enact during the TTOs. The findings show that ISTs have opportunities to work on and learn to enact the practices of setting up a task, using goals to work towards, supporting mathematical discussions, organising the board and using representations. Opportunities for learning these practices have also been found in previous studies (cf. Kazemi et al., 2016; Lampert et al., 2013; Valenta & Wæge, 2017), which have also found opportunities in TTOs in the enactment phase of cycles of enactment and investigation (cf. Fauskanger, 2019; Gibbons, Kazemi, Hintz et al., 2017). In this paper, we have focused on the practice of using representations. The findings show that TTOs especially have the potential to create opportunities for ISTs to learn how to present students' mathematical ideas in writing and also show the importance of representing student ideas as accurately as possible while also focusing on the mathematical correctness of the representation. Balancing the dilemma between student talk and mathematical correctness has not previously been found in research on TTOs in rehearsals and is thus a unique finding from this study. Our findings also indicate that the ISTs might need more mathematical knowledge for teaching (MKT) and that the TTOs can be a point of departure for strengthening ISTs' MKT (cf. Ghouseini, 2017).

Previous research on TTOs in enactment (Gibbons, Kazemi, Hintz et al., 2017), as well as in rehearsals (Lampert et al., 2013), challenges future research to elaborate on how TTOs as a procedure in PD can be sustained and developed. By using the data material from the MAM project, it is possible to study the development of TTOs in each group for a two-year period. Further analyses of the data material will also make it possible to learn more about whether and how the supervisors develop their TTO expertise (cf. Gibbons, Kazemi, Hintz et al., 2017). Similar projects in new contexts are also welcome in order to study the potential of using TTOs in new contexts. In the Norwegian context the new guidelines for initial teacher education highlight ambitious teaching practices (cf. Mosvold, Fauskanger, & Wæge, 2018) and the number of days in field practice in schools has been extended. Based on the promising opportunities for ISTs to learn ambitious teaching practices through TTOs in the enactment of teaching (Fauskanger, 2019), studying TTOs in student teachers' field practice will be an important context for future TTO research.

## Acknowledgment

We would like to thank to all the participants in the MAM project.

## How does the professional vocabulary change when pre-service teachers learn to analyse classroom situations?

Marita Friesen<sup>1</sup>, Carmel Mesiti<sup>2</sup> and Sebastian Kuntze<sup>1</sup>

<sup>1</sup>Ludwigsburg University of Education, Germany; [friesen@ph-ludwigsburg.de](mailto:friesen@ph-ludwigsburg.de); [kuntze@ph-ludwigsburg.de](mailto:kuntze@ph-ludwigsburg.de)

<sup>2</sup>University of Melbourne, Australia; [cmesiti@unimelb.edu.au](mailto:cmesiti@unimelb.edu.au)

*We conducted a university course with pre-service teachers specifically focused on learning to analyse the use of multiple representations in classroom situations. We were particularly interested in the professional vocabulary pre-service teachers used when they analysed these classroom situations. Before and after the course, we collected 136 written analyses from 17 pre-service teachers who were asked to evaluate the use of multiple representations in four classroom situations. Our findings indicate that the pre-service teachers' professional vocabulary improved with respect to breadth and specificity. They also used more terms related to essential aspects of theory on multiple representations. As teachers' increased and appropriate use of professional vocabulary appears to play a role with regard to their competence in analysing classroom situations, further research into this topic is encouraged and might give insight into corresponding competence development.*

*Keywords: Teacher education, analysing classroom situations, professional vocabulary.*

### Introduction

Being able to analyse classroom situations, that is to identify and interpret events which are relevant for students' learning, is an important prerequisite for providing students with adequate learning opportunities and learning support (e.g., Sherin, Jacobs & Philipps, 2011). Since the use of multiple representations and the ability to flexibly change between them plays an essential role for the learning of mathematics (Duval, 2006; Acevedo Nistal et al., 2009), teachers' ability to *analyse classroom situations regarding the use of representations* can be described as an important aspect of mathematics teachers' professional competence (Friesen & Kuntze, 2016; Friesen, 2017). The question of how such a competence can be developed and how competence development in that field can be assessed and described consequently merits special attention in mathematics teacher education.

The study presented in this paper connects our prior research of pre-service teachers' growth in analysing classroom videos (Friesen, Dreher & Kuntze, 2015) with teachers' use of professional vocabulary when analysing classroom situations regarding the use of representations (Friesen, Mesiti & Kuntze, 2018). Since the International Classroom Lexicon Project (e.g., Mesiti & Clarke, 2017) has drawn attention to the professional vocabulary teachers use when describing classroom phenomena, it has been assumed that what teachers identify and interpret when observing classroom situations might not only be channelled by their knowledge but also by *what they can name*. Taking also into consideration that learning the language of a discipline can be regarded as part of learning the discipline itself (e.g., Schleppegrell, 2007), we assumed that documenting pre-service teachers' use of professional vocabulary might provide insight into their development when they learn to

analyse classroom situations. In this next phase of our research, we turn our attention to change in pre-service teachers' professional language when they learn to analyse classroom situations regarding the use of multiple representations.

Below we outline our study's theoretical background, starting with multiple representations and their role for the teaching and learning of mathematics. After presenting the state of research into teachers' competence of analysing and teachers' use of professional vocabulary, we follow with a description of the university course from which we obtained our data.

## **The use of multiple representations in the mathematics classroom**

The use of multiple representations plays a crucial role for the teaching and learning of mathematics. As mathematical objects are abstract in nature, they can only be accessed by using representations such as: formulae, graphs, diagrams, tables, written and spoken language (e.g., Goldin & Shteingold, 2001). Bruner (1966) coined three stages of representation in which any idea or body of knowledge can be presented to a learner: by action (*enactive* representation), by images or graphics (*iconic* representation) or by symbolic propositions (*symbolic* representation). According to Duval (2006), representations of mathematical objects can be organised in a more fine-grained manner in so-called representation *registers*. Each register (e.g., oral or written language, symbols, shapes, drawings, sketches, diagrams, graphs, etc.) contains some information about the mathematical object it stands for or emphasises certain aspects of the mathematical object. Since many tasks involve several representation registers and some registers are more efficient for solving problems than others, the use of *multiple registers* of representations can be regarded as indispensable for the teaching and learning of mathematics. Teachers and students generate and use multiple representation registers for introducing new topics, for explaining, for solving problems and for sharing ideas in the classroom (Duval, 2006; Acevedo Nistal et al., 2009).

Numerous studies show, however, that using multiple representations of a mathematical object and changing between them involves high cognitive demands for the learners (Ainsworth, 2006; Duval, 2006): The changes between multiple representation registers, so-called *conversions*, require the learners of mathematics to identify and coordinate the relevant constituents from different representation registers. It can consequently lead to serious problems in understanding when students fail to see that different registers (e.g., verbal explanation, written symbols and drawing) represent the same mathematical object (Duval, 2006).

For this reason, mathematics teachers have to be able to *analyse classroom situations* regarding the use of multiple representations in order to support their students in connecting different representation registers when conversions occur (Friesen & Kuntze, 2016). We define such competence of analysing as a teacher's ability "to link relevant observations in a classroom situation to corresponding criterion knowledge so that unconnected changes of representations can be identified and interpreted with respect to their role as potential learning obstacle" (Friesen, 2017, p. 39). Being able to analyse classroom situations as described above can be regarded as highly relevant for students' learning with multiple representations and thus for the instructional quality in the mathematics classroom.

## The role of professional vocabulary for analysing classroom situations

Representations of practice in the form of video clips, narratives, student-teacher dialogues or cartoons play an important role when pre-service and in-service teachers learn to analyse classroom situations (e.g., Sherin, Jacobs & Philipps, 2011). Breaking down practice into its constituent parts requires, however, a *specific language* for describing and naming these parts (Grossman et al., 2009). It is also assumed that learning the language of a discipline is a part of learning the discipline itself (Schleppegrell, 2007). There is hence a consensus that having a specific language for describing teaching practice is essential in pre-service teacher education as well as for the discussion of in-service teachers' practice and its development within the teaching community (Grossman et al., 2009). At the same time, the teaching community has been characterised as suffering from a lack of professional language (Grossmann et al., 2009) whereas different communities, speaking different languages, have been found to employ different naming systems (e.g., Mesiti, Clarke, Dobie, White & Sherin, 2017).

In this context, the International Classroom Lexicon Project (e.g., Mesiti et al., 2017) seeks to document the *professional vocabulary*, or lexicon, mathematics teachers use *when describing classroom phenomena*. Research teams in ten countries (Australia, Chile, China, the Czech Republic, Finland, France, Germany, Japan, Korea and the USA) are currently identifying and comparing the lexicon of their middle school teachers (e.g., Mesiti & Clarke, 2017). Mesiti et al. (2017) argue that teachers' interactions with classroom settings are mediated by their capacity *to name* what they see and experience. The concept of teacher noticing (e.g., Sherin, Jacobs & Philipps, 2011) plays an important role in this context; it is assumed that what teachers identify and interpret in a classroom situation is not only constrained by their knowledge and experience but also by *what they can name* (Mesiti et al., 2017). We therefore concluded, that the professional vocabulary teachers use also provides potential for research into teachers' competence of analysing the use of representations. In a corresponding study, we took an initial step and documented the professional vocabulary used by in-service teachers in their written analysis of classroom situations regarding the use of representations (Friesen, Mesiti & Kuntze, 2018). The results encouraged us to use a similar method for the documentation of pre-service teachers' professional vocabulary before and after a university course with the objective to gain insight into the participants' development when they learn to analyse classroom situations. In the following paragraphs we will describe the university course, our research questions and our method for documenting the pre-service teachers' professional vocabulary.

## Learning to analyse: a university course

The objective of this single semester course is to develop pre-service teachers' competence when analysing the use of multiple representations. It is offered on a regular basis at Ludwigsburg University of Education (e.g., Friesen, Dreher & Kuntze, 2015). At the beginning of the course, key elements of theory related to the use of multiple representations in the mathematics classroom are introduced. Accordingly, criteria are developed which are used during the course for the analysis of videotaped classroom situations and textbook learning material. The core of the course work is the collaborative and criteria-based analysis and reflection of how multiple representations are used and dealt with in learning material and classroom situations. Emphasis is put on the pre-service teachers'

ability to distinguish different registers of representation and to identify unconnected conversions and interpret them with respect to their role as potential learning obstacles. In this context, the participants become acquainted with specific terms from theory on using multiple representations in the mathematics classroom, such as *register*, *conversion*, *change of representations*, *connection of representation registers*, etc. (cf. Duval, 2006). The course sessions also provide the opportunity to further develop and improve learning material and classroom situations according to the theory-based criteria. The pre-service teachers are, for example, encouraged to create alternatives for the teachers' reactions in videotaped classroom situations with the aim to support students in using multiple representations and making connections between different representation registers.

## Research interest and research questions

What teachers see in classroom situations might be channeled by *what they can name* and it might consequently be assumed that teachers' professional vocabulary plays a role with respect to their degree of competence and sophistication in analyzing classroom situations. We are consequently interested in how professional vocabulary develops and how the professional vocabulary used by pre-service teachers changes during a single semester university course. Building on our prior research (Friesen, Mesiti & Kuntze, 2018), we are particularly interested in identifying changes in the professional vocabulary of pre-service teachers after having learned to analyse classroom situations regarding the use of multiple representations. This leads to the following research questions:

- What professional vocabulary do the pre-service teachers use for analysing classroom situations before and after a course focusing on the use of representations?
- In what way does the professional vocabulary change?

## Sample, methods and data analysis

The data analysed in this study was collected from 17 mathematics pre-service teachers who studied the university course described above. All but one of the pre-service teachers were female, between 21 and 27 years old ( $M_{age}=23.2$ ;  $SD_{age}=1.5$ ) and in their sixth or seventh semester.

In order to address the research questions, we asked the pre-service teachers at the beginning and end of the university course to evaluate other teachers' teaching in four different classroom situations (learning of fractions, grade six). The classroom situations were presented in a paper-and-pencil test in the two formats text (student-teacher-dialogues complemented with pictures of the teacher-generated and student-generated representations) and comic (cf. Friesen, 2017). Each classroom situation was followed by an open-ended question: *How appropriate is the teacher's response in helping the students to solve the task? Please evaluate the use of representations and give reasons for your answer.* The narratives of the four classroom situations were designed in a similar way: A group of students struggle with solving a task, they show the teacher their workings with a certain representation register (e.g., calculation, written symbols) and ask the teacher for help. Initially, the teacher tries to support the students with a verbal explanation. As they still do not understand, the teacher changes the representation register (e.g., by making a sketch or drawing). However, the teacher does little to connect the student-generated and the teacher-generated representations and there is no support for the students to see that the different representations belong to the same

mathematical object. Based on the theory of learning with multiple representations as outlined above, such unconnected conversions are very likely to cause further problems in the students' understanding. The teacher's response can therefore be evaluated as not appropriate for helping the students in all of the four classroom situations.

As the 17 pre-service teachers were asked to analyse four classroom situations before and after the university course, 136 written answers could be examined for this study. In order to extract the professional vocabulary from the pre-service teachers' answers, we adopted a method previously developed with similar research involving in-service teachers (Friesen, Mesiti & Kuntze, 2018). We were interested in identifying change with respect to the professional vocabulary in use by pre-service teachers before and after the course, hence, the answers from the pre-test and the post-test were analysed separately. As a first step, lexical items (nouns, verbs, adjectives, adverbs carrying the meaning of the sentence) were extracted from the pre-service teachers' written answers. As classroom phenomena were also described using terms which were non-lexicalised (i.e. not expressed as a single word), we included such terms in a second step of analysis. In the next step, we grouped the extracted terms in lexical categories which we had derived in our prior study (Friesen, Mesiti & Kuntze, 2018): (1) terms related to general pedagogical practices which are not specific to the mathematics classroom, (2) terms related to mathematical content and to practice specific to the mathematics classroom and (3) terms related to representations and their use in the mathematics classroom including stages of representations, representation registers, changes of representations and the connection of registers. Figure 1 shows these steps of analysis for a pre-service teacher's answers from the pre-test and the post-test (same classroom situation).

<p>Ich finde die Erklärung am Zahlenstrahl nicht wirklich geeignet, da es auch eine formale Erklärung ist.</p> <p>Die erste Erklärung (<math>\frac{2}{3}</math> geht öfter in 6 als 1) finde ich verständlicher. Das könnte ikonisch dargestellt werden, um eine anschauliche Erklärung zu geben.</p> 	<p>I think that the <b>explanation with the number line</b> is not really appropriate because it is also a <b>formal explanation</b>. I find the first <b>explanation</b> (<math>2/3</math> go more often in 6 than in 1) is easier to <b>understand</b>. This could be <b>represented iconically</b> in order to give an <b>illustrative explanation</b>.</p> <p><b>(pre-test, written analysis for classroom situation 1)</b></p>
<p>Es ist gut, dass die Lehrperson andere Darstellungen verwendet und es nicht nur anhand der Rechnung zu erklären versucht.</p> <p>Ich finde es nicht gut, dass die Lehrperson zwei verschiedene Darstellungen nutzt (vielleicht wie oft passt <math>\frac{2}{3}</math> in 6, am Zahlenstrahl, Rechenoperationen).</p> <p>Sie verknüpft diese Darstellungen nicht miteinander. ## Results

The analysis of the pre-service teachers' written responses for professional vocabulary resulted in the extraction of 422 terms (pre-test) and 359 terms (post-test). Figure 2 indicates that the share of terms related to representations and their use in the mathematics classroom has increased from pre-test to post-test (from 38% to 52%).

**Figure 2: Extracted terms organised in lexical categories, pre-test and post-test**

A closer examination of the terms that were most frequently used to describe phenomena of the presented classroom situations reveals that there was little change between pre-test and post-test concerning the lexical categories (1) general pedagogical practices and (2) mathematical content/practices. The terms that were most frequently used to describe general pedagogical practices were *(to) explain/explanation* and *(to) understand/understanding* both in the pre-test and the post-test. The terms that were most frequently used to describe content and practices specific to the mathematics classroom were *fraction*, *(to) divide*, *(to) multiply* and *result* both in the pre-test and the post-test. This is very similar to the terms most frequently used by in-service teachers when analysing the same classroom situations (see Friesen, Mesiti & Kuntze, 2018 for a list of terms). The change in the pre-service teachers' professional vocabulary from pre-test to post-test became visible in the lexical category grouping terms related to representations and their use in the mathematics classroom. First, we compared the shares of subcategories, as can be seen in Figure 3. About half of the terms related to representations were used to describe different representation registers. The share of terms used to describe stages of representations decreased from pre-test to post-test, whereas, in the post-test, more terms were used to describe classroom phenomena related to changes of representations and the connection of registers; both essential aspects for learning with representations.

**Figure 3: Terms related to representations, change in subcategories between pre-test and post-test**

The terms changed, however, not only regarding their number but also regarding quality. In the case of terms used for describing registers of representations, we found for the pre-test that besides the specific terms *number line*, *diagram*, *drawing* and *pizza*, the general term *representation* was used 45 times to describe very different kinds of registers in the four classroom situations. In the post-test, the pre-service teachers used the general term *representation* only 15 times. Instead, terms with *register* appeared 15 times to describe the same phenomena (e.g., diagram register, drawing register, verbal register etc.) or the pre-service teachers extended the word *representation* by adding a more specific description, e.g., *representation with pizzas*, *iconic representation*, *verbal representation*, etc. In the case of terms for describing changes of representations, the pre-service teachers used terms such as *choose* or *use another representation* in the pre-test. The most frequent terms for describing changes of representation were constructions with *illustrate*, such as *illustrate the problem with pizza slices* (2 and 8 times, respectively). In the post-test, more specific terms such as *change of representations* and *conversion* could be found in the answers (6 and 12 times, respectively).

## Discussion

Whereas the language used by students and teachers in the mathematics classroom plays an essential role in mathematics teacher education and corresponding research, the professional language teachers use for analysing classroom situations and describing classroom phenomena has so far garnered less attention. The argument that teachers are not likely to identify and interpret classroom phenomena that they cannot name underlines, however, the importance of supporting the development of a professional lexicon as part of teacher education programmes. The aim of this study was to document pre-service teachers' professional lexicon with a focus on representations and to examine if pre-service teachers' use of professional vocabulary changes when they learn to analyse classroom situations in a university course. Although this study is limited to a small sample and to analysing the use of representations, its findings encourage further research into this topic and further development of the applied methods. The documentation of the pre-service teachers' professional vocabulary before and after the course revealed a change concerning several aspects: First, the pre-service teachers' lexicon concerning multiple representations and their use appears to have grown and has become more specific at the same time; additionally, the professional vocabulary used in the post-test is, for example, characterised by a wider range of terms for aspects that play a central role for learning with multiple representations (changes of representations, connection of registers) and also indicates a greater level of specificity regarding terms related to registers of representation. It might be concluded that having a name for certain registers can help to identify them whereas identifying different registers of representation can be seen as necessary prerequisite to identify conversions and to interpret them as potential learning obstacles. The relation between teachers' professional vocabulary and their corresponding competence of analysing should consequently be investigated in more depth. A next step is to bring together the documentation of teachers' professional vocabulary and their competence scores when analysing classroom situations regarding specific criteria.

<sup>2</sup>State University of Campinas – UNICAMP, Brazil; [cmribas78@gmail.com](mailto:cmribas78@gmail.com)

*In this work, we focus on the meaning prospective mathematics teachers assign to a set of students' productions and the feedback provided to these students. Based on these findings, we discuss prospective teachers' interpretative knowledge required for providing a fruitful feedback to students, having their reasoning as the starting point. Data collection (written responses) for this investigation took place at a workshop involving 19 prospective teachers from a Chilean university. Thematic analysis of their responses revealed two distinct types of feedback, namely that grounded in the nature and focus of the interpretation provided, and that focusing on the content of prospective teachers' knowledge.*

*Keywords: Mathematics teachers' interpretative knowledge, error analyses, teachers' feedback.*

## Introduction

Teachers' knowledge is one of the core factors considered when developing highly demanding mathematical practices (Ball, Thames, & Phelps, 2008). Thus, in that sense, it is essential to focus on the content of such knowledge and, in particular, on the dimensions that would allow teachers to develop such mathematical practices, having the students' own reasoning and understanding as a starting point for the mathematical discussions, as well as for determining the feedback to be provided to these students. By better understanding the provided feedback, the aim is to enrich (prospective) teachers' knowledge and experience related to teaching practice. The knowledge grounding such type of practice is perceived as specialised.

In order to deepen and broaden our understanding on the content of teachers' interpretative knowledge and promote its development, we have been developing tasks for teacher education with a specific focus of developing teachers' knowledge (e.g., Jakobsen, Ribeiro, & Mellone, 2014; Policastro, Mellone, Ribeiro, & Fiorentini 2018, submitted). We have been using tasks that probe into teachers' interpretative knowledge in different teacher education contexts (initial, continuous, and complementary) as a prompt to orchestrate mathematical discussions (Bussi, 1996). The aim is to develop the solvers' awareness (Mason, 2001) and specialised knowledge—in this case, the Mathematics Teachers' Specialized Knowledge (Carrillo et al., 2018). Such specialised knowledge would permit teachers to give meaning to non-standard student reasoning (Mellone, Jakobsen, & Ribeiro, 2015), as well as to better understand the causes of students' errors (Tulis, 2013), thus treating them as real learning opportunities in Borasi's (1994) sense.

In the scope of a broader project, the aim of the present study is discussing secondary prospective teachers' Interpretative Knowledge (IK) based on the feedback they provide to students when analysing and commenting on productions students provided to a specific mathematical problem.

## Theoretical Framework

Shulman (1986) emphasised the need for integration of pedagogical and disciplinary knowledge in teacher education. Other researchers contributed to the mathematics teacher development, proposing

to move away from a segregated and advanced training in “pure” mathematics to focus on the development of specialised knowledge that allows the teacher to teach mathematics. Amongst several teachers’ knowledge conceptualisations that have emerged, in the scope of the work we have been developing, we assume the specialised nature and content of teachers’ knowledge in the sense of the Mathematics Teachers Specialized Knowledge (MTSK) conceptualisation (Carrillo et al., 2018). Teachers’ specialised knowledge grounds teachers’ interpretations of the students’ comments and productions (e.g., Di Martino, Mellone, Minichini, & Ribeiro, 2016).

Interpretative Knowledge is perceived as the knowledge that allows teachers to give sense to pupils’ answers, in particular to those that contain errors, or to “non-standard” solutions, i.e., adequate answers that differ from those teachers would give or expect (Jakobsen et al., 2014). It sustains the teachers’ ability to support the development of pupils’ mathematical knowledge, starting from their own reasoning, even if students’ ideas are incomplete and/or non-standard. Moreover, IK is associated with the notion of discipline of observation and, in particular, with the idea of teachers working “on becoming more sensitive to notice opportunities in the moment, to be methodical without being mechanical” (Mason, 2001, p. 61). Such knowledge thus allows teachers to consider errors and non-standard reasoning as learning opportunities (Borasi, 1994; Mellone et al., 2015).

One way to enrich prospective teachers’ interpretive knowledge is to offer opportunities to face student productions and to provide and discuss feedback, as part of their teaching practice. The term feedback is defined as “information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one’s performance or understanding” (Hattie & Timperly, 2007, p. 81). The feedback can be constructive, i.e., one that includes hints, corrections, examples or explanations. Kulhavy and Stock (1989) termed this type of feedback as elaborative and defined it as any method that goes beyond indicating only the answer is correct or incorrect. Still, there is no consensus that providing elaborative feedback benefits learning more than simply indicating whether the answer is correct (Shute, 2008). Some authors even argue that complex and detailed information can counteract the effectiveness of feedback. Santos and Pinto (2010) studied the evolution of written feedback provided by a middle school mathematics teacher, reporting that her feedback evolved, developing plasticity, adjusting to the specific students or to the tasks, creating reflection moments by delivering elaborate clues, and encouraging the correction of the situation.

In the present study, we examined prospective mathematics teachers’ interpretative knowledge by analysing the feedback they provided to students. The quality of the feedback has been the greatest influence on student performance (Black & Wiliam, 1998), thus opportunities for interpreting students’ productions are perceived as chances for improving feedback and students’ learning.

## Methods

In the present study, we focus on the answers given by 19 prospective mathematics teachers (PTs), who worked in small groups on interpreting students’ productions related to a math problem adopted from Cañadas, Castro, and Castro (2008). Most participating PTs were in the seventh semester of a 10-semester course and had already completed courses in mathematics, pedagogy, and mathematics education, and had some school practice experience.

The tasks were conceptualised following a particular design (e.g., Ribeiro, 2016; Ribeiro, Mellone, & Jakobsen, 2013), whereby the first part focused on accessing and developing PTs’ MTSK, while

the Interpretative Knowledge – Interpretative Task – and the provided feedback was examined in the second part. Here, we focus on this last part of the task, as the goal is to examine PTs' IK when interpreting students' productions and the feedback provided. In the first step of the task implementation, PTs were required to solve a problem that would later be explored with their students (Figure 1).

Complementarily, PTs were asked to refer to and reflect upon their own difficulties when solving the problem. In the next phase of the task, PTs were provided with three student productions, and were required to give meaning to each one of these productions, as well as provide what they consider to be a fruitful feedback to each student. The productions included in the task either contained errors, were incomplete, or involved a non-standard approach to problem-solving. Here, we discuss some productions included in the task, as shown in Figure 2(a)–2(c).

Imagine you have white and grey square tiles of the same size. We make a row with the white tiles and then surround the white tiles with grey tiles, as the drawing shows:

1. How many grey tiles would you need if you had 1320 white tiles and wanted to surround them in the way you did in the drawing?

2. How many grey tiles are necessary for any number of white tiles?

**Figure 1: Tiles problem (Cañadas et al., 2008)**

Through the proportions, you can determine the number of grey tiles needed:

5 white → 16 grey  
 1320 white → x grey  
 $x = \frac{1320 \cdot 16}{5}$ ;  $x = 264 \cdot 16$ ,  $x = 4224$  grey tiles.

**Figure 2(a): Camilo's productions**

$5 \rightarrow 16$   
 $1320 \rightarrow x$

$x = \frac{1320 \cdot 16}{5}$   
 $x = \frac{21120}{5}$

(1) Grey tiles  $x = 4224$   
 (2) According to the relationship that occurs in the rule of three (5 is to 16, as x is to y).

**Figure 2(b): Araceli's productions**

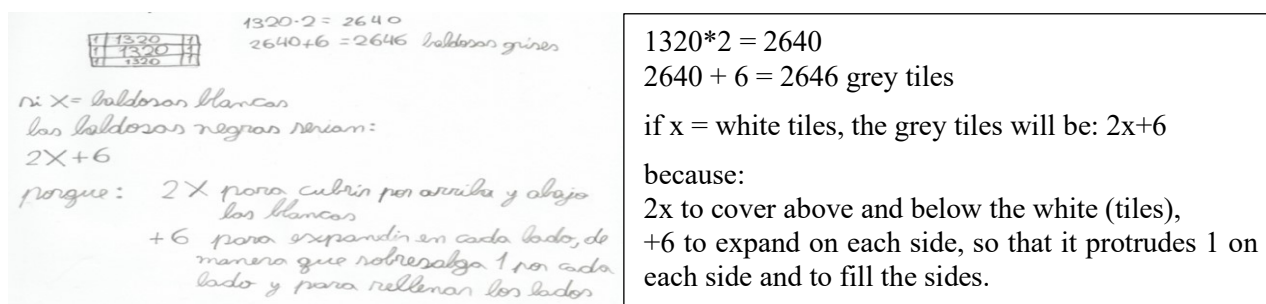

Figure 2(c): Javier's productions

The data utilised in the analyses included PTs' productions when solving the Interpretative Task, focusing on PTs' perception of the problem difficulty and the feedback given to three students based on the solutions offered. The written feedback that the prospective teachers provided to the students' answer was analysed categorizing the emergent feedback.

## Analyses and discussions

Data was analysed in two phases. As noted earlier, all participating PTs were first asked to solve the problem in small groups and discuss any difficulties they encountered. In the next phase, feedback the PTs provided to Camilo and Aracelli based on their productions was discussed (these students utilised a similar strategy for solving the problem).

### Difficulties in solving the problem

Eight of the nine groups of PTs solved the problem correctly, while the remaining group adopted the "rule of three" which yielded incorrect answer (Figure 3). When this group examined the solutions provided by other PTs, they were able to identify their mistake (pertaining to task interpretation) and subsequently provided a correct answer.

Figure 3: Mistake in understanding the problem

Concerning the PTs' difficulties, four out of nine groups stated that they had difficulty understanding how to represent the figure when the number of tiles increased (e.g., "We doubt how the white tiles were placed."; "Yes, because we did not know in what way the tiles would be grouped."). These results confirm that PTs had difficulties in understanding the statement of the problem, even though the manner in which the tiles should be grouped was explained explicitly in the problem statement "we make a row of white tiles" (see Figure 1).

### Categorising the feedback

Most of the PT groups pointed out that both Camilo and Aracelli (Figure 2(a) and (b)) solved the problem by incorrectly applying the "rule of three" without giving further explanation of how they should have proceeded, while some groups provided indication on the way the problem should be addressed. When analysing the feedback provided to these two students based on their productions, four categories emerged in relation to Camilo's and Aracelli's solutions:

- (i) Feedback on how to solve the problem: Guide on how the students should proceed to solve the problem, particularly stating that they should think inductively.

- (ii) Confusing feedback: When the feedback seems to be correct, but it can be confusing for the student.
- (iii) Counterexample as feedback: An example is used to refute the error exposed.
- (iv) Superficial feedback: The content of such feedback was insufficient (too broad or inconsistent) to allow the solver to understand its meaning.

### (i) Feedback on how to solve the problem

Two PT groups focused their feedback on explaining to the student how he/she should proceed in order to solve the problem. They specifically indicated that the problem should be approached inductively, suggesting that the student should think what happens if there is one white tile before considering, what happens if there are two, three white tiles and so on. How many grey tiles would there be in each case? Then, they prompted the student to think about what happens in general terms. We observed that these PTs could correctly interpret the students' mistakes, and thus indicate the correct approach to solving the problem.

### (ii) Confusing feedback

One of the groups focused on explaining why the number of grey tiles is not proportional to that of the white tiles. They stated that "proportional thinking should not be used, since the number of grey tiles does not increase by the same amount as white tiles; thus, they are not proportional" (see Figure 4).

d) Realizar por proporción la actividad es decir  
cada 5 baldosas blancas hay 16 grises

$$\frac{5}{16} = \frac{1320}{x}$$

$$x = 4224$$

la manera de abordar el problema es errónea  
ya que no se usa el pensamiento proporcional ya que  
la cantidad de baldosas grises no aumenta en la misma  
cantidad que las baldosas blancas por lo tanto no son propor-  
cionales.

Entonces si podemos afirmar  
que las baldosas que están  
arriba y abajo de las baldosas  
blancas están en proporción  
si contar  
los bordes

después preguntar ¿que pasa con ~~los bordes~~ la cantidad  
de baldosas en los bordes, cuando aumentan o disminu-  
yen las baldosas blancas?

Para llevar a que el alumno haga la conexión entre la cantidad de baldosas  
superior e inferior más la baldosa de los bordes, de ~~aprox 1320~~ 1320  
para que generalice para cualquier número de baldosas blancas.

Perform the activity by proportion, that is, for every group of 5 white tiles, there are 16 grey tiles.

$$\frac{5}{16} = \frac{1320}{x}, x = 4.229.$$

The way to approach the problem is erroneous, since proportional thinking should not be used, because the number of grey tiles does not increase by the same amount as the white tiles. Therefore, they are not proportional. So, yes, we can say that the tiles that are above and below the white tiles are in a 1:2 ratio, not counting the edges.

Then ask what happens with the number of tiles at the edges when the white tiles increases or decreases? Lead the student to make the connection between the number of upper and lower tiles plus the tiles at the edges before prompting him/her to generalise for any number of white tiles.

Figure 4: Confusing feedback

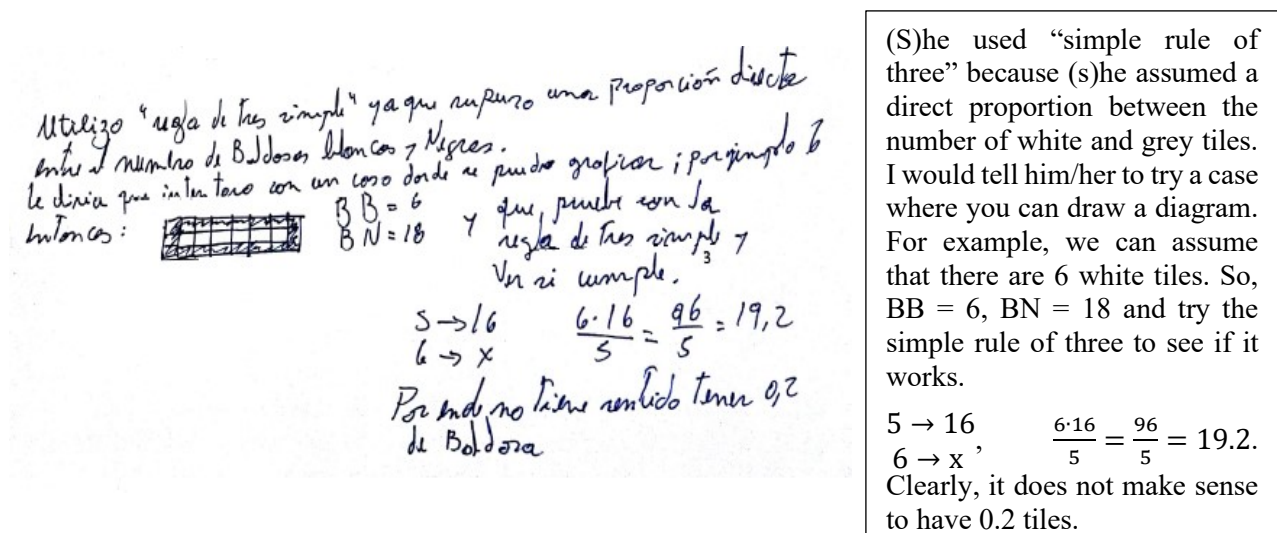

We posit that the last expression can lead the student to incorrectly conclude that, if the number of grey tiles increases/decreases by the same amount as that of the white tiles, those variables are proportional. Instead, feedback should focus on the fact that the number of tiles does not increase/decrease “by the same proportion.”

Second, they stated, “we can affirm that the tiles that are above and below the white tiles are in proportion 1:2, without counting the edges.” Thus, they explained when the figure would be proportional. Although this reasoning is true, it could be confusing to the student, because the problem is not one of proportionality. As a result, this was termed as *confusing feedback*. In sum, although the PTs in this group could interpret the students’ mistakes, when providing an elaborated feedback, they opted for a rather complex solution, which can confuse the students.

### (iii) Counterexample as feedback

Two groups used a counterexample to respond to the student (Figure 5). In this excerpt, a group provided feedback suggesting that the student should draw a figure for the case of 6 white tiles with their 18 grey tiles (if proportional), while also applying the “rule of three” that would yield 19.2 grey tiles. The group interpreted this as a contradiction, along with the impossibility of having 0.2 tiles. However, it would have been more informative to argue that there is no multiplicative relation between white and grey tiles.

This group used a *counterexample* in their feedback to confirm that the number of grey tiles is not proportional to that of the white tiles. The use of a counterexample requires that the teachers have a comprehension of the mathematics knowledge involved in the problem (KoT), as this would allow them to provide an explanation for student’s errors. From the MTSK perspective, teachers are required to have the mathematics knowledge of the theme that allows approaching the problem in the correct way, but also ability to explain why other ways do not work. Explaining why something is incorrect requires interpreting the students’ reasoning and building feedback on these mistakes.

Handwritten student work (left):

Utilizo “regla de tres simple” ya que supuse una proporción directa entre el número de baldosas blancas y negras.  
 le diria que intentara con un caso donde se pueda graficar; por ejemplo 6  
 entonces:   $BB = 6$   $BN = 18$  y que pruebe con la regla de tres simple y ver si cumple.  

$$\begin{array}{l} 5 \rightarrow 16 \\ 6 \rightarrow x \end{array} \quad \frac{6 \cdot 16}{5} = \frac{96}{5} = 19,2$$
  
 Por ende no tiene sentido tener 0,2 de baldosa

Typed transcription of feedback (right):

(S)he used “simple rule of three” because (s)he assumed a direct proportion between the number of white and grey tiles. I would tell him/her to try a case where you can draw a diagram. For example, we can assume that there are 6 white tiles. So,  $BB = 6$ ,  $BN = 18$  and try the simple rule of three to see if it works.

$$\begin{array}{l} 5 \rightarrow 16 \\ 6 \rightarrow x \end{array}, \quad \frac{6 \cdot 16}{5} = \frac{96}{5} = 19.2.$$

Clearly, it does not make sense to have 0.2 tiles.

Figure 5: Counterexample as feedback

### (iv) Superficial feedback

Some of the feedback on Camilo’s and Aracelli’s productions was *superficial*, that is, too vague for a clear understanding by the student. For example, PTs stated: “I would ask what is proportion, so

that [students] can argue if it can actually be used in the exercise,” or “I would ask if the rule of three is used for all cases. . . . Analyse if there is a proportion to apply the rule of three.” The nature of such feedback would neither allow students to understand their mistakes nor to envisage how to proceed in order to solve the problem correctly.

### Some final comments

Some prospective mathematics teachers experienced difficulties in understanding and interpreting the posed problem, which is in the space of problems (and content) they will need to work on with their students in the near future. This finding highlights the need for enhanced preparation that would ensure that prospective mathematics teachers can solve the problem independently in order to, at least, be able to perceive a correct typical answer (Ribeiro et al., 2013).

Data analysis further revealed two dimensions of feedback study participants provided to students: the nature and focus of the interpretation provided, and the content of prospective teachers' knowledge. In the feedback on *how to solve the problem*, the groups focused on explaining how students should proceed in order to obtain the correct solution, disregarding explaining why the original answer was incorrect. Feedback that was classified as *confusing feedback* and *counterexample as feedback* focused on explaining why there is a mistake. Such feedback is particularly linked with the elements of PTs' space of solutions, usually referred to as having a single approach to guide to students (Jakobsen et al., 2014). Further, when the PTs attempted to provide elaborate feedback, they supported their explanations with erroneous arguments, or worded it in a way that can be confusing for the students. These feedback categories reveal some critical points that need to be addressed in teacher education in order to enrich and expand the *superficial* or *confusing feedback*, empowering a meaningfully interpretation that should have students' reasoning, knowledge, and understanding as a starting point for the mathematical discussions to be developed.

# Using participant generated influence maps to gain insights into the influences on early career primary teachers' teaching of mathematics

Alison Godfrey

University of Leicester, United Kingdom; [ag384@le.ac.uk](mailto:ag384@le.ac.uk)

*Set within a study looking to understand influences on early career primary teachers' teaching of mathematics through analysis of the personal perspectives of eight participants, this paper discusses the use of a 'visual data' approach. Participants were asked at the end of the two-year research period to create maps showing the relative and overlapping influences on their development over the previous two years as teachers of mathematics, describing their thinking to the interviewer as they did so. Deeper and broader responses have resulted, giving richer data than using verbal data alone, whilst this approach has proved to be a very interesting and motivating experience for the participants. New insights have emerged as to how early career teachers see the influences on their development as teachers of mathematics.*

*Keywords: Teacher characteristics, professional development, elementary school mathematics, research tools.*

## Introduction

This paper outlines how a participant generated visual technique contributed to a study that seeks to gain insights into the influences on early career primary teachers' teaching of mathematics.

Whilst there is a minimum required mathematical qualification for all those entering the teaching profession in England, early career teachers have varied mathematical backgrounds, attitudes and beliefs about the subject. They enter a complex and changeable educational landscape where schools have considerable freedom in the organisation of their mathematics teaching and offer varied opportunities for professional development (Advisory Committee on Mathematics Education, 2013). The study followed eight primary school teachers through their first two years of teaching and sought to answer the research question: How do factors related to the teacher themselves and factors related to the school context combine to influence the development of early career primary teachers' teaching of mathematics? The participants entered the teaching profession with a range of mathematical backgrounds and all studied for their teaching qualification at the University of Leicester.

The aim of the tool outlined in this paper was to support participants to articulate their views on the influences on them as early career teachers of mathematics, and the connections between these influences. Participant-generated visual data had been successfully used in previous interviews and similarly this new tool was developed to achieve greater depth and breadth in interview responses than from purely verbal techniques, enabling participants to have more control over their responses whilst providing some structure. In addition, the tool was designed to be interesting and motivating, both as an ethical end in itself and to encourage participants to give the fullest responses possible.

## Theoretical background – influences on teacher development

The literature identifies a number of potential influences on teachers as they develop their teaching of mathematics, relating both to the teachers themselves and their school context. These include a

teacher's beliefs, their background, including the interrelated aspects of subject knowledge, attitudes to mathematics and emotions, and their proactivity in response to reflection on their practice within their school community.

A teacher's beliefs about what makes a good mathematician can influence their practice (Ernest, 1989). Ernest considers, for example, that those who believe mathematics to be about accumulating skills and rules see themselves as "instructors, aiming to develop skills mastery in their pupils, while those who see mathematics as a unified body of knowledge to be understood, see themselves as "explainers", aiming to develop conceptual understanding of this knowledge in their pupils. Recent discussions in the UK about a mastery approach in the teaching of mathematics are in line with the relational understanding described by Skemp (1976) and have focused on securing "a deep, long-term, secure and adaptable understanding of the subject" (NCETM, 2015), but it cannot be assumed that all teachers seek to teach for this type of understanding.

Building on Shulman's seminal papers (1986, 1987), researchers have acknowledged that a teacher's subject knowledge in various forms influences their practice. Askew et al. (1997) found that the connectedness of teachers' subject knowledge "in terms of the depth and multi-faceted nature" of the meanings and uses of concepts in mathematics (p. 69) is particularly influential. Ball, Thames, & Phelps (2008), for example, emphasise the importance of Specialised Content Knowledge (SCK), knowledge that is specific to teachers of mathematics, enabling them to explain procedures, analyse errors and consider appropriate examples. Additional background elements that teachers bring to their classroom practice are their own emotional disposition towards mathematics and perceived competence in the subject (Di Martino & Zan, 2010).

A teacher's practice can change over time, influenced by their personal reflection on practice and proactivity to make changes within the context of their teaching community (Turner, 2008). Although the influence of their school context is likely to have a significant impact on an individual teachers' professional development opportunities, the community within the school might have a range of different foci and agendas (Levine, 2010) and the current provision for Continuing Professional Development (CPD) for teachers in England is fragmented and inconsistent between schools (ACME, 2013).

My study seeks to extend the existing literature, particularly exploring the relative importance and interconnected nature of these factors through highlighting teachers' own perspectives.

## **Visual Data**

There is agreement in the literature that participant-generated visual data, i.e., that "generated through the data collection process" (Wall, Higgins, Hall, & Woolner, 2013, p. 3), can provide additional and complementary data to verbally answered interview questions (e.g., Prosser, 2007; O'Kane, 2000). It can add breadth and depth, facilitate deeper thinking and assist participants to reveal additional information, views and emotions that may not have been revealed through verbal questioning alone. It is also empowering, giving participants a greater voice in the research process and allowing them more control over the content of the discussions (O'Kane, 2000), and it can be motivating and fun for the participants (Wall et al., 2013).

A range of tool designs have been used in educational research to support visual data collection. *Q-sorting* involves the sorting of statements into a defined template alongside or in addition to a verbal interview. Data can be analysed quantitatively and thus statistical comparisons can be made between participants, offering an in-depth and systematic approach to analysing subjectivity (Thomas & Watson, 2002). *Diamond ranking*, similarly, is a technique that can be used within interviews to explore the participant's perceptions or ideas, as they rank images or statements within a nine-section diamond-shaped structure (Wall et al., 2013). Usually, the activity of ranking these is accompanied by the participant talking through their rationale for how they placed the items within the diamond structure and the sorting exercise acts as a stimulus for discussion.

Although the literature reviewed suggests visual techniques can be valuable to the researcher, the quality of data is dependent on the quality of the facilitation and how the data relates to other data being collected (Wall et al., 2013). A full rationale is therefore needed for the use of my approach and how verbal questioning was used alongside the visual strategy.

## Methodology

An initial interview at the end of their one year postgraduate teaching course focused on each of the eight participants' relationship with, and attitude to, mathematics and their progress in teaching the subject as a student teacher. Twice yearly interviews over the following two years, including discussion of documentation related to their progress as early career teachers, provided evidence on their ongoing development as teachers of mathematics. Interview questions were designed to probe the participants' beliefs, attitudes and subject knowledge for teaching mathematics, what they perceived to be the characteristics of effective teachers of mathematics and their perspectives on their development as teachers of the subject. Within each interview they also talked about two particular lessons: their chosen *best* and *most challenging* lessons since the previous interview. Participant-generated visual data was a particular feature of the interviews, which combined verbal questioning with a range of visual tools, including participants graphing their relationship with mathematics (Godfrey, 2017), visually organising statements about subject knowledge and discussing points about secure learning in mathematics from concept cartoons (Samková & Hošpesová, 2015). Through these means evidence was collected of factors influencing their development as teachers of mathematics.

For the final interviews of the project, I developed a new visual tool to assist participants in talking in greater depth and breadth about the influences on them as a teacher of mathematics and in particular to discuss the relative importance of these factors and the way the factors combined. Given the longitudinal nature of the study, a secondary purpose was to ensure that the interview was interesting and motivational since visual techniques could provide variety and interest (Wall et al., 2013).

Rather than using an open question such as, "What has influenced you as a teacher of mathematics?", I decided to provide some prompts to ensure that participants discussed the likely influences the literature suggested would have an impact on their trajectory as teachers of mathematics, even if only to discount these, thus ensuring breadth in responses. Four prompts were provided: "My own background as a learner of mathematics and my feelings about the subject" (labelled *background* on the photographs below and aimed at participants considering their own subject knowledge, attitude to mathematics and emotions); "My beliefs about what makes a good mathematician" (labelled

*beliefs*); “My school context and changes within the school context – i.e. the influences that I have had from being here in this particular school” (labelled *school*); “My own self-imposed changes/actions through my proactivity and reflection on practice” (labelled *reflection*).

In order to ensure that the participants considered the relative influence of these labels, and where they overlapped, circles of translucent plastic in different sizes and colours were provided. Each participant was asked to match the largest influence to the largest circle, the second largest influence to the second largest circle, and so on. They were then asked to arrange the circles to match the impact of these influences and the relationship between them, overlapping them if appropriate, and to verbalise their thinking as they did so (see Figure 1). Thus, an interactive approach was used, with some structure given for their thinking, but without the constraints of diamond ranking or q-sorting. Participants were free to create and adapt their mapping to fit their way of thinking.

**Figure 1: Rama's influence map**

Various follow-up questions were planned that could be used to further probe about the impact of these influences, for example: “How do you think having a strong maths background has impacted on your teaching of the subject? Has your attitude to teaching mathematics changed? What are your beliefs about what makes a good mathematician? Have you felt well supported by your school in these first two years of teaching? How do you feel about changes imposed by your school? What motivates you to develop your own practice?”

The design of the tool facilitated detailed narratives from individuals, gave them some control over the content of the discussion and allowed comparison between participants.

## Findings

In considering the relative influences of the factors and how these overlapped, participants reflected on how, why and to what extent these influences were connected, thus giving a depth of response that might not have been communicated purely verbally. Rama, for example, explained:

The most important [...] is my proactivity and reflection on my practice. [...] I always like to reflect on my lessons and try to make it better. I always try and think, was it right for my children, was it not, let's change it a little bit. [...] This [reflection] goes with this [beliefs] because I have really strong thoughts of what makes a good mathematician and how it should be taught in a lesson and what I want to get out of the children [...] that's helped me to reflect, if that makes sense.

Participants varied the extent to which they overlapped circles to show the significance of connections. This can be seen on Rama's map (figure 1) where there is a larger overlap between reflection and beliefs than between school and beliefs. This second overlap was created as she discussed working alongside a colleague with similar beliefs: "We actually want the same thing – we've both thought let's change it and not try to use the workbooks".

The structure of the influences map seemed to be effective in supporting participants' articulation of ideas, which they might not otherwise have discussed, thus giving additional breadth to the data collection. The use of the cards meant that participants had to mention aspects that for them had little or no influence – data which would probably not have been obtained from a straight verbal question.

Gina commented:

My own self-imposed changes are probably the least because there's been so many other things that have to be put in place that I've had to just go by the wayside with those.

Without prompting, Gina may not have mentioned this; her comments support the overwhelming influence of her school context (figure 2).

**Figure 2: Gina's influence map**

For some participants, the influence map prompted their thinking beyond the structure I had proposed. Penny, for example, used the four cards as a starting point to consider additional elements in her personal situation. She was keen to stress that the impact of her school context was very small, other than being sent on courses, one specific course in particular. She described the impact that this one hour mathematics course had on her practice due to gaining both new ideas, which she implemented from the following day, and renewed enthusiasm for implementing changes in her teaching of mathematics: "The course was brilliant – just gave you that impetus to carry on, gave you ideas to do, spot on". We improvised to create a further map label for *courses* and also for *research*, referring to my project, which she considered of particular significance because it caused her to reflect, look back at her practice and consider changes she could make. Summing up how my previous interview had caused her to reflect and change her practice, she said, "I relooked at everything after your last visit."

Penny's final map is shown in figure 3. Again, the overlapping here is interesting, with other influences strongly linking with the learning she gained from the course and a strong connection shown between the influence of being involved in my research and her reflection.

**Figure 3: Penny's influence map**

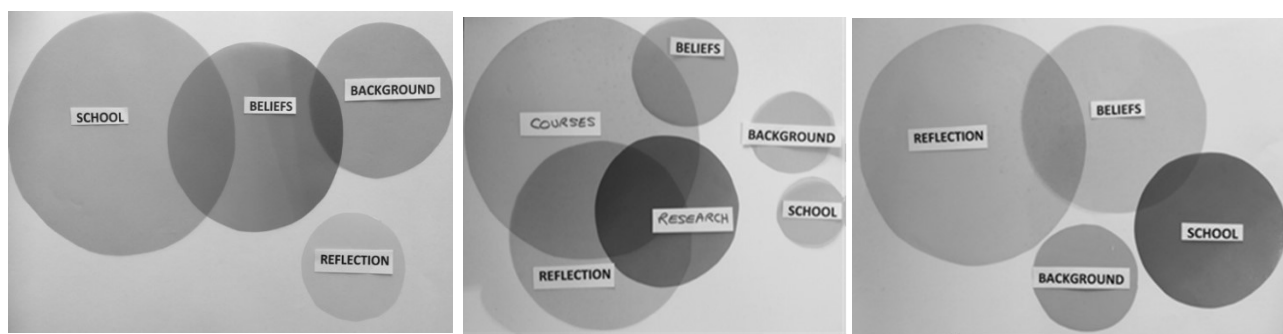

The control that Penny and others took over the use of the map to express their opinions demonstrates that a benefit of using the tool was the ready engagement of participants who had already been interviewed several times. This aspect was further evidenced by specific comments made by Rahim, who clearly found the process stimulating:

That was a really good opportunity for me to reflect on what different things have influenced me and how I feel like I've progressed based on different elements, so that was a really helpful exercise.

As illustrated above, the analysis of the data from the influences tool is enhanced with the addition of the verbal data given alongside the visual. From this starting point, further analysis is being undertaken to explore other evidence of these influences from earlier interviews. Interview data has been summarized using a mind mapping technique to facilitate this process. Individual narratives are being developed and some comparisons made between cases, including those with different qualifications and interest in mathematics.

A brief example of how the visual and verbal data from the creation of the maps is being integrated with other data comes from one element of Gina, Penny and Rama's maps (Figure 4). These maps show a very contrasting picture of what they feel has influenced their development as teachers of primary mathematics, but for all the influence of their background as a learner of mathematics and their feelings about the subject ('BACKGROUND') was considered a relatively small influence. Gina, who has the weakest mathematical background of the three, overlapped the circles relating to her beliefs and background, giving the following commentary as she created her map:

I think my own background always sticks in my mind because I know there were things that I feel like I didn't learn well enough that really impacted me later on, so I'm very hyper aware that when children don't get something that we can't just leave them there.

**Figure 4: Contrasting influence maps: Gina, Penny and Rama**

Penny has her own mathematical background, which, in her case, includes a Master's degree in mathematics, as a separate and smaller influence than the other influences on her because, although she “loves maths”, her teaching of the subject would “just happen regardless”. Rama similarly stated that although her mathematical background was important, she “had grown as a person” since her days as a learner of mathematics. However, other evidence from across their series of interviews highlighted that both were keen to pass on their love of mathematics to children and that their strong subject knowledge was a foundation on which they proactively sought to develop their practice.

## Conclusion

Initial analysis across all the participants in the study indicates the different perceptions early career primary teachers hold of the influences on them as teachers of mathematics. Supported by the use of the influence-mapping tool, participants were explicit about the relative impact of each of the suggested influences on their development and how these influences were inter-connected. The map supported depth and breadth of responses, whilst giving the participants some control over the content of their discussions and the motivational aspect of the tool was appreciated by the participants.

Whilst not directly comparable because of participants' different interpretations of the headings used, useful insights can be drawn from the range of influence maps. The influences of the school context and self-imposed changes through proactivity and reflection on practice were strong influences for most of the eight participants. Only two placed the four influences in the same order. Even then, their maps visually contrast with differences in the way the circles were overlapped, and this is reflected in contrasting verbal narratives. Further analysis of the broad data set is being undertaken to explore how factors related to the teacher themselves and factors related to the school context combine to influence the development of early career primary teachers' teaching of mathematics.

*Researchers in mathematics teacher education are beginning to investigate the nature and development of mathematics teacher educator (MTE) expertise. Consistent with our sociocultural perspective on learning, we conceptualise mathematics teacher educator learning as participation in social practices that develop professional identities. In this study we used Valsiner's zone theory to investigate identity formation in a pair of mathematics teacher educators – one a mathematician and the other a mathematics educator – who collaborated to develop new approaches to teacher education that integrate content and pedagogy. Analysis of interviews with the MTEs traced their identity trajectories from past to present to possible futures, highlighting their capacity for individual agency in changing their environment or seeking out professional learning opportunities.*

*Keywords: Mathematics teacher educators, identity, Valsiner's zone theory.*

### Introduction

Researchers in the field of mathematics teacher education are becoming interested in how mathematics teacher educators (MTEs) themselves learn and develop (e.g., Beswick, Chapman, Goos, & Zaslasky, 2015; Chapman, 2008). The nature of MTE expertise has most often been conceptualised in terms of content and pedagogical knowledge and their interaction (e.g., Chick & Beswick, 2018; Zazkis & Zazkis, 2011), while the process of MTE development has been explained through reflective self-studies tracing growth through practice (e.g., Tzur, 2001). Our research takes a different approach, drawing on sociocultural theories of mathematics teacher development (Lerman, 2001) to propose that MTE learning is better understood in the context of social and cultural experiences that develop their professional *identities*. We view identity as a performative process of *becoming* that addresses social interactions and institutional contexts, while acknowledging that an individual's knowledge, beliefs, and attitudes can influence their identity enactment. Our study contributes to the field by extending our previous investigations of mathematics teacher identity (Bennison, 2015; Goos, 2013) to examine identity formation in mathematics teacher educators – both mathematicians and mathematics educators who teach in initial teacher education programs.

In Australia, as in many other countries, secondary initial teacher education programs are structured so that future teachers of mathematics learn the content they will teach by taking courses taught by mathematicians in the university's mathematics department, and then quite separately they learn how to teach this content by taking content-specific pedagogy courses within the university's education department. Such arrangements offer few opportunities to interweave content and pedagogy in order to develop mathematical knowledge for teaching (see Cooper & Zaslavsky, 2017, for an example of co-teaching). Integration of content and pedagogy was the aim of the study we report on here – the *Inspiring Mathematics and Science in Teacher Education* (IMSITE) project – which deliberately

fostered collaboration between mathematicians and mathematics educators in teacher education programs. The research question that gives focus to this paper is: How does interdisciplinary collaboration between mathematicians and mathematics educators shape their identities as MTEs?

## **Theoretical framework**

Our previous research on mathematics teacher identity adapted Valsiner's (1997) zone theory of child development to study interactions between teachers and their professional environments. In this paper we elaborate on Goos's (2014) mathematics teacher zone theory framework and draw on other research on MTE development to consider influences on MTEs as learners.

Valsiner (1997) extended Vygotsky's concept of the zone of proximal development (ZPD) to incorporate the social setting and the goals and actions of human participants. Valsiner redefined the ZPD as a set of emerging possibilities for development that arise when individuals negotiate their relationships with the learning environment and the people in this environment. Thus for MTEs, the ZPD represents possibilities for development of new kinds of knowledge, beliefs, and practices related to preparing future teachers (Chick & Beswick, 2018; Cooper & Zaslavsky, 2017).

Valsiner (1997) introduced two additional zones to explain human development. The first is the zone of free movement (ZFM), representing environmental constraints that may either hinder or enable access to particular areas or resources or ways of acting with resources. For MTEs, constraints might include their perceptions of the knowledge and motivation of teacher education students; the structure of teacher education programs (e.g., extent of connection between courses on mathematics, general pedagogy, mathematics teaching methods); and university organisational structures and cultures that influence timetabling, allocation of resources, and norms of what counts as "good teaching". The second new zone is the zone of promoted action (ZPA), representing the means by which an individual's actions are promoted. For MTEs, the ZPA could represent teacher education approaches promoted via reflection on their practice, their research with teachers, participation in formal professional development or informal interaction with colleagues (Chapman, 2008; Tzur, 2001).

The ZFM and ZPA are dynamic and inter-related and form a ZFM/ZPA complex that directs development along a set of possible pathways. However, individuals still have a degree of agency in changing the environment and their relationships with people in order to achieve their emerging goals. Thus identity is shaped, but not fully determined, by participation in social practices. The possibility of exercising agency within a structured social system is key to understanding identity in terms of developmental trajectories that link past, present, and future (Wenger, 1998).

## **Research design and methods**

The IMSITE project was undertaken over three years in six Australian universities and involved a team of 23 university academics who were either education specialists (mathematics and science educators) or discipline specialists (mathematicians and scientists). Its purpose was to improve the quality of teacher education by encouraging collaboration between Faculties and Schools of science, mathematics and education on course design and delivery. Within each university, these interdisciplinary teams developed and implemented approaches targeting recruitment and retention strategies that promote teaching careers to undergraduate mathematics and science students,

innovative curriculum arrangements that combine content and pedagogy, and continuing professional learning that builds long-term relationships with teacher education graduates.

This paper is concerned with the collaboration between a mathematician (Leonard) and a mathematics educator (Joanne) at one of the participating universities. We selected this pair as the focus for the paper because a zone theory analysis of their interdisciplinary collaboration reveals interesting insights into the productive tensions that shape MTE identities.

Leonard and Joanne were interviewed together by the first author at the end of the first year of the IMSITE project, and separately by the second author midway through the project's third year. They were asked to describe their prior history of collaboration, the extent of collaboration between mathematicians and mathematics educators in their university, barriers to and enablers of such collaborations, and activities that they considered to be successful in bringing together mathematicians and mathematics educators. Interviews lasted for 20 to 40 minutes and were transcribed in full.

To analyse the interview transcripts we used the approach developed in our previous research with teachers to trace identity trajectories from past to present to possible future (Goos, 2013), which allowed us to capture the temporal character of identity as a process of becoming (Wenger, 1998). We began by annotating interview transcripts to identify responses that provided information about the MTEs' past, present, and future ZPDs, ZFM, and ZPA, which we interpreted in terms of the theoretical framework outlined above. We then constructed a table for each interview with columns for the ZPD, ZFM, and ZPA and rows for past, present, and future influences. The annotated interview excerpts linking the MTEs' responses to both zonal and temporal dimensions were then electronically copied and pasted into relevant table cells, and a single summary table was produced. We inspected the table horizontally, across columns, to identify alignments and misalignments between the zones within a given time period. We inspected the table vertically, across rows, to identify events that triggered a change in alignment between ZPD and ZFM/ZPA from past to present or that could anticipate a change from present to future. This analysis aims to reveal productive tensions arising from a misalignment within the zone system that led MTEs to change their environment or seek new learning opportunities. The findings are discussed in the next section and summarized in Table 1. Interview excerpts are labelled with the relevant analytical category (ZPD, ZFM, ZPA) to illustrate the relationship between data and theory.

## Findings

The analysis begins in the temporal dimension of the *past*, and looks across the zonal dimensions of the ZPD, ZFM, and ZPA. Because the two academics had not yet begun to collaborate their identity trajectories are analysed separately here. Leonard was an applied mathematician working in the School of Mathematics and Statistics. He held a PhD in physics and also a Diploma in Education (an initial teacher education qualification for secondary school teachers) that he completed several years ago to better understand how teachers were prepared. Joanne was an experienced teacher of secondary school mathematics with a PhD in mathematics education, who worked in the School of Education in a different Faculty from Leonard. Leonard taught large undergraduate mathematics classes with students from different degree programs, while Joanne taught mathematics pedagogy subjects to

future secondary school teachers: thus both MTEs had well-developed mathematics content knowledge and pedagogical knowledge appropriate to their teaching assignments. Before the IMSITE project started they had met each other in various professional contexts. For example, Joanne had been President of the national mathematics teacher association and Leonard was involved in a mathematical enrichment program for secondary school students. Their *past ZPDs*, before joining the IMSITE project, therefore offered possibilities for development of shared knowledge and collaborative teacher education practices.

However, both MTEs reported barriers to collaboration in the form of institutional structures and cultures that defined their zones of free movement. The structure of the initial teacher education programs at this university created disciplinary “silos” that separated content from pedagogy: there was no coordination between the School of Education and the School of Mathematics and Statistics when it came to preparing future teachers. Leonard also claimed that the mathematics department was not interested in educational research.

Leonard: Educational research is always viewed as a kind of second tier research activity compared to discipline research, and compared to, say, industrial linkage research. (Interview 2; ZFM)

At the same time, Joanne found it difficult to raise the visibility of mathematics education in the university, and even within her own School and Faculty.

With respect to the zones of promoted action experienced in the past, Leonard reported having been positively influenced by two mathematician colleagues whose research had been in mathematics pedagogy. Because pedagogical research was not considered a mainstream activity in his discipline, “meeting the right human beings at the right points in time” (Interview 2; ZPA) was important for his development. He was encouraged by these colleagues to attend mathematics education conferences, where he was able to spend more time with Joanne, a regular participant. For Joanne, conferences, research with teachers and reflection on her own teacher education practice were key elements of her ZPA as a MTE.

Summarising *past* zone configurations: Leonard’s and Joanne’s MTE identities developed along mostly separate trajectories. Leonard’s past ZFM did not allow or value his development as a MTE because of established cultural norms in his department. However, he did not see this as a serious barrier.

Leonard: Given that I actually love the educational side of things, it wasn’t a problem for me. (Interview 2; ZPD)

Leonard’s past zone configuration was characterised by productive tension between his desired direction for development (part of his ZPD) and the university’s ZFM/ZPA complex, which did not seem to allow, and did not promote, a trajectory towards pedagogical research. He had attempted to resolve this tension by seeking out an external ZPA in the form of mathematics education conferences. No such tensions were evident within Joanne’s past zone configuration.

We move now to the temporal dimension of the *present*, encompassing the IMSITE project and the collaboration between Joanne and Leonard. Thus the unit of analysis is now the pair of academics.

At the time the IMSITE project began, Leonard said that his position as a relatively senior academic made it possible for him to pursue educational research collaborations that might pose a career risk for younger mathematics academics. Yet he admitted not fully understanding the disciplinary norms of educational research.

Leonard: I don't really know how it works inside an education department – each kind of discipline is like a different country with its own rules and social norms. (Interview 2; ZFM)

Future	<p style="text-align: center;">TENSION: Maintaining MTE identity trajectory after project funding ends</p>		

**Table 1: Zone theory analysis of Leonard's and Joanne's MTE identity trajectory**

Joanne described a parallel experience where she worked hard to establish her academic credibility with the mathematicians she encountered in her role as President of the national mathematics teacher association. Thus at the start of the IMSITE project Leonard and Joanne were developing the kinds

of knowledge, beliefs, and goals that would be encouraged by the project – that is, their emerging *present ZPDs* were conducive to interdisciplinary collaboration.

Nevertheless, neither Leonard nor Joanne believed that institutional factors involving, for example, teacher education program structures, academic workloads and budgets, could be overcome, even though IMSITE participants in other universities had managed to do so.

Joanne: I dismissed that idea fairly early on, even though I heard them [other IMSITE participants] talking about it. I couldn't see how it would work in my context. (Interview 2; ZFM)

Despite these difficulties, another element of Leonard's and Joanne's zone of free movement, related to their joint perception of the students they taught, gave rise to a further productive tension between their interest in collaborating and the barriers that stood in their way. Leonard taught mathematics courses and Joanne mathematics pedagogy courses in a 5-year Bachelor of Science/Bachelor of Education degree. In this program students took mathematics content subjects in the first two years, and did not experience mathematics pedagogy subjects until the third year, by which time many had dropped out of the program. This was a common program structure in Australian universities, with mathematics and mathematics education academics based in different Schools and teaching into the program but seldom interacting with, or even knowing, each other. Joanne recounted a crucial development that occurred when the IMSITE project brought her into closer contact with Leonard and they realised they were teaching the same students.

Joanne: I said to you, you know what? You teach the students maths and I teach them education. We should at least be sharing what we know about the students; starting to compare, contrast, talk about issues, like retention. We started talking about the fact that we would lose some of them. (Interview 1; ZFM)

Accepting what they could not alter about their institutional context (ZFM), Leonard and Joanne set about making small changes to build a sense of community and collective identity as future mathematics teachers amongst their students. To do so they developed three initiatives. The first involved social networking events that brought together beginning students who were studying mathematics, but not yet any education subjects, in the first year of their degree, and later years students who were studying mathematics pedagogy and had been on school placements. Leonard led the second initiative, which rearranged tutorials in his large first year mathematics subject so that they were timetabled and streamed to allocate all future teachers to the same tutorial class, thus helping them to identify with peers who were aspiring to a teaching career. The final initiative, organised by Joanne, was an annual mathematics education alumni conference that connected her current students with recent graduates, experienced secondary school mathematics teachers, mathematicians, and mathematics educators.

Each of these initiatives required some modification of the institutional ZFM (e.g., altering the tutorial timetable and allocation of tutors and rooms; finding times and university venues for social networking events) to bring the institutional environment into alignment with the MTEs' trajectory of identity development. The initiatives were made possible by the IMSITE project, which offered a ZPA that promoted collaboration and provided the necessary resources (e.g., funding for a project

officer). The project supported the growing academic credibility of mathematicians who were developing a non-traditional identity in educational research.

Leonard: The impact of the project is measured in a more tangible way than just counting up the number of publications and citations. So I'm very happy that I'm part of a project that's got visible positive tangible impacts. (Interview 2; ZPD)

Summarising *present* zone configurations: the IMSITE project appears to have created a modified ZFM/ZPA complex for Leonard and Joanne that offered possibilities for these MTEs to develop new knowledge and practices for teacher education, thereby expanding their ZPDs. To the extent to which this occurred, we could say that the project developed their identities as MTEs, which now seem to be on interconnected trajectories.

Anticipating the *future* zone configurations of these MTEs raises the question of sustainability once IMSITE project funding ended. While both Leonard and Joanne were comfortable with being recognised as “champions” of a collaborative approach between their disciplines, they wished to share their experience with other mathematics educators and mathematicians, both within and outside their own university, so that their ideas could be taken up and adapted to different contexts. There was a sense, then, that their future identity trajectories would be oriented towards seeking further opportunities for collaboration.

## Discussion

In this paper we have begun to explore how interdisciplinary collaboration between mathematicians and mathematics educators can shape their identities as MTEs. Using the theoretical lens provided by Valsiner's (1997) zone theory, we have shown how individuals can exercise agency by changing their professional environment or at least their interpretation of the constraints it imposes (zone of free movement), as well as seeking out opportunities for professional learning outside their immediate environment (zone of promoted action). In addition, incorporating the idea of *productive tensions* into zone theory creates a theory of goal-directed change that can be used to understand MTEs' identity development. For example, Leonard's and Joanne's new goal of cohort building in the teacher education program motivated them to work around institutional constraints to connect mathematics content with mathematics pedagogy. We would also highlight that individuals can experience multiple and fluid identities because of their membership of different communities: Leonard and Joanne saw themselves as mathematics teacher educators who were crossing boundaries between their respective disciplines. The ways in which MTEs negotiate multiple identities, and the extent to which they can inspire others to cross disciplinary boundaries while preparing future teachers, deserves further investigation to enhance our understanding of their professional learning and development. Boundary crossing and identity formation of MTEs also needs to be studied in other cultural contexts that present different, or fewer, challenges to interdisciplinary collaboration.

## Acknowledgment

This project was funded by the Australian Government Office for Learning and Teaching (grant #MS13-3174). Following the cessation of the OLT in June 2016 the Australian Government Department of Education and Training continued to support the Enhancing the Training of

Mathematics and Science Teachers program and projects. The views expressed in this article do not necessarily reflect the views of the Australian Government Office for Learning and Teaching or Department of Education and Training.

# Analyzing attitude towards learning and teaching mathematics in members of professional learning communities: A case study

Birgit Griesse

Paderborn University, Germany; [birgit.griesse@math.upb.de](mailto:birgit.griesse@math.upb.de)

*This paper presents a first step in a larger study in the context of professional learning communities following a five-day professional development course in stochastics at upper secondary level. Its focus is the analysis of one teacher's attitude towards learning and teaching mathematics in connection with his first teaching sequence on inference statistics after taking part in a professional learning community. The aim is to explore his views in reference to learning as transmission of knowledge actuated by the instructor or as a constructive activity by the learner. This is realized on the basis of the account the teacher gives on his teaching, on his observations in class, and on his reasons for the decisions involved. Additionally, a Q-sorting with statements for transmissive and constructivist views on learning was employed. Together, our investigations of the data reveal a nuanced picture of the teacher's attitudes and notions, of the diverse learning support he offered, and of perspectives of his further professional development.*

*Keywords: Teacher professional development, professional learning community, constructivism.*

## Introduction

In the course of their active careers, teachers need to regularly adapt their work due to shifts such as changes in curriculum guidelines, an altered structure of their classes, or technological development. In Germany, various innovations constitute challenges, e.g. competence-orientation, digitalization, and inclusive settings. The increased emphasis on statistics and probability theory is particularly relevant for teachers at upper secondary level. It has created a high demand for mathematics teacher professional development (PD), and a majority of teachers report that they would like to have more PD than they receive (OECD, 2009, Figure 3.5). However, after decades of neglecting stochastics, “the more challenging a reform is to teachers’ existing beliefs and practices, [...] the more it may need [...] ongoing professional development to achieve depth” (Coburn, 2003, p. 9). Theoretically corroborated PD courses, designed e.g. by researchers and teacher educators in the German Center for Mathematics Teacher Education (*Deutsches Zentrum für Lehrerbildung Mathematik*, DZLM) aim to fulfil the demand for sustainable PD that impacts not only at the surface but effects a real change towards learning based on understanding. Professional learning communities (PLCs) which allow teachers to reflect and discuss their teaching stand the chance to contribute substantially to this goal. Nevertheless, mid- or long-term professional growth fostered by the activities connected with a PD course remains under-researched.

In order to describe individual PD appropriately, it is advisable to first classify the underlying attitudes towards the learning and teaching of mathematics (as in Grigutsch, Raatz, & Törner, 1998) because “the affective cannot be separated from the cognitive” (Brown & Coles, 2011, p. 864): “A teacher’s belief about how students engage in mathematical activity and learn are critical factors in the ability and tendency to design and carry out inquiry-based instruction” (Lloyd, 2002, p. 150). To

be particular, mathematics educators and academic researchers tend to take the view that mathematical knowledge needs to be (re)constructed by the learner in order to be understood properly, and teachers often feel constrained by the necessity to also adequately prepare their students for tests and examinations presumed to stress routines and algorithms – even if the majority of teachers report constructivist views on learning (OECD, 2009, Figure 4.2). Thus, there is the possibility, if and when these two positions clash, that the potential benefit of a PD course suffers. Thus it is a meaningful first step in the evaluation of the impact of a PD course and the PLCs that emerged in its wake to a) investigate the attitude towards the learning and teaching of mathematics held by the participants of the course. Later steps include exploring b) what the participating teachers relate and reflect about their lessons, c) what tasks and tests they use, d) the correlations between their attitudes, their reflections, and their tasks, and finally e) theorizing about possible reasons for the connections.

## Theoretical background

There are numerous epistemological theories on the evolvement of mathematical knowledge (e.g. APOS by Dubinsky, cf. Arnon, Cottrill, Dubinsky, Oktac, Roas Fuentes, Trigueros, & Weller, 2014; *Abstraction in Context*, cf. Dreyfus, 2012; or the theory on advanced mathematical thinking found in Tall, 1997), and many share the basic belief that learners need to actively (re)construct mathematical knowledge in order to comprehend it. The corresponding view on how mathematics should be taught is described as *relativistic*, meaning an instructional style “based on [...] student understanding” (Wilson & Cooney, 2002, p. 132). These attitudes can be summarized under the label *constructivism*, viewing mathematics as a process, seeing learning as an independent and discursive activity pursued by the learner, and trusting in students’ eagerness and ability to learn.

However, particularly concerning beliefs on how mathematics should be taught, another, *transmissive* (or *dualistic*, according to Wilson and Cooney, 2002), view gains importance: of mathematics as a toolbox containing recipes and algorithms that solve tasks, of definite solutions, of learning by following examples and instructions.

There is consensus that epistemological beliefs on how mathematical knowledge is constructed and beliefs on how mathematics should be taught are not perfectly congruent: Studies (Chan & Elliot, 2004) found correlations, though mostly both traits are found in individuals. Moreover, it remains an open question if transmissive and constructionist views are the extremes of one dimension or two separate dimensions (Voss, Kleickmann, Kunter, & Hachfeldt, 2011). It is to be expected that an individual teacher may exhibit attitudes for both transmissive and constructivist positions, e.g. that he or she may seem convinced that acquiring knowledge is an active process demanding discussion and exchange of ideas, but at the same time prefer teaching methods that rely on guided step-by-step instructions or an instructor demonstrating the only correct way to solve a task very early on. This ostensible contradiction may allow deeper understanding of teacher practices in combination with their convictions and therefore an important gain of insight for research in mathematics teacher PD.

What is more, studies have identified mathematics as the subject that is most often taught in a pre-structured way (OECD, 2009, Figure 4.5), so this may be particularly true for the subject we are interested in. Previous research has shown that, not only for mathematics, “short-term professional development initiatives often remain at the surface and do not effect the desired change” (Roesken,

Pepin, & Toerner, 2011), which is ascribed to the fact that the underlying beliefs are not easily changed and the beliefs on how mathematical knowledge is built sustainably influence the way teachers teach mathematics. PLCs present a chance to address these beliefs and allow access to participant teachers' views and maybe even classrooms.

The relevance of teachers' transmissive or constructionist views towards teaching and learning is most often seen in connection with students' progression and performance in tests. This is not our main focus here; we intend to understand teachers' attitudes towards learning and teaching first, with a later perspective on exploring their individual PD. Our research questions for this paper are:

- (RQ1) What attitude towards learning and teaching mathematics does a teacher show in connection with having taught stochastics after partaking in professional development on this topic?
- (RQ2) In how far can this attitude be categorized as transmissive or as constructivist?

### **Circumstances of the study**

The data collected for this study must be seen in connection with an approved five-day PD course on stochastics at upper secondary level conceptualized by DZLM mathematics educators and researchers (Oesterhaus & Biehler, 2014). The course stretched out over several months and covered a broad range of stochastic content, strictly following the principle of promoting understanding. Some participants of this course came forward to partake in subsequent work in a professional learning community (PLC) with other teachers from their respective schools. For this, selected contents of the PD course were presented, discussed, and adapted. This allowed a unique insight into teaching practice in connection with a radically constructivist PD approach. Changes in the curriculum had involved teaching in-depth stochastics, which traditionally is often avoided. Consequently, the PD course was well-frequented, and participants were motivated.

### **Methodology**

Interviews with individual teachers were conducted after he or she had taught a sequence on stochastics, usually covering probability, tree diagrams, conditional probability, binomial distributions, and in advanced courses also hypothesis testing. The interviews were conceptualized to serve the overall research purposes and thus followed a guideline touching on the teaching sequence (underpinned by the course register, worksheets etc.) with specifics about didactic decisions, students' reactions, PLC meetings and the individual's benefit for professional growth connected to them, and cooperation among teachers. For the research focus presented here, interviewees' utterances were examined for passages revealing indications for the respective teacher's attitude towards learning and teaching, and wherever possible, these passages were categorized as referring to a transmissive or a constructivist view. In the examples given below, Vic<sup>1</sup> recounts a classroom situation typical of a constructivist teaching attitude, and Joe reports that his students opposed his approach to establish understanding and demanded a more transmissive method.

---

<sup>1</sup> All names given are aliases. Teachers' statements were translated from German by the author.

Vic: I ventured to say, frequently: I'm lost here, I have to think about this again. Or: You are right, as far as I can see at the moment. And the next time, I could say: I thought about this, and it occurred to me that ... (Vic\_1, 01:05:25)

Joe: Subsequently, they [the students] reproached me: Why did we start with a task that is not one-to-one relevant for the exams? (Joe\_1, 00:02:55)

In this case study, we concentrate on Vic, who is an experienced teacher with hardly any history of teaching stochastics himself, but who addressed teaching this content in an advanced course.

			address tasks that can be solved in different ways			
		discuss their ideas with others	(re-)invent mathematical contents	apply established rules, formulae, procedure		
	follow the well-structured explanations of the teacher	address imperfect ideas in class	allow individual strategies, even if wrong	secure insights individually	work in a self-regulated way	
quote exact definitions and mathematical terms	learn many rules and terms by heart	develop routines by drill and repeated practice	to use technical terms correctly	understand the meaning behind mathematical ideas	master mathematical procedures accurately	think strictly logically and precisely
1	2	3	4	5	6	7

**Figure 1: Q-method score sheet by Vic, statements (abbreviated here) placed in given fields, from “1: less important” to “7: superimportant”**

The Q-method (Fluckinger & Brodke, 2013) is a popular tool for assessing personality. Subjects (in our case, teachers participating in a PLC at their school, after one of them had attended the five-day PD course) are asked *not to rate* statements (like in Likert-scale surveys) but to rank them by placing them on a score sheet of a given shape (see Figure 1, where statements are condensed to keywords). This way, the common case is avoided that the vast majority of statements are rated as equally “very important”. In a Q-survey the number of fields on the “important” right side of the score sheet is limited. The Q-sorting can take place with statements printed on cards to be physically placed on the score sheet, or with digital alternatives (e.g. FlashQ by Christian Hackert, <http://www.hackert.biz/flashq>) that can be sent via e-mail; we use both.

			+			
		+	+	-		
	-	+	+	+	+	
-	-	-	-	+	-	-
-1	-4	+3	+8	+5	+0	-7

**Figure 2: Calculation of Q-index  $-1-4+3+8+5+0-7=+4$ , transmissive statements with negative, constructivist statements with positive algebraic sign, absolute values by position**

The 16 statements used for our investigation of attitude towards the learning of mathematics, the so-called Q-sample, are taken from Jaschke (2017). Eight statements each represent the transmissive or

the constructivist view. For example, *Learners are to develop routines by drill and repeated practice* (bottom statement in column 3 in Figure 1) stands for a transmissive perception of learning, and *Learners are to work on mathematical problems in an autonomous and self-regulated way* (top statement in column 6 in Figure 1) describes a constructivist notion. The completed score sheet allows the calculation of an index: Transmissive statements are equipped with a negative algebraic sign to their respective position; constructivist statements retain their respective position with a positive algebraic sign; the index is calculated by adding up all values (Figure 2 shows an example). In our survey, this results in index values between -20 (clearly transmissive) and +20 (clearly constructivist).

## Results

Vic's utterances in the interview reveal his differentiated perspective on the learning and teaching of mathematics, containing elements both of transmissive and of constructivist attitude.

### Interview utterances categorized as transmissive

Vic reports that at the beginning of the teaching unit, he opted for a guided approach ("I set that [the null hypothesis in the introductory example], [...] and then I defined the errors of the first and second kind", Vic\_1, 00:19:58) with clear-cut step-by-step tasks for the students ("Then I kept to the worksheets from [name of publisher]: [...] very well preprocessed, for filling in, for working with", Vic\_1, 00:21:33). He continues to secure the essence of the lessons and calculations by scanning and printing important summaries from his preferred publisher's material in color on his home printer (Vic\_1, 00:21:55), thus choosing scripted synopses over students' individual résumés.

### Interview utterances categorized as constructivist

On the other hand, Vic sees the narrow solutions provided for the marking of central exams critically (Vic\_1, 00:31:59). He relates that his students "had to try out [their approaches at calculating the probability of an error]" (Vic\_1, 00:20:36), which is typical of a constructivist view. He very much appreciates the fact that his students liked to take part in discussions, and acknowledges that both himself and the students profited from these interactions (Vic\_1, 00:58:25). Vic appreciates the creative strategies some of his students use (e.g. when attempting to solve a third degree polynomial equation by trying systematically, Vic\_1, 00:35:56), although he is aware that in exams, such strategies can result in an inconvenient loss of credits (Vic\_1, 00:36:31). His concerns about his students' performance also become clear when he talks about the case of a student who did not abide to "what is to be done at school, [he] always reinvented the wheel" (Vic\_1, 00:38:48) and thus was graded lower than his presumed potential – until in the final exams, when he came out with full credits. This experience boils down to the fact that a constructivist approach to learning bears the danger of demerits. Still, Vic likes to offer a choice (Vic\_1, 00:28:04) of different topics or complexities. He also appreciates it when understanding is promoted (like in double tree diagrams, where a higher base rate results in a higher number of false-positive diagnoses, Vic\_1, 00:25:59, 00:26:14, or in a responsive spreadsheet that enables the observation that with a higher sample size, the standard deviation of a random variable decreases, but the mean stays the same, Vic\_1, 00:53:37).

### Interview utterances referring to affective aspects

Vic also keeps an eye on students' motivation ("And they found that interesting, I think", when referring to the latter of the above examples, Vic\_1, 00:53:55), particularly as he has learned that

many students in this course possess a pronounced dislike against probability and stochastics (“the term *stochastics* brought horror to some students’ – about a third of the course – faces at first”, Vic\_1, 00:56:12). He does not lose hope of imparting some of the fascination he feels to his students and underpins this with anecdotic evidence of a student who was rather successful, in spite of her initial strict dislike (Vic\_1, 00:57:25). He is particularly aware of offering alternative procedures to weaker students (e.g. using absolute numbers when calculating conditional probabilities, Vic\_1, 00:26:35) and values their potential (“when I was able to reconstruct it, I gave full credits”, Vic\_1, 00:26:51). Vic mentions more than one incident of perceiving distinct learning difficulties, e.g. when he recounts that some students were at a loss when having to transfer routines to new contexts (Vic\_1, 00:33:33).

### **Vic’s vision of ideal teaching**

As a prospect, when considering how to teach the content next time, Vic’s ideal of constructivist instruction based on solid content knowledge becomes clear; he phrases his goals as “feeling more at home” (Vic\_1, 00:47:00) in inference statistics, as “enhancing my collection of tasks” (Vic\_1, 00:47:59). His vision of the teaching he would like to conduct in the future encompasses extended phases of reflection (Vic\_1, 00:50:00), which he substantiates with the observation that what students find out themselves stays in their minds, even if it is wrong (Vic\_1, 00:50:00), thus displaying his awareness of the pitfalls of self-guided learning and his own responsibility for his students’ learning goals and their examination performance.

### **The Q-sorting**

Vic’s Q-sorting produces the Q-index +4, a moderately constructivist view. We found that particularly his positioning of the transmissive statements are worthwhile interpreting. One of the transmissive statements considered most important reveals Vic’s concern with his students’ learning outcome: *Learners are to master mathematical terms and procedures reliably and accurately* (column 6). The other one describes what you could call a general goal for mathematics lessons: *Learners are to think strictly logically and precisely* (column 7). The transmissive statements rated least important by Vic also tell a story (see columns 1 and 2 in Figure 1): They refer to rote-learning without considering if the content is understood. The overall picture presented by this Q-sorting can be summarized as rejecting mindless routines, emphasizing autonomous exploring, but simultaneously keeping an eye on learning goals.

### **Discussion**

Vic’s data indicates his constructivist belief of sustainable learning as an active process that needs time to explore, to discuss, and to reflect in order to be effective, based on his personal experience. Nevertheless, his responsibility to promote all students’ learning success makes him avoid very open approaches to new content that might throw some students off track, and he makes sure that learning outcomes are clearly communicated and accessible for everyone. This illustrates one of Clarke’s (1994) important principles of PD, that “changes in teachers’ beliefs about teaching and learning are derived largely from classroom practice” (p. 38). Vic’s teaching decisions are also influenced by the specific students in his course. There are some students keen to debate and discuss, some rattled by the prospect of having to come to grips with the unpopular content, and others with limited mathematical abilities. As a consequence, Vic does not follow only one approach in his teaching, but

switches between more guided and more open activities. The reasons he gives do not stem from general scientific results but from current observations of this specific group of learners and previous experiences that form his treasure trove and enable him to draw on his collection of reactions, explanations, examples, and tasks that can support a variety of learners to overcome their unique learning obstacles. His aim of augmenting this trove with more tasks in order to further improve his teaching metaphorically sums up this perspective. Vic's attitude towards the learning and teaching of mathematics cannot be seen as one place on a line with the poles *transmissive* and *constructivist view*, although the Q-index +4 gives an orientation and acts as a first classification. Vic's reports on his teaching as flexible with respect to individual learners and variable teaching aims (such as introducing a topic, or corroborating a procedure in preparation of a centralized exam). When analyzing his teaching decisions in more detail, e.g. his choice of task or method later in our ensuing studies, we need to consider these variables, too.

### Further research perspectives

As indicated above, this paper presents a first step in a larger study aimed at investigating the impact of a PD course and its subsequent PLCs on the professional growth of the members of these PLCs. The next steps could be as follows:

- Broaden the investigation of attitude towards the learning and teaching of mathematics to more members of the PLCs.
- Analyze PLC members' reflections in interviews in terms of evidence for professional growth.
- Explore PLC members' tasks and tests used when teaching selected content.
- Look for correlations between teachers' attitudes, evidence for professional growth, and their tasks and test, and search for qualitative and theoretical corroboration that (some of) these correlations are causal.

In discussions at CERME, other lines of research were suggested for consideration, such as taking a closer look at the interactions among the PLC, or concentrating on affective aspects, e.g. specificities of the content, or teachers' expectations of what they should be able to achieve.

Altogether, these lines of research raise the hope of generating interesting results.

*During CERME10 in Dublin, a collaboration between the University of Turin and the University of Frankfurt has been initiated. The outcome was a module of a Massive Open Online Course (MOOC) for in-service teachers to improve mathematics teaching by creating outdoor math trail tasks for their students with the help of MathCityMap (MCM). MCM is a digital tool to create, manage and run math trails with mobile devices. Teachers had to create math trail tasks that were in line with previously defined task design guidelines to complete the MOOC module. An expert review system was used to improve and ensure material quality. The involvement of the teachers, the efforts of the reviewers and, in general, this collaboration have given satisfactory results that will be presented in this paper.*

*Keywords: MOOC, MathCityMap, teacher education, expert review system, material quality.*

## Introduction

Since October 2015, the Department of Mathematics “G. Peano” at University of Turin, Italy, has been engaged in an innovative initiative: the *Math MOOC UniTo* project (cf. Taranto et al., 2017). The project provides MOOCs (Massive Open Online Courses) for Italian in-service mathematics teacher education, with the use of the platform DI.FI.MA. (<http://difima.i-learn.unito.it>), a Moodle platform, managed by the mentioned department, where more than 2,500 Italian teachers of all school types are enrolled. The aims of these online courses are to cover the main topics in the official Italian programs for secondary school (Arithmetic and Algebra, Geometry, Relations and Functions, Uncertainty and Data) from a mathematical, didactical, and methodological point of view, and to give teachers an opportunity for professional development at the national level. So far, three MOOCs have been delivered: *MOOC Geometria* (based on geometry contents, from October 2015 to January 2016); *MOOC Numeri* (based on arithmetic and algebra contents, from November 2016 to February 2017) and *MOOC Relazioni e Funzioni* (based on relations and functions contents, from January 2018 to April 2018). In the following, we concentrate on the last one, which we will indicate as *MOOC Rel&Fun* in the following.

During CERME10 in Dublin, some team members of the MOOC Rel&Fun became acquainted with the *MathCityMap* project (MCM). This project has been developed by the Goethe University of Frankfurt, Germany, and enables teachers to implement smartphone supported mathematical trails in mathematics classes. One key feature is the MCM web portal. It allows teachers to easily create tasks in their local surroundings and therefore fits well into a MOOC for teacher education, since the MOOC-teachers learn necessary skills online and can directly apply them by creating tasks in their environment. A collaboration between these two projects was established with the intention to

provide an innovative approach to teach the mathematical contents of relations and functions in the real world with the support of technology on the one hand. On the other hand, the MCM project (including the math trail idea) is an expanding project and it was worth introducing and disseminating it in Italy. This paper aims to report outcomes and examples of mathematical tasks created by MOOC-teachers according to MCM task design guidelines, as well as to explore potentials of an expert review system as one way to ensure task quality in a MOOC environment.

## **Theoretical framework**

### **Mathematics trails**

Blane and Clarke (1984) were among the first ones to present the mathematics trail idea to a broader scientific audience. According to Shoaf, Pollak and Schneider (2004, p. 11), math trails are accompanied by a trail guide booklet showing mathematically interesting places and tasks, usually including a map, for the user to follow. A meta-analysis on outdoor learning indicates that students do not only remember fieldwork and outdoor visits for many years, but also the experience of outdoor learning is considered “more effective for developing cognitive skills than classroom-based learning” (Dillon et al., 2006, p. 107). Students need to understand the problem, find an appropriate mathematical model, collect data, work mathematically and validate and discuss their answer. These activities come close to the modelling cycle as described by Blum and Leiß (2005) and help to promote modelling.

The mathematical contents depend on the tasks that a math trail offers. Problems in the field of geometry and measurement are obvious, since many geometrical forms shape our environment. Nevertheless, it is possible to find many tasks in the other content fields of mathematics. In contrast to original trails, math trails at school are not voluntary; they are mostly prepared by teachers for their students with a focus on a certain topic and are subject to organizational obstacles. Since the available time is usually set by lessons of a certain period (e.g., 45 or 90 minutes) and the learning group consists of about 20 to 30 individuals, it is necessary for the teacher to structure the math trail activity well to be a success. There are many aspects a trailblazer has to consider while creating a math trail. For this reason, task design guidelines, which are presented in a following paragraph, have been formulated to help authors generate material with high quality.

### **The MathCityMap project**

The MathCityMap project combines the idea of math trails with the possibilities of web technologies and mobile devices (cf. Gurjanow, Ludwig & Zender, 2017). With the help of the MCM web portal (<https://mathcitymap.eu>), teachers can digitally create and manage tasks and trails. Furthermore, the web portal offers task templates, many public tasks, and the possibility to automatically generate a PDF math trail guide. The purpose of the MCM web portal is to make the challenge of creating a math trail more convenient. It is available in eleven languages (Italian included, thanks to the collaboration born with Math MOOC UniTo). The MCM application for smartphones is a digital math trail booklet that uses GPS to display the tasks position on map and presents the task to the users. Additionally, users benefit from a stepped aid system, in case they get stuck and an automatic feedback system that evaluates entered answers. The app is meant for persons (e.g., students) who would like to walk a math trail.

## MCM content quality assurance

“Carefully designed classroom tasks can be a powerful tool for enhancing the quality of math and science teaching, influencing the classroom culture and fostering students’ learning” (Maaß et al., 2014, p. 8). This is also the case for math trail tasks, since they constitute the core of the math trail activity. Web communities (e.g., Wikipedia or GeoGebraTube) that allow users to create content in general face the issue of maintaining quality standards. Peer or expert reviews are a common way to ensure quality in academic papers and material produced by different authors (Price & Flach, 2017). MathCityMap implements an expert review system to maintain a high quality of published tasks and trails. Experts are selected for each participating country. They are often experienced teachers or academics from the field of mathematics education who are well informed about specific circumstances of mathematics teaching in their respective country. The experts may decide if the task or trail meets the quality criteria and accept the publication or, if revision is needed, they decline the publication with a message, indicating necessary changes (cf. Jablonski, Ludwig & Zender, 2018). Published content can be viewed and accessed by all visitors or app users.

Task design guidelines have been formulated to help new authors and to ensure a good user experience. These guidelines are the basis of the MCM review system. The first set of aspects is derived from popular published math trails like “A mathematics trail around the city of Melbourne” (Blane & Clarke, 1984), “Maths Trailing in Dorset” (Ashworth, Cobden & Johns, 1991, p. 7) and from a more general description on how to create math trails by Shoaf et al. (2004, p. 10) and the British Association of Teachers of Mathematics (1991). The first collection of task design guidelines that come from the intersection of all of these sources, deals with the challenge of creating outdoor tasks.

1. Uniqueness. Every task should provide a picture that helps to precisely identify the situation, the object of the task and what the task is mainly about.
2. Attendance. To solve a task, the user should have to be present, therefore the task data can only be obtained locally. This also means that a picture and description of a task should never be enough to expose the solution.
3. Activity. The one who solves the task must be active in some way (e.g., measure, count or sketch).
4. Multiple solutions. The task should be solvable in various ways.
5. Reference to reality. “Problems that arise naturally from the situation are best” (Shoaf et al., 2004). The task should not appear too artificially.
6. Tools. The tools that are required to solve the task should be noted on the trail guide. In general, you should not expect people to bring extraordinary tools.

The second set of aspects deals with challenges of mathematics trails as a teaching method. After preparing the math trail the teacher steps back in a passive role, while students actively discover the trail in small groups. To support the groups in case they cannot find an approach to solve the problem, the MCM app provides a stepped hint system.

7. Stepped hints. Every task should provide at least two hints.

8. Sample solution. Authors should provide an elaborated sample solution including measured data.

### Research Question

In the MOOC Rel&Fun, as regard the use of MCM, MOOC-teachers were invited to generate math trail tasks connected to the topic of relations and functions. In order to improve material quality, Maaß et al. (2014) recommend that teachers should experience and reflect new tasks themselves prior to develop own material. However, for their nature, the math trails are bound to particular surroundings. It leads to the fact that MOOC-teachers were not able to experience MCM math trail tasks before designing their one, since the existing Italian tasks were - at that time - few and only located in Turin (where the MOOC team worked). Nevertheless, it was a main concern of the module to produce tasks that are in line with the task guidelines. This leads us to our research question: *What are advantages and disadvantages of an expert review system to ensure material quality?*

### Methodology

MOOC Rel&Fun, like those who preceded it, is open, free, and available online for teachers on the DI.FI.MA platform. It consists of modules with a duration ranging from one to two weeks. Each module requires the performance of a task. Once the task is executed, the platform releases a badge<sup>1</sup>. The users have time to perform the task from the beginning of the module in which it is inserted, until the closing date of the MOOC. The MCM module started in the fourth week of the MOOC Rel&Fun and lasted 2 weeks (since MOOC Rel&Fun lasted 11 week in total, the MOOC-teachers had 7 weeks to be able to accomplish the task provided by the module). As already mentioned above, the aim of the module was to learn how to use a new technology (MCM web portal and app) to create a math trail task on the subject of relations and functions. In the following, we explain in detail the integration of MCM into the MOOC Rel&Fun. In particular, we refer to *German team* meaning the MCM members, while with *Italian team* we mean the MOOC Rel&Fun members.

The MCM module begins by sharing the theoretical and technical aspects of MCM with the participants. The German team made a video in which they illustrated the spirit of the MCM project to the MOOC-teachers. The voice output was in English. The Italian team added Italian subtitles. Subsequently, it was necessary to make the MOOC-teachers autonomous to work with MCM, namely, allow them (i) creating new tasks; (ii) compiling a new trail; (iii) using the MCM app to walk a trail. Therefore, for each of these points a video tutorial was necessary. Both the teams agreed that for these videos the voice should be in Italian. So, the German team prepared English transcriptions and the Italian team added the voice to the mute tutorial videos made by the German team. Having clarified the technical details, it was time to show some examples to the MOOC-teachers. In the web portal, there were already some tasks, but they were mostly in German or English. A few months before the start of the MOOC, in October 2017, the German team visited Turin to explore the city with the Italian team. They together created and implemented some Italian tasks in the web portal.

---

<sup>1</sup> Digital badges are a validated indicator of accomplishment, skill, quality or interest that can be earned in various learning environments (Carey, 2012). In the case of our MOOC, they are created by a course administrator and then they can be issued automatically by the platform each time the user accomplish the tasks required within the module.

Subsequently, the Italian team prepared some Sways<sup>2</sup>, where the methodological and mathematical details of each task were explained. In addition, a card with the criteria for designing a good task (task design guidelines), formulated by the German team, has been loaded onto the platform available to the participants. In this way, the teachers had high quality examples to take inspiration from and all the information needed to perform the module task. This one consisted of (i) creating a math trail task on the web portal on the topic of relations and functions; (ii) requesting publication of the task through the review process; (iii) sharing the link of their public task on a specific repository created in the MOOC module. Only three members of the Italian team were responsible for reviewing the MOOC-teachers' math trail tasks. They could directly approve the task for publication if it complied with the task design guidelines. Otherwise, they declined the publication by sending an e-mail to the MOOC-teacher through the MCM review system explaining the reasons for the refusal. The data on the review effort was gathered from the MCM review database. It stores each review that was performed by each Italian reviewer and links it to a particular task. The module ends with a questionnaire that intends to investigate the MOOC-teachers' satisfaction level on MCM and their intention to use it again with their students.

## Data analysis

There were 358 enrolled teachers in MOOC Rel&Fun. As far as the MCM module is concerned, 287 tasks were created by the MOOC-teachers. 257 of them were added to the review system. Among these, at the closing of the MOOC, 231 tasks (90%) were considered to meet the task design guidelines and therefore got published. The Italian team performed 396 review processes (multiple reviews until publication of a task are possible) to ensure content quality. The MCM review database shows that among the 257 tasks that were submitted to get published, 119 (46%) tasks matched the MCM task design guidelines on their first review, 138 (54%) tasks did not. The MOOC-teachers revised 112 out of the 138 (81%) declined tasks according to reviewers' feedback and were later on published. In reality, the situation has been a little more complex. The tasks that were directly accepted were not always in line with the design criteria, so there were less than 119 tasks that matched task design guidelines on the first review. The Italian team has indeed noticed this: when they immediately declined the tasks, the MOOC-teachers not always revised and submitted their tasks again for review. Instead, when reviewers sent feedback with a request of revision without declining the task<sup>3</sup>, the MOOC-teachers made the changes and the reviewers could approve their task like if these revised tasks were their first submission. However, unfortunately, we are not able to exactly quantify this data.

In the following, we indicate the common errors identified by the Italian team for declining the MOOC-teachers' tasks.

<i>Most common errors</i>	<i>Less frequent errors</i>
---------------------------	-----------------------------

<sup>2</sup> Sway (<https://sway.office.com/>): Microsoft tool that allows users to combine text and media to sustain the showing of online content.

<sup>3</sup> Sending personal emails, like the MOOC team used to do for other commitments in the MOOC (i.e. soliciting the MOOC-teachers to get the badge of the modules, ...).

Instruction of the task unclear or ambiguous, namely in the same task there was more than one question	picture related to the task unclear and not always shared according to the indications
No indication of the unit of measure in the task instruction	incorrect geolocation <sup>4</sup>
Solution provided without the data collected or without the calculations made <sup>5</sup>	inserting the entire solution in the hints
If the solution was expressed by a range of possible values, this range was not always indicated in a plausible manner	inserting more than one hints in the space that is generally dedicated to a single hint
Solution difficult to read because the text editor was not used <sup>6</sup>	create the task inside the school premises <sup>7</sup>

**Table 1: MOOC-teachers' common errors designing a math trail task with MCM**

We now show an example of activity that has been published. The task in Figure 1 was created by a teacher from Lecco (a city in Northern Italy) for students of grade 11.

**Figure 1: Pendulum equation as a function of time**

- ☐  $s(t) = 0,94 \cdot \sin(360^\circ t / 2,33)$   
☐  $s(t) = 1,88 \cdot \sin(360^\circ t / 2,33)$   
☒  $s(t) = 0,94 \cdot \cos(360^\circ t / 2,33)$   
☐  $s(t) = 1,88 \cdot \cos(360^\circ t / 2,33)$

**Figure 2: Solution as a multiple choice**

This is her delivery: “Starting from a position that forms an angle of about 44 degrees with the vertical, determine the equation that describes the displacement by the swing, as a function of time, while it oscillates. The units of measurement to be used are the meters and the seconds”. The teacher chose to represent the solution as a multiple choice (Figure 2) and inserted three hints: (i) a YouTube video (<https://goo.gl/dqJuMH>); (ii) an image (Figure 3); (iii) a sentence: “Calculate the amplitude of the movement (maximum displacement) and the time of complete oscillation”. She indicates that the tools needed to solve this task are the folding ruler and the calculator. She also clearly describes the procedure she followed for the resolution.

“I moved the swing to form an angle of about 44 degrees with the vertical (Figure 4). I measured the length of the wire and I got 1.36 m. Taking advantage of the stopwatch of the phone I measured

<sup>4</sup> someone had put the Mole, a typical monument of Turin, in Switzerland

<sup>5</sup> someone was looking for the monuments data on the internet, so he did not actually go there in person to find the data

<sup>6</sup> i.e. m2 instead of m<sup>2</sup> to indicate the square meters

<sup>7</sup> if on the one hand this was done for security reasons related to the responsibilities that teachers have on their students when they propose activities outside of the school; on the other hand, in this way, the possibility of making the task accessible and usable by anyone is lost.

the time it took the swing to make one full oscillation. I repeated the same operation three times and I calculated the average time. So, I got that to make a complete oscillation it takes 2.33 sec. I calculated the maximum displacement  $A = 1.36 \cdot \sin(44^\circ) = 0.94$ . Finally, I wrote the pendulum equation as a function of time:  $s(t) = 0.94 \cdot \cos(360^\circ \cdot t / 2.33)$  with  $t$  in seconds”.

Figure 3: Second hint

Figure 4: Explanation of the solution

## Discussion and Conclusion

The collaboration between Math MOOC UniTo and MathCityMap was a success. MOOC-teachers were very engaged and created almost 300 math trail tasks all over Italy. 142 MOOC-teachers completed the questionnaire inserted in the MCM module and the 76% of them were satisfied with the module contents and would recommend MCM to colleagues. Although the MCM module provided tutorial videos, as well as best practice examples and explicitly formulated task design guidelines, not all and not immediately were able to meet the task of the module. The review phase was indeed challenging and demanding. In fact, if we consider the data of the MCM review database, only 46% of the created tasks met the task design criteria. The expert review system helped to improve a total of (at least) 112 tasks (44 %). At the end of the module, 90% of the tasks were considered good quality and allowed their respective authors to obtain the desired module badge. The quota of revised tasks (112 out of 138, 81%) is remarkably high and shows that teachers accepted and appreciated the expert feedback. In general, teacher education that aims to improve mathematics classes through high quality material, especially those that want their participants to create own material adapted for their students, need to take care of material quality (Maaß et al., 2014). In the case of a MOOC for teacher education, the expert review system turned out to be a suitable method to achieve this goal. In total 396 review processes were necessary to implement the review system during the MOOC MCM module. On the one hand, we recognize that a disadvantage of the review system is that of having to manually write reviews. This implies that reviewers must be highly motivated to accomplish this task and to assure high-quality materials. On the other hand, the possibility of giving highly adapted feedback that considers not only the mathematics but also the cultural background and the educational landscape of mathematics classes in Italy, could be identified as a major advantage of the review system. However, the success of the review system relies on the willingness of the participating teachers to accept the review and to revise the task. Since we did not explicitly examine factors that lead to a revision of a task, the willingness can be traced back to a mixture of a high-quality feedback

combined with the desire to obtain the module badge and the satisfaction with the module contents. Finally, we can certainly state that the engagement of MOOC-teachers in creating the math trail tasks and the efforts made by the reviewers have constituted a heritage, not only for the MOOC community but also for all MCM users.

### Initial conditions and requirements

Subject-specific content knowledge is an essential component of professional teacher knowledge (for the concept of professional knowledge see for example Schwarz, 2013). It forms a basis for the ability to judge a specific topic's significance for an entire subject and thus forms an important requisite for didactical reflections (Dreher et al., 2018). Considering this, mathematics teachers' content knowledge must comprise not only advanced insight into specific topics but also a netlike overview of mathematics as one, consisting of notions and relations between them as well as methods and basic principles. A survey in a second-year lecture on arithmetic showed that the students were not able to connect what they heard about equivalence relations, functions or groups to corresponding contents they had learned in previous lectures (e. g. congruence and the group of congruence mappings in geometry, isomorphisms and linear functions in linear algebra).

To achieve that students are able to see these parallels, a university curriculum for future teachers demands cross-links between the single courses. Basic notions (such as sets, functions, algorithms, relations...) that are found in diverse mathematical subdomains seem suitable for serving as cross-links between scientific lectures, both, in a horizontal and a vertical way. This would transfer Bruner's (1969) concept of fundamental ideas and a spiral curriculum onto teacher education, also suggested in Dreher et al. (2018, pp. 330 f.).

Basic ideas and fundamental notions can be found when one looks into the history of a subject as they should appear throughout time (Schweiger, 1982), though maybe in different disguises. Apart from that aspect, including the history of mathematics into teacher education has been suggested long-since, presumably bearing a whole lot of further benefits (Schubring, 2000; Katz, 2000; Jankvist et. al., 2016), for example experiencing mathematics as a process conducted by human beings rather than as a mere product and thus influencing future teachers' beliefs. In addition, through history of mathematics one learns about the synthesis of notions and terms. This is of special importance for future teachers as it surely facilitates due decompression of scientific content into school content, which requires thorough analysis. (Dreher et al., 2018, 331)

Generation, clarification and precision of mathematical concepts and notions require the use of language (e.g. Morgan et al., 2014). Without language, definitions and propositions could not be worded and not be taught either, so language forms another essential part of content as well as pedagogic content knowledge. Due to increasing heterogeneity in pupils' language abilities, it is necessary that future teachers learn to illustrate subject matters on differing language levels and that they become able to vary by those levels.

## The Hildesheim concept of “Learning along Keynotes” (LaK)

We suggest that integrating the three keynotes – basic notions, history and language of mathematics – into a teachers’ curriculum and thus cross-linking the courses supports the construction of a professional teacher content knowledge as required. Therefore, the keynotes should become a constitutional part of all scientific lectures throughout studies. Our poster presents a concept of how the three keynotes might constitute a scaffolding for a spiral curriculum, where historical and language elements serve as enrichment as well as embedding of basic contentual and methodical concepts. We also present an exemplary concretization for the basic notion “algorithm”.

LaK started 2018 in a first-year (linear algebra) and a second-year (arithmetic) lecture at the university of Hildesheim. Historical and linguistic tasks that are mostly integrated into exercises associated to the lectures comprise transferring formulas into common language or working on original historical texts.

To emphasize the netlike structure students are encouraged to design concept maps for a selection of basic notions (see poster for complete list) and augment them in the course of their studies, starting from first year and going on through all lectures. The next step will be to design appropriate tasks for all scientific lectures as well as a research frame for evaluating the concept in the form of a long term study.

# Teacher education: Developing the individual within the collaborative

Fiona Haniak-Cockerham

Manchester Metropolitan University, England; [f.cockerham@mmu.ac.uk](mailto:f.cockerham@mmu.ac.uk)

*This study explored student teachers' ability to develop their own teaching identity whilst teaching collaboratively as a trio in a "University School Model" of initial teacher education. The paper considers this from a psychoanalytical viewpoint in which the student teachers' emotions and desires are explored in relation to how they experience their work with their peers. The main focus is on how they negotiated the tensions around differing individual pedagogies within the group whilst maintaining the delicate balance between compliance and integrity. The paper concludes that it was through the process of navigating these tensions that they challenged their own pedagogy and in the course of working collaboratively, modified their developing teacher identity.*

*Keywords: Collaboration, identity, emotion, psychoanalysis.*

## Introduction

Although 'a considerable amount of current research on teaching and teacher education focuses on teacher collaboration' (Meirink et al., 2007, p.145), previous research tends to focus on qualified teachers supporting each other, or qualified teachers' collaboration with student teachers. Taking a different approach, this paper is concerned with student teachers collaborating with their peers. The paper describes the thinking behind the "University School Model" (USM) and the way in which the author worked with student teachers over the course of a year. Employing Britzman (1998, 2003, 2010) and Bibby's (2011) psychoanalytical approaches to teacher education, it acknowledges there are emotional tensions in developing a teacher identity but that learning to teach is a social process requiring negotiation. Although there is a resistance to changing their perception of teaching, the USM incurs differing pedagogies and argues that this is central in supporting student teachers' development and their autonomy. It considers the university tutor's role and implications for initial teacher education (ITE).

## Literature review: Collaborative teaching and multiple placements

A significant amount of research has focused on the role of collaborative practice (Cajkler et al., 2014; Eraut, 2007; Meirink et al., 2007) and the effect this has in supporting the developing professional. Cajkler et al. (2014, p.521) found that planning lessons collaboratively led teachers to be 'more courageous and give greater responsibility to students to manage their own learning'. Their study also suggests that collaboration led to a greater willingness for pedagogical risk-taking and 'opportunities for participants to develop individual expertise leading to greater confidence to make changes... and address learning challenges with creative and engaging approaches' (Cajkler et al., 2014, p.526). They conclude that working collaboratively allows for a deeper study of pedagogy.

Teachers in their developing years take on a challenging role within the first weeks on teaching placement, and can struggle to survive in extremely crowded and demanding environments (Eraut, 2007). Their survival depends on being able to reduce their cognitive load by prioritisation and routinisation, and therefore they may not focus on the pedagogical issues within their teaching (Eraut,

2007). However, collaborative teaching contexts enable sharing of responsibilities within the classroom and therefore more space for reflection, allowing for routinisation to be less of a necessity in the first few weeks, but developed reflectively with evaluation over time.

Collaborative practice in a 'traditional' model of teacher education takes the form of the student teacher working as an 'apprentice' with the class teacher or a subject mentor. Student teachers in this situation may feel obliged to incorporate advice and ideas from 'expert' teachers and mentors in their school placements into their own teaching, therefore becoming merely compliant with the ideas that have been shared rather than being co-constructors of them. A related issue is that established teachers may find it difficult to articulate their practice to student teachers on placement, since what started as explicit routines in their early experiences have become tacit routines over time (Eraut, 2007). In contrast, teaching with student teacher peers means that routines which are not yet instinctive can therefore be evaluated and re-assessed together, becoming established in unison. This shift from working alongside more experienced teachers towards working and collaborating with peers is the context for this research.

### **The University School Model of teacher education**

During my necessarily infrequent visits to observe student teachers during their school placements as part of traditional ITE programmes, I was often dismayed to see students who had previously been creative and innovative in their teaching revert to procedural didactic methods. One reason for this commonly observed gap between the theory learnt at the university and the practice seen in school (Allen, 2009) is that the student teacher in placement is isolated from the support and advice of the university tutor. Too often, the once inventive and imaginative practice enthused over at the university is sacrificed to ensure compliance with the reductionist process-driven teaching dominant in many school placements (Cockerham & Timlin 2014).

To address this issue, Manchester Metropolitan University developed a collaborative teacher education programme, namely the 'University School Model' (USM) in 2010. The USM involves placing six student teachers in a school, where they teach collaboratively in two groups of three, as well as individually. The unique attribute of this model is that the university tutor works in the placement school alongside teachers and student teachers, visiting weekly for a whole day. This provides an opportunity to observe and work regularly with student teachers, supporting the integration of practice based on theory and promoting teacher autonomy and professionalism in a more cohesive manner.

Collaborative teaching during these placements is paramount in developing innovative lessons as well as encouraging student teachers to become more reflective practitioners. "Learning about teaching is a collaborative activity" (Northfield and Gunstone, 1997, p.49) and the USM works on the assumption that it is most productive when conducted in groups where ideas and experiences can be discussed. Although working in a group with differing pedagogies and priorities can lead to tensions and emotions that student teachers find hard to navigate, differences of opinion are crucial in fostering discussion and debate about their perceptions of what makes a "good" mathematics teacher, enabling them to identify and articulate their beliefs about teaching (Meirink et al., 2007). The research

questions which frame this paper are: What opportunities for student teacher's development arise from the USM of collaborative teaching? What emotional support and tensions are evident whilst working collaboratively in the USM?

## **Theoretical framework**

The field of psychoanalysis has many influential perspectives, however this paper focuses on the approaches of Britzman (1998, 2003, 2010) and Bibby (2011) due to their specific insights into mathematics education. Britzman (2010) asserts that psychoanalysis is the best way to turn education 'inside out' in order to start to understand something of its emotional situation and its inhibitions, symptoms and anxieties. She claims that it is 'one of the few practices and theories in the human professions that begins with and is affected by the relation between our object world and our sense of relationships with self, others and knowledge' (Britzman, 2010, p.86). Student teachers are placed in a situation of negotiating the balance of being a student themselves whilst trying to teach others, and what characterises the relationship between student teachers and their 'others' is the dependency and desire to be seen as already knowledgeable without having to learn (Britzman, 2003). Britzman (2003) also discusses the overfamiliarity of the teacher profession as a significant contribution affecting those learning to teach: student teachers draw on their subjective experiences of teaching from their previous experience of education, as a pupil. We all know what a teacher is and does from our years of observation in our own school system growing up, leading to the scenario that 'many students leave compulsory education believing that "anyone can teach"' (Britzman, 2003, p.27). For Anna Freud (cited in Britzman, 2010) this denial of needing to learn how to teach is the ego's defence against its own vulnerable certainty. Consequently, teachers rarely disclose 'the more private aspects of pedagogy: coping with competing definitions of success and failure, and one's own sense of vulnerability and credibility' (Britzman, 2003, p.28). Britzman (1998) argues that learning to teach demands a change in the learner, in that they must reconsider their previous speculations. Education depends on persuading the student teacher to transcend conflict in order to learn, and psychoanalysis insists that the conflict is purely internal. Therefore, the problem of learning to be a teacher becomes 'how the social and the individual can come to tolerate ethically the demands of the self and the demands of the social' (Britzman, 1998, p.8)

However, the beliefs we have about teaching are formed not only from our conscious perceptions of good teaching, but also our unconscious self. Earlier experiences we have relating to vulnerability, that of being educated, create resonances in the unconscious, and these unconscious phantasies are projected onto our current situations, that of being a teacher, affecting our beliefs and values and structuring our actions (Bibby, 2011). Thus, unconscious processes profoundly influence and are intertwined with more conscious processes (Britzman, 1998). The unconscious part affects the way we view the self, the self we project to others and the decisions we make.

The sense we make of ourselves, our identity, our ego, is made up of a layering of identifications that we have either found or been presented with 'out there' (Bibby, 2011), and is therefore dependent on other people's responses to us. This is in contrast to the popular image student teachers bring to their teaching practice, that of 'teaching as an individual activity, privatised by the walls between classrooms' (Britzman, 2003, p.63). In order for the student teachers to reflectively question their

teaching identity, it is crucial that they experience images provided by others; this system of judgements frames how we come to be seen and known in terms of being located in the others' field (Bibby, 2011). You can only know yourself through interactions with others, learning to teach therefore is a social process of negotiation (Britzman 2003). Lacan (cited in Bibby 2011:34) states that there is a gap between the 'me' the trainee teacher is experiencing themselves, including what they see mirrored by other people, and the 'me' they would like to experience; desire is the urge to close the gap between these two versions of 'me'. This can be the cause of significant anxiety for the student teachers. There exists a tension between anxiety and desire, there cannot be one without the other and there can be no learning without them (Britzman, 1998), therefore this is an emotional conflict that they must negotiate in order to learn how to teach.

## **Methodology**

This research was carried out at Manchester Metropolitan University (MMU) with twelve student teachers on a Post Graduate Certificate of Education course (PGCE). The participants were members of my personal tutor group, who were placed in two 'University Schools', chosen on the basis of their previous experience of working as a placement school and their established expert practice. All twelve students agreed to take part in the study, and were assured of their anonymity and given the option to withdraw at any time. I discussed the ethical implications of the situation at length with them, and assured them that it would not affect the support or grading that they received throughout the year. In the USM, students teach two out of their three classes in the first placement as a trio and only one out of the three classes in the second placement. Other lessons are taught individually. Every week the university tutor visits for a full day throughout both placements, working alongside the students to help with planning, observe lessons, give feedback and advice, and provide pastoral support throughout the year.

There are four key sources of data in this research. I used a reflective journal to capture an autobiographical perspective on my practice, as the visiting university tutor. The student teachers reflect weekly on their progress on their placements as part of the PGCE course, and these were used to provide insights into their developing teacher identity. I held four focus groups during the placements to discuss various issues, including on one occasion my delivery of a lesson which had been planned by six of the student teachers, and observed by the students and the class teacher. At the end of the lesson the students gave me feedback, along with the class teacher. The lesson was also video recorded, and played to the focus group. At the end of the PGCE course, once the students' grades and final forms were completed, they participated in individual semi-structured interviews, focusing on their experiences of working in the USM, their ability to work collaboratively and the tensions surrounding this, and reflecting on the teacher they became as a result of their experiences. Both focus groups and interviews were audio recorded. This paper focuses on the interviews, analysed with a particular emphasis on considering the emotional aspect of teaching collaboratively and the effect this had on their developing identities as teachers. The data was operationalised by the theoretical framework and a thematic analysis was conducted. Two of the themes are discussed in this paper with respect to the research questions.

## Findings

### Teaching collaboratively

One of the main issues facing the student teachers in the USM is the idea of teaching collaboratively. They come to the course thinking that they simply require some practice in the classroom and that will be sufficient in making them a ‘good teacher’. The idea of having to work alongside other student teachers who may not be as strong as them, may not agree with them, may hold them back in their teaching or may be seen as needing support, was difficult:

Edward: When we all found about the trios, we were all definitely concerned.

Sarah: When we heard about it initially we were a bit like, oh, I don’t want to do that. I want to go in by myself.

Jennifer: I was a bit apprehensive about the trio at first, cos I just thought I don’t want to do it, I don’t want to be held back or whatever by someone else.

A common perception was that ‘learning’ from a peer is not effective for teacher education; they wanted to be in the classroom alone. There was an intrinsic denial that being influenced by their peers would support their own development as a teacher; they felt that learning can only take place from an experienced ‘teacher’. The prevalent idea was that education is the knowledge given by the expert and received by the novice.

Carol: I thought “well, you are just a trainee like me”. I found it easier to draw on people who had more experience than my own, than the people that I was working with.

The university tutor has a delicate role to play in this situation. The dichotomy of being influential in the student teachers’ developing pedagogies, whilst also have a role in ensuring the collaborative nature of the placement is effective:

Carol: I think, especially because when you are working in a three, the people are very different, they come from very different walks of life with very different ideas and opinions. And to have that visit every week [from the university tutor] it lubricates the situation and helps everyone to have a common idea and stops one personality maybe dominating others.

In spite of their misgivings and the tensions of the situation, the students reported that the support they receive from collaborating with peers in their lessons and in planning, means that they can try innovative teaching strategies with reduced fear of failure:

Sarah: But I think you have the opportunity to try different things...[you can] try it. Because there are three of you it can’t go drastically wrong.

### Developing the individual within the collaborative

There is a subtle balance to strike when teaching as a trio, between gaining credibility and recognition for your individuality in the classroom and successfully working together and collaborating with your peers. The need to ensure that you are being assessed individually is often a contentious issue:

Carol: because people come into this and they are like this is *my* training I think that is the heart of it. This is *my* training and I need to push myself forward even though we are collaborating. Unless people are willing to give that idea up...you end up getting caught up in a situation where you're like oh alright this is all about *me* too.

Whilst teaching collaboratively there are multiple 'others' constructing the student teacher's view of themselves. The students needed to orchestrate the experience of working with their peers and negotiate how their potentially conflicting pedagogical beliefs would inform their teaching. They also needed to work with the class teachers and subject mentor in whose classroom they were a guest, and therefore expectations to comply. In addition, they needed to work with the university tutor who comes with their own views about effective teaching, and also to manage their own internal beliefs based on their prior experience of education of the teacher they want to be. The latter is the most difficult to modify, since how students see themselves in the role of the teacher is the "phantasy" that has led them to undertake this journey. There is a strong desire to become this teacher and therefore the inclination to teach as they were taught is hard to challenge, but is a crucial element in learning to teach. The importance of these personal histories is the independence of individual journeys: the experience that one person had of education, and which has shaped their desire to be a teacher, is different to anyone else's experience:

Justin: I kinda remember things, of ways I was taught ....and I think if that's the way that I learnt it and I thought it was good then, maybe students now will think it's a good way to learn as well.

Edward: Yeah, because obviously I had my feelings of what I wanted to be as a teacher. Shafia obviously had her idea, which was definitely a lot closer to Claire's [the class teachers] than mine.

The notion of "teaching practice" is thus about the individual finding a path between these fluctuating versions of themselves. In Edward's case, his strong sense of the teacher he wanted to be was brought into question by the class teacher and his collaborative partner. Edward was adamant that he was not willing to change his teaching style. However, by the end of the placement he reflected back to say:

Edward: I think it has changed me slightly on where I was going to be, or where I thought I would be, but I think that was more for the better.

### **Emotional support and tensions**

Inevitably, the student teachers are all vying for their persona and their pedagogy to be dominant. When working as a group, if lesson planning and making decisions regarding how to teach a topic lead to differing views, this tension brings with it a strong emotional element. There is a sense of anxiety amongst the student teachers about which methods to teach, how to deal with behaviour, and how to manage the learning. The desire to teach the best lesson possible and be a successful teacher leads to further anxiety. This emotional tension can be difficult to navigate if the lesson is not being planned and delivered in a manner which reflects the teacher they are striving to become. However, the presence of anxiety and therefore desire is needed in order to progress; to close the gap between the image they see of themselves and the image which is projected to others.

However, there is also an opportunity for a student's ego to protect itself from the judgement of others by not contributing ideas and hiding behind the work of others. If the lesson does not go as well as planned there is an opportunity to remove yourself from the emotional disturbance of the feedback because you can convince yourself that this was not your lesson:

Edward: Because I don't like conflict too much so I just like "ok we will do it that way". I think that's probably bad in terms of teaching...going into a lesson and not being fully committed to the lesson...because it's not the way I wanted to do it.

The student teachers' anxiety at the start of the placement about not wanting to collaborate and the desire to teach on their own was alleviated in all of the participants in this research; this was mainly explained in terms of the emotional support they gave each other. This outweighed the emotional conflicts of teaching as a trio, with the anxieties and tensions this incurred:

Jennifer: If you go into it big headed, that you're the best teacher ever and you don't need it [the support from your peers] you'll fail because you need the people around you, you need that safety blanket.

Edward: It's nice having people around you that are in the same boat...obviously, you have two other people who are kind of your back bone in that sense and are supporting you

Overall the concern about them developing into the teacher they envisioned at the start of their placement was diminished throughout the year and the USM facilitated their ability to explore their autonomy and their agency in developing their teacher identity.

Jess: I think it has been easy to develop, there has been lots of support. This model has been really good for that. And I've not been one for asking for help but the help was always there.

Alison: You are obviously not always going to get on with your trio, it is inevitable that you are going to have differences, but you'll become the teacher you want to be in the end anyway.

## Conclusion

The 'University School Model' of ITE aims to foster collaborative learning which supports student teachers in developing as teachers informed by the university and protected to some degree from mere compliance with placement school practices. What this research has found is at first there is a resistance to working collaboratively in a classroom, due to a host of emotional reasons: their ego, their preconceived perceptions of their teacher identity, fear of being held back. However, throughout the placement, students' ideals about teaching are challenged through working with peers, and although they may resist the change, the situation allows them to develop their pedagogy in a 'safe' environment. Collaboration with their peers allows them to shift their version of themselves, and experience differing pedagogies without the possibility of failure resting solely on their shoulders. The pressure of compliance from their supporting teachers and the university tutor are still perceptible, but the collaborative nature supports them in the negotiation and articulation of their

teacher identity. It allows creative and innovative lessons to be explored due to the support of the other student teachers in the room, with a shared responsibility, yet with an emphasis on their personal development. The students' final overall conclusion was that they all individually achieved their desire of becoming the teacher they wanted to be, despite their original notions of this being challenged. This research highlights the nature and role of emotion in the development of student teachers' teacher identities. It is interesting to consider how 'the teacher they wanted to be' at the start of the PGCE evolves as a result of experiences in the USM and the effect the individual personalities in their trios had on their development. It also highlights the role of the university tutor as a facilitator in this development. These are areas to be explored further.

# Teacher Professional Development and Collegial Learning: A literature review through the lens of Activity System

Frida Harvey and Anna Teledahl

Örebro University, Sweden; [frida.harvey@oru.se](mailto:frida.harvey@oru.se); [anna.teledahl@oru.se](mailto:anna.teledahl@oru.se)

*This study maps key features of effective Teacher Professional Development (TPD) and the framework of Communities of Inquiry (CoI), in an effort to gain an understanding of how these features contribute to teachers' collegial learning. Activity system, as described by Engeström (1987)/(1999), is used as a theoretical lens which allows for the visualization of TPD as a complex system. The result indicates that, apart from differences in the level of detail in the description of various features, there are differences in the demands the two models place on teachers. Establishing norms that promote collegial learning, in which critical inquiry is expected, emerged as a critical issue. This highlights the importance of viewing any variant of TPD as a process, in which the functions of features shift. Awareness of this process may prove important in designing and implementing future TPD initiatives.*

*Keywords: Activity Systems, Collegial learning, Communities of Inquiry, Teacher Professional Development*

## Introduction

In recent years, there have been calls for raised achievement in mathematics in a number of European countries, of which Sweden is one. In an effort to respond to these calls, the Swedish National Agency for Education (SNAE) launched several teacher professional development (TPD) initiatives, which build on the idea of collegial learning. SNAE describes collegial learning as activities in which teachers collectively and systematically analyse their teaching, in an effort to develop their practice and improve student achievement. Several studies have identified a shift in TPD where a traditional culture of viewing TPD as single occasions of "new knowledge being handed to teachers", is replaced by a new culture (e.g. Villegas-Reimers, 2003). Evaluations of the largest of these Swedish initiatives, Matematiklyftet [the Mathematics Lift], show that teachers, who have participated, have developed their ability to plan, carry out, and reflect on their teaching. What is left to investigate is in what way the various features of the initiative have contributed to this development (Österholm, Bergqvist, Liljekvist, & van Bommel, 2016). The question of what it is that makes TPD, and in particular, the kind of TPD which is based on ideas of collegial learning, effective, acts as a starting point for our study. We aim to explore this question through an inquiry into previous research on what makes TPD, in general, effective, but also by turning to a specific theory for collegial learning, Communities of Inquiry (CoI). In order to tackle the complexity of TPD as an endeavour we have turned to Cultural-Historical Activity Theory (CHAT). By using Engeström's model of activity systems (1999) we believe we can create a model of TPD and collegial learning that accounts for multiple dimensions, thus offering an opportunity to understand possible tensions between the two models of which the latter is part of the former.

## Purpose and guiding research questions

By viewing TPD as an activity system, and categorize findings from previous research as parts of this system, we believe we can gain a comprehensive understanding of different aspects of collegial professional development. We hope that such insights will contain a problematization of prerequisites for TPD, which may prove helpful in future TPD initiatives. First, we investigate the question: *What characterizes effective professional development of teachers?* When we have mapped aspects of TPD, we look for differences between these and the corresponding aspects of the particular form of TPD known as *Communities of Inquiry*. The latter is expressed in the question: *What are the possible similarities and differences between general models for effective teacher professional development and Communities of Inquiry?*

## Theory

Cultural-Historical Activity Theory (CHAT) is a theory that offers both an analytical and conceptual framework to understand human practices. The theory takes a social perspective on human actions and learning, meaning that human activities are understood in relation to their history, culture and context (Engeström, 1987). Within CHAT, Engeström (1987) has developed a model for analysis, which he calls activity system. An activity system is “the smallest and most simple unit that still preserves the essential unity and integral quality behind any human action” (p. 81). Activity systems have been used increasingly as a research framework in educational research in recent years (Gedera & Williams, 2016).

**Figure 1: Activity system, as illustrated by Engeström (1999)**

The activity system consists of six nodes as shown above. The *object* is the underlying “true” motive for the activity. *Subject(s)* are the participants who share the object of activity, for example teachers in a TPD-community. *Mediating artefacts* are the tools, with which the object is achieved. A tool can be a material object but also a procedure. *Rules* describe the rules and norms, both explicit and implicit, which are shared by the participants in the activity. *Community* refers to the context to which the subjects belong. This context may also include others, for example those who, in different ways, contribute to a shared object. *Division of labour* describes both the expressed roles of the subjects and the implicit hierarchical structures. To every activity system there is also an *outcome*, which can be defined as the change and/or result of an activity. A central aspect of CHAT is the analysis of tension within and between the nodes of the activity system. It is imperative to development and learning, to identify such tensions. (Definitions are a synthesis of Engeström, 1987; Engeström, 1999).

Engeström (1987) stresses that an activity system can have any size, it may consist of one single person or an entire society. All those who share the object of an activity are part of the activity system. In educational research, the activity system has been commonly used as an analytical tool to interpret data, foremost for its usefulness in making the context of educational processes visible (e.g. Jaworski, 2009; Walshaw & Anthony, 2008). In this article, TPD is seen as one activity system.

## Method

In our aim to investigate what research says about effective collegial TPD, we turned to literature in two different ways. 1) In order to identify key features TPD in general, we turned to studies, which implemented a meta-analysis of previous research. Meta-studies offer opportunities, not only for quick and easy access to numerous studies in a specific field, but also to take advantage of a synthesis aimed at highlighting, comparing or critiquing, the most prominent aspects of a particular phenomenon. It is, however, important to consider that meta-studies often lack the nuances and depth, which systematic reviews of existing literature, provide. To partly counter such drawbacks we chose meta-studies conducted by researchers, which we through extensive reading, perceived as prominent researchers in the field of TPD: Borko (2004), Desimone (2009) and Darling-Hammond, Hyler, and Gardner (2017). 2) The concept of TPD encompasses a number of different models for professional development. Collegial learning is a specific model for professional learning that has gained popularity in recent years. In Sweden, the model is the preferred model in national development initiatives. In order to compare the key features of TPD with research on collegial learning as a specific model for TPD, we chose to focus on the framework of Communities of Inquiry (CoI), as described by Garrison (2016), since this can be understood as a particular framework for collegial learning. To further anchor, the general framework of Garrison, in the context of mathematics education we also chose to include Jaworski's article on CoI in mathematics teaching development (Jaworski, 2008). Teacher learning and professional development are complex endeavours, which are difficult to grasp. In order to deal with this complexity we turned to Engeström's description of an activity system, consisting of six nodes. Viewing TPD as an activity system, allowed for the mapping of, not only the various concepts involved, but also the relations between these concepts. The activity triangle thus offered a visual, as well as analytical tool, with which we could manage the inherent complexity.

Viewing collegial TPD as one single activity system, which then constituted our unit of analysis, allowed us to explore the literature through the questions; what does research say about *the object, the subjects, the division of labor, the mediating artefacts*, etc. Salient features were noted in table 1. After having created an image of collegial TPD as a complete activity system, we explored each node looking for similarities, differences and possible gaps in our collective knowledge. Our aim is to provide insights into PD that will prove helpful in future initiatives.

## Key features of an activity system for effective teacher professional development

In this section, key features of effective TPD as well as aspects of CoI are organized in relation to the nodes of the activity system. Similarities and differences found in each node are compiled in Table 1, and further presented in more detail under each of the headlines.

<b>Node</b>	<b>Effective TPD</b>	<b>Communities of Inquiry</b>
<i>Subject</i>	Teachers, facilitator	Teachers, facilitator
<i>Object and outcome</i>	Teacher learning, changes in practice	Better understanding of what is being questioned, developed thinking/reflection, inquiry is a way of being, connecting ideas/experiences and applying new ideas in practice. All the above lead to changes in practice
<i>Mediating artefacts</i>	Long term activities built on active learning, content focus related to subject matter knowledge, task with relevance for classroom practice	Questioning of practice or problems in practice as a starting point for critical discussions, sharing, comparing and developing experiences and ideas through critical discussions, exploratory working methods, inquiry as a tool, inquiry cycle
<i>Rules</i>	Collective support, trust, challenging/critical discussions, active learning	Critical review of experiences, ideas and results of teaching, exchange of experiences is not enough, inquiry as a way of being, open communication
<i>Community</i>	Teachers' beliefs and prior knowledge, school reforms	Social context; for example, educational content and communication medium
<i>Division of labor</i>	Facilitator foster norms of critical discussions, teachers act as active learners	Facilitator designs and organizes the meetings (structure and content), proposes tasks, keeps discussions focused, problematizes discussions, gives feedback and guides the teachers, teachers are inquirers who explore and analyse their teaching practice

**Table 1: Similarities and differences between effective TPD and CoI**

### Subject

In all the three meta-studies, TPD initiatives are described as including more than one participant. This can be seen as a reflection of a focus on collective participation. Borko (2004) mentions teachers and facilitators as subjects, while Desimone (2009) and Darling-Hammond et al. (2017) mention only teachers as subjects in TPD. The teachers, together with a facilitator, are all participants in the framework of CoI (Garrison, 2016). Facilitators seem to have a more pronounced and central role in CoI than in research on effective TPD.

## Object and outcome

Borko (2004) has investigated the impact of TPD on teacher learning whereas Desimone (2009) makes it clear that TPD should increase teacher learning *and* change practice to be seen as effective. It may be seen as unproblematic to view teacher learning as the object of the TPD activity system. Desimone's reference to a *change in practice*, however, highlights an uncertainty regarding what teacher learning entails. When it comes to CoI, Garrison (2016) argues that learning is manifested in teachers' different ways of thinking, reflecting and acting, which is the result of activities where the focus is on connecting different experiences and ideas, rather than just sharing them. Jaworski (2008) pinpoints this difference by arguing that the teachers, not only change their thinking regarding certain phenomena, but that they develop inquiry as a way of being, they are "taking the role of an inquirer; becoming a person who questions, explores, investigates and researches within everyday, normal practice" (Jaworski, 2008, p. 312). This indicates that the process of inquiry instead of being a means, turns into the object. Teachers who collectively act as inquirers, into their own teaching, have opportunities to tackle didactical and pedagogical challenges in a systematic and effective way.

## Mediating artefacts

The mediating artefacts described in research of effective TPD can be categorized into three overall categories; 1) long term activities built on active learning (Darling-Hammond et al., 2017; Desimone, 2009), 2) content focus related to subject matter knowledge (Borko, 2004; Desimone, 2009) and 3) tasks with relevance for classroom practice (Darling-Hammond et al., 2017). The content focus limits the scope of the TPD, and acts as a guard against diversions and irrelevant questions, and it can therefore be seen as a mediating artefact. Darling-Hammond et al. (2017) argue for the importance of feedback and opportunities for reflection, while Borko (2004) is more explicit regarding the implementations when she proposes that classroom-material such as video recordings, student work and lesson plans, could be the starting point of professional development for teachers. In CoI there are more specific examples of mediating artefacts. For example Jaworski (2008) proposes that the long term activity should be designed as inquiry cycles where teachers plan lessons, act & observe, reflect & analyse and finally get or give feedback on the lessons. This cyclic process, where the questioning of practice is a starting point, can carry on for longer or shorter periods. Such a model offers a concrete tool to use in the TPD. In relation to the second category, Garrison (2016) proposes that the content should be focused on sharing, comparing and developing experiences and new ideas through critical discussions. To the third category, Garrison adds that the tasks should be exploratory in character. Jaworski uses the expression "inquiry as a tool" (p. 310) with which she argues that teachers need to use, for example, questions and exploratory methods to practice and develop inquiry as a way of being. What Jaworski (2008) and Garrison (2016) propose can be understood as a refinement of the more general categories found in research of effective TPD.

## Rules

Norms concerning collegiality seem to be important in effective TPD (Borko, 2004; Darling-Hammond et al., 2017). Borko (2004) stresses the importance of trust, which enables challenging discussions on teaching, and she argues that this is one of the most important

features of TPD. Desimone (2009) and Darling-Hammond et al. (2017), stress that teachers are expected to be active learners. In CoI, the importance of a critical review of experiences, ideas and results of the teaching, is stressed. This is something that goes beyond the mere exchange of experiences (Garrison, 2016; Jaworski, 2008). Garrison (2016) argues that norms of inquiry require open and risk free communication, where all participants can share ideas and experiences, without the risk of being ridiculed or attacked. Before such norms, of active learning, critical reviews and inquiry, are established however, they can be considered artefacts mediating learning, rather than part of a set of ingrained expectations. The rules and norms are quite similar between effective TPD and CoI. There is, however, in the case of TPD as well as CoI, a lack of description of how, and by whom, these rules and norms should be implemented and established.

### **Community**

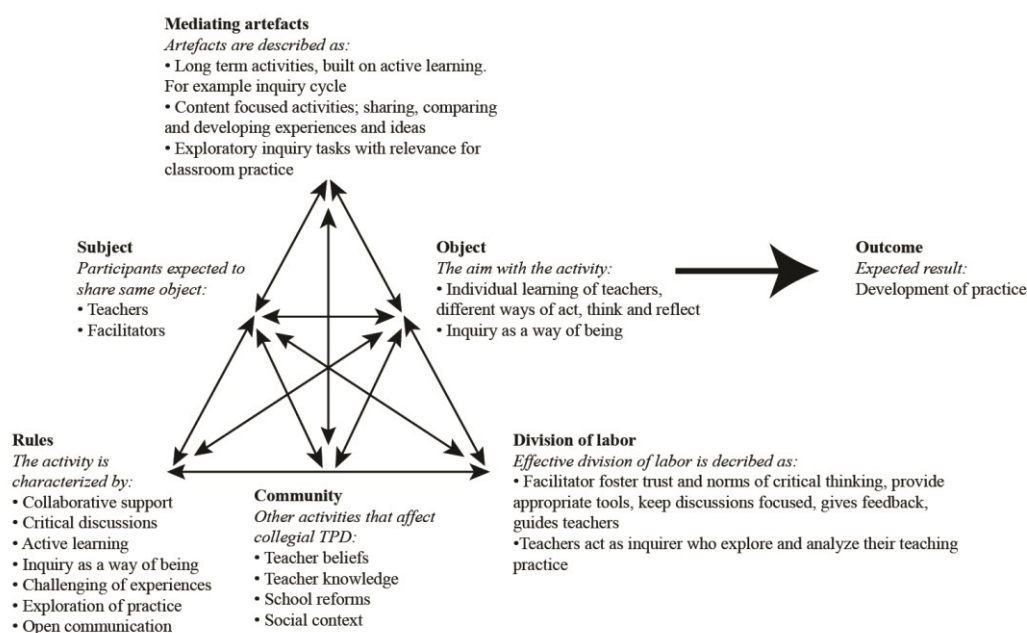

The participants in a TPD are also participants in other contexts where teacher learning and improvement of practice is the motive. Consequently, for TPD to be effective it must be in consonance with teachers' contexts, for example prior beliefs and knowledge (Desimone, 2009). Desimone also mentions the importance of coherence between the content of TPD and for example school reforms. In the same vein Garrison (2016) argues that individuals are inseparable from their context. Examples of elements of the social context, mentioned by Garrison, are educational content and communication medium. Aspects concerning community seem quite peripheral in research of both effective TPD and CoI, which indicates that the concept may not be well defined.

### **Division of labor**

Desimone (2009) and Darling-Hammond (2017), which only mention teachers as subjects, argue that teachers need to be active learners, which could be understood as taking on a role. Borko (2004) describes the role of the facilitator, whose most important task is to foster trust and norms, which enable discussions. All three studies describe several key features such as time, active learning, norms of collegiality etc., but it is not clear, who is responsible for their implementation, or for upholding them, once they are established. According to CoI, the facilitator has a leading role. Garrison (2016) argues that the facilitator's task is to design and organize the activities, as well as to keep the conversations focused and exploratory in order to create rich and meaningful discussions. This could entail posing challenging questions, giving feedback or guiding teachers. The teachers are described as inquirers who participate actively in discussions, as well as explore and analyse their teaching practice. Garrison stresses that the teachers should be increasingly independent in the learning process. Although division of labor is described in more detail in CoI, concerning the role of the facilitator, little is said about how the facilitators should work to achieve this trusting, but also challenging, work environment. This points to an area where more research is needed.

### **Discussion**

By using Engeström's (1987) activity system, we have tried to visually represent what research says about effective TPD and CoI.

**Figure 2: Activity system for effective collegial teacher professional development**

Aspects of effective TPD and CoI, which have proved complex, are mainly those that can be sorted under the nodes: object, rules and, mediating artefacts. Some key features were sorted under more than one node in our categorization. Inquiry is positioned under each of these three nodes. This demonstrates the complexity of teacher learning, but also the flexibility of this framework. As the activity evolves the content of the nodes shifts, and creates a dynamic system. The activity system as an analytical framework thus has potential to identify different phases of the learning process. The inquiry process is an example of a process, which initially can be seen as a tool to foster changes in the way teachers approach a certain issue. When the tool however has become a part of teachers' natural approach, its function shifts and it can be seen as part of the rules and norms that govern the teachers' interaction. Jaworski (2008) argues that inquiry may be seen as a way of being and therefor can be seen as the object of TPD. CHAT as an analytic lens allowed us to view inquiry as a process, which can be found under the three nodes, object, rules or mediating artefacts, depending on what stage of a TPD initiative we are analysing. Theoretically, there is a considerable difference between viewing a process as a means or as a goal, which could generate what Engeström (1987) calls tensions in the activity. Empirically, however, it is natural that you can adopt a process by using it, by living through its different steps.

If the process of inquiry is viewed as a mediating artefact, something that can be used to achieve the goal of learning, then this is the aspect in which we find the greatest difference in detail, between previous research on TPD in general, and CoI. Inquiry, exploration and challenging of experiences are examples of concepts from CoI that refines some of the key features of effective TPD. Jaworski (2008) and Garrison (2016) stress that simply talking or sharing experiences, is not enough for a collegial activity to result in learning. Collective, critical and systematic reviews and analysis of experiences and practice are crucial to building new collective knowledge and collegial learning. We believe this constitutes a tension, between a new collegial culture and a previous, more individually oriented culture. A culture, which no longer equates,

passively acknowledging other's accounts of their teaching, with learning that informs and changes one's own practice, requires engagement from the teacher community. It places demands on the analytical and social skills of the participating teachers, on the pedagogical skills of the facilitator, and on the organization, that supports collegial work. In order for the teacher community to meet such demands, teachers as well as school administration need an awareness of the prerequisites for collegial learning that are highlighted in this article. In order for collegial learning to be successful, several important norms, such as trust and risk-free, open communication, must be implemented. Collectively asking questions about, investigate, or critically review, one's own practice requires a social environment, in which trust is considerable. Few examples are given on how the teachers and/or a facilitator should foster such norms. This is characteristic for many of the key features presented in figure 2. Research offers pointers on *what* and *who*, but very little is said about *how* the processes can be achieved. The processes leading to collegial learning is an area in need of more research.

*This paper deals with a study that relates to the understanding of the concepts that constitute part of symbolic thinking. The goal of the study was to understand how pre-service teachers (PST) and preschool teachers (PT) understand and use the mathematical symbols  $<$ ,  $>$ , and  $=$  when comparing numbers, figures and shapes of different sizes and thicknesses. Using both quantitative and qualitative methods, we examined a study population of 71 PST attending a course for teaching mathematics to pre-schoolers and 149 PT. Our results show that the majority of participants did not answer the questions correctly, with a significant difference between how the two groups validated their answers, indicating that the participants do not correctly understand that mathematical symbols should only be used in the mathematical context.*

*Keywords: Preschool teachers, pre-service teachers, mathematics education, early childhood, mathematical symbol.*

## Introduction and theoretical framework

Mathematical language in Early Childhood is a language of symbols, concepts, definitions, and theorems. It does not develop naturally like a child's natural language, but needs to be taught (Ilany, & Margolin, 2010). In essence, children are engaged in mathematics in daily life from birth, and today's global trend is to introduce "formal" mathematics at a young age. Preschool math practice aims to develop mathematical awareness and cultivate mathematical thinking from an early age, thus shaping the child's future mathematical thinking, general thinking, and cognitive abilities. Studies have shown that the volume and quality of preschool math practice predict a child's success in math in elementary school (Clements, & Sarama, 2006, 2015).

The first skills include being able to use the concepts of "bigger", "smaller," and "equal to" to recognize differences between objects. Some PT introduce the mathematical symbols  $=$ ,  $<$ , and  $>$  already in preschool and, unfortunately, ask the children to use these mathematical relational symbols to compare non-mathematical objects. This leads children to believe that these symbols are not restricted to mathematical values and, moreover, even when comparing numbers, to use them incorrectly. For example, a child in grade one may write " $6 < 4$ " because the four looks bigger and thicker than the six, indicating that he is looking at the numbers as graphical entities and not mathematical ones. Such instances have led to the study of how PST and PT themselves use these mathematical symbols (Hassidov, & Ilany, 2017). Different quantities are compared through relations of order using various strategies based on the properties of these relations. According to Cantor's (1971) sorting principles, the set of real numbers has an intrinsic linear order. In other words, between any two quantities, one and only one of three following options holds true: (i) the two values are equal to each other; (ii) the first is greater than the second; (iii) the first is smaller than the second. If we

plot real numbers on a number line, two numbers,  $a$  and  $b$ , are equal only if the points that represent them coincide. If  $b$  is greater than  $a$ , the point representing  $b$  will be to the right of  $a$ . Here, we can also say that  $a$  is less than  $b$ . It is useful to present the ways that a relationship between two quantities can be described by using three pairs of relations, where each proposition of the pair is the negation of the other:  $a = b$      $a \neq b$ ;  $a > b$      $a \leq b$ ;  $a < b$      $a \geq b$ . Recall that the strategies used to compare two quantities are based on the general properties of comparison relations. The relation of equality is an equivalence and maintains the three properties of any equivalence relation: reflexivity,  $a = a$  (each value is equal to itself); symmetry,  $a = b \Leftrightarrow b = a$ ; and transitivity,  $a = b \& b = c \Rightarrow a = c$  (two values equal to a third are also equal to each other).

Symbolic reasoning means the ability to grasp the meaning of a symbol representing an object or idea, without having an expression in the symbol itself (Bialystok, 1992). It is an evolving ability and one of the developing expressions of thought (Thomas, Jolley, Robinson, & Champion, 1999). Its development is characterized by changes that occur in the form of the mental representation of an object. Young children believe that the symbolic representation reflects the nature of the object it represents (Bialystok, 1992). For example, children may write the names of large objects using large letters (Thomas et al., 1999). Nemirovsky and Monk (2000) noted that young children do not distinguish between the symbol and the object that the symbol represents. The early development of symbolic reasoning in children should allow them to properly use mathematical symbols later in formal math. Teaching mathematics to pre-schoolers today requires professional knowledge on the part of the PT (Charalambous, Panaoura, & Philippou, 2009). Unfortunately, studies conducted in recent years indicate that PT assigned with teaching preschool mathematics do not have adequate knowledge. This may stem from negative personal experiences or a lack of appropriate training in college (Hassidov, & Ilany, 2014, 2015). They often use the knowledge and experience they bring from daily life, meaning that they might not always give the correct mathematical importance to the symbol. If PT incorrectly understand the use of mathematical symbols, it is reasonable to assume that they will subsequently pass this misinformation on to the children, leading to incorrect use in the future. It is thus crucial to teach the proper mathematical use of symbols from the preschool level (Hassidov, & Ilany, 2017). PT often use the knowledge and experience they bring from daily life, meaning that they might not always give the correct mathematical importance to the symbol. If the teachers incorrectly understand the use of the symbol, they will subsequently pass this on to the children, leading to their incorrect use in the future. Although young children can identify symbols and write them, this does not necessarily reflect an understanding of the symbol's mathematical meaning or their relationship to numbers. The concept of equality is an especially difficult concept to comprehend for children, since this term can be used both relationally and mathematically. Using the “=” symbol incorrectly with children makes it even harder for them to properly understand its concept.

Many studies have examined how children of various ages comprehend the “equal” sign. They show that children aged 5–12 tend to perceive the equal sign as an operational symbol and not as a sign of comparison. PST translate the symbols as a command to perform a mathematical operation. It is important to grasp that the meaning of a symbol cannot be changed by non-mathematical factors (such as a change in size or other physical factor). In a study dealing with the knowledge of PST and PT regarding their understanding of the significance and use of mathematical symbols between numbers, Hassidov and Ilany (2017) found that PST and PT do not fully understand that mathematical

symbols should relate only to the mathematical nature of the object. If one number was written in a larger, smaller, or thicker format than another, they often regarded the physical qualities and not the mathematical (i.e., the values of the numbers). Furthermore, even when they used the symbol correctly, the reasoning behind its use was often flawed.

## Research Questions

This study examines how PST and veteran PT understand the concepts of  $>$ ,  $<$ , and  $=$ . Its objectives were twofold:

- 1) How do PST and PT comprehend and use the relational symbols ( $>$ ,  $<$ , and  $=$ ) in perspective of "Numbers" and "Quantity"?
- 2) Is there any difference between how the two groups comprehend and use these symbols?

## Method

The study population comprised 71 second- or third-year PST participating in a year-long course dedicated to the teaching and learning of mathematics in early childhood and 149 veteran PT. Data were collected via semi-structured interviews and a 25-item questionnaire designed by the authors. Of the 25 questions in the questionnaire, eight (questions 1, 2, 3, 17 and 7, 9, 10, 16) addressed the use of mathematical symbols between shapes and numbers that had some graphical difference (size, thickness, placement) (Table 1). Respondents were asked to either place a relational symbol between two figures or indicate "X" if they believed there was no appropriate answer, and then justify their answers. Analysis was both qualitative and quantitative.

Questionnaires were filled out by the PST before any formal study of the subject. The researchers interviewed a random sampling of 30 PST. This was followed by a class discussion on the use and meaning of mathematical symbols, and the subject's place in the preschool curriculum. Questionnaires were filled out by the PT and then individual interviews were conducted to ascertain the PT reasoning for their answers. Relevant background information was collected (e.g., professional experience).

## Results

Overall, not one of the participants gave the correct answer and justification for questions 1, 2, 3, and 17. Even the very few who gave the correct answer ("X") gave flawed justifications, the correct one being that these symbols cannot be used for graphical objects and only for numerical entities. A significant difference was found between the two groups: a large number of PT did not supply any justification for their reasoning (58.4% for question 1, and 57.7%, 60.4%, and 66.4% for questions 2, 3, and 17, respectively) compared to the number of PST who did not (19.8%, 14.1%, 16.9%, 28.2%, respectively).

**Questions for example: 2; 17** (Quantitative) asked which mathematical symbol, if any, should be placed between the shapes of different sizes and thickness.

**Question 2:** contained three smileys. The results were similar to question 1: most did not answer "X," and those who did, justified it incorrectly. Similarly, there was a significant difference ( $p < 0.001$ ) between the groups (see Table 2). The vast majority of both PST and PT answered "=", indicating that they focused on the number of smileys (numerical properties). However, one preschool teacher said:

“There are the same number of smileys, but the area is different.” That is, her answer was based on quantity, but her justification also considered the shape. Another wrote “I counted the smileys.” One wrote: “Based on my experience, I would teach that the second is larger. But there can be different levels,” indicating that she feels that different criteria can be used under different circumstances. One PST teacher wrote: “I looked at the number of smileys. There is no importance to the length of the rectangle, only the number.” One PST teacher indicated “=” but wrote “The same quantity in each rectangle, although the left rectangle has a greater area.” Those who indicated “<” justified their answer by indicating either the size or thickness of the rectangles. One preschool teacher answered, “They look to me to be the same, except that one rectangle is longer.” A PST teacher who marked “<” wrote “the rectangle on the right is thicker and coloured.” Again, although 4% of the PT gave the correct answer (“X”) their justifications were incorrect. For example: “They cannot be compared because the shapes are not the same.”

Question	Possible Answers							
	<		>		=		X	
	PT	PST	PT	PST	PT	PST	PT	PST
1   	98	100	0	0	0	0	2	0
2   	5	0	16	6	74	94	4	0
3   	95.4	96	1.3	1	1.3	3	3	0
17  +   	1.3	0	2.7	4	92	90	4	6
7 $\frac{1}{2} \square \frac{1}{4}$	14.1	0	*80.5	*97.2	0.7	0	4.7	2.8
9 $5 \square 5$	0	0	26.2	14.1	*70.5	*77.5	3.3	8.4
10 $6 \square 4$	17.4	2.8	*77.9	*91.6	0	0	4.7	5.6
16 $2 \times 3 \square 6$	1.3	0	6	0	*86	*98.6	6.7	1.4

**Table 1: Quantitative (questions 1, 2, 3, and 17) and Numerical (questions 7, 9, 10, and 16) - Analysis of the responses of PST and PT (all values represent percentages, \*correct answer)**

Differences between correct answers: Question 7  $p^*=0.001$ , distribution  $p=0.006$ ;

Question 10  $p^*=0.01$ , distribution  $p=0.01$ ; Question 16  $p^*=0.003$ , distribution  $p=0.032$ .

Justification for question 1	Graphic properties*		Numerical properties*	Both size and quantity*	No answer*	Number who gave correct justification	
PST	N	1	56	0	14	0	
N=71	%	1.4	78.8	0	19.8	0	
PT	N	6	53	3	87	0	
N=149	%	4	35.6	2	58.4	0	
Justification for question 2							
PST	N	2	52	7	10	0

PT	N	18	41	4	86	0	
N=149	%	12.1	27.5	2.7	57.7	0	
Justification for question 3							
PST	N	1	57	1	12	0	
N=71	%	1.4	80.3	1.4	16.9	0	
PT	N	3	54	2	90	0	
N=149	%	2.1	36.2	1.3	60.4	0	
Justification for question 17	Another answer X						
PST	N	10	36	4	20	1	0
N=71	%	14.1	50.7	5.6	28.2	1.4	0
PT	N	4	44	1	99	1	0
N=149	%	2.7	29.5	0.7	66.4	0.7	0

**Table 2: Quantitative analysis (value and percent) of the justifications given by PST and PT to questions: 1; 2; 3: 17** \*  $p < 0.001$

**Question 17:** Each side had two triangles, one being “upside down.” On the left, they were in a single row with a plus sign (“+”) between them. On the right, they were one on top of the other. Once again, the vast majority (94% of PST and 96% of PT) answered incorrectly and there was a significant difference ( $p < 0.001$ ) between the justifications they gave (Table 2). One preschool teacher who indicated “>” said: “There are two triangles and the addition operation, so that side is larger than the right side.” One who indicated “=” wrote, “We haven’t learned this yet.” Another gave an answer that seemed confused, “They are equal from two standpoints. One is that on each side one triangle goes up, and one goes down. So, they make the shape of an equilateral diamond.” A teacher who indicated “=” said, “The placement of the triangles is not important. What is important is their quantity.” One PST who answered “X” justified it with “There is no answer because I didn’t know which symbol to use. There are two triangles on each side, but they are not arranged the same.” Some PT answered “X” because they did not know which of the others to use.

**Questions for example: 9; 10; 16** (Numerical) asked which mathematical symbol, if any, should be placed between numbers of different sizes and thickness.

	PST	N=71	PT	N=149

Because of the size of the numeral.	0	0	4	6

**Table 3: Numerical - analysis (value and percent) of the justifications given by PST and PT to questions: 7; 9; 10 and 16**

**Question 9:** Table 1 shows that 77.5% of the PST and 70.5% of the teachers answered correctly, but as can be seen in Table 3, only 45.1% of the PST and 16.1% of the teachers who answered correctly

gave the correct explanation. Of those who gave an incorrect explanation, 2.8% of the PST and 13.4% of the teachers gave the reason to be the graphic form of the numbers, and 12.7% of PST and 4.7% of the teachers referred to the quantity of items (one numeral) on each side. One reason given by a teacher indicated her deliberation between the graphic or numerical quality of the numbers: “It depends on how one looks at the question: according to shape, one is larger than the other; according to numerical value, they are equal.” Of those who answered incorrectly, 8.5% of the PST and 1.3% of the teachers argued that no symbol could be put between the digits because there can be multiple answers based on how one looked at the question (“Both numbers have the same value but not the same size and thickness”). 11.3% of the PST and 11.4% of the PT argued the number on the left is larger. One PST wrote: “Looking at the numbers, they are equal in terms of quantity or value, but the type is bigger and it’s confusing.”

**Question 10:** Table 1 shows that 91.6% of the PT answered correctly compared with 77.9% of PT (Table 3). This question deals with getting to know the first ten numbers. From table 1 it could be seen that there is a significant difference in the scattering distribution between kindergarten PST to PT ( $\chi^2_{(2)} = [9.271, p=0.01]$ ). It can also be seen that 91.6% of the PT answered correctly, compared to 77.9% of the kindergarten PT ( $\chi^2_{(1)} = [6.19, p=0.01]$ ). In Table 3 we see that 63.4% of the PST and 24.8% of the PT correctly explained that it was due to the sequence of numbers. Some participants (8.5% of PST, 5.4% of PT) incorrectly based their answer on the number of items on each side and not their numerical value. Of the incorrect answers, 17.4% of the PT, but only 2.8% of the PST answered that “four” was larger than “six” based on the numbers’ graphic properties.

**Question 16:** Table 1 shows that 98.6% of the PST answered correctly compared with 86% of PT ( $p<0.01$ ). Of the 21 (14.1%) of PT who answered incorrectly, 10 answered “X,” claiming that a number of answers were possible, and 9 (6%) claimed that  $3 \times 2$  was greater than 6 due to the graphic properties of the numerals (Tables 1 and 3).

**Additional findings.** Interviews and discussions with the PST and PT revealed that most of them thought it was possible to use more than one mathematical symbol, between numbers, as an answer.

## Discussion and conclusions

This study found that most of the participants failed to answer the questions correctly. The justifications given to the questions show a significant difference between the PST and PT with respect to how many justified their answers, yet it is clear that all participants did not appreciate the significance of the mathematical symbols and how to use them, specifically, that mathematical symbols should be used only for mathematical symbols. This was clear since even when the answer given was correct (“X”), the justification was generally incorrect (Hassidov & Ilany, 2017; Ilany & Hassidov, 2018). The results of this study show that PT feel that mathematical symbols may be used in different ways, depending on context: sometimes with respect to the quantity and sometimes to the shape or size of graphical images and they did not restrict them only to their mathematical significance. The conclusion is that the participants do not properly understand the significance of the symbols =, <, and > nor how to use them. This will, in all probability, mean that they will not teach the concepts properly to preschoolers. Indeed, studies have shown that PT believe the signs can be used in many ways. Using the same words in everyday life and in mathematics leads to misconceptions regarding the meaning of the mathematical signs. PT thus do not see any problem if

a child writes “**5** > 5,” and have stated that they teach the child to use the symbol “>” between two objects, as “in this case the size is important; in another case the length may be important. It depends on the context.” PT may even believe it is correct to use two different signs at the same time; however, they must understand the cognitive conflict that this gives children and must understand that it is never possible to use two different signs between two numbers at the same time. PT must be made aware that the signs “<, >, and =” must be used only in the mathematical sense. PT who incorrectly see quantity as a graphical concept and do not see the mathematical significance will, most likely, pass on this misconception to the children. This might lead the children to think that the size of the number or graphical object is what determines the relationship and which symbol to use.

# Similarities and differences in problem solving: case of “exhibition grounds”

Radka Havlíčková, David Janda, Derek Pilous and Veronika Tůmová

Charles University, Faculty of Education, Prague, Czech Republic; [derek.pilous@seznam.cz](mailto:derek.pilous@seznam.cz)

*Keywords: Problem solving, Number paths.*

## Introduction

Problem solving strategies play one of the major roles in mathematics education research in the last decades (Schoenfeld, 1992). Its importance naturally arose from teaching practice in which teachers work with solving strategies intuitively, on the basis of their own experience, without any particular theoretical framework. One of the authors made an interesting observation in his teaching: there are problems with no simple algorithmic solution and more than one solution in which both mathematically less experienced solvers and more experienced solvers find the first solution in comparable time, but the more experienced solvers are more successful and faster when finding all the solutions of the problem. Therefore, measuring of reaction time when solving such problems might capture the difference between the above groups of respondents. If it is the case, this connection could be used as a further source of information about particular heuristic strategies with implications for teaching practice and teacher preparation.

## Theoretical background

Since Polya (1957) introduced the modern conception of heuristics in mathematics education, a lot of research effort has been put into the exploration and description of possible connections between the level of mathematical knowledge and the ability to solve non-procedural problems. Problem solving process, and especially differences between more and less experienced solvers, have been examined by many authors. Lester (1994) summarized main findings in this domain when characterizing a good problem solver by five basic characteristics. We follow these findings when formulating our research questions:

1. What relationship is there between the time of finding the first solution and the time of finding all the solutions for different groups of solvers?
2. What relationship is there between parameters of the solutions such as the number of solutions, their order and multiplicity of submission, and the solver's knowledge?

## Methodology

The learning environment called *exhibition grounds* is in accordance with our motivation as it provides problems to solve with several solving strategies and more than one solution. The task is to go through all the rooms of the exhibition center. A solver records his/her way by filling numbers into the squares (see Figure 1). Each room can be passed only once. Some rooms are filled by numbers from the start which means that these rooms must be visited in a prescribed order. The start and end rooms must be on the border of the grid and one can go only left, right, up or down from one room to another. It is forbidden to jump rooms, go diagonally, go through the same room twice or leave empty rooms behind. The solution is correct when each square is numbered with different numbers from 1

to  $m \times n$  for an exhibition ground with  $m$  rows and  $n$  columns. The exhibition ground used in the study and all correct solutions are shown in Figure 1.

**Figure 1: Exhibition ground used in the study with all the correct solutions**

The research sample consists of two groups of respondents, 49 students of general high school of age 16–17 and 28 future mathematics teachers in 1<sup>st</sup>–3<sup>rd</sup> year of their study. The sample is an opportunity one as our study was exploratory. The exhibition ground from Figure 1 was used in the study. There was no time constraint and students received no information that their reaction time is measured due to our previous findings that this kind of information can significantly influence a solver's behavior (Pilous & Janda 2017). In total, 77 respondents submitted 305 correct solutions.

## Results and conclusions

Each respondent found at least one solution, only 15 respondents in total found all five solutions, 12 from the high school and 3 from the university. Due to the small number of solvers who found all the solutions, direct comparison as described in RQ 1 (first solution vs. all solutions) is not significant here. However, several relationships between the time of finding the first solution and the time of finding all the solutions for both groups of solvers was found. The university respondents found the first solution as well as all solutions approximately twice as fast in average as the high school respondents, but they spent less time overall on the task and found less unique solutions in average. Both groups shared a dominant order of submitted solutions, especially for the first two. We also observed similarity between series of average solving times of both groups. The significance and interpretation of this observations will be subject of a forthcoming study.

## Formulating our formulations: the emergence of conviction as becoming mathematics teacher educators

Tracy Helliwell and Julian Brown

University of Bristol, UK; [tracy.helliwell@bristol.ac.uk](mailto:tracy.helliwell@bristol.ac.uk) and [julian.brown@bristol.ac.uk](mailto:julian.brown@bristol.ac.uk)

*This paper is an expression of how the authors are collectively becoming mathematics teacher educators, as they write and speak into one another's lives through the process of co/autoethnography. Extracts are presented from extended conversations between the authors, illustrating their process of formulating through reflecting on, and consciously appreciating, their unformulated actions as mathematics teacher educators. In their expression of the process of becoming, the authors begin to formulate the notion of conviction. From their enactivist perspective, they see their convictions emerging through the process of becoming mathematics teacher educators and their process of becoming mathematics teacher educators as the emergence of their convictions.*

*Keywords: Becoming, mathematics teacher educators, co/autoethnography, conviction.*

### The development of the mathematics teacher educator

There is a separation articulated in literature within the domain of mathematics teacher education, between what is termed as a 'mathematics teacher educator' and what is termed a 'didactician'. Even (2014) characterises didacticians as a subset of mathematics teacher educators, specifically, didacticians are mathematics teacher educators who "work in the field of teaching development with practicing [sic] teachers, including university faculty as well as practice-based mathematics educators" (p. 329). The particular feature here of the didactician is the focus on the development of *practising* teachers. Didacticians are not necessarily based at a university and include, for example, professional development providers and teacher-leaders. For us, we use mathematics teacher educator (MTE) in reference to ourselves. This is not to say that we do not work with practising teachers, but it is important to note that we are both based in a university where we work primarily with prospective teachers of mathematics on a one-year course, where prospective teachers work towards a Postgraduate Certificate in Education (PGCE), that includes qualified teacher status. We each have over ten years of experience teaching mathematics in secondary classrooms having both completed our PGCEs at the same university in which we now work, on the same course that we now teach. Tracy completed her PGCE in 2003 and has worked as an MTE for two and a half years. Julian completed his PGCE in 2006 and has worked as an MTE for one year.

As a community of teacher educators who value teaching practices that incorporate teachers researching their own teaching, there is a discernible argument that, as teacher educators, we too should participate in such inquiry into our own teaching and development. The development of mathematics teacher educators (MTEs) is a growing area of research within mathematics education. One useful distinction that has been made within this research domain is between what is termed "the *education* of mathematics teacher educators" and "the mathematics teacher educator *as learner*" (Krainer, Chapman, & Zaslavsky, 2014, p. 431). Research on the education of MTEs reports on studies of the preparation and professional development of MTEs through formal courses and programs designed specifically to prepare educators to educate teachers. Research on the MTE as

learner, however, places its emphasis on the “teacher educators’ autonomous efforts to learn, in particular, through reflection and research on their practice” (p. 432). MTEs are in a powerful position to research their own lived experience as insiders, rather than outsiders looking in, both as practitioners and researchers, researching their own practice. However, it is still being acknowledged (see e.g., Lin & Rowland, 2014) that only a few *full* studies exist where the prime focus is on the learning of the MTE (see e.g., Nicol, 1997; Tzur, 2001), rather than the learning of the MTE being reported on as a derivative of the research conducted by those MTEs.

One such full study on the learning of the MTE from Tzur (2001) is one in which he tells the story of his own development as a mathematics teacher educator through self-reflective analysis. This work from Tzur demonstrates how powerful self-reflection can be and how it can form the basis of rich data about what it might mean to learn as an MTE. Another significant piece of research is found in Nicol’s (1997) thesis; *Learning to teach prospective teachers to teach mathematics*, which is a study that investigates the problems, tensions, and dilemmas that she experienced as a beginner teacher educator learning to teach prospective elementary teachers. Her study reports her efforts in designing and investigating a pedagogy of mathematics teacher education, which makes attempts to place inquiry at the focus of teaching and learning.

### ***What and how mathematics teacher educators learn***

In 2008, a series of International handbooks of mathematics teacher education were published, in four volumes (with new editions currently underway). Volume 4: *The mathematics teacher educator as a developing professional* (Jaworski & Wood, (Eds.), 2008), described as focusing on the knowledge and roles of teacher educators working with teachers in teacher education processes and practices, is divided into three sections: Challenges to and theory in mathematics teacher education; Reflection on developing as a mathematics teacher educator; and Working with prospective and practising teachers; what we learn; what we come to know. A distinction being made here, which is also made by Lin and Rowland (2014) in their critical overview of research on teacher knowledge and professional development from a decade of PME (Psychology of Mathematics Education) conference proceedings, is between *what* and *how* mathematics teacher educators learn. For Lin and Rowland, studies on *what* MTEs learn are “classified as aiming to reveal or characterise mathematics educator’s learning outcomes”, whereas studies of *how* MTEs learn aim to “explore or comment on mathematics educators’ learning processes” (p. 509). According to Lin and Rowland, MTE learning had not been frequently reported on and studies that investigate how-oriented-questions were the least frequent of all (they identified three research reports over the decade of proceedings). This paper is one response to the gap in the *how* of MTE learning, but in reporting our research, we also accept the inevitability of the *what*; in reporting any research, including research into process, there is an immediate objectification.

### ***Becoming mathematics teacher educators***

In his 1962 essay, Rogers offers a vision of an individual who is in the process of becoming a fully functioning person. The individual that Rogers describes is becoming “all of one piece”, where the “distinctions between ‘role self’ and ‘real self’, between defensive façade and real feelings, between

conscious and unconscious, are all growing less” (p. 29). Here, we begin to comprehend the process of becoming as a unification of ourselves at the surface level with ourselves at the level of depth.

If we consider becoming from the perspective of learning, Hager and Hodkinson (2009) adopt a metaphor of learning *as* becoming in that “people become through learning and learn through becoming whether they wish to do so or not, and whether they are aware of the process or not” (p. 633). This view of learning as an inevitable process, rather than as a fixed state of having become (as with, for example, an acquisition model of learning (see Sfard, 1998)), signifies a change in the learner themselves as well as a change in the activity the learner is engaging with.

From an enactivist perspective, we see knowing as doing through being in and bringing forth a world in which we participate. The process of coming to know is thus a process of *becoming* through which both knower and known are transformed. Within enactivism, knowing is embodied, yet extends from the body of the individual in that the individual is not seen as distinct from the world but embedded in “a series of increasingly complex systems” (Sumara & Davis, 1997, p. 416) such as classrooms or universities. Unlike constructivism, where the focus is on cognitive knowing, enactivism considers alternative ways of knowing, including non-cognitive ways. In terms of epistemology, a useful categorisation of types of human action is made by Davis (1996, p. 193) that is, the “formulated” (cognitive) and the “unformulated” (non-cognitive) and with enactivism, the emphasis is on the unformulated. Davis goes on to propose that “formulations continually emerge from our unformulated actions” (pp. 193–194) and it is through this constant emergence that we develop our habits as MTEs, our “know-how” (Varela, 1999, p. 19). In contrast to know-how, we “know-what” through a process involving “reflection and conscious appreciation” (Varela, 1999, p. 19) and therefore becoming MTEs can be viewed as a process of continual emergence of our formulations (know-what) through jointly reflecting on, and consciously appreciating, our unformulated actions (know-how), and so it goes on.

### **Becoming mathematics teacher educators *through* co/autoethnography**

Julian: I think when we spoke before, you made use of that [word] when you talked about what happened in a maths class, in your classroom.

Tracy: But I used that without really thinking about what it meant. I mean, I don’t think I’ve ever thought about what it meant quite like I am now.

Our conversations are not bounded by a working day and move beyond strict boundaries of a workplace agenda to touch on concerns of our wider lives. We seek to make explicit use of extended conversations with one another to support our becoming through continual emergence of our formulations. Having captured two such extended conversations, we draw on co/autoethnographic (Coia & Taylor, 2005) methods, moving us beyond our accounts of our unformulated actions, as we write and speak into one another’s lives. As enactivists, we reject the strict separation of self/other that appears in existing co/autoethnographic literature (e.g. Coia & Taylor, 2005) and instead look to the co-emergence of shared meaning through being connected (Begg, 2001) in becoming MTEs together. For us, the process of co/autoethnography does not *enable* our becoming, rather our combining in the process is itself the becoming. In what follows, we present three extracts from two of our extended conversations, illustrating our process of formulating through reflecting on and

consciously appreciating our unformulated actions as MTEs. We see these extracts as expressions of our becoming.

### **Extract 1: Modelling being in a classroom**

- Tracy: I just didn't feel like I could do it. I didn't feel like I could just go and tell this 25-year-old man to stop rocking on his chair, whereas if he was a 16-year-old boy, I wouldn't have any issue doing it.
- Julian: So, you saw this as an issue with teaching adults?
- Tracy: I didn't know what else it could be, I mean, they're adults and they're children, that's the difference right, but it's not that, it just didn't make sense at the time.
- Julian: And now?
- Tracy: And now I'd quite happily tell someone not to rock on their chair in the PGCE group, and I think the difference is how I see myself, in that role, not as authoritarian or something, but that I'm modelling being in a classroom, and suddenly then it's okay. So, I'm doing it for a different reason. I'm not trying to teach him not to hurt himself. I mean he might do, he might well hurt himself, but, it's then not about me and my issue that they're adults. That's not the issue anymore. The issue is that I want that room to feel like I want their classrooms to feel; safe and respectful.
- Julian: Modelling being in a classroom feels like another one of those tenets.
- Tracy: Yes, it is! and suddenly, I've got this conviction and now I *can* go and tell people to stop rocking back on their chairs.

### **Extract 2: Your relationship is with the mentor**

- Julian: I've felt really positive about the opportunities that have come up to work on mathematics with the school-based mentors when I've gone into schools for joint lesson observations.
- Tracy: During the lessons?
- Julian: Yes, but also afterwards. There have been one or two cases that I guess have stayed with me, of the three of us talking after the lesson and carrying on working on the mathematics, like moving from area of compound shapes to think about conversion between units of measurement in area, and then in volume. The sharing of different images to illustrate those felt really powerful between the three of us.
- Tracy: Say more...
- Julian: So, part of it was me exploring the wisdom of the course that in the debrief conversations we as university tutors are really working with the mentors. I suppose at this point, it has been partly me trying to inhabit the convictions that were spoken in the context of the course. But now I can see that it also really connects with something that emerged for me strongly when I moved from the PGCE course to

start in my first school, which was about working on mathematics together as teachers.

Tracy: So, you were carrying this on from your role as a teacher, with other teachers?

Julian: Well, yes. But really, that move to my first teaching job was a sense of loss, of no longer having those spaces to work together on the mathematics. And it's something I've tried to grow again ever since. So, working with the mentor feels like modelling as well as working on the mathematics, creating a space together to unpack what's going on. It has developed another layer of significance for me. I feel a conviction about the value of creating those spaces with the mentor, who might then expand the spaces throughout their work with our prospective teacher.

### **Extract 3: Working at the meta level**

Tracy: We talked before about an algebra session where I used a visualisation. I hadn't spent long enough working through what I was going to say in setting up the visualisation, so it wasn't a surprise that there were a few different versions of what people were seeing.

Julian: What people were seeing as the image?

Tracy: Yes, their mental images. Having said that, if I had somehow set it up so perfectly that everybody saw the same thing, then we wouldn't have spent that period of time testing out one another's images, I had to work quite hard to make sure that happened and that was a good discipline for them to experience I think.

Julian: I think you said that you'd commented along those lines during the session, something about it being important to spend time making sure everybody was seeing the same thing.

Tracy: Yes, that's working at the meta level right? I think I might have said something similar doing this in a mathematics classroom though so that's not something new.

Julian: So, what is new, what is different now?

Tracy: Someone from the group asked a question while I was setting up the visualisation and I refused to answer it, I think maybe I gestured something to communicate that when it happened, and then much later on, I returned to it and addressed my not answering someone's question explicitly. Then I think I said something like, "something you need in the classroom, if you're going to do visualisation, is to establish the rules, and I don't think I established the rules clearly". I don't think I would have said that in my classroom at school. Again, that is about being meta, being explicit about my decision making.

Julian: For me there is also something there about when to step in and step out of the mathematics.

Tracy: Yes, a splitting of my attention in that moment, I knew it had to be dealt with, but not at that time, it got logged as something that had to be returned to. It's not that they must do visualisation, but that if they choose to, there are some rules, rules that I had conviction about as a teacher. I guess my conviction now, as a mathematics teacher educator, comes from these experiences in the classroom.

### **Our emerging formulations: formulating the formulating**

The extracts above serve to express snapshots of our process of becoming MTEs, each one offering a sense of us formulating our unformulated actions as MTEs. This next section serves to express our emerging formulations from having brought these extracts together, formulations that have arisen for us through a process of reflecting on and consciously appreciating within and across these three snapshots. The title of this section is our attempt at emphasising the continual emergence of new formulations, through formulating (expressed in this section) the formulating (expressed in our extracts). One way of us consciously appreciating the formulating expressed within these three extracts is by looking for patterns both within each extract and across all three extracts.

Each extract is richly veined with marks of the formulations articulated about the university course with which we work. The tenets we hear in these extracts, "I'm modelling being in a classroom"; "as university tutors we are really working with the mentors"; "that's working at the meta level right?", were previously heard in conversations with Laurinda Brown, who was PGCE tutor to each of us, and Alf Coles, who has worked on the course with Laurinda and whom we joined as PGCE tutors. We have articulated to one another the "trying on" of these tenets at the level of unformulated actions. Through the process of becoming MTEs we have begun to make sense of these tenets in ways that we find meaningful. Acting on these tenets and developing a sense of owning them can also be seen as formulating our formulating.

There is a sameness which has become apparent to us as we search for patterns across the extracts, that reflects something of the structure of each one in relation to how we view the process of becoming as the continual co-emergence of our formulations from our unformulated actions. In extract 1, an unformulated action for Tracy was *not* moving to stop one of the PGCE students rocking on his chair. In extract 2, an unformulated action for Julian was his carrying on working on the mathematics. In extract 3, an unformulated action for Tracy was refusing to answer a question. From these unformulated actions, we try out different formulations on one another as they co-emerge. From the extracts we see these formulations are then followed by a sequence of further re-formulations, marked by, for example, "but it's not that"; "yes, but also"; "well, yes. But really"; "having said that".

An element of what guided our choice of extracts to present is the emerging theme of conviction. So strong has this theme become for us in our conversations, we are no longer able to separate what appears from these extracts to be changing or emerging convictions from how we are becoming MTEs. What follows is a further formulating, the focus this time on becoming MTEs *as* the emergence of convictions.

## Becoming mathematics teacher educators as the emergence of convictions

In the extracts above, we draw repeatedly on language of conviction as we work on our formulations. In formulating conviction, we look first to Descartes (1991), who adopted conviction to describe a state of belief “when there remains some reason which might lead us to doubt” (p. 147), and knowledge as “conviction based on a reason so strong that it can never be shaken by any stronger reason” (p. 147). If conviction is to be characterised as belief, strongly held, then it carries with it some particular quality that sets it apart from other states of believing.

For us, however, the sense-making process that informs statements, which might be labelled as beliefs, is inherently a product of the emergent interactions of the (changing and changed) individual with the (changing and changed) world, for which we adopt the enactivist term “structural coupling” (Reid et al. 2000; Maturana, 2002, p. 15). We are interested in how our own sense of conviction emerges and becomes something that can be articulated as we are becoming MTEs. We see changes in conviction as a manifestation of changes in our structural coupling, strengthened (or weakened) through the process of formulating our unformulated actions. Gallagher and Zahavi (2008) identify conviction as fundamentally intertwined with changes in ourselves,

I remain the same as long as I adhere to my convictions; when they change, *I* change. Ideals and convictions are identity-defining; acting against one’s ideals or convictions can mean the disintegration (in the sense of a dis-integrity) of one’s wholeness as a person. (p. 206)

Thus, as our convictions change (or emerge) then we change, through a process of becoming. It is our convictions that define us as MTEs (our “identity”) and to act against our convictions, for example, if Tracy were to *not* model a classroom with the PGCE group or if Julian were to *not* model being a mentor, would “mean the disintegration (in the sense of dis-integrity)” of ourselves as MTEs.

We recognise in ourselves the sense of integrity that comes from being able to identify the alignment of our actions and our convictions. Within the Cartesian epistemology mentioned above, conviction might be seen as a deficient form of knowing, a position held when there is still doubt. The identity-defining property of conviction, however, makes conviction, for us, more than a label. From our enactivist perspective, we see the emergence of our convictions as coming to know. We view our convictions emerging through the process of becoming MTEs, and our process of becoming MTEs as the emergence of our convictions.

It was our intent to present in this paper the process of our becoming, the process of our formulating. We acknowledge that in the creation of this paper there exists a paradox. The value for us continues to be in the formulating (the *how*) but we accept that what gets presented here is inevitably a formulation (the *what*) at a point in time.

# Tasks Designed for Training Secondary Mathematics Teachers Using Technology

Alexánder Hernández, Josefa Perdomo-Díaz and Matías Camacho-Machín

Universidad de La Laguna, España;  
[alexander.hernandez@ull.edu.es](mailto:alexander.hernandez@ull.edu.es); [jperdomd@ull.edu.es](mailto:jperdomd@ull.edu.es); [mcamacho@ull.edu.es](mailto:mcamacho@ull.edu.es)

*The central purpose of this research is to design a series of prompts that arise based on classroom events that emerge when using technology to solve problems. We analyze several teaching situations that occur when solving problems using GeoGebra and study a case involving two mathematics majors who are taking a course called “Mathematics for Teaching”. These prompts offer a resource for training future secondary school mathematics teachers, through the development of their Mathematical Understanding for Secondary Teaching [MUST] (Heid, Wilson, & Blume, 2015).*

*Keywords: Problem solving, Teacher education, Technology, GeoGebra.*

## Introduction

When training mathematics teachers, it is agreed that the knowledge of the discipline that teachers require is substantially different from that needed by other professionals who also use mathematics (Ball, Thames, & Phelps, 2008). This knowledge includes knowing *what* and *how*, which Kilpatrick, et al. (2015) incorporate to expand the construct *Mathematical Knowledge for Teaching* into *Mathematical Understanding for Teaching* (p. 13). This mathematical knowledge and its use in the classroom are described in detail within the MUST framework (Heid, Wilson, & Blume, 2015) and will be used in this research. One of our reasons for using this framework is that it relies on analyzing the experiences of secondary school mathematics teachers. These experiences generate prompts based on a series of events that arise during the teaching and learning process, and that are used to build resources for training teachers.

The experiences that arise in teaching and learning contexts where technology is involved exhibit specific characteristics that have to be identified and analyzed. What specific events appear when using technology? Are there differences from those that arise when using paper and pencil? Can prompts be developed based on these technological events?

The goal of our research is to identify those events that take place during a problem-solving scenario that relies on technology, and to generate prompts based on these events. We believe that these prompts would be much more difficult to generate in a problem-solving context that relies solely on the use of pencil and paper. To this end, we analyze the case of two students solving a problem using Dynamic Geometry Systems (DGS).

## Conceptual framework

When selecting a framework for our research, it is important to consider the nature of teachers' knowledge. In this regard, Heid, Wilson, & Blume (2015) note that

Any such Framework needs to capture the dynamic nature of teachers' use of mathematics in their teaching rather than simply to list knowledge, skills, and proficiencies for teaching mathematics. (p. 41)

This is why we opted to select the MUST reference framework to define the prompts that arise when using technology while solving problems. As defined by Kilpatrick, et al. (2015), a prompt is:

an episode that has occurred in the context of teaching mathematics (usually in a mathematics classroom) and raises issues that illuminate the mathematics understanding that would be beneficial for secondary teachers. (p. 3)

The mathematics understanding referred to in the above paragraph may be viewed from three perspectives, *Mathematical Proficiency*, *Mathematical Activity* and *Mathematical Context of Teaching*, each with different strands (see chapter 2 from Heid, et al., 2015, for more details). *Mathematical Proficiency* refers to the mathematical knowledge and skills that a teacher needs in order to teach the subject in secondary education, which includes not only the mathematics associated with this educational level, but also that in previous and subsequent levels. When we speak of *Mathematical Activity*, we refer to the set of specific mathematical actions that a teacher has to do as part of the profession, such as linking concepts, justifying arguments and generalizing mathematical facts. Lastly, *Mathematical Context of Teaching* includes aspects of mathematical understanding that come into play exclusively in the teaching profession, such as, for example, understanding how students think mathematically, recognizing the mathematical nature of their questions and mistakes or recognizing when a mathematical argument or solution provided by a student is incomplete or satisfies the conditions of a problem.

To define these prompts, we first identify events that occur in various problem-solving episodes. Santos-Trigo and Camacho-Machín (2013), taking into account Polya's work, analyze different paths taken by a solver when faced with the task of solving a problem using technology. Based on this analysis, they identify five episodes: *Comprehension Episode*, *Problem Exploration Episode*, *The Searching for Multiple Approaches Episode*, *Extension Episode* and *The Integration Episode* (for more details, see Santos-Trigo & Camacho-Machín, 2013).

In this paper, the analysis will focus on the first three episodes: *Comprehension Episode*, *Problem Exploration Episode* and *The Searching for Multiple Approaches Episode*. These episodes are detailed later in this paper.

In the context of DGS, the *Searching for Multiple Approaches Episode* is particularly relevant, as this episode requires, not following the same steps, but rather attempting to use different concepts in each path in order to enhance the problem-solving process and the learning of mathematics.

## Methodology

### Participants

Data were collected from a Problem-Solving Workshop implemented during nine two-hour sessions of the course *Mathematics for Teaching*, where students solve the tasks in pairs, using GeoGebra. The workshop was taught in the computer laboratory to seventh-semester mathematics majors who, in a short time (two years), will be qualified to be secondary school teachers. There were eighteen

students enrolled in this course which main goal was to introduce university mathematics students to the knowledge for teaching secondary school mathematics.

### Task

In the workshop, the students solved a total of four problems that had previously been analyzed by the research team. In this paper, we analyze only one of the problems we call *Equal chords*.

*Equal chords*: There are two circles with centers at A and C. Two lines are drawn from each center that are tangent to the other circle. The points where these tangents intersect with the circles define two chords, IJ and KL (see Figure 1). Prove that the lengths of these two chords are the same,  $IJ=KL$ .

**Figure 1: The equal chords task**

The main characteristic of this task is that the statement includes a figure that the students must construct in order to solve the problem. The construction of the figure gives the problem a series of affordances that are important to mathematical understanding for secondary teaching. Santos-Trigo (2019) notes that

With the use of GeoGebra, these questions become relevant not only to identify and explore needed to draw the figure, but also provide an opportunity for learners to connect the problem goal with a series of mathematical ideas and resources to solve and extend the initial statement. (p. 73)

### Data

Three types of data were gathered for the analysis: the GeoGebra files, the handwritten notes and the recordings of the student pair work sessions, which were made using the OBS Studio software.

In this research report we use a case study methodology to present an analysis of the work done by a pair of students, Evan and Sophie, while solving the problem *Equal chords*. Both the students and the activity were chosen due to the quality and variety of their discussions.

## Data Analysis and Results

### Comprehension Episode

The students began by reproducing the figure shown in the problem statement. Both agreed in the way in which the circumferences, the intersection points and the chords were drawn, but they disagreed when representing the tangent lines, which entailed a combination of mathematical and technical aspects involving the use of the DGS.

The GeoGebra graph shown the two circles

*Sophie:* What are you doing?

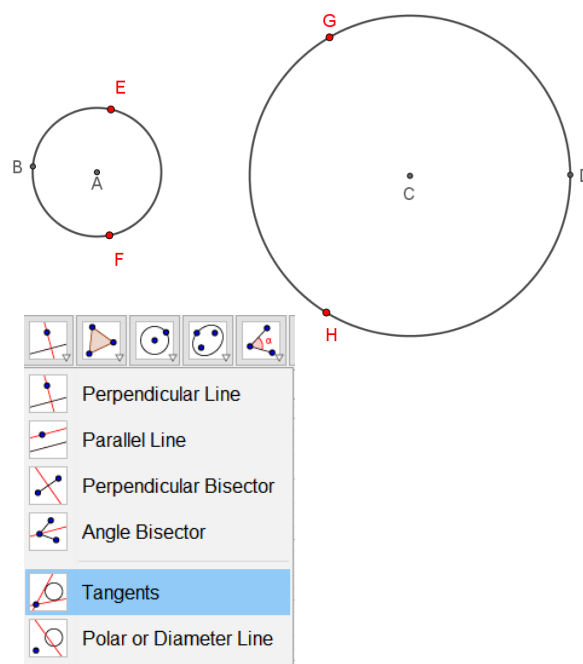

*Evan:* Are the points...? [referring to the tangent points]

*Sophie:* Yes?

*Evan:* Yes, E,F,G,H [draws them on the circle] and now from here.

*Sophie:* Wouldn't that be later? With the construction of the intersection point between the tangent and the ...

*Evan:* No, leave from there. We have to calculate now. Click on that [indicating to Sophie the perpendicular line tool to expand the menu], tangents and points

With the “Tangents” tool selected, they click on one of the centers and the points drawn on the circumference. Nothing happens.

*Sophie:* Yes, right

They repeat the process several times. At one point, they click on the circumference and the tangents appear.

*Evan:* What did you do?

*Sophie:* I clicked on the circumference, not on the points [referring to the points they had drawn earlier]

It is important to realize that the concept of a straight tangent to a circle from an outside point involves three objects: the outside point, the circle and the straight tangent. These objects are related with one another and with other objects, like the tangent point and the radius (which is perpendicular to the tangent). The “Tangent” tool is a programmed function whose inputs are a point and a conic section or curve. This means that when the students try to represent the straight tangent by selecting two points, GeoGebra helps them realize that the tangent point cannot be placed by “eyeballing” it, as one would do with pencil and paper; rather, a relationship must be established between the outside point

and the circle. Moreover, this way of building tangent lines is robust, as it allows preserving the tangency when any of the objects is dragged. This first event yields the following:

Prompt 1
Two students want to represent the tangent lines to a circle from an outside point. To do so, they represent a point that is on the circumference and then use the “Tangents” tool by selecting that point and the outside point. The software does not generate the tangent line. In fact, the software does not show anything. Why is this? What important properties relate the radii of the circumference and the straight lines tangent to it?

**Table 1: Prompt that arose during the Comprehension Episode**

### Problem exploration episode

The students finished building the figure and verified that the chords indeed have the same length. Then, by dragging the centers of the circles or the points that define their radii, they verified that the property holds in a variety of individual cases. They considered how to demonstrate their equality. During this episode, the students did several online searches and measured angles, segments and the arcs of the circumferences. (Figure 2)

**Figure 2: Construction with auxiliary objects**

They drew other lines, like AC, which passes through both centers, and another connecting the points where the tangents intersect, M and N, looking for relationships that would let them show the equality of the chords. They considered different possibilities: (i) The lengths of the minor arcs IJ and KL are the same; (ii) the line perpendicular to chord KL that passes through C also passes through A; (iii) the trigonometric ratios of angles MOA and MOC are related by the common side MO of the right angles MOA and MOC; (iv) triangles API and MOA are similar and equal to KQC and MOC. This episode yielded conversations like the following:

*Evan:* Now we have to see what the relationship is between the two circles and the tangent lines.

*Sophie:* The length of the arc is not the same, is it?

*Evan:* Well...

*Sophie:* No, because the line is the same but this one has more of an arc and this one less [pointing first to chord IK and then KL], so that has nothing to do with it, you see?

*Evan:* But their lengths are the same [moves his hand in an effort to explain]. Do you have a string?

The discussion was mathematical in nature. Can two arcs be traced on the same segment that have the same length? The students' intuitions differed, with Sophie thinking that different arcs have different lengths, and Evan thinking the opposite, stating that if the two ends of a piece of string are fixed, they can be arranged to create different curves. They tried to settle their differences by calculating the lengths of the arcs using GeoGebra. This yields the second prompt.

Prompt 2
Using GeoGebra, a student traces out different arcs of a circle atop the same segment and measures their length, concluding that they are all the same. How might this relationship be justified?

**Table 2: Prompt that arose during the Problem Exploration Episode**

### Searching for Multiple Approaches Episode

At the end of the first session, a group discussion was held in which the various properties observed by all the pairings were presented, some of which had not been previously identified by Evan and Sophie, such as, for example: (i) line AC bisects angles GAH and ECF formed by the tangent lines (Figure 2); (ii) the radii of the circles at the tangent points are perpendicular to the tangent lines. The students considered proving that the chords are equal by approaching the problem in three different ways: (i) by writing the general equations for the tangent lines and attempting to find the equations for the circles to solve the systems; (ii) by using the fact that line AC bisects the angles that form the straight lines and studying the trigonometric ratios of the right angles API, MOA, KQC and MOC; (iii) by finding similarity relationships between triangles API and AGC, along with triangles KQC and EAC. Being unsuccessful with the first two approaches, they focused on the third.

*Sophie:* Why did you draw that? [referring to triangle AGC]

*Evan:* Because this new triangle is similar to these two [referring to triangles API and MOA]

*Sophie:* The big one?

*Evan:* Yes

*Sophie:* ...but, why is it similar?

*Evan:* Because the angles are the same

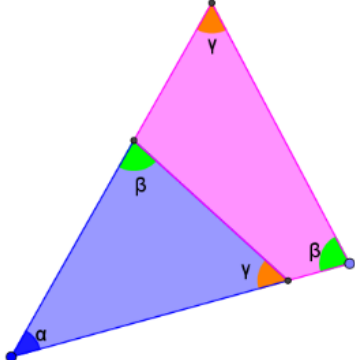

*Sophie:* I know that, but are you sure that this one here... If the big one were similar, shouldn't

*this be a right angle?  
[referring to angle ACG]*

*Evan: No, similar doesn't mean they  
are superimposed, it means  
they are equal to one another*

This event, arising from two similar triangles not in the Thales position, yields the following:

Prompt 3	
<p>In a Problem Solving class to solve problems with help from GeoGebra, a student measures the angles in two triangles, as shown in the figure, and concludes they are similar. When this is pointed out to a classmate, the latter is surprised because the sides are not parallel. Should a pair sides not be parallel?</p>	

**Table 3: Prompt that arose during the Searching for Multiple Approaches Episode**

## Conclusions

By using technology, students can devote time to look for mathematical properties, discuss them and explore different approaches to verify them. We have seen how these types of discussions give rise to interesting events for developing prompts that would not easily arise in a context with no technology. The questions that students ask themselves by making use of technology would not arise if using paper and pencil. For example, Evan and Sophie, when representing the tangent lines from an outside point, consider the objects that define them and how they can be drawn so as to preserve their property of being tangent to the circle.

In this research report we identify three events that resulted in three prompts of a different nature, depending on how the episodes in which technology is used to solve problems are framed: *Comprehension Episode*, *Problem Exploration Episode*, *The Searching for Multiple Approaches Episode* (Santos-Trigo & Camacho-Machín, 2013). We also saw that when technology is used to solve problems, situations arise that cast doubt and arouse interest in the participants, the prospective mathematics teachers. We have also shown that by analyzing these moments, the opportunity is created to propose activities to train mathematics teachers. The mathematical endeavor that is revealed when the time comes to solve mathematics problems that are properly selected, when technology is present, has been shown to be an important element for improving the mathematical understanding of properties and results that have often been forgotten. We believe that this type of activity must be part of the initial training of mathematics teachers.

These prompts serve as resources for promoting the development of Mathematical Understanding for Secondary Teaching, offering opportunities to reflect on the mathematics related to them. What are the underlying mathematical concepts? What mathematical structures are involved?

Heid et al. (2015) argue that in the context of training future teachers, developing situations provides an opportunity to think about the content of secondary education curricula, to develop activities that are based on events related to the use of GeoGebra, activities that generate opportunities to think concurrently about the contents of the curriculum and the mathematical ideas that can be explored with DGS, and to connect them both.

# Opportunities for Adopting a Discourse of Explorations in a Professional Development Setting

Einat Heyd-Metzuyanim<sup>1</sup> and Talli Nachlieli<sup>2</sup>

<sup>1</sup>Technion – Israel Institute of Technology, Haifa, Israel; [einat.metz@gmail.com](mailto:einat.metz@gmail.com)

<sup>2</sup>Levinsky College of Education, Israel; [tallin@levinsky.ac.il](mailto:tallin@levinsky.ac.il)

*We examine the productiveness of discussions in a professional development (PD) towards explorative mathematics instruction (EMI). The artifacts used in the PD session under examination were a video-clip of a classroom discussion, together with the Quadrants coding scheme, a scheme originally developed for research purposes. We define productive discussions by relying on the linguistic tool of lexical chains that point to lexical cohesion. The analysis shows that the use of the coding scheme as an artifact, together with a video clip, offered increased opportunities for surfacing misalignments between the teachers' framing of learning and instruction and the PD leader's framing of it. These misaligned frames, which draw on the Acquisition Pedagogical Discourse, vs. Explorations Pedagogical Discourse, are usually difficult to surface.*

*Keywords: explorative mathematics instruction, productive pedagogical discussions, professional development, lexical cohesion*

## Introduction and theoretical background

For the past three decades, calls for more reform, student-centered, instruction, are voiced in mathematics education (Gregg, 1995). We adopt the Commognitive framework, and define such instruction as explorative mathematics instruction (EMI), teaching that provides students opportunities for explorative participation (Heyd-Metzuyanim, Tabach, & Nachlieli, 2016). Efforts to help teachers adopt explorative teaching practices are widespread, mainly through professional development (PD) (Sztajn, Borko, & Smith, 2017), yet the processes of learning these practices have not yet been sufficiently explicated and theorized.

Whereas teachers who teach in a teacher-centered approach rely on an *Acquisition Discourse*, those who promote student-centered instruction rely on an *Explorations Discourse*. Our use of Discourse (with a capital D) here comes to signify the historical, social and institutionalized nature of these pedagogical Discourses, which are not just a matter of how teachers and teacher-educators talk, they exist in documents, regulations and curricula. One of the best examples of the Explorations Discourse can be found in "reform" documents such as the NCTM (2000). The Acquisition Discourse does not have such institutional documents as exemplary instantiations, yet it is the common Discourse that is often seen in classrooms worldwide (Nachlieli & Tabach, 2018). In documents, it can often be found as the anti-thesis of actions valued by the Explorations Discourse (for example, by stating that teachers should *not* be using their time in the classroom for 'drill and practice' or that students' ideas are those that need to be heard, *not* teachers') (Heyd-Metzuyanim & Shabtay, 2019). Pedagogical discourse (with a small d) – that discourse which includes teachers' talk (inter or intra-personal) about *how, what and whom* to teach, draws upon the pedagogical Discourses, often in a multi-voiced combination of Explorations and Acquisition Discourses. There is never a teacher (or teacher

educator) that talks "purely" in one of these Discourses, but PD leaders or teacher educators that try to move teachers towards more explorative instruction often draw more on the Explorations Discourse, whereas teachers who are initial participants in such PDs often draw more on the Acquisition Discourse.

Acquisition Discourse rests on the assumptions that learning mathematics entails acquiring a certain set of facts and skills, where the role of the teacher is to "dispense" this knowledge, and the role of the student is to "acquire" it. Accordingly, teachers relying on an Acquisition Discourse value the demonstration (by the teacher) and the execution (by the student) of precise procedures. Different realizations of mathematical objects (Sfard, 2008), as well as different procedures for solving similar problems are less valued since they are not necessarily efficient and since they can be a source of "confusion" for the students. In contrast, Exploration Discourse frames learning as a form of participation in a community, where mathematical objects are explored and narratives about them are authored by students, facilitated by the more experienced participant, namely the teacher. Teachers relying on the Explorations Discourse value the presentation of different realizations of mathematical objects, and the authoring of narratives by students, even if those are not yet articulated precisely according to the rules of the mathematical community (Heyd-Metzuyanim & Shabtay, 2019).

Previous studies have shown that shifting from Acquisition towards Explorations pedagogical Discourse is a difficult and complex process (Heyd-Metzuyanim, Smith, Bill, & Resnick, 2018b). It has also been shown that this process involves *misaligned frames* (Heyd-Metzuyanim, Munter, & Greeno, 2018a). Frames are those parts of the pedagogical discourse that relate to interpretations. They are usually tacit, and take form in what people notice, accentuate and foreground. In relations to these frames of classroom instruction, Heyd-Metzuyanim et al. (2018a) differentiated between the *subjectifying* aspects of frames, namely, those interpretations relating to *who* speaks in the classroom, and the *mathematizing* aspects of frames: what mathematical objects and routines are talked about. In their study of a US teacher participating in a PD intended to promote EMI, Heyd-Metzuyanim et al. (2018a) noticed that the teacher was well aligned with her PD coach in relation to the subjectifying aspects of framing the envisioned lesson that they were planning together: they both valued students' discussion, group work and agency. Yet with relation to the mathematizing aspects of the frame, they differed. While the PD coach aimed to expose students to different realizations of the mathematical object at the focus of the lesson, the teacher was focused only on the execution of specific procedures. This misalignment went unnoticed during the coaching session, yet led to the failure of the lesson planned together by the two parties. This case highlighted the need to study what factors can contribute to more productive discussions in a PD setting, which can surface misalignments and provide opportunities for teachers to engage with more implicit aspects of the Exploration pedagogical discourse.

Productive discussions in PD settings have been the focus of increasing numbers of studies (e.g. Borko, Jacobs, Eiteljorg, & Pittman, 2008). Many have pointed to the usefulness of video to increase the productiveness of teachers' conversations as well as the utility of observation-assisting artifacts such as protocols and scoring rubrics to fix teachers' attention on important aspects of instruction (Borko et al., 2008; Schoenfeld, 2017). Yet studies examining the usefulness of video and observational artifacts rarely explicate what "productive discussions" actually means. In our specific

context of promoting EMI, our assumption is that teachers in the PD setting start out by mostly drawing on Acquisition Discourse whereas the PD leader draws mostly on the Explorations Discourse. This may lead to tacit differing interpretations (frames) that go unnoticed since the participants (teacher and leader) assume they are talking about the same thing while in fact they are framing teaching-learning interactions differently, in accordance with the differing Discourses on which these frames draw. Thus, a productive discussion, in the context of these sessions, would be *a discussion that surfaces misalignment between Acquisition frames of teachers vs. Exploration frames of the PD leader*.

We turn to the notions of *lexical cohesion* (Halliday & Hasan, 1976) and *lexical chains* (Morris and Hirst, 1991) to conceptualize productiveness of discussion for our purpose. Cohesion is a semantic term that refers to the meanings that exist within the text (Halliday & Hasan, 1976). Cohesion occurs where the interpretation of some element in the text is dependent on that of another. As argued by Morris and Hirst (1991), lexical chains help determine coherence and discourse structure, and hence the larger meaning of the text. We adopt the idea here to study the cohesion of the text that was produced by the teachers and instructors during the discussions in the PD and thus to learn about the productivity of the pedagogical discourse by visually showing the topics discussed and followed and the specific words chosen by different participants. Our research goal is thus to characterize productive discourse processes that promote pedagogical discourse of explorations by examining discourse cohesion and its relation to the surfacing of misaligned frames.

## Method

The study took place in the context of the TEAMS PD program (Teaching Exploratively for All Mathematics Students), a program that included 16 4-hours sessions over two years (2016-2017). The PD introduces teachers to the 5 Practices for Orchestrating Mathematics Discussions (Smith & Stein, 2011) as well as to Accountable Talk™ tools (Heyd-Metzuyanim et al., 2018b). Teachers participating in this program were relatively experienced (ranging from 15-31 years of teaching). 14 of the teachers taught in middle-school and 2 taught in elementary school. 9 teachers continued from the 1<sup>st</sup> to the 2<sup>nd</sup> year. At the end of the first year, we analyzed the first year data using the Quadrants coding scheme (QCS) (Stein et al., 2017). The analyzed data included 3-4 video-recorded lessons of each of the participating teachers. Our analysis revealed that teachers were adopting explorative instructional practices to varying extents. In particular, our findings showed that teachers had trouble to maintain Explicit Attention to Concepts (EAC) whenever they raised Students Opportunities to Struggle (SOS). Through the process of analyzing teachers' videos according to the QCS, we came to the realization that such a process may be beneficial for the teachers as well. Therefore, we chose to open the second year of the PD with introducing the QCS and the findings of our analysis.

For the current study, we watched and partially transcribed all 16 PD sessions. Partial transcriptions were intended to capture the activities of the session, as well as important conversations and themes. Based on these partial transcriptions, we focused on the first session of the 2<sup>nd</sup> year since it was a pivotal session in several aspects. First, it was where we made our first use of the QCS (Stein et al., 2017) together with video, in attempt to assist teachers to better grasp our vision of EMI. We thus chose to present two rubrics (EAC and SOS) to the teachers, together with a de-identified video of

one lesson which we thought was particularly rich in opportunities for EMI. The rubrics each include 4 or 5 levels with 1 being lowest. Presentation of the full rubrics is beyond the scope of this report but the relevant parts for the reported discussion will be detailed in the findings section. Viewing this session at the end of the year, after all sessions were observed and partially transcribed, revealed that this indeed was a session where intense pedagogical reasoning occurred, yet only in specific episodes. To better understand these occurrences and the discursive processes underlying them, we fully transcribed the session, after which we chose two clips from the discussion. These clips were similar in that they both referred to the QCS (in particular, to the EAC rubric) as well as included some “example” of instruction to talk about, yet different in that one of them was before the video was shown and the other after it. This offered us an opportunity to examine more closely the role of the video, together with the QCS, in the rising level of productiveness of the talk.

## Findings

The session that we chose to focus on began with Talli (2nd author and leader of the PD) presenting to the teachers the results of the 1<sup>st</sup> year video analysis, in order to launch the main focus of the 2nd year PD plan: to work with teachers on how to preserve conceptual depth while letting students author mathematical narratives and struggle with problems on their own. Talli then presented the teachers two rubrics from the QCS: the EAC and SOS rubrics. Teachers were asked to read the rubrics in groups, discuss them, and were then called for a whole-group discussion. She opened by stating that there are no simple criteria for determining if the EAC level is 4, 3, 2 or 1 and that there could be “significant arguments” around them, but that those arguments are important because “they help us notice nuances”.

The discussion started in rather unproductive ways. One teacher, Rony, was asked, based on her former experience with coding videos according to the Quadrants scheme, to give an example of a “level 4” of EAC. She tried doing so, yet other teachers related more to the specificities of her example and her choice of concept words, than to levels of the EAC rubric. The lexical chain analysis performed on this episode revealed that the EAC lexical chain died off right after Rony's description of her envisioned lesson and was not picked up by other teachers. Talli cut off this discussion quite promptly, as she was sensing the teachers were not relating to the subject that she considered to be the goal of the discussion. Einat (1<sup>st</sup> author) tried giving examples of lessons that were coded as ‘4’ vs. lessons that were coded as ‘3’, yet these were not very productive in eliciting lexical chains focused on elements from the EAC rubric either.

Following that, Talli announced that they will be seeing a 16-minute video-clip of an 8<sup>th</sup> grade classroom discussion around a ratio problem. She first gave out the task so that teachers got an opportunity to solve and discuss it shortly before viewing the video. The task read as follows:

*Dafna prepared a necklace of blue and red beads. Two fifths of Dafna's necklace were blue and the rest were red. Draw four different possible necklaces.*

Following the viewing of the clip, Talli opened the discussion:

2.1 Talli                      Let's start with the attention to concepts

- 2.2 Valerie I did not see here much attention to concepts, by the way... attention to concepts... there wasn't much. I hardly wrote any concepts here (on her "scoring" worksheet).
- 2.3 Talli Which concepts?
- 2.4 Lena But attention to concepts needs to be at the beginning of the lesson? Already? They just started...
- 2.5 Veronica But we didn't watch the end of the lesson, when **the teacher** summarizes all the things that appear on the board. ...She called to the board all sorts of student groups so that they show what they-.... And **she** wanted actually, on the board, to show all sorts of ways, all sorts of different answers, so that other kids from the different groups see what others were thinking. I think that what we are not seeing is the end (made by) **the teacher**, that should be at the end of the lesson, after all the answers are shown on the board.

We see the discourse in this excerpt as productive, since all speakers repeatedly relate to the same lexical chain, that of EAC (underlined). We also see all teachers relating repeatedly to the video-clip (in wavy underline), referring to actions observed in it. This shows us the productiveness of the video as a tool for supporting the cohesion of the talk, as well as for focusing the teachers on EAC. The lexical chain of EAC remained active for 17 turns. Within it, some teachers objected to Valerie's assertion that there was not much attention to concepts. For example:

- 3.1 Yafit I think that actually there is attention to concepts because, as someone says the answer, she repeats things, and then she asks them "do you agree? Disagree?" It's a type of, it's also a type of explication of a concept. Or clarification. Attention to concept does not have to be writing the concept on the board. Also, along the way they said, someone there said the word ratio, (quoting the teacher) "oh, you talked about ratio, what did you mean?" And then he, like, so I think it's also a type of attention to concepts.

As the discussion continued, some ideas for concepts that would have justified a higher scoring of the EAC rubric started being voiced by the teachers. These included "ratio", "expansion", "part whole relationship" and "correspondence". Talli revoiced and summarized these ideas, and then she tried eliciting other ideas. She asked

- 3.2 Talli What else do you have to say about the... what we saw here? What other concepts she-, what did the teacher do with these concepts?

Talli's intention here was to stir the conversation to several mathematical ideas that she thought were prominent in the clip, yet none of the teachers seemed to notice them. In particular, she was frustrated by the teachers' lack of appreciation of the students' ideas, and most importantly one idea which related to the routine of dividing the blue beads to two, finding out the basic unit, then multiplying it by 3. The teachers only noticed the routine (employed by the first two students in the clip) of expansion: multiplying both sides of the ratio by a constant number. Despite her questions, the teachers only repeated the concept names (expansion, part-whole) raised before. As Talli was ready to give up and stir the conversation to the issue of scoring the clip, Valerie said:

- 3.3 Valerie The fifth, also
- 3.4 Talli The fifth, what?
- 3.5 Valerie I don't know, the fifth disturbs me here
- 3.6 Talli In what way does it disturb you?
- 3.7 Valerie Because a fifth of what? Of the blues? The reds? Which fifth (is it) here?

3.8 Naomi The fifth of the group (Yafit: The fifth as a part, a part)

3.9 Valerie But it's a split group. The group is split. Which fifths are (they) talking (about)? The 1 out of 5 blues? Of the reds?

Now, a lively discussion revolved with multiple lexical chain entries, focused on the "fifth". Veronica stated it was "once two fifth, once three fifths", adding that "it's dividing by two or dividing by three. It depends what they want the fifth (for)".

One teacher, Lena, got confused by all this discussion of finding "fifths". She said

4.1 Lena But **we** already know how many reds and how many blue there are.

For Talli, this was a good opportunity to highlight one of the student routines she saw as most significant in the video clip:

4.2 Talli No, but, **one student** came and said another idea. **She** said, listen, "you want to create more necklaces? If you tell me how many blue (beads) there are, **I** will already tell you how many reds there are ... **I** will take the blues, **I'll** divide them by two because ... all the blues are two fifth, **I** will find this one part. The other part **I** will multiply by three, to find the red (ones)". That's the fifth. That's the idea of the fifth

4.3 Lena Oh, OK. So **that's** a different division.

Lena's short exclamation is an important indicator of the productiveness of this exchange, where the lexical chain around the "fifth" was prominent, along with the lexical chain reporting on students' speech in the video. Although there are good reasons to believe most of the teachers did not see the importance of the students' routines of division in search of a "unit", Lena's exclamations showed it most clearly. Her first request for clarification [4.1] made use of the "how many" quantification word. It is therefore highly probable that she was only seeing the routine of multiplying the two sides of the ratio (as this routine relates to natural numbers, 2 and 3, multiplied by a coefficient of expansion). In addition, her use of "we" in 4.1 for objecting on what "we already know", indicates she was not making any differentiation between her own mathematical reasoning and the students' mathematical reasoning. In contrast, when she used the word "division" after Talli's explanation [4.3], Lena was probably already seeing the routine of dividing into fifth and using the fifth as a unit (since only with relation to this routine, the word "division" makes sense). Also, Lena's use of "that" indicates that she was now differentiating between her own mathematical reasoning and that of the revoiced student. This change may have resulted from Talli's repeated reference to the voice of the student (seen in the I pronouns of the video actions lexical chain).

### Misalignment of frames

The productiveness of talk, which rose considerably once the video and coding scheme were introduced to the discussion, made certain misalignments between Talli and the teachers more apparent. Interestingly, Talli was able to pick up in real time only on the mathematical aspects. The subjectifying aspects remained hidden until the analysis was performed.

The misalignment of the mathematical aspects of frames was most noticeable in the discussion of the "fifth" and in what the teachers saw as important mathematical narratives versus what Talli saw as important. Talli interpreted the video clip as containing rich stems for discussion of the ratio object, including visual realizations of 2 different "necklaces", the fractions  $2/5$  and  $3/5$ , the signifiers 2:3

and some verbal statements describing routines for calculating the ratio. She therefore thought the clip should be scored as a 3, where, according to the EAC rubric

One or more concepts are discussed and/or defined in some detail. This entails **explicit** noting of the concept in a whole-class setting. Explanation and/or elaboration of critical features of the concept may be incomplete, and connections to the larger web of mathematical ideas ... are notably present, but weak (EAC rubric level 3, the Quadrants coding scheme).

In contrast, the teachers hardly saw any "concepts" in the clip. It seems that for them, "concepts" meant keywords on the board, together with explicit explanations *made by the teacher*. They were not searching for stems of different realizations of the ratio object. Talli therefore insisted on eliciting more ideas about "concepts", until finally the "fifth" was raised by Veronica [3.3].

The misalignment of frames in the subjectifying aspect was more nuanced. It appears only when one looks closely at the pronouns relating to the performer of actions (**bolded**) in the lexical chains referring to the video (wavy-underlined). While Talli talked about routines that surfaced in the discussion, focusing mainly on those narratives authored by the students, the teachers almost solely focused on the teacher. Veronica [2.5] as well as Yafit [3.1], even while "defending" the lesson as containing more attention to concepts than Valerie claimed, still based their justifications on the actions of the teacher ("**She** wanted to show", "**she** repeats (what the students has said)", "**she** asked"). This focus on the teachers' actions, both for evaluating what *did* happen and what *did not* happen in the lesson in terms of EAC, was prevalent in most of the teachers' talk.

## Discussion and Conclusions

This paper's goal was to characterize productive discussions in PD settings that promote EMI, by surfacing misalignments between frames of the PD leader, who was drawing on the Explorations Discourse and frames of the teachers, who were relying on the Acquisition Discourse. Our analysis of the PD pedagogical discussions included identifying lexical chains, both those relating to the rubric of EAC and those relating to the video-clip. This analysis showed that by using a video-clip of a classroom discussion and the Quadrants rubrics, misalignment between the teachers and the PD leader surfaced, and could therefore be referred to and further discussed. The misalignment in mathematizing aspects of the explorative frame, which are often difficult to notice (Heyd-Metzuyanim et al., 2018a), surfaced in this discussion well. However, subjectifying aspects of misalignment that related to whose contribution is valued (students or teacher), remained hidden during the discussion, perhaps because they were not attended to in advance by the PD leader. Our findings strengthen earlier studies regarding the usefulness of using video together with rubric scores in a PD setting (e.g. Schoenfeld, 2017). The contribution of this study is also methodological, in introducing and exemplifying the use of linguistic tools to analyze the productiveness of PD discussions.

## Acknowledgments

This study and the TEAMS project are supported by the Trump foundation, grant no. 220.

# On the efficiency of a professional development program for mathematics teachers in upper-secondary schools in Iceland

Freyja Hreinsdóttir

School of Education, University of Iceland, Iceland; [frejyah@hi.is](mailto:frejyah@hi.is)

*Keywords: Out-of-field teachers, upper secondary school, ICT, professional development*

## Introduction

The poster is about an ongoing study on the efficiency of a two year long in-service program for 25 mathematics teachers at the University of Iceland.

In 2014 a report was published by the ministry of Education in Iceland on the teaching of mathematics in upper secondary school in Iceland (Jónsdóttir et al. 2014). The report states that among other issues there are relatively many out of field teachers teaching mathematics, there is very little use of tasks that promote creative reasoning and use of ICT in the teaching of mathematics in upper secondary school is not very common. There is a shortage of educated mathematics teachers in the country and the Icelandic mathematics curriculum is rather vague on the use of ICT in mathematics so teachers in general do not feel required to use it. Many of the teachers interviewed expressed the need for more professional development which they felt was inadequate in Iceland.

After the report was published the University of Iceland started a two year long in-service program in the fall of 2015 for 25 mathematics teachers at the University of Iceland. The number of upper-secondary mathematics teachers in Iceland is about 150 so this was about one sixth of the total number of teachers. The aim of the program was to educate out-of-field teachers on various aspects of mathematics and mathematics education as well as to increase their use of ICT in the teaching of mathematics. The first course in the program was an intensive ICT course covering GeoGebra, LaTeX, software for screencasts etc. The teachers were taught basic use of the software and given assignments to do in their own teaching. This was followed by courses in combinatorics, statistics, mathematics education, calculus, number theory, geometry and mathematical modelling.

## Surveys

During the 2 years the participants filled in 3 surveys where they were asked about: their expectations, organization of the program, usefulness of individual courses, the program as a whole and if and how it had affected their teaching and more.

## Use of ICT

At the end of the first course (September 2015) the teachers filled out a survey (partially based on Goos & Bennison, 2008) on their knowledge and views on several types of software as well as the likelihood of using them in their future teaching. Their view was generally positive, they had learned a lot, they viewed ICT as something that could be used to help students understand mathematics and had plans to use ICT in their teaching. At the end of the program (June 2017) the actual use of ICT had been a little less than they had planned.

## Expectations and reasons for participating in the program

The main reason the participants stated was that they wanted to learn more mathematics and they were interested in the content of the program in general. They expressed (in answers to open questions) that they wanted to be better at teaching and believed that learning more mathematics would make them more secure in their teaching. The next most popular reason was learning to use ICT. The possibility to meet other teachers and collaborate with them was not rated very highly as a reason to join but turned out to be a valuable experience.

## Program as a whole

When asked to evaluate the program as a whole (in June 2017) the answers were generally positive but some disappointment was expressed such as “there should have been more practical didactics teaching us how to teach certain material”.

## Long term usefulness of the program

Teachers decide in general to participate in a PD program because they have some expectations about a positive outcome. Sometimes these expectations are unrealistic and sometimes there is a clash between these expectations and the plans of the PD organizers and teachers (see e.g. Nipper et. al. 2011 and Liljedahl 2014). It is important that PD organizers are aware of this and try to address this in their work. In the organization of the PD program mentioned above the ambition was to improve mathematics teaching in upper secondary schools in Iceland so it is therefore of great interest to examine further the long-term usefulness of the program. In an ongoing investigation selected participant are being interviewed about their overall view about the program, how they handled the differences between expectations and reality and if and how the program has resulted in changes in their teaching. It is also of interest to see what obstacles they have come across when they wanted to make a change in their teaching.

# Algebraic solutions of German out-of-field elementary school teachers

Lara Huethorst

TU Dortmund University, Germany; [lara.huethorst@math.tu-dortmund.de](mailto:lara.huethorst@math.tu-dortmund.de)

*In Germany out-of-field elementary school teachers are a frequent phenomenon but not regarded as unproblematic. In order to foster the pupils' algebraic thinking, teachers themselves need to be aware of the structures. Additionally, tasks which foster process-related competences too can only be set when the teacher knows which discoveries can be made by using a specific task. In this article theoretical background is given to process-related competences, teacher training and out-of-field teaching at German primary schools. A teacher training course is presented and first insights into the algebraic solutions of the participating teachers are given.*

*Keywords: Professional development, teacher training, out-of-field teaching, algebraic thinking.*

## Introduction

In Germany, out-of-field teaching, which is to be understood as trained primary school teachers who have been trained in different subjects than mathematics, exists fairly frequently in primary schools due to terms and structures of the first and second phases of teacher education. As a result, a national study points out that nearly one third of all interviewed primary school teachers, according to their own statements, teach mathematics outside their area of expertise (Richter, Kuhl, Reimers, & Pant, 2012). Hence, teacher training courses are needed to support teachers in teaching their daily mathematics courses. Therefore, this paper presents a teacher training course for out-of-field primary school teachers with the focus on usage of task formats to foster process-related competences.

Firstly, process-related competences are described and why out-of-field teaching cannot be regarded as problem-free. In a second step, the design of the study is described. Thirdly, the teacher training design is presented to lead to the fourth part of giving insights into how out-of-field mathematics teachers themselves solve arithmetic tasks.

## Theoretical background

There are several widespread theoretical topics relevant to fully acknowledge the key findings of the study which are briefly described in what follows below.

### Process-related competences

In the German framework, agreements for elementary schools, math competences are divided into two different but intertwining kinds. On the one hand, there are content-focused competences, including numbers and operations; space and shape; data; frequency and probability; and sizes and measuring. On the other hand, there are so called process-related competences. They include problem-solving, arguing, communicating, presenting and modelling (KMK, 2004). By now, the latter are found in almost every curriculum in all German federal states. They are considered to be indispensable for a successful usage, acquisition and implementation of mathematics (KMK, 2005). The following example explains that in more depth:

Number-chains follow the rules of the Fibonacci sequences. The two first numbers are start numbers,

**Figure 1: Number-chains**

which can be chosen freely from all natural numbers including 0 (they can also be identical or different). This task is one of those which “have the potential to address algebraic thinking” (Steinweg, Akinwunmi, & Lenz, 2018, p. 283). Not only (early) algebra can be fostered with number-chains but process-related processes as well.

The children need to get adequate assignments and support. An assignment which fosters the competence of arguing is, for example, one which asks the students to (1) guess what happens when the first start number is increased by one, (2) calculate four examples and test their guess, (3) derive a rule from that and (4) give justification for the rule. It is important to describe and generalize the finding so that the children acquire knowledge about connections and relationships between numbers.

Eichholz (2018) showed in her study on out-of-field teachers in German elementary school that some of the participating teachers show little knowledge about these process-related competences. This indicates that there is a necessity to have a closer look at how teachers can be supported in learning and teaching general mathematics competences.

### **Out-of-field teaching in German primary schools**

Due to the federal education system in Germany, study regulations vary widely in the 16 federal states. Although non-obligatory framework agreements state that studies at university to become a teacher comprise content knowledge and pedagogical content knowledge in both German and mathematics and an additional third subject (KMK, 2013), this is not the case in all states. For an overview on whether the education in the first and second phase of teacher education brings forth more generalists or specialist see Porsch, 2017. The principle of class teacher (Porsch, 2016) is dominant in German elementary school so that out-of-field teaching occurs frequently. However, there are enormous variations in percentages of teachers who teach mathematics without being fully educated from about 1.5% to almost 45 % in the different federal states (Richter *et al.*, 2012).

Nevertheless, it is widely known that the competences of a teacher have considerable impact on the competences of their pupils. COACTIV, a German wide additional study to PISA, for example, showed that both content knowledge and pedagogical content knowledge of a teacher have an impact on students’ performances (Baumert & Kunter, 2011). There is not only a high correlation between content knowledge and pedagogical content knowledge, content knowledge also proved to be mandatory for pedagogical content knowledge (Krauss *et al.* 2008). Moreover, “[m]ore traditional beliefs were associated with more traditional practices” (Stipek, Givvin, Salmon, & Mac Gyvers, 2001, p. 221), such as emphasis on performance or speed, which contradicts the contemporary views on how a good mathematics class should look like. As Porsch (2015) pointed out, out-of-field teachers agree less often with constructivist views and therefore, according to self-disclosure, realize them less often.

These results imply that there is a need to focus research on out-of-field teaching in German primary schools and its consequences. However, there are quite contradictory results in German research. While a nationwide investigation showed that elementary school students have poorer scores when

being taught by an out-of-field teacher, which is especially true for the weakest 5% (Richter et al., 2012), reanalysis of the same data indicates opposing results. Ziegler and Richter (2017) state that other reasons are responsible for the comparably weak performances of these pupils. The fact that children with weaker cognitive skills and migrant background experience more out-of-field teaching could be an explanation for the first result. Nevertheless, it needs to be investigated why there are such differences in out-of-field teaching concerning that group of elementary school pupils.

### **(Pre-)Algebra in German primary schools**

“Generalizations are the life-blood of mathematics” (Mason, Burton, & Stacey, 2010, p. 8). However, “German primary curricula and standards mention studies on algebra in a very limited way, if at all” (Steinweg, Akinwunmi, & Lenz, 2018, p. 284). Nonetheless, problems like little conceptual knowledge of variables are as present in Germany as they are in other countries (ibid.). This does not mean that there are no opportunities in German elementary school to foster algebraic thinking – but it stays implicit: “The objective is to encourage teachers to integrate algebraic thinking into their classroom. Moreover, the aim is to enable teachers to become aware of their already addressing algebraic thinking” (ibid., p. 286). The presented part of the study focuses on the algebraic thinking of teachers based on the assumption that teachers cannot set adequate tasks to foster algebraic thinking if they have not completely understood the mathematical structures themselves. This knowledge provides them with the opportunity to concentrate the pupils’ focus on interesting patterns and structures.

### **Teacher training**

“Professional teachers require professional development” (Wilson, & Berne, 1999, p. 173). That there is a need for teacher training is commonly known, so various research results can be used to develop and legitimate the presented teacher training course. There are five core features which can be identified in most research literature: (1) duration, (2) content-focus, (3) active learning, (4) collective participation and (5) coherence (i.e., Desimone, 2009; Garet, Porter, Desimone, Biram, & Yoon, 2001). Derived from these core features of teacher training, the German National Center for Mathematics Teacher Training (Deutsches Zentrum für Lehrerbildung Mathematik, DZLM) has developed six design principles: participant orientation, competence orientation, diversity of teaching and learning, case study, stimulating cooperation and stimulating reflection (Barzel, & Selter, 2015). The following project is affiliated to the DZLM, however, elaborating on the six DZLM design principles is not possible in the scope of this paper (see Barzel, & Selter, 2015).

### **Design of the study**

“Practice, at least in education, requires a cyclic alteration of research and development” (Freudenthal, 1991, p. 159). That is why this study was performed cyclically and was constantly revised. Prediger’s working group has developed a Design Research Cycle that is specifically adapted “for teachers with a focus on content-specific professionalization processes” (Prediger, Schnell, & Rösike, 2016, p. 97). The cycle is divided into four working areas which are “(a) specifying and structuring PD goals and contents in hypothetical intended professionalization trajectories, (b) developing the specific PD design, (c) conducting and analyzing design experiments in PD settings,

and (d) developing contributions to local theories on professionalization processes” (ibid., p. 98). The examined course was performed three times, with results from the first two courses being presented.

To gain insights into the level of knowledge and the beliefs of the participating teachers – about 25 in the first two circles – before and after the course, several research tools were used. At the beginning of the first lesson and in the last there were two different questionnaires. The first examines beliefs of how mathematics is learned, how it must be taught, the teachers’ self-concept regarding the process-related competences and other related features. These items are all from tested questionnaires which fulfil common quality criteria. The second questionnaire, which was designed by the author, is about how the participants themselves solve two different elementary school tasks. An operative change must be described in a first step. In a second step, the changes must be explained at elementary school level and, thirdly, the participants are asked to give an algebraic explanation. Each participant generates his or her personal code, so that the questionnaires stay anonymous but can be matched. Data evaluation is made mainly qualitatively by comparing pre- and posttest results and (possible) changes in beliefs. However, categories have been created, to allow statements about trends. Additionally, semi-standardized interviews with volunteers were conducted. The focus is on the questionnaire about the elementary school tasks to gain answers to the research question: How far do the algebraic solutions of out-of-field teachers primary school teachers, who participate in a training course with a focus on tasks (formats) to foster the process-related competences, change?

### Design of the teacher training course

Based on the core features of teacher training and the DZLM design principles, the constructed course is presented briefly, before one exemplary period is described in more detail.

There are five appointments which last three hours. For each meeting one typical elementary school task format is combined with one process-related competence (except modelling), so that the participants gain knowledge in two different ways. On the one hand they are supposed to completely understand the task on a deeper mathematical level. On the other hand, they should be able to use their (newly gained) knowledge to set assignments which foster the process-related competences as well as the content-related ones (with help from Primakom, a platform for out-of-field teachers on which they can undertake training – regardless of point or period of time or place).

	Topic of the appointment	Primakom pages
1	Fostering process-related competences – documentation with the example of discovery calculation packs	• Mathematics – more than calculation
2	Recognizing and explaining patterns and structures, operative changes with the example of Fibonacci sequences	• Fibonacci sequence • Arguing
3	Discovering and communicative math classes – math conferences with the example of number pyramids	• Number pyramids • Communicating
4	Combinatorics – problem solving strategies of pupils with the example of “building colorful towers”	• Building colorful towers • Problem solving

5	Good geometric tasks – building up concepts of symmetry and space with the example of fold-and-cut tasks	<ul style="list-style-type: none"> <li>• Fold-and-cut-tasks</li> <li>• Presenting</li> </ul>
---	----------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------

**Table 1: Topics of the Appointment**

Between two appointments there are always approximately four school weeks, distance phase, so that the participating teachers have the opportunity to try out what they have acquired in the presence phase beforehand. Reflecting on one's own lessons can be enabled only when following this concept of *duration*, which is essential, according to Hippel (2001), when wanting to take the step from professional knowledge to professional action. In order to provide support during the distance phases, each topic is supplemented with one or two pages of an internet site (<https://primakom.dzlm.de>). The *content focus* is realized through the concentration on task formats and process-related competences. This covers the point of *coherence*, since these tasks can be found in almost every elementary school mathematics textbook allocated to different grades and are adaptable for all grades so that every participating teacher can use what is learned during the presence phases in their own class in the distance phases. To satisfy *active learning*, the participating teachers solve assignments with the focus on algebraic structures of the task. Additionally, they are asked to illustrate their findings using elementary school appropriate material, for example sachets, and variables.

## First results

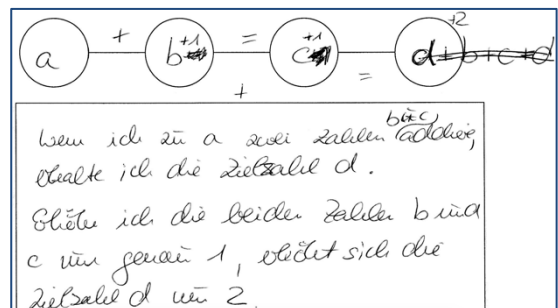

In the questionnaire about the teachers' solutions of elementary school tasks, in this example number-

**Figure 2: Operative changes in number-chains**

chains, the teachers are asked to describe operative changes in number-chains, to give an explanation where these changes derive from what they could use in their elementary school classes and to give an algebraic explanation. It becomes clear that the participating teachers differ widely in their explaining and algebraic competences at the beginning of the course. Two examples, in each case of the same participants, of the pre- and post-tests for the following

tasks are presented in what follows below: "Give an algebraic explanation (with variables) for the changes of the last number. Also give a reason for your algebraic explanation". As shown in table 1, number-chains have been discussed during the course.

In contrast, the other task in the questionnaire has not been talked about during the course. The first example of the pre-test illustrates that some conventions are known, for example, that variables are represented by small letters and often start with a. The explanation is, "When I add to  $a$  two numbers  $b + c$ , I get the final number  $d$ . If I increase both numbers by 1, the final number increases by two". But the formation rules do

**Figure 3: Pretest teacher A**

not become clearer by the variables because they do not show the connections between the two starting numbers and the final number. That is why it cannot be counted as an explanation for the increase of the final number. But it has been recognized that the second starting number has increased by one, the third number as well and the final number by two. Nonetheless, the causal relation to the

formation rules is not established. In the post-test, it can be seen that some other mathematical conventions have not been noted, such as that the notation of two variables without an operation sign stands for multiplication instead of addition. In the teacher's explanation, however, it becomes clear that she knows it is addition: "In the addition of two variables  $b$  is taken twice, so that the result is increased by two times  $b$ ". This could be

**Figure 4: Post-test teacher A**

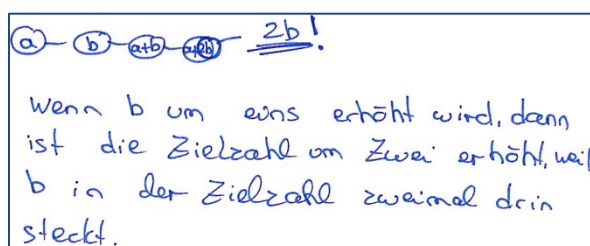

because, during the course, the elementary-school-appropriate representation to support the pupils' generalizing competences are little sachets and no operation sign is needed in this case.

Teacher B tries to illustrate the formation rules similar to teacher A. She describes: "The first number-chain consists of (in the little chart) a: starting number, b: 2nd number, c: 3rd number, d: final number. The other numbers need to change". This, again, is no illustration of the formation rules of the number-chains. But the changes are marked by the numbers in the circles, although this is not highlighting why these changes occur. In contrast to the pre-test, the post-test

**Figure 5: Pre-test teacher B**

shows a different result for teacher B as well. She highlights the  $2b$  by circling and underlining and explains "When  $b$  is increased by one, the final number is increased by two because  $b$  is two times in the final number". The formation rule gets evident through the used variables, but she does not use numbers to illustrate the changes. Nonetheless, she explains that because of two  $b$  in the final number, by whichever number  $b$  is increased, it is doubled in the final number. This is, in contrast to the pre-test, a very good algebraic explanation.

**Figure 6: Post-test teacher B**

Both examples show that there is a growth in algebraic competences for these two teachers. While in the beginning the formation rules cannot be expressed algebraically, the post-test shows that they can illustrate the changes and the reason for this case after the course. Their explanations change from being descriptive to being explanatory. This tendency emerges in a first analysis for the elementary school appropriate explanation as well as for the algebraic explanation. Before the course, the changes were described, but the answers of the participating teachers were not fully coherent and explanatory. This is only true for some teachers. A few participants were able to express the reasons for the operative changes in the pre-test as well. However, there is a very rare, in this case only one, questionnaire which is categorized as being fully explanatory in both questions (elementary school

appropriate and algebraic). Whether the teachers were not able to see where the changes derive from or whether they could not express it properly, either with words or variables, cannot be answered.

## Conclusion and outlook

This shows that there is a need for teacher training courses that foster the teachers' algebraic competences. They are often able to name the changes and to describe them, but they are not able so explain why these changes occur and where these changes derive from. In order to foster students' algebraic thinking and use the (full) potential of a task to foster content-focused and process-related competences at the same time, teachers need to be aware of the mathematical patterns and structures of such a task. Teachers need to be able to decide whether a student's explanation is sufficient; teachers themselves need to know what is important to explain and not only to describe a process. In a next step, the other task of the questionnaire, which has not been discussed during the course, will be analyzed further. This may give insights into how far the participating teachers are able to transfer what is learned to other tasks. The solutions for both task formats will be categorized so that more than trends can be named. Additionally, the interviews will be considered to underline detailed analysis of some participants. Further investigations on design principles for teacher training courses and possibilities to support teachers need to be done.

# Mathematics teacher educators' critical collegueship

Suela Kacerja<sup>1</sup> and Rune Herheim<sup>1</sup>

<sup>1</sup>Western Norway University of Applied Sciences, Norway; [skac@hvl.no](mailto:skac@hvl.no); [rher@hvl.no](mailto:rher@hvl.no)

*In this paper, we apply the ideas of Lord (1994) about critical collegueship to understand how mathematics teacher educators (MTEs) can work together to become more critical in their teaching practices. There is relatively little research on MTEs' learning and development from a critical perspective. Our study examines a group of MTEs working together to develop novel teaching and do research about initiating critical discussions. During two meetings, the MTEs discussed their different perspectives after using indices such as the Body Mass Index (BMI) in teaching. Identified examples of Lord's elements were a willingness to seek and try out promising ideas, and being open to share perspectives and ask for arguments. Such collaboration supports reflections for developing teaching and research.*

*Keywords: Critical collegueship, mathematics teacher educators, reflections.*

## Introduction and previous research

There are several studies concerning mathematics teachers' knowledge for teaching (e.g. Ball, Thames, & Phelps, 2008; Rowland, Hucksteps, & Thwait, 2005), as well as mathematics education courses designed for mathematics teachers' professional development. Zaslavsky and Leikin (2004) pointed to the lack of research on becoming a MTE and lack of formal training programs. "Mostly, teacher-educators are 'self-made'" (Zaslavsky, 2008, p. 94). Some studies about MTEs focus on the mathematical knowledge for teaching mathematics teachers (Zopf, 2010), and MTEs' practices in providing professional development (Kuzle & Biehler, 2015). In a historical overview, Jaworski (2008), in line with Zaslavsky & Leikin (2004), found that a very small number of studies reflect on the MTE's learning "from engaging in teacher education, through reflecting on their own practice, or through research into the programs they design and lead" (p. 3). Our study is a contribution to narrow this gap by focusing on how MTEs can collaborate to become more critical about their teaching practices.

According to Zaslavsky and Leikin's (2004) model of MTEs' professional development, MTEs learn through learning (facilitated by an experienced MTE) and through teaching (to mathematics teachers), while collaborating with other colleagues of similar or differing expertise. The need for MTEs to reflect, individually and collectively, on different aspects of their own practice and development is pinpointed as important for their learning (e.g. Tzur, 2001; Jaworski, 2008; Zaslavsky & Leikin, 2004; Garcia, Sanchez, & Escudero, 2007). Individual reflections upon the different stages of becoming an MTE include reflections on learning mathematics, learning to teach it, learning to educate mathematics teachers, and learning to mentor educators (Tzur, 2001). In collective reflections between colleagues when preparing and teaching different courses, practices such as sharing experiences, reading and conducting research, and continuous efforts to improve courses (Roth McDuffie, Drake, & Herbel-Eisenmann, 2008), as well as MTEs adopting theoretical perspectives to examine their teaching practices (Garcia et al., 2007), can influence MTEs' development.

Zaslavsky (2008) argued that one of the identified practices, from which MTEs can learn, is the choice and design of tasks and resources by which students can learn specific content or ways of teaching. In our research group, we collaborate on identifying and implementing new teaching ideas that can promote critical mathematical discussions (in line with Skovsmose, 1994) amongst pre-service and in-service teachers. We collectively reflect upon the implementation of these ideas in our own teaching. One idea we aim to investigate in our project is the use of indices as mathematical models for in-service teachers to experience initiating and developing critical discussions about the role of mathematics in society. Indices, such as the BMI, have proved to be fruitful entry points to such discussions (see Kacerja et al., 2017). Reflecting collectively as MTEs upon our own practice can help us learn more about being teacher educators (Roth McDuffie et al., 2008; Zaslavsky & Leikin, 2004).

In the data presented in this paper, we reflect as a group upon our experiences with critical discussions after two colleagues had tried out a task about the BMI with in-service teachers. We investigate how we communicate in the group and how we invite and present ideas and perspectives from a critical colleagueship perspective (Lord, 1994). Critical colleagueship is a particular type of collegiality and is elaborated on in the next section. The question we pose in this paper is: *What aspects of critical colleagueship can mathematics teacher educators' collaboration bring about?* By focusing on the critical colleagueship aspects by Lord (1994), we explore how such a collaboration can support our work as MTEs.

### **Critical colleagueship among mathematics teacher educators**

Lord (1994) emphasised professional development of teachers and discussed critical colleagueship as one kind of colleagueship to support teachers' reflections. Colleagues sharing interests and experiences, being open and respectful, willing to try out new ideas and to be critical, are crucial conditions for such a colleagueship. The main difference between critical colleagueship and other kinds of collective reflections is the support of a "critical stance toward teaching" (p. 192). The critical stance in our study means we do not only share our ideas with colleagues, but we also ask for, and articulate, the assumptions behind these ideas.

Lord (1994, pp. 192–193) identified six characteristics of critical colleagueship:

1. Creating and sustaining productive disequilibrium through self-reflection, collegial dialogue, and on-going critique; 2. Embracing fundamental intellectual virtues (e.g. openness to new ideas, willingness to reject weak practices or flimsy reasoning, accepting responsibility for acquiring and using relevant information, willingness to seek out the best ideas, greater reliance on organized and deliberate investigations, assuming collective responsibility for creating a professional record of teachers' research and experimentation); 3. Increasing the capacity for empathetic understanding; 4. Developing and honing the skills and attributes associated with negotiation, improved communication, and the resolution of competing interests; 5. Increasing teachers' comfort with high levels of ambiguity and uncertainty; and 6. Achieving collective generativity.

The characteristics for which a colleagueship can be considered critical, according to Lord, have to do with a sense of responsibility for seeking improvement and accepting that the best solution is not yet achieved. It requires participants to be comfortable with uncertainty and to make efforts to develop

and accept new ideas by self-reflection and on-going critique. Differences are seen as driving forces that can facilitate a productive disequilibrium. Our joint interest as MTEs is to learn more about ways of fostering critical discussions in teacher education about the role of mathematics in society. The ideas within critical collegueship support such group reflections. This is the reason why critical collegueship is chosen as a framework for analysing the discussions.

While Lord (1994) defined critical collegueship for groups of teachers reflecting together, Males, Otten, and Herbel-Eisenmann (2010) used Lord's framework to study the collegiality of a group of mathematics teachers and researchers. They identified challenging interactions in which participants asked questions to push for in-depth reflections, and located elements of Lord's intellectual virtues in those interactions. In our paper, we apply critical collegueship within a group of MTEs. We extend critical collegueship as one way of thinking about professional development of MTEs, by reflecting upon our own discussions. In line with Males et al., we focus on the discussions when different perspectives about practice come into play. It is in these situations that it becomes more likely for MTEs to argue for their ideas and invite the colleagues to share their perspectives.

### **The study, participants, and data analysis**

The study focuses on a group of seven teacher educators, including the two authors, collaborating on developing teaching and research. In this paper, we use data from two meetings in which teaching about indices and critical discussions was focused upon. All seven of us took part in the first meeting shortly after TE1<sup>1</sup> and MTE2 had collaborated on a 3-hour workshop on indices for in-service teachers. This was part of a course in Numeracy across the curriculum. The in-service teachers discussed the BMI task for 60 minutes in two groups of six persons. They examined the BMI's mathematical components and formula, its use in society, and the appropriateness of using indices in school teaching. In the next semester, we had a second meeting and continued to discuss ideas for developing our teaching about indices as part of our project. In addition, we discussed a research paper we had written about stimulating critical discussions in mathematics where data from in-service teachers' discussions were analysed (see Kacerja et al., 2017).

The two meetings were audiotaped and transcribed. In line with Lord (1994), we, the authors, investigate discussions when different perspectives in teaching and research come into the fore as driving forces. An example of this is when one MTE argued that we should teach a kind of scheme for dissecting indices, while one of the others thought it was important for in-service teachers to be free to investigate. The first author identified such interactions from both meetings, and both authors examined them from a critical collegueship perspective. We also looked for the use of words such as "yes", "maybe", "but" etc., in order to identify the different characteristics of the critical collegueship. The examples presented in the following are representative for the situations where different perspectives occurred.

---

<sup>1</sup> TE1 is a teacher educator within social science, while the six others are within mathematics education, thus MTE.

## Different perspectives

As previously argued, we identified discussions showing different perspectives on two related topics – the ways to teach critical skills, and the mathematical level in the discussions. We now analyse aspects of critical colleagueship in the chosen utterances.

### Different perspectives on how to teach critical skills

The first meeting begins with TE1 describing the teaching and his experiences from the workshop. The goal of the lesson was to create an awareness about the importance of being critical to the use and misuse of numbers in society. While TE1 and MTE2 agree upon the goal, differences came to the fore about how to achieve that goal. TE1 then said, “It was actually too little time and too much material” in the teaching session before the group discussions, and continued by saying:

TE1: I wish I had more time, and maybe do something more, dissect an index to really give them a useful example, a template in principle, a recipe, how one can approach an index. How one can take the pieces apart and see what those mean, what the different numbers mean, the different variables in an index.

TE1 explains what he would do differently next time to improve his teaching. He is critical to his planning of “too much material” and shows by this self-reflection a characteristic of critical colleagueship. For him, a way to achieve the goal could be to show the teachers an example of how one could criticise an index, by dissecting it and working with its different components to get a sense of the numbers. The use of “maybe” indicates an openness in his reflection. This is strengthened by the wording “I wish”, a choice of words that makes it possible to characterize the whole utterance as a “what if ...?” approach, a focus towards what can be possible to do. A few utterances later, MTE2 presents a different opinion:

MTE2: Yes, and as you said TE1, one can look at this from two sides; how much material should they be presented with beforehand for a discussion like this, and how much should they not [be presented with] ...

MTE2 starts with a “yes” and acknowledges TE1’s point of view. However, she also wants to bring into attention another point of view. There is a dilemma about how much guidance the in-service teachers should get before they start exploring the problem themselves. MTE2 does not comment upon the goal of the lesson, she is only trying to look at an alternative way for achieving it – she creates some disequilibrium. From Lord’s (1994) perspective, disequilibrium provides participants with opportunities to reflect upon other’s ideas and bring their own arguments into the discussion.

MTE2 elaborates afterwards on her argument with a “because” and exemplifies with an episode from the in-service teachers’ group discussions in which one teacher was fascinated about how much she had learned. For MTE2, this is an argument that supports the idea of giving teachers the opportunity to explore the use of mathematics, without necessarily having ready-made schemas, as TE1 suggested. MTE2 argues that the dialogue the in-service teachers had is important for learning to explore, while a recipe “can limit the dialogue and they [the in-service teachers] can become preoccupied with doing it the same way [as the MTE]”. The argument concerns potential negative effects from presenting a recipe; it could hinder the teachers’ explorations and make them adhere too

strictly to the TE's schema. MTE2 provides arguments to support her idea of giving the teachers some space to explore the problem themselves, emphasizing dialogue, wondering and exploration. She presents ideas and counter-arguments, thinks aloud and refers to examples. MTE2 sets some standards for the level of reasoning required for the group discussions to be fruitful, in line with Lord's (1994) emphasis on negotiation and improved communication.

In all of the utterances presented above, as in other cases of disequilibrium in our data, the participants start their utterance by acknowledging the colleague's point of view using phrases like "yes", and "agree", and then introduce an alternative view starting by "because" and supported by examples. Acknowledging colleagues' ideas and arguments relates to Lord's focus on "the capacity for empathetic understanding" (1994, p. 192). By using phrases such as "maybe" and "you can look at it from two sides", TE1 and MTE2 apply some fundamental intellectual virtues in their discussions by opening up for other opinions. They acknowledge the others' views and seek the best ideas by looking at the topic from different points of view. TE1 and MTE2 use classroom examples to support their arguments by using relevant information. This is typical for the participants in both meetings, and in line with previous research (Males et al., 2010). The MTEs explore together how to initiate critical discussions in their teaching without having the answers available. They are, as Lord (1994) put it, coping with uncertainties and ambiguities that TE1 and MTE2 reflect upon.

### **Different perspectives on the mathematical level in the discussions**

Exploring the mathematics of the BMI, and the in-service teachers' mathematical competence to do that, also generated different perspectives. In the first meeting, MTE4 stated that the teachers did not explore in depth the mathematics behind the chosen index. Similarly, TE1 pointed to the lack of mathematical competence as a barrier that hindered the teachers in doing so. He supported his argument by referring to what the teachers expressed during the discussions. This fits with his earlier reflections about how he would organize the teaching differently next time to help teachers overcome this barrier, showing again signs of self-reflection for improving his teaching.

Another disequilibrium occurs in the second meeting, when discussing an article in which we all looked at the competence showed by in-service teachers when working with the BMI task. Similarly to TE1 and MTE4, MTE5 thinks there were "relatively little mathematical discussions". MTE6 asks MTE5 what mathematical discussions are in her opinion. MTE5 answers that she is thinking about discussing mathematical concepts. MTE6 then adds, "Yes ... but there is also a broader understanding of mathematics, of mathematical discussions, to discuss mathematics in use and its role in society". As MTE2 also did earlier, MTE6 accepts MTE5's perspective about what she regards as mathematical discussions with a "yes", but he also introduces his perspective by saying "but there is also". MTE6 presents his view by arguing, in line with a critical mathematics education approach (Skovsmose, 1994), that mathematical competence includes being able to use mathematics and evaluate its use in different contexts. Mathematics goes beyond discussing mathematical concepts; it also involves a broader perspective of its use in society. This is reflected in the goal of the lesson formulated by TE1. MTE6 supports his argument by focusing on competences the teachers showed in their discussions from this extended perspective on mathematics by saying: "They showed many good reflections connected to challenges about indices, and about indices in a school context."

It is possible to identify several fundamental intellectual virtues in this discussion. The MTEs are invited to share ideas and arguments, problems are investigated from different viewpoints, and viewpoints are elaborated upon with several arguments before deciding the next step. In the two meetings, the MTEs clarify their expectations about in-service teachers showing mathematical competence, but also the competence to evaluate and criticize how mathematics is used in society. They search for better ideas to improve the teaching about critical discussions, as Lord (1994) emphasized, as they continue to reflect about the tasks. At the end of the second meeting, when MTE4 wonders if she should ask more targeted mathematics questions in the next teaching session in order to guide the teachers to thoroughly explore mathematics, MTE2 argues:

MTE2: One thing is to go more in depth into the mathematics [of the index], if they are able to do that. But we would also like them to stay there and understand that there is something here that could be necessary for them to understand. They see its meaning ...

MTE2 acknowledges again the other colleagues' idea of more in-depth exploring of the mathematics. She then continues in line with her earlier ideas about giving the teachers the time and possibility to discover things by themselves, to get the feeling that they need to learn something. She connects this to the meaning the teachers themselves would give to an index, and to the mathematics of the index.

So far, the MTEs have shared their ideas, been open-minded for other arguments and ways of doing, argued for their views, and presented alternative points of view. One could then ask what effect this exchange of ideas has on the MTEs and their collaboration. By the end of the meeting, MTE2 continues with a proposal for further developing the task about critical mathematics and BMI:

MTE2: As you [MTE4] mentioned with proportionality ... Is it possible to design a teaching session where one first goes through the main mathematical ideas of the index? But not specify the index. Then talk [teach] about inverse proportionality without saying that it is the BMI we are talking about ...

MTE2 starts with taking into account MTE4's earlier idea of proportionality. By raising a question, "is it possible to design ...?", MTE2 tries to negotiate with MTE4 and the others to find a teaching approach that takes into consideration many of the colleagues' comments. She proposes one way to organize the session by starting with some teaching about the mathematical concepts of BMI, such as inverse proportionality, but without giving any scheme for how to do it. By so doing, the in-service teachers would be given some mathematical foundation when exploring the mathematics of the formula, as MTE5, TE1, and MTE4 called for. At the same time, MTE2 takes care of her own idea of giving the teachers the freedom to explore by adding "then they [the in-service teachers] could get the BMI formula and see if they connect it [to inverse proportionality]. We haven't tried that". MTE5 agrees with MTE2 by saying "I thought the same ... teaching about proportionality independently of the index". MTE6 also supports MTE2's idea by saying, "start the teaching with some mathematics". Everyone agrees that it is a good idea to try out MTE2's proposal. The negotiation highlights the importance of giving the in-service teachers more support to develop and show mathematical competence, while at the same time giving them freedom to show their competence on reflecting upon the mathematics' use in society. The MTEs have together come to an idea while trying to avoid

the pitfalls expressed earlier by the colleagues, a kind of “collective generativity” (Lord, 1994). The best agreed upon solution in this round of discussions is to teach some mathematics and see if this will help the teachers in their discussion of the index.

## Conclusions

In this paper, we have focused on identifying aspects of critical collegueship in mathematics teacher educators’ collaboration on developing teaching about critical discussions. We singled out utterances when colleagues had different perspectives because it is when we disagree that we ask each other for more arguments. This is a vital element of the critical collegueship perspective as it creates conditions for the participants to dig into the assumptions behind their ideas, and thus adopt a critical stance in terms of Lord’s framework. We, MTEs, are also in a position to reflect better upon our own views when challenged to argue and exemplify the teaching, and modify it for better results. In this aspect, our results fit with findings from Males et al. (2010).

During the collaboration to develop our teaching, there were particularly two aspects that generated different perspectives. One aspect is about the way of organizing such teaching and the amount of guidance to give teachers, and the other concerns expectations about the level of mathematics in the teachers’ discussions. We, MTEs, discuss different perspectives and consider them, showing several elements of Lord’s framework, especially fundamental intellectual virtues such as openness to new ideas, respect, and seeking better solutions. We support our points of view with arguments from classroom examples, as MTE2 and TE1 did, and from theoretical ideas influenced by critical mathematics education (see Skovsmose, 1994), as MTE2 and MTE6 did. Examining our practice with theoretical lenses, as with the critical perspective lenses, is a way for us to develop as MTEs (Garcia et al., 2007).

At the end, the agreed solution covers some of the challenges discussed in the two meetings. The engagement brings about some collective generativity. The solution indicates that we, MTEs, value the development of teachers’ mathematical competency, but also the importance of the freedom to develop their critical competence by not giving them too much guidance. In this way, we move forward in developing our understanding of what critical mathematical discussions are and how to support them in our teaching. As Roth McDuffie et al. (2008) pointed out, sharing experiences, looking for improvement in our practice, and doing research together, facilitate such development. It can be concluded that we, MTEs, enrich our own views by listening to our colleagues’ arguments and by trying to make sense of their reasoning, when we collectively reflect upon and analyse our work.

Given the very few possibilities for MTEs to develop their knowledge and skills, and given that collaboration of MTEs about teaching and research is a common practice, it is important to study what and how such collaborations can support the MTEs’ work, as we have done in our study. Lord (1994) discussed critical collegueship as a way to support teachers’ reflections. In this study, the concepts in Lord’s elements of critical collegueship helped us identify and discuss the potential such collaboration has in supporting MTEs’ reflections.

*To investigate the development of the progressive incorporation perspective for effective mathematics teaching, a multi-case study with seven out of twenty-six prospective secondary mathematics teachers was conducted for fourteen weeks during a methods course. The course was built on four-core ideas: quantitative reasoning, task-analysis, conceptual analysis and interviewing. In this paper, we report on the change in prospective teachers' conceptions of mathematics and mathematics learning upon completion of working on quantitative reasoning. Results showed that quantitative reasoning might bring about change on prospective teachers' awareness on practices such as attending to students' thinking and distinguishing their mathematics from their students' mathematics. Results suggest the inclusion of quantitative reasoning in methods courses in mathematics teacher education.*

*Keywords: quantitative reasoning, teacher education, prospective teachers*

## Introduction

Education of prospective teachers is an ongoing challenge (Chapman, 2016; Grossman & McDonald, 2008). Although there has been considering effort on the change of prospective teachers' practices in methods courses, there is still need for focusing on significant change in prospective teachers' thinking about mathematics teaching and learning (Chapman, 2016). In fact, researchers argued that the possible reasons for the difficulty of change might be due to the lack of pedagogical principles prospective teachers need to hold (Jin & Tzur, 2011; Simon, 2006b). Such principles involve developing i) a view of mathematical understanding consistent with the problem-solving view, ii) a view of mathematics learning (Simon, 2006b) and (iii) the teachers' distinction between their mathematics and their students' mathematics (Silverman & Thompson, 2008; Simon, 2006b). Silverman and Thompson (2008) also suggested that prospective teachers need to have an image of (e.g., hypothesize) how their students might come to think of mathematical understandings they envision. In this paper, we embrace these as core practices.

Previous research depicted evidence of these proposed difficulties. Particularly, Yeh and Santagata (2015) study showed that prospective teachers regarded students' procedural fluency as evidence of conceptual understanding. Results also showed that prospective teachers detected student actions as evidence of student learning rather than attending to their thinking. Similarly, Simpson and Haltiwanger (2016) study showed that prospective secondary mathematics teachers had difficulty in interpreting student mathematical thinking in written work. They suggested studying the ways to develop prospective teachers' abilities to make sense of students' thinking. It is in this respect that, in this study we investigated the possible affordances quantitative reasoning (Thompson, 1994) might

provide prospective teachers in terms of the pedagogical principles they need to hold regarding the nature of mathematics, mathematics learning and mathematics teaching. We investigated the following research question: What changes in the prospective teachers' awareness on the practices of effective mathematics teaching might develop focusing on quantitative reasoning during methods courses? Results showed a change in prospective teachers' views on the nature of mathematics. They were also able to characterize procedures and concepts in relation to quantitative reasoning. In addition, they realized the need to distinguish their thinking from students' thinking as well as developing a sense of what mathematics learning means. With this report, we propose that in methods courses prospective mathematics teachers need be given opportunities to engage in tasks focusing their attention on quantitative reasoning. We make suggestions on how to include such tasks pointing to our experience as teacher educators. In the next section we provide our reasons as to why we considered quantitative reasoning as part of the methods course we developed. We explain our reasons with connections to the teacher perspectives framework (Jin & Tzur, 2011) based on which the larger study was conducted.

## Theoretical Framework

In the larger study of which this study was part, our purpose was to examine the prospective secondary mathematics teachers' development of the progressive incorporation perspective to teach mathematics effectively during methods course. Jin and Tzur(2011) postulated the teacher perspectives framework following on the work of (Heinz, Kinzel, Simon, & Tzur, 2000; Simon, Tzur, Heinz & Kinzel, 2000; Tzur, Simon, Heinz, & Kinzel, 2001). They used the term "perspectives" to refer to both the knowledge and beliefs teachers might hold regarding the nature of mathematics, mathematics learning and mathematics teaching and also the practices they might engage in based on such acknowledgment. Tzur and his colleagues proposed that teachers holding CBP (conception based perspective) would act accordingly with the views of radical constructivist epistemology. Therefore, they suggested that PIP would be a more realistic target for the teacher education since "a PIP-rooted teacher's practice can engender students' learning processes envisioned by CBP without requiring the teacher's explicit awareness of such view..."

Therefore, for the first part of the methods course, we used quantitative reasoning framework (Thompson, 1994). Thompson (1994) defined quantitative reasoning as an individual's analysis of a situation into a quantitative structure. So, quantities live in an individual's conception of situations such that in order for an individual to comprehend a quantity, the individual must have a mental image of an object and attributes of this object that can be measured (Thompson, 1994). For instance, a rectangular shape could be thought as an object with the attribute, area, that could be measured. Then, a fraction could be thought as a quantity as the measure of a particular size of the total area of the rectangular shape. For the construction of quantities, Thompson differentiated numerical operations from quantitative operations. Quantitative operations are the non-numerical operations an individual mentally act. For instance, equi-partitioning the total area of a rectangle in purpose of determining a particular size would be an example of quantitative operations. Numerical operations are the result of the evaluation of quantitative operations. So, an individual imagining the fraction such as  $\frac{1}{2}$  as a quantity, can engage in equi-partitioning of the shaded area of a rectangular shape showing  $\frac{1}{2}$  into more equal pieces (e.g., equi-partitioning into five more equal pieces). This numerically results in the

fraction  $5/10$ . Thompson stated that over emphasis on the numerical operations prevent students to learn mathematics meaningfully. Therefore, he proposed that prospective teachers need to pay attention to the mental processes (i.e., quantitative operations) required of an individual for the development of mathematical understandings (Silverman & Thompson, 2008). They stated,

“the prospective teacher must put herself in the place of a *student* and attempt to examine the operations that a student would need and the constraints the student would have to operate under in order to (logically) behave as the prospective teacher wishes a student to do.” (p. 19).

So, we hypothesized that if we engage prospective teachers’ in tasks focusing their attention on the distinctions between quantitative and numerical operations, their awareness on the students’ mathematical reasoning might develop. This also might have allowed them to pay attention to the nature of mathematics. That is, in this framework mathematics is built through an individuals’ mental actions and the results of these actions. This view of mathematics aligns with the problem-solving view in which “...mathematics is built from human activity: counting, folding, comparing, etc.” (Confrey, 1990, p. 109). A teacher with progressive incorporation perspective or conception based perspective is also expected to hold this view of mathematics (Jin & Tzur, 2011)

## Method

### Participants

Seven prospective secondary mathematics teachers participated in the study. They were at their fifth-year of study at one of the universities, in which the medium of language is English, in Turkey. We chose these prospective teachers for the following reasons: First, their GPA’s (Grand Point Average) ranged between 3,44 and 2,76 out of 4,00. This provided a spectrum of GPA’s of all prospective teachers taking the methods course; two in the top, three in middle and two in the lower range. Second, based on the first week of the classes and the written-pre assessment we gathered prior to teaching sessions, we observed them as verbal individuals. That is, they were talkative, and, volunteered to participate in the continuing five-set of interviews till the end of the study.

### Data Collection

Data were collected for a total of five weeks during the methods course the first author taught. The methods course was four hours per week. For this multi-case study (Yin, 1984), we conducted classroom teaching experiments for the teaching sessions (Cobb, 2000) (see Figure 1).

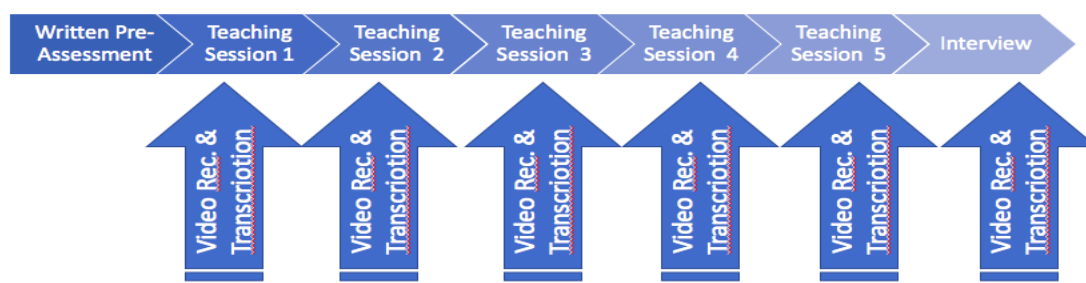

Figure 1: The data collection period during the methods course

In this method, the teaching sessions are planned in advance. However, for each teaching session, we revised the (sub) learning goals depending on our hypotheses about prospective teachers’

development. Prior to the teaching sessions, we gave a written pre-assessment to prospective teachers to collect their thoughts on mathematics learning and teaching. Then, each of the teaching sessions was videotaped and transcribed afterwards. Prospective teachers also kept weekly journals concerning both in-class and out-of-class discussions, due online of the night after each class. The classes were Tuesdays and Thursdays, so that we could watch the videotapes and read the journals in between the teaching sessions. In the journals, we purposefully asked prospective teachers to reflect back and forth on the relationships among the constructs discussed. In this way, each teaching session was revised and re-planned based on the ongoing assessment. Then, we conducted an interview upon completion of working on quantitative reasoning. Data sources included prospective teachers' written responses to pre- assessment and the journals; transcripts of the videotapes of i) whole-class discussions and iii) the interviews. These data seemed central to understanding the shifts in the practices contributing to advances on the part of prospective teachers.

### **The Procedure**

The first set of classes in the methods course included mostly concrete examples to focus on the nature of mathematics. First, we included tasks in terms of the distinction between prospective teachers' thinking on quotitive and partitive division types based on measuring and equal sharing (quantitative operations). For this, we asked prospective teachers to come up with a word-problem for which the solution was given as  $10/5=2$ . Then, we asked them to sort different division problems they came up with into two categories by paying attention to the similarities and differences. They worked in groups to sort the word-problems. Following they shared their ideas during the class discussion. With this task, we wanted to direct their attention to both their classmates' and their own mental actions (i.e., measuring and equal sharing) and the numerical operations, such as division, they used. Then, we asked them to think about the two examples in chapter 1 from Van de Walle (2007). In these examples, Marlena and Darrell, two students' work on division problems are shared. We wanted to observe and assess if they could focus on these students' mental actions—measuring and equal sharing. After that, we had a classroom discussion on chapter 1 from Van de Walle (2007). The next week, we asked prospective teachers to work in groups to come up with a way to teach improper fractions to 5<sup>th</sup> grade students. For this, we also asked them to explain their thinking for instance what  $11/6$  means to their group members. We wanted to take their attention to again to their classmates' mental operations as well as theirs. Following, we provided them with the first author's articulation of the understanding of improper fractions (Tzur, 1999) from the point of view of quantitative operations. Also, for the out-of-class activity, prospective teachers considered the first author's articulation of between-state ratio (Karagoz Akar, 2007) based on a task from a reform curriculum (Everyday Mathematics) and had a discussion on it during the next class hours. Then, in the third week, we taught the geometric meaning of differentiation using a task we modified from the national reform-based curriculum. Following week, we used a task sequence to teach the algebraic and geometric meaning of the binomial form of complex numbers (Saraç & Karagoz Akar, 2017). We also had a discussion on Thompson(1994). For the out-of-class activity, for both of the teaching sessions on differentiation and complex numbers, prospective teachers were asked to articulate on reasoning processes they have engaged in.

### **Analysis**

We analyzed the data using the constant comparative method (Strauss ve Corbin, 1990). In this method, the researcher constantly reads and analyzses data both during and at the end of the data collection. Also, s/he reads the data and compares and contrast his/her hypotheses (conjectures) both within all data from one participant and among participants. Therefore, we read the transcripts of the teaching sessions, the journal entries and the transcripts of the interviews line by line. Our goal was to determine what core-practices these seven prospective teachers' recognized and developed during these five weeks. Reading the transcripts of the teaching sessions and the journal entries from the first week together with the written-pre assessment, and the transcripts of the data from the interviews at the end of the five weeks, we all coded the data individually. Then, comparing the list of codes on the data from each participant, we came up with a set of codes representing the whole data. Following, we came together to discuss and have a consensus on the codes. We then finalized the list of the codes depicting prospective teachers' awareness of the core-practices. In the following section, for illustrative purposes, with reference to the data from one prospective teacher, Mina, in the middle range of seven prospective teachers, we share the results. Focusing on data just from one prospective teacher, we hope to maximise the possiblity of the reader's achieving some familiarity with the context for the analysis.

## Results

### Beginning of the study

As stated earlier, in the second week of the study, we had asked prospective teachers to discuss in groups how to teach improper fractions to 5th grade students. Then, all the groups choosing a representative shared their ideas in the class discussion. Mina spoke on behalf of his group members and other prospective teachers agreed upon the idea: They first started with proper fractions and used it to work towards improper fractions.

Mina: First, we thought that they (referring to students) need to know proper fractions. Like, they need to know that they are between 0 and 1. Like this could be shown by shading some part of shape, like rectangle. Like for instance dividing the shape into 6 pieces and shading 5 pieces and counting 5 pieces. But then this should be shown on the number line dividing the interval between 0 and 1. Then, in the same way we can divide the interval between 1 and 2 into six pieces. Now, we divided the interval between 0 and 1 into six pieces and divided the interval between 1 and 2, then when we count like 1,2,3,4,5 until 11, the number  $11/6$  will be in between 1 and 2. Then what  $11/6$  means because because we divided each piece into 6, they will know that the denominator is 6 and since we counted until 11, they will know that that point will correspond to  $11/6$ . Like they will see that  $11/6$  is there.

S1: Super idea

S2: I think it is very meaningful showing it with the number line.

As the excerpt showed, prospective teachers viewed mathematics as obviously apperant to their students as it seemed to them. Such knowledge existed in the drawings they shared with their students. That is, their view of mathematics corresponded to a Platonist view of knowledge. They also agreed on using the number line to depict the connections to their students supposedly acquired previous knowledge such as proper fractions. This suggested that they considered that their students would think the same way as they think.

### End of the five weeks period

Data from the interviews at the end of the five weeks period showed a change in prospective teachers' awareness on the nature of mathematics and their students' thinking.

Questions asked during the interview	Mina's answers	The codes depicting data from the interviews on seven prospective teachers
Why do you think that we have focused on the quantitative reasoning framework?	Like I thought while working on them like mathematics includes two processes like it has procedures and the meanings behind those procedures... For instance $\frac{1}{2}$ like was thinking numerically earlier. For instance when I say $\frac{1}{2}$ is equivalent to $\frac{5}{10}$ , like I say now that multiplying with 5 has a meaning when I divide the shape into two equal pieces and then shade one part. That multiplying with 5 means for me now dividing the shape, $\frac{1}{2}$ , into 5 more equal pieces. Like those numbers have meaning....So like we work on quantitative and numerical operations so that like we will know the reasons behind like formulas...	Mathematics is made up of both numerical and quantitative operations—a human activity  Awareness of the need for key mathematical ideas
Remember we asked you to articulate on your engagement in the tasks focusing on differentiation and complex numbers. How do you think that this experience might benefit you a prospective teacher?	Like yes as I said earlier like we should know the mental processes of our students like how they think... I saw my process now I can focus on theirs...  Like to imagine how they might think so that they could learn like construct them connecting them...	Awareness of the need to focus on students' thinking  Awareness of their students thinking differently from theirs
How do connections in conceptual understanding occur?	Eeee like linking them ...like it is like to me mathematical understanding, what is the reason behind this. Like I said earlier not numerical, quantitative...	Awareness of the nature of mathematics learning with understanding

Table 1: Codes depicting prospective teachers' awareness of the core practices.

As the codes depicted, there was a change in prospective teachers' awareness of the views on the nature of mathematics. Data showed that, for instance, Mina regarded mathematics knowledge as human activity, aligned with the problem solving view. Also, he was aware of the need to understand mathematics meaningfully so that he could anticipate his students' thinking to help them construct

those ideas on their own. In addition, he was aware that his thinking would be by nature different from his students' thinking.

## Discussion

In this study, we investigated the change in prospective teachers' awareness on the practices involved in effective mathematics teaching once they engaged in tasks focusing on quantitative reasoning during methods courses. Results showed that their views on the nature of mathematics has changed. Contrary to the data from the beginning, after engaging in tasks requiring them to analyze both their and their classmates' thinking in terms of quantitative and numerical operations for almost one and a half-month period, they started viewing mathematics as a human activity. Regarding the teacher perspectives framework (Jin and Tzur, 2011), this change is the first stage for the development of progressive incorporation perspective. Though, research on beliefs suggest that establishing change is not easy (e.g., Wilson and Cooney, 2002). Still, we argue that asking prospective teachers to reflect on and write about specifically their own thinking might have brought about the change in their views on the nature of mathematics. So, we propose to the field such task as a core practice for teacher educators to use in methods courses. Yet, with caution, we argue that there is need to examine the effect of engagement in tasks focusing on quantitative reasoning on both prospective and inservice teachers' beliefs on mathematics. Results also showed that prospective teachers' awareness on the need for focusing on their students' thinking developed. In addition, they recognized that their thinking processes would by nature differ from their students' thinking processes. Previous research emphasized the need to study the ways to develop prospective teachers' abilities to make sense of their students' thinking since they had difficulty in interpreting thinking (Simpson & Haltiwanger, 2016). In addition, research has shown that prospective teachers confused students' procedural fluency with conceptual understanding (Yeh & Santagata, 2015). To the contrary, results of this study indicated prospective teachers' awareness of the nature of concepts and procedures. Therefore, we suggest focusing on quantitative reasoning during methods courses as a possible way to provide prospective teachers for paying attention to their students' thinking differentiating their procedural fluency from their concepts. We also recommend the use of tasks focusing on quantitative reasoning in professional development workshops for inservice mathematics teachers. As a final note, considering the core-practices as conglomerate components of effective mathematics teaching, we suggest that the effect of quantitative reasoning on both prospective and inservice teachers' mathematical knowledge for teaching might be investigated.

*The study reported here explored how secondary mathematics teachers, participating in a school-based video club, communicated with each other and with the facilitator along the different sessions of the club. Specifically, their evaluative comments were analyzed, with respect to the non-judgmental norms that this club aimed to nurture. Three types of evaluative comments were identified, reflecting varying degrees of teachers' capability to interpret and discuss observed teaching moves while attributing possible rationalizations to the filmed teacher's decisions. It was found that the amount of highly judgmental comments decreased as the club proceeded, allowing for a more productive communication.*

*Keywords: Video club, school-based professional development, peer-discussions.*

### **Introduction**

Video club is a form of professional development that has become known since the early 1990's (Sherin, 2004; Sherin & van Es, 2009). In a video club, a group of teachers meet on a regular basis, usually under the guidance of a facilitator, to watch and discuss classroom video selected according to a certain aim. Different video clubs vary in their goals, agendas and the frameworks employed to direct teachers' conversations. For example, a video club can be established around the aim of enhancing teachers' proficiency to notice and analyze students' mathematical thinking (Sherin, Jacobs, & Philipp, 2011; van Es & Sherin, 2008). Another case is a club focusing on a certain teaching proficiency, such as running class discussions (Coles, 2010). Video clubs can be school-based, or alternatively region or university-based, but in general groups are meant to be small enough (usually 5-15 participants) to allow for genuine peer-conversations and sharing of ideas and insights.

One of the core issues associated with conducting video clubs is establishing norms of discussion. Apart from the basic intent to ensure a climate of trust, where teachers feel safe to raise ideas, norms also "orient individuals to one another, as well as to how information is communicated, what constitutes an idea worthy of investigation, and how to make sense of one's practice" (van Es, 2009, p. 104). Different video clubs may embrace different norms, according to their focus, goals and agenda. However, there is an apparent consensus in the literature that teachers' comments slipping into evaluations, judgments or negative reactions, lead to discussions with little value (Coles, 2010; Jaworski, 1990; van Es & Sherin, 2008).

In this paper we report on a study conducted within one video club, in which we explored the types of evaluative comments made by teachers and followed their frequency along a sequence of sessions. In the following, we describe the context of this club and the emergent research question, present a brief account of the data collection and analysis means, and demonstrate central findings.

## Context, rationale and research question

The video club studied was conducted as part of a professional development project named VIDEO-LM (Viewing, Investigating and Discussing Environments of Learning Mathematics), developed at the Weizmann Institute of Science in Israel. The project is aimed at promoting secondary mathematics teachers' reflective skills, as well as their mathematical knowledge for teaching. A large collection of videotaped lessons serve as learning objects and sources for discussions with groups of teachers within video clubs. The videos are taken, in a sense, as “vicarious experiences” which allow for indirect exploration of one's own perceptions on the practice of mathematics teaching, through the observation of unknown peers in action (Arcavi & Schoenfeld, 2008; Karsenty, 2018). Peer-conversations are guided by the use of an analytic framework, comprised of six viewing lenses through which the lesson may be discussed: (1) mathematical and meta-mathematical ideas around the lesson's topic; (2) explicit and implicit goals that may be ascribed to the teacher; (3) the tasks selected by the teacher and their enactment in class; (4) the nature of the teacher-student interactions; (5) teacher dilemmas and decision-making processes; and (6) beliefs about mathematics, its learning and its teaching as inferable from the teacher's actions (for further details on the framework and its utilization, see Karsenty & Arcavi, 2017; Karsenty 2018).

VIDEO-LM clubs maintain an agenda based on the working assumption that the filmed teacher is acting in the best interest of his/her students. Thus, observers are required to “step into the shoes” of the filmed teacher in an attempt to understand his/her goals, decisions and beliefs. This ‘exercise’ of attributing reason to another teacher's moves is meant to encourage reflective thinking about the span of possible actions and decisions available within teaching situations. VIDEO-LM facilitators attempt to establish nonjudgmental norms of discussion, through the redirection of highly evaluative comments into “issues to think about”; instead of judgmental comments about the filmed teacher's decisions, participants are asked to consider alternative paths and their ensuing tradeoffs.

To date, more than 70 VIDEO-LM clubs were conducted across Israel. The specific club at the focus of this study was a school-based club, held during 2017 in an urban high school in the center of Israel. The school's population is characterized by a high proportion of low achievers, and most students study mathematics towards the basic level of Matriculation<sup>1</sup>. The mathematics department includes 7 teachers, 5 of them with a teaching experience of over 30 years, and 2 with under 10 years of experience. Only 2 teachers in this team teach the higher Matriculation mathematics tracks exclusively, whereas the other 5 teach mainly in the basic track. The facilitator of this VIDEO-LM club (the second author of this paper) is a member of this department. Although being the youngest teacher in the team, he is the only one who has taken a VIDEO-LM facilitator course and had become a qualified facilitator, and his colleagues all agreed to participate in the club under his lead.

## Setting

The club met 8 times during the year (about once a month), with each session lasting around 2 hours. In a preliminary discussion with the head of department, it was decided that the club will focus on

---

<sup>1</sup> In Israel, the mathematics Matriculation exam is obligatory for receiving a Matriculation certificate, and can be taken in one of three levels: basic, intermediate or high.

videotaped lessons filmed in low-track Matriculation classrooms, due to the characteristics of the school mentioned above. In the first 6 sessions, the facilitator (henceforth: YP) selected videos of teachers unknown to the team, from the VIDEO-LM collection. In the 7<sup>th</sup> session, YP showed a video of his own teaching, and in the last session the group watched a lesson taught by one of the other teachers, who volunteered to be videotaped for this purpose.

### **Rationale and research question**

This video club enabled investigation of a situation that is less explored in the literature on video clubs for mathematics teachers; unlike most cases, where the facilitator is external to the group, here the facilitator was a fellow-teacher from the same team. This situation potentially allows for intimacy among participants, who are familiar and comfortable with one another, with no outsiders present. This was an interesting opportunity for us to study what teachers talk about, and how they communicate. The emerging research question was thus the following: What characterizes the peer-conversation taking place in a school-based VIDEO-LM club, facilitated by a member of the group?

### **Data collection and analysis**

Data was collected mainly through video recordings of 7 out of the 8 sessions (one session was audiotaped). The recordings were supplemented by a researcher journal where YP documented his insights. The content analysis performed on the collected data included the following steps:

1. Performing a coarse transcription of all the recorded data from sessions, and identifying recurring themes/issues of interest.
2. Selecting sessions for in-depth analysis. Of the six sessions in which videos of unknown teachers were discussed, we decided to select the first two and the last two (# 1,2,5,6) to enable a perspective on shifts over time. In addition, the two sessions in which videos of team members were discussed (# 7,8), were also selected for analysis. These six sessions were then fully transcribed.
3. Segmenting transcripts into units of analysis. The basic unit was defined to be an idea unit, i.e., a transcript section in which one idea appears, whether in a single turn or along a number of turns.
4. Classifying each idea unit into one of the themes detected in step 1, using the Atlas.ti software.
5. Identifying categories within each theme (e.g., within the theme of evaluative comments, levels of evaluations were identified).
6. Systematically categorizing all turns of talk according to the identified categories. This classification was validated by two researchers.

### **Findings**

One of the interesting themes identified in step 1 of the analysis, was teachers' evaluative comments. About 18% of the idea units were classified within this theme. As described earlier, VIDEO-LM clubs attempt to establish nonjudgmental norms of discussion. Thus, it was interesting for us to categorize types of evaluative comments and examine whether there were any shifts in the teachers' adherence to the expected norms. In this report, we focus solely on this issue.

We identified three categories of evaluative comments. These categories are stated and illustrated below. Due to space limitations we limit the illustrations to examples from 2 sessions.

**Category (a):** Decisive negative judgment towards teaching moves observed in the video.

This category was characterized by keywords such as ‘you cannot do this’; ‘unacceptable’; ‘it’s disturbing’; ‘I would never do that’; ‘it hurts to see this’, etc.

Example (a)1.

In Session 1, teachers watched a lesson on the topic of exponential growth and decay, given in a low-track 11<sup>th</sup> grade. When asked to relate to the teacher’s decisions that they have noticed, the following conversation evolved between the facilitator and one of the teachers:

- 94 Sapir: Another decision of the teacher that’s disturbing, to me personally it’s extremely disturbing, the children are passive, there’s no textbook to read from, he writes the question and answer on the board for them... which is pretty organized, okay, but [...] I wouldn’t have written the question, only the answer. But the children see the question in front of their eyes in the textbook. That is, to me it was very disturbing that the children sit like that [crosses her arms] like...
- 95 YP: So let’s ask the same question again. The teacher arrived in class, apparently in the beginning of the year, and said “you have no textbook” [...] He arrives and decides to write the exercises on the board, one by one. We’ll see it also later, each exercise he writes on the board, the question and sub questions...
- 96 Sapir: What’s the advantage in this? I don’t...
- 97 YP: I’m asking you.
- 98 Sapir: I don’t see an advantage.

In this communication, Sapir not only harshly criticizes the teacher’s decision not to use a textbook, but also rejects any attempt to find a possible reason for it. Her use of words such as "extremely disturbing", "very disturbing" and her refusal to respond to YP's requests to take the teacher's viewpoint, are all signals of a high level of negative judgmental talk.

Example (a)2.

In Session 2, teachers watched a lesson in analytic geometry in a low-track 12<sup>th</sup> grade, introducing the concept of a canonical circle. At a certain stage the teacher, together with the students, arrived at the equation  $x^2+y^2=13^2$ , by applying the Pythagorean theorem to a triangle drawn in the first quadrant (with one side on the x-axis, another side parallel to the y-axis, the point (x,y) as the edge of the hypotenuse, and  $R=13$ ). Then, he asked what if  $y=0$ , wrote on the board  $x^2=13^2$  and under this, following a student’s answer, wrote  $x=13$ . He then showed the point (13,0) on the graph. Following the video, Olga criticized the fact that the teacher did not state the negative solution, -13:

- 507 Olga: You can’t write that and not say a word.
- 508 Iris: You can.
- 509 Olga: You can’t.
- 510 Iris: You can.
- 511 Olga: No.
- 512 Iris: In a weak class you can.
- 513 Olga: No.

This communication between Olga and Iris is an example of an unproductive argument. It starts with a back and forth "you can, you can't" exchanges, devoid of any justifications. Then, after three such exchanges, Iris brings in a justification based on the circumstances of this being 'a weak class', to which Olga simply answers 'no', without relating to the content of Iris' claim. Later in the session, when the facilitator brings forward the issue of the teacher's beliefs, Olga returns to her objection:

- 601 YP: What, in your view, are the teacher's beliefs about the students' role in the lesson, about the teacher's role in the lesson?
- 602 Olga: Okay, I relate this to what we talked about, let's say... If I would have heard such a thing like  $x^2=13^2$  and the answer... I would have said to the students, [I would have] stopped and said to the students, do you agree with what I wrote? I give them the floor and I want to hear their response.
- 603 YP: Okay, and what did he [the teacher] do?
- 604 Olga: He didn't do such a thing, at all.
- 605 YP: So what is his belief, derived from that?
- 606 Olga: So maybe like Iris says, that he didn't want to cut the flow and he continues, but I think **it's unacceptable**.
- [...]
- 631 YP: Did you perceive any belief that he might have regarding low achievers? Let go of yourself for a moment, detach yourself. [...] did you see anything that you can say "I think that his credo about low achievers is XYZ", did you see something like that?
- 632 Olga: There are several things here that, let's say, bother me
- 633 YP: Not what bothers you...
- 634 Olga: No, when I begin, let's say, with these students, I would start differently.

In the above episode, we see Olga solely focusing on what she sees as undesirable teaching moves [602, 632, 634], despite the recurring request of the facilitator's to "detach herself" and to state the teachers' beliefs [605, 631, 633]. Although, in line 606 she feebly cites Iris's reasoning in response to this request, she immediately goes on to state that it is "unacceptable".

**Category (b):** Disagreement with moves observed in the video, and proposing an improvement.

This type of disagreement often came in the form of suggestions, sometimes as if the filmed teacher was present in the room, and avoided decisive negative judgments. Keywords are 'you need to'; 'you should'; 'it's worthwhile'; 'I'm used to'; "I'm not sure about this", etc.

Example (b)1.

In session 1, Uri relates to the teacher's choice to introduce exponential growth and decay as a case, or continuation, of geometric series:

- 142 Uri: [the teacher says that] exponential growth and decay is like a geometric series and that's it. It's a little different, **you need to explain**, from daily life. I even would have given an example of materials that decay, even just an example of a person losing 3 percent of his weight, like, what is decay?

Example (b)2.

In the video screened in session 2, the students phrase a definition of a circle which is incorrect: “a circle is a central point with all points at the same distance from it”. The teacher writes it on the board, and gradually refines it by erasing and replacing several words, until the written definition is “a circle is all the points that are at the same distance from a certain point”. Olga comments:

- 380 Olga: Also it's worthwhile to explain what was not good.  
 381 YP: Ah, you think this is something that's missing?  
 382 Olga: I think it's missing.  
 383 YP: But could it be that it would harm the students had he explained what was not good?  
 384 Olga: I think it's important to explain, to make an emphasis on it.

Clearly, Olga's words “it's important to explain”, as well as Uri's words “you need to explain”, signify a more tolerant and less negative critique than the ones raised by Sapir and Olga, as demonstrated above. Such moderate disagreements are more likely to open up inquiries shared by the group, rather than a direct clash as seen earlier in Example (a)2.

**Category (c):** Inspecting possible reasons for observed teaching moves, even if the speaker disagrees with them or testifies that s/he would not have performed such moves in his/her class.

This category is less characterized by specific keywords, and more by whole sentences that convey a complex view on the subject at hand, as demonstrated in the next example.

Example (c):

This example goes back to the issue of writing “ $x^2=13^2$ ;  $x=13$ ”. In contrast to Olga, Iris expresses a much more elaborated stance towards the choice not to write  $x=-13$  on the board:

- 490 Iris: Perhaps it's a flaw... I would not leave on the board  $x^2=13^2$  and then  $x=13$ , I would not leave this on the board.  
 491 YP: Yes, I saw that it bothered you in the middle [of watching the video].  
 492 Iris: Yes, you saw that I flinched. So I would have written  $x_2=-13$ , I would show that these are exactly these symmetrical points that we talked about, but I think he gained more than he lost by not paying attention to it, I think it's...  
 493 YP: It bothered you, but...  
 494 Iris: It's to his credit that he didn't correct this.  
 495 YP: Why do you think, why didn't he correct it? Obviously he knows that it's plus-minus.  
 496 Iris: [...] he didn't want to linger, he wanted to continue in the same line... I think it's nice, I'm not sure I could have done this.

Category C, as exemplified in Iris' stance, demonstrates the ability to view a certain practice from the perspective of another person.

In addition to these three categories of evaluative comments, we identified a fourth category associated with evaluation, which we termed “adhering to non-evaluative norms”. This category included all turns in which an explanation to the observed teaching actions was offered, without personal reservations, or turns in which the speaker objected to judgmental comments of peers.

The frequency of all four categories across the six analyzed sessions appear in Table 1.

Category	Session 1	Session 2	Session 5	Session 6	Session 7	Session 8
(a) Decisive negative judgment	26.67%	21.74%	20.75%	67.74%	0.00%	0.00%
(b) Disagreement, proposing improvement	34.67%	33.70%	0.00%	22.58%	20.00%	47.06%
(c) Justifying a different perspective	8.00%	32.61%	18.87%	9.68%	50.00%	17.65%
(d) adhering to non-evaluative norms	30.67%	11.96%	60.38%	0.00%	30.00%	35.29%

**Table 1: Frequency of turns classified to categories a-d, out of all turns classified as evaluative**

As can be seen, the amount of decisive negative judgmental comments decreased over the sessions, with the exception of session 6. We note that YP was displeased with his facilitation of session 6, and that this session merits a closer analysis, not carried out yet, in order to better understand its occurrences. We also note that the lack of judgmental comments in the last two sessions may be partly attributed to the fact that the videos were of lessons taught by team members, present in the discussions. We conjecture that gradual adaptation to the VIDEO-LM norms, combined with sensitivity to colleagues, has brought up this absence of decisive negative judgments.

Regarding the other types of evaluative comments, that are more productive in nature, no patterns were discerned in the analyzed data.

Theme	Session 1	Session 2	Session 5	Session 6	Session 7	Session 8
Evaluation	31.58%	17.78%	10.53%	16.67%	9.09%	8.33%

**Table 2: Frequency of idea units classified to the theme of evaluation, out of all classified idea units**

Inspecting the frequency of idea units classified to the theme of evaluation (see Table 2), clearly shows that teachers allocated less and less of their attention to the act of evaluation (again, with the exception of session 6), hence more attention was given to other foci of discussion (e.g., pedagogy oriented towards low achievers). We see this shift as a positive one; if the video is used more as an artifact around which to raise issues of practice, and less as a source for criticism, it is more likely that reflective thinking will take place.

## Discussion and Conclusions

Our goal in this study was to examine the characteristics of peer-conversations taking place in a school-based VIDEO-LM club, facilitated by a fellow teacher who was an integral part of the group. We focused on one of the most important norms of VIDEO-LM sessions: avoiding judgmental talk. We constructed a categorization system that helps to distinguish between different types of evaluative comments. This is, to the best of our knowledge, a novel endeavor. The types of evaluative comments found in our analysis differ in their degree of potential productiveness: while type A is clearly unproductive (and this coheres with conclusions of previous studies), in type B teachers are able to move slightly beyond criticism and offer suggestions for improvements of teaching moves. However,

they still can only see the situation from their own perspective, thus their “span of possibilities”, or teaching repertoire, does not seem to expand. In type C evaluations, teachers move beyond their own perspective and provide a rationale for a teaching decision that they themselves would probably not have taken. This is a form that seems to be at least partially productive as it offers revisiting one’s habitual practices. Finally, type D comments can be seen as productive as they may result in reflecting upon and perhaps modifying one’s own practice.

Our findings show a decrease in evaluative discourse over the course of the year, at least in type A comments. This is an encouraging finding, as it points to shifting towards more productive forms of discussions. For facilitators, the awareness of the process by which such a decrease can occur is of practical importance. For researchers, this methodology can provide a fruitful path towards a better understanding of how and under which circumstances evaluative talk can be decreased.

*This paper investigates how teachers portray their teaching role in a professional-development community. By analyzing data from five groups, the goal of the study is to understand how teachers navigate between several discourses advocating different classroom practices and how the role is portrayed within these practices. In the majority of interactions, teachers position themselves within a traditional teacher discourse, an official Swedish discourse, or a reform-oriented discourse. The analysis provides examples of different teacher roles both within and between groups. Teachers who advocate a reform-oriented teacher role indicate that, in this type of role, they face challenges, and they stress that they need more specialized content knowledge.*

*Keywords: teacher role, pedagogical reform, traditional pedagogy, professional development.*

## Introduction

In initiatives to reform teaching and learning of mathematics, professional development of teachers is typically an essential part. A central component in such professional-development programs is often teachers' collegial discussions (Cobb & Jackson, 2012). Within professional-development programs, collegial discussions may be seen as a means to facilitate teacher development, which, in turn, is conceptualized as a means to improve and change classroom practices (Desimone, 2009). The opportunities created in collegial discussions for teacher development, however, are related to the characteristics of these discussions. In this paper, we examine one characteristic of collegial discussions: how the role of teachers is discussed and constructed. In particular, we are interested in understanding how teachers navigate between several discourses of advocated classroom practices and how the teacher role is portrayed within these practices. For this purpose, we conjecture that Sweden provides a productive case study. The argument for such a conjecture is that in the early years of the OECD, Sweden was one of the leading countries in educational policy. But with medium results on PISA tests and a shift toward students' learning outcomes, the mode of governance changed. Sweden has now become a country that needs advice in order to raise its educational performance (Pettersson, Prøitz & Forsberg, 2017). In the last decades, education systems have been radically and extensively transformed (Pettersson et al., 2017) and conflicting discourses about mathematics teaching and classroom practices are currently being exchanged in Sweden (Ryve, Hemmi, & Kornhall, 2016). In the traditional discourse, the instructive role of teachers is emphasized, whereas another official discourse emphasizes the role of the teacher as a motivator who should not disturb the students' development. Finally, a reform-oriented discourse stresses that teaching should be student centered and teacher led (see Ryve et al., 2016; Hemmi & Ryve, 2015). In this context, we pose the following research question:

How do teachers navigate in collegial discussions between discourses that advocate different classroom practices and the role of teachers within these practices?

We examine this question by analyzing five groups of mathematics teachers engaged in collegial discussions as part of a national large-scale professional-development program in Sweden.

## **Perspectives on the role of teachers**

There seems to be a consensus within mathematics education research on how students learn mathematics, as exemplified in the publication by the National Council of Teachers of Mathematics (2000). This document contains recommendations for teachers whereby students should develop procedural knowledge and conceptual understanding, be able to reason mathematically, and be able to communicate mathematical ideas. To achieve such aims, teachers have to work differently than the “traditional” way of teaching. In traditional classrooms, students work with procedural tasks and have few opportunities to reason and draw the connection between key mathematical concepts. To achieve high-quality teaching, new forms of teaching are required, which are based on the thinking of students (Franke, Kazemi, & Battey, 2007).

### **Teacher role**

Two decades ago, Fennema et al. (1996) asserted that the role of a teacher had evolved from demonstrating procedures to helping students build their mathematical thinking. They described two types of teachers: reform-oriented and traditional. Reform-oriented teachers think that students learn best by doing and learning mathematics on their own and that the teacher’s responsibility is to facilitate learning, and traditional teachers think that the teacher’s responsibility is to direct and control all classroom activities and that the students are responsible for absorbing and processing the given information. Even today, scholars and researchers use these labels to describe the role of the teacher (Louie, 2016). Although this is not a definite observation, in reform-oriented classrooms, teachers are responsible for facilitating discussions of the students’ approaches to mathematical tasks so that all students are actively involved in the discussion. The teacher role includes carefully inserting questions and explanations to ensure that the mathematical strategies and ideas of the students are clear to all learners (Franke et al., 2007).

The role of the teacher is important to describe a productive mathematical classroom and effective mathematics teaching. White (2003) emphasized the importance of the teacher role to include and influence the mathematical thinking of all their students. The teacher must value student ideas, explore student answers, incorporate students’ background knowledge, and encourage student-to-student communication. These two first themes are quite similar to Fraivillig, Murphy, and Fuson (1999) who describe successful teaching as eliciting student solution methods, supporting the students’ conceptual understanding, and extending the students’ thinking. Hahn & Eichler (2017) investigated the impact of a professional-development course on teacher’s beliefs toward teaching and learning mathematics. Three teachers were interviewed after the course; their responses with reference to teaching and learning of mathematics changed from a transmission-oriented view to a more constructivist-oriented view. Cai, Wang, Wang, and Garber (2009) summarized studies

from more than ten countries on what teachers emphasized as the characteristics of effective teaching and identified the following common themes for strong mathematical knowledge: All teachers highlighted that an effective teacher should have a strong background in mathematics. They should have a personality that conveys enthusiasm about teaching and students. Teachers should stimulate students' thinking and be good listeners to interact with their students more effectively. Lastly, the ability to manage a classroom was an important characteristic of an effective teacher.

As previously mentioned, a shift has occurred from teacher-centered teaching to student-centered teaching. Teachers who value student-centered teaching often use various strategies and tools to engage students in learning and tend to believe that students construct their own knowledge through active investigation and meaningful exploration (Kutaka et al., 2018). According to the standards of the National Council of Teachers of Mathematics (2000), which influence the Swedish national curricula, the student's role in the classroom is to engage in solving challenging, nonroutine tasks. Students should explain and justify their reasoning, make connections between solutions and key mathematical ideas, and share mathematical authority with the teacher in assessing what is a mathematically acceptable solution and on what grounds. To build on these standards, teachers should develop and build on the students' thinking in the classroom.

## **Method**

### **Context**

Between 2013 and 2016, the Swedish National Agency for Education launched a 649 million kr (approximately 65 million euro) curriculum-based professional-development (PD) project. Called “Boost for Mathematics” (Skolverket, 2018), this project aims to improve the teaching of mathematics. The most central components are 24 modules, eight per grade level (1–3, 4–6, and 7–9), developed to support teachers working in teams to plan, establish, and reflect on pedagogical practices in the mathematics classroom. The curriculum is distributed digitally from a website (<http://www.skolverket.se/kompetens-och-fortbildning/larare/matematiklyftet>) and includes articles, instructions, images, and video films. Each module is designed to support groups of teachers (during one semester) in engaging in eight iterations containing individual preparation, collective planning with colleagues, individual classroom teaching, and collective reflections on classroom instruction. In the PD program, teachers complete two modules, taking one module per semester. The PD sessions are held at each school with the support of a trained coach. This study is part of a larger study that was carried out in a Swedish municipality, wherein all public elementary schools ( $n \approx 40$ ) participated in the PD program. This paper focuses on five randomly selected schools. The number of participants in these groups, including the coach, ranged from 6 to 12 persons for a total of 39 teachers. The data were collected by videotaping two meetings of each group, where the first meeting was based on collective planning with colleagues and the second meeting was based on collective reflections on classroom instruction. This study analyzes a total of 10 sessions, which were held quite early in the second module during the spring semester, ranging from 33 to 90 min (two sessions for five groups), with the average being 63 min.

## Analysis

To understand how teachers navigate between different discourses when they engage in collegial discussions, we have chosen, as described in the context, to look deeper into collective planning and reflections on classroom instruction of five groups of teachers. The groups had been working together with “The Boost for Mathematics” for about six months and had established norms of participation that could affect teacher participation.

As part of data reduction, we began by identifying and transcribing all discussion episodes that related to the teacher role. In part of the analysis, we defined an episode of pedagogical reasoning as a coding unit:

Units of teacher-to-teacher talk allow teachers to exhibit their understanding of an issue in their practice. Specifically, episodes of pedagogical reasoning are moments within teachers’ interactions in which they describe issues in, or raise questions about, teaching practices that are accompanied by some elaboration of reasons, explanations, or justifications (Horn, 2007, p. 46).

Episodes of pedagogical reasoning in which teachers explicitly discuss their roles were analyzed. On the basis of the literature on the teacher roles and the Swedish context, we portray three different teacher roles that may appear in the discussion among the teachers in this project.

The traditional role: teachers emphasize themselves as instructors who offer clear explanations and present the content clearly. There is, therefore, no need for much knowledge about the students’ mathematical thinking. Furthermore, the teacher stresses classroom management.

The reform-oriented role: teachers emphasize the anticipation of and building on the students’ knowledge. Furthermore, the teachers design, initiate, and follow-up learning opportunities. Moreover, they challenge the students to think and interact. The teachers summarize and show connections, as well as discuss different solutions, mathematical ideas, and misconceptions with their students.

The official Swedish teacher role: teachers emphasize the motivation of students to make connections among different subjects. The teacher’s role is to be a coach and help make learning fun. Mathematical knowledge on the part of the teacher is not necessary, but social skills are essential. The teacher should be reactive, rather than proactive, to the student’s needs. This role could be compared to “discovery-learning” which, as proposed by Alfieri, Brooks, Aldrich, and Tenenbaum (2011), emphasizes students’ motivation, discovery of facts and relationships by students themselves, and that the teacher must provide guidance only on the students’ request.

## Results

The general overview of the episodes of pedagogical reasoning shows that all the three discourses were present in the teachers’ collegial discussions. We identified 13 episodes in which the teachers emphasized the traditional role, 16 episodes that represented the official role and 14 episodes that represented a reform-oriented role. Even though the total number of these three discourses were

quite similar, we found differences among the groups. In one group, we identified seven episodes representing the traditional role and one episode representing each of the other two groups. In another group, there were five episodes representing a reform-oriented role and two episodes representing the official role. Depending on different situations, teachers also navigate between roles. For instance, the teachers' role is portrayed differently when they discuss the introduction of a lesson, often portrayed as a traditional teacher role to introduce and show students procedures. In the middle of the lessons, students mainly worked in pairs, and a more apparent official teacher role appeared to motivate the students such that all students took part in the discussion. The episodes also revealed differences in how the teachers regarded their own roles. For example, when the teachers discussed the reform-oriented role, they expressed, to a great extent, the challenges of such a role. In the remainder of this chapter, we present some examples of episodes representing the different roles. In addition, the episodes illustrate the affordances and constraints related by the teachers to the different roles. All transcribed materials were translated from Swedish and all the names are pseudonyms.

This excerpt illustrates a traditional teacher role. In this group, each teacher presented and discussed their reflections on their own classroom instruction. In this episode, one of the teachers, Louise, emphasized her own role as an instructor who offered explanations of the content. She talked more about what she did as a teacher (I wrote, I took) than about the students' roles.

Louise: First, we had that thought-board (Swedish: Tanketavla) in common and I wrote this on the board because when I had done this and copied up I wrote everyday language and mathematical language so they could see which one. Then I gave them a very easy task, I took seven plus ten, and started in the middle. I had not even thought that we could start other places. Then we made it in common and I used an example, and I noticed that there were some who wrote exactly the same words that I had written. They wrote it and drew exactly the same.

Further on in the same discussion, there are several instances of these types of descriptions of the teacher's role, such as "First, I explained what is a thought-board and made a presentation in PowerPoint. After that, I tried to explain what everyday language is and what mathematical language is as well." The teachers speak of the role of the teacher as that of a transmitter of knowledge who explains to students what to do and models the tasks for the students. The students are, in a way, invisible in these discussions because, when the teachers talked about the lessons, they base the discussion on the task, as opposed to how the students worked with these tasks.

In the next excerpt, Mike reflects on his last lesson. His plan was to spend time discussing the tasks. Realizing that this plan would not work, he let his students finish their work. He assumed the role of a motivator who guided and supported his students but would not disturb them when they were working. His role was more that of a coach.

Mike: They worked with a problem attached to which I thought would be the fraction and percentage we have worked with from 32 rich mathematical problems. This

related to going to the theatre with different prices. What amazed me was that it was so astoundingly slow at the beginning when the students were going to work with the problem. I do not know if it was, I am not sure, because of the interruption or if their brains had an overturn or whatever it was. Because I feel that I did not intend to spend so much time, because I thought that these two first tasks they will blow away so I really could spend time on showing and discussing in whole class and so on. No, this turned out to be a lot of pilotage and support and everything we talked about earlier.

In episodes identified as the official role, the teachers are in the background motivating their students, and encounter a rather passive teacher role. They often reflect on their lessons regardless of whether their students had a fun time. Furthermore, in such episodes the teacher does not intend to discuss the mathematical content with their students other than to prepare the students for the mathematical content. In the next example, Amy describes the teacher role as one of asking questions to move the students forward. She supports the students' thinking by letting them present their thoughts. Amy wants to build upon their thinking using examples from them that are different but correct. In addition, she wants to challenge their thinking. She describes her role as proactive rather than reactive. We can find several representatives of a reform-oriented teacher role in how Amy reflects on her own role as a teacher.

Amy: When you (teacher) ask better questions, or better questions, but questions that make their reasoning go forward. But at this point I am in the start phase. It is great and I have written them on a piece of paper so that I can have a little note to watch and remember and get going. Ehh. Yes and then even more, I do it today, but even more show in different ways to think that the children can come up and show themselves, or like today, when we should make the diagnosis, and introduced to the children that we used different examples that they could see that aha, I thought in this way, and even that might be right and so.

Several episodes in which the teachers related to the reform-oriented role reveal the challenges of such a role. Sarah expresses her limitation about the mathematical concept of "relationship." She finds it difficult to understand. She notices that, in her student-centered teaching, she has problems with teacher-led questions to guide the students further because of her weak understanding of the concept of "relationship." Even if she supports the reform-oriented teacher perspective, she faces difficulties in implementing it:

Sarah: I am very inexperienced in talking about relationships to lead him in a good way. I have another group that is also on their way but they write in a different way. Here, I feel that I need to develop because they have written what they see as a pattern, and already at an early stage, they say we have seen the pattern. I feel when I explain this, my question is— what is a relationship, what is it?

## Discussion and conclusion

The preceding excerpts are presented to show how teachers navigate between several discourses of advocated classroom practices and how the teacher role is portrayed within these practices. We found three different teacher roles: a traditional-oriented teacher, a reform-oriented teacher, and an official discourse-oriented teacher. The portraying of the teacher role varies both within a group of teachers and between groups. Within a reform-oriented perspective, the findings reveal a particular discourse describing how teachers portray their role. Teachers find this type of role quite hard to fill in their classroom. They especially emphasize the challenge of acquiring the requisite specialized content knowledge (Ball, Thames, & Phelps, 2008). In a way, teachers have remained in the previously dominant discourse in Sweden of encouraging and discussing mathematics, and they do not highlight other parts of the reform discourse that relate to the role of the teacher in setting goals, challenging, conducting discussions, etc. The findings also show that teachers who portray their role as official often blame students when they reflect about their own role in the classroom and their lessons. A reform-oriented teacher with a student-centered and teacher-led lesson does not blame student difficulties on inherent traits. This can be helpful in understanding how teachers use students' ideas as a support in teaching (Jackson, Gibbons, & Sharpe, 2017).

How teachers talk about their own role can be helpful in understanding their potential for learning in collaborative meetings to improve and change classroom practices (Desimone, 2009). The findings reveal conflicting discourses about the teacher role and classroom practices (Ryve et al., 2016). Such conflicting discourses may affect the potential for teacher learning as they are not made explicit and resolved.

This paper has focused on how teachers portray the teacher role. Further developments and studies will compare this evolution between different groups of teachers and explore the connections between the teacher and student roles.

*This paper discusses the type of research lesson planned by mathematics teacher educators participating in a lesson study cycle. An earlier study found that mathematics teacher educators' research questions were not clearly formulated and as a reason, their initial lesson plans for research lessons did not make student teachers' learning visible. This follow up study analysed the lesson plans further before and after comments from knowledgeable others and looked into the type of lesson planned to be conducted, with the hypothesis that the type of lesson would determine the type of student teacher learning made visible. Data in form of lesson plans were collected from five teacher education colleges. Theory driven content analyses was used and Skemp's (1976) categories of instrumental and relational teaching were the point of departure. The findings include that the initial lesson plans were mostly presenting instrumental type of lessons, but after comments from the knowledgeable others, the revised lesson plans were presenting a more relational type of lessons with student teachers' learning more visible.*

**Keywords:** Malawi, mathematics teacher education, lesson study, type of research lesson.

### Introduction and background

Lesson study is a new concept in Malawi teacher education and it is also relatively new in Malawi education as a whole. Lesson study was introduced to mathematics teacher educators in all public primary teacher education colleges as a form professional development and as part of a five year project which aims at improving the quality of mathematics teacher education in Malawi (Kazima & Jakobsen, 2018). The project is wide and professional development of mathematics teacher educators is one out of five components. In the project, we decided on using lesson study as a model for professional development because lesson study offers the opportunity for the teacher educators to work together and to study and learn from their own teaching. Since it was the first experience of lesson study in Malawi teacher education, we developed a research project, alongside the professional development, to study the teacher educators' understanding of lesson study. The research was informed by previous studies of lesson study outside Japan as discussed below. The findings from our first study (Fauskanger, Jakobsen & Kazima, 2018) prompted us to do this follow up study where we ask the following research question: Which type of research lesson do Malawi teacher educators plan in their first experience with lesson study? Details are discussed in the following sections. First,

we situate our study by discussing relevant previous research on the use of lesson study in new contexts outside Japan.

Lesson study originated from Japan where it has been practiced for more than a hundred years. It is so much part of the teaching profession that it is like air to teachers in Japan (Fujii, 2014). Studying own teaching and learning from students' learning is key to lesson study in Japan, thus having a clear research question and carefully planning a research lesson that reveals students' learning are important aspects of Japanese lesson study (Takahashi, 2013). Due to its success in Japan, lesson study has been introduced to many other contexts outside Japan and many report on benefits that are experienced by teachers or student teachers that participated in the lesson studies (da Ponte, 2017). However, many also report on challenges that participants experience when implementing lesson study for the first time. There are at least four related challenges that inexperienced participants face. First, they do not always see the importance of a research question as a starting point for planning their research lessons (Bjuland & Mosvold, 2015; Fujii, 2016). Second, they often overlook the importance of predicting students' responses (Lewis, Perry, & Murata, 2006). Third, they do not emphasise on planning focused observation of students' learning (Bjuland & Mosvold, 2015, Fujii, 2016). Fourth, they do not plan for teaching activities in order to make students' learning visible (Bjuland & Mosvold, 2015).

Lesson study in Africa has been reported used in a few countries including Malawi, Uganda and Zambia (Fujii, 2016, Ono & Ferreira, 2009). In these three countries, the reported lesson study was initiated by some Japan related initiatives supported by the Japan International Consultative Agency as part of aid towards the education sector. Fujii (2014) studied the lesson study in Malawi and Uganda schools and revealed a number of misconceptions among the teachers implementing the lesson study. Some of the misconceptions were that the teachers did not distinguish lesson study from workshop. The after teaching discussion often focused on the teacher and how the teacher can improve and not necessarily on students' learning. He also found that re-teaching of the research lesson was taken as necessary regardless of the outcomes of the first teaching. These misconceptions illustrate further the challenges of introducing lesson study to new context outside Japan.

In more recent years, there has been growing use of lesson study in teacher education. Larssen et al. (2018) report from a review of lesson study in teacher education where they found that there were variations in the way lesson study was adapted to new contexts, for instance, how observations were conducted. This emphasizes the challenges of lesson study when introduced to inexperienced participants in new contexts.

## **Methodology**

Data were collected within the professional development that was designed for the Malawi mathematics teacher educators by the wider project. For the purpose of this paper, the lesson plans analysed are produced by all mathematics teacher educators at five teacher education colleges. Two teacher education colleges participated in the first year, and three participated in the second year. The professional development started with a three day workshop that introduced the teacher educators to lesson study. The teacher educators were also introduced to concept study of multiplication and fractions, the two concepts which the teacher educators suggested they find most difficult to teach

and would like to research on. During the three days, the teacher educators also worked in groups and started designing their research lesson. The three authors of this paper facilitated the workshop and acted as knowledgeable others in discussing the planned lesson study. After the workshop teacher educators from each teacher college continued working together drafting their initial lesson plan, before it was sent to the knowledgeable others for comments. The knowledgeable others provided comments and encouraged the teacher educators to revise and improve their lesson plans. The process from the introductory workshop to final lesson plan took at least about four months (May-September). In this study, we collected all initial draft lesson plans and final lesson plans after revisions.

The lesson plans were analysed using theory driven content analysis (Hsieh & Shannon, 2005). The first study drew from literature and focused on three aspects of research question, prediction and observation (Fauskanger, Jakobsen & Kazima, 2018). In this follow up study, we draw on Skemp (1976) and use the two categories of teaching mathematics (i) instrumental and (ii) relational as the point of departure. Skemp (1976) divided teachers' mathematical understanding into two divergent categories: (i) Instrumental understanding—a lower version of understanding—for example rote memorization of algorithms and (ii) Relational understanding, which encompasses a deep, conceptual understanding. When relating his framework to teaching, Skemp (1976) suggests that a teacher who teaches from an instrumental paradigm cannot produce students who learn mathematics relationally. More recent studies confirm that conceptual and connected mathematical knowledge is a premise for conceptual teaching (Tchoshanov, 2011). This highlights the importance of studying whether Malawi teacher educators' research lessons tend to be of 'the type' instrumental or 'the type' relational.

## **Results and discussion of findings**

### **Teacher College A**

The research lesson plan from Teacher College A focused on multiplication of two-digit numbers using different strategies. In their initial lesson plan draft, the teacher educators planned that student teachers would be asked to use as many strategies for multiplying two-digit numbers as possible, and then later share their strategies with the rest of the class. Then student teachers would work in groups to critique the different strategies that were presented. The research lesson was planned to be an instrumental understanding type of lesson (Skemp, 1976) because the emphasis was on the strategies or algorithms and on how to perform the algorithms. There was no explicit emphasis on understanding why the strategies would work, thus the research lesson focused on what to do and not the reasoning behind the strategies. In Skemp's (1976) words, the lesson seemed to be about 'rules without reason'. However, there were opportunities for relational understanding (Skemp, 1976) where the lesson plan suggested that student teachers should present their work on the chalkboard. The interaction that could go on between the student teachers presenting their work and the rest of the class could include explaining how as well as why their strategies work. Another opportunity was where the student teachers were going to be asked to critique the different strategies presented for multiplying two-digit numbers. This could include discussions of the mathematical reasoning behind each strategy. The lesson plan was silent on this and therefore in the enactment of the plan the teacher educators could easily miss the opportunity.

Comments from the knowledgeable others were explicit in pointing out that explanations of reasons why the strategies work should be included in the plan. For example they commented:

(...) one important point is not only to ask them [student teachers] to demonstrate how to solve [the tasks] using their own strategy, but to explain WHY their strategy/algorithm work – this is important. For example, many of the algorithms use the [distributive] property that  $67 \times 28 = (60 + 7) \times (20 + 8)$  and then different ways of multiplying the parenthesis is behind the algorithm. (...)

So we propose to ask them [student teachers] to demonstrate and explain why the algorithm work.

After revision, Teacher College A's lesson plan included suggestions from the knowledgeable others in that it was explicit that student teachers will be required to give reasons for why their strategies would work. As an example, the teacher educators added to the goals of the lesson the statement: "student [teachers] will explain why different strategies work." The lesson structure also changed from focusing on student teachers practicing different strategies of multiplying two-digit numbers to student teachers' understanding of, and reasoning behind, the different strategies of multiplying two-digit numbers. The teacher educators wrote in the revised plan that they "want students to understand and appreciate that there are a variety of strategies when multiplying numbers and reasons why these algorithms work." In relation to evaluation, the teacher educators wrote "[a]re student [teacher]s able to justify their strategies" as one of their criteria for evaluating their research lesson. This indicates that the revised lesson plan was not only focusing on the 'what' to do when multiplying two-digit numbers, but also on the 'why', thus a movement towards a relational understanding (Skemp, 1976) type of lesson.

### Teacher College B

The first research lesson plan from Teacher College B, started with a demonstration by the teacher educator on how to represent multiplication of mixed numbers using paper as a resource. This was followed by the teacher educator asking the student teachers to work in groups and come up with other resources they can use for modelling the same multiplication and finally for the groups to demonstrate their representations to the rest of class. The lesson had the potential to be relational if the groups' demonstrations and discussions of their representations included justifying why their representations would work. However, the lesson plan did not indicate that such discussions would take place. Without the justification and mathematical explanations of why the representations work, then the lesson would be only for instrumental understanding with student teachers copying what the teacher educator did without much understanding. Comments on this first draft of the lesson plan from the knowledgeable others were explicit in suggesting that the teacher educator should not demonstrate and let student teachers copy their procedure, but rather should ask student teachers to do the task as a problem solving activity. The knowledgeable others wrote:

... before demonstrating, you are recommended to invite the students to solve the problem. Only if you invite them to find solutions by themselves, you will be able to learn about their strategies. It would also be interesting if you started the lesson with a more open problem for the students to solve. Problem solving makes it easier for you to observe students' strategies and their learning.

This change in focus has the opportunity to make the research lesson become a relational understanding type of lesson (Skemp, 1976). The knowledgeable others also commented that the

lesson should not only focus on modelling and how to do the different representations using various resources but should also emphasise why each of the representations works. The teacher educators at College B revised their research lesson plan and implemented the suggestions from the knowledgeable others. The revised lesson plan started with the teacher educators presenting a mixed number multiplication problem and asking the student teachers to work in groups and to investigate possible resources they can use to model the mixed number multiplication. This change from demonstrating for the student teachers to asking them to investigate in a problem solving manner, made the lesson shift from the instrumental lesson it was at first to a relational type of lesson. The rest of lesson plan, however, was still not explicit on soliciting justifications and mathematical explanations for the resources and modelling presented by the student teachers. Thus, the research lesson could still miss opportunities for more relational understanding by student teachers.

### Teacher College C

The initial draft lesson plan from Teacher College C was for a research lesson that started by asking student teachers to model addition of two fractions with the same denominator. According to the lesson plan, this was something that the student teachers had done in the previous lessons. The lesson proceeded to group activity of modelling of addition of fractions with different denominators with step by step instructions from the teacher educator. The lesson was an instrumental understanding (Skemp, 1976) type of lesson because the student teachers could have easily completed all the tasks by following the instructions without understating the mathematical reasoning behind the procedures. Comments from the knowledgeable others suggested changes that could lead to a more relational type of lesson, but were not explicit on this. For example, where teacher educators wrote that they intended to invite the student teachers “to model addition of  $2\frac{3}{5} + 1\frac{1}{2}$  using papers ... [using] the following procedure – model whole’s i.e. 2 and 1 by ensuring that the size [of the whole] is the same.” The knowledgeable others commented that: “you can let the student teachers reflect on this and not tell them immediately that the size (area) has to be the same - so this can also be a point of observation. Do the student teachers understand that the size has to be the same?”

Although not explicit, the knowledgeable others suggested that student teachers should not be told immediately what to do but should be left to first think for themselves and find their own strategies of solving the problems presented. This was important because it could shift the instrumental lesson to a relational lesson, and it could also offer opportunities for teacher educator to observe student teachers’ learning.

The revised research lesson plan by Teacher College C took the advice of the knowledgeable others. The revised lesson plan was a relational type of lesson because the teacher educator posed the questions to the student teachers and allowed them to find solutions without giving the step by step instructions. The lesson plan also included prompts for asking the student teachers to explain their solutions. For example, the teacher educators wrote that they would ask the student teachers to “explain their solution strategies to the class” and to “facilitate student [teacher]s’ discussion on their solutions in order to understand ideas behind the solutions.” These changes have the potential to bring out student teachers’ reasoning and justifications for their solutions into the lesson, and might result in a relational understanding type of lesson (Skemp, 1976).

## Teacher College D

Teacher College D's research lesson plan was on division of fractions. Their initial lesson plan started with a demonstration by the teacher educator modelling division of two fractions using the number line. This was followed by an activity for student teachers to do in groups. The activity was another example of division of two fractions and student teachers were to model using number line in the same way as demonstrated by the teacher educator. Finally, there were more exercises for the student teachers to practice. The student teachers could do these activities by copying the teacher educator's example without much understanding. This was a typical instrumental type of lesson where the teacher educator demonstrates an example and the student teachers observe and later imitate and copy the process on other examples. Comments from the knowledgeable others suggested that the teacher educators should not demonstrate how to model the division of fractions on the number line, instead should just pose the question to the student teachers and let them think and come up with their own ways of modelling the division; "This might be a nice way to start the lesson ... if you start with a more open approach, it is easier to observe students' thinking". The teacher educators were also challenged to think more carefully about the pairs of fractions they use as examples or tasks in the division of fractions lesson because some pairs of division are easier to model than others. For example the knowledgeable others wrote: "This [referring to  $1\frac{1}{5} \div 1\frac{1}{6}$ ] is really difficult to model. Why have you chosen these fractions for the students to model on the number line? You are recommended to think carefully about which fractions to use and in what order".

In reaction to these comments, the teacher educators revised the research lesson plan to a more relational type of lesson. The revised lesson plan started with easier fractions to model and posed the question to student teachers to work in groups and find ways of modelling the division of given fractions. The group activity was followed by individual work where student teachers were asked to model more division of fractions tasks. This lesson had the opportunity to be a relational type of lesson because the student teachers would not be told what to do and copy, instead they would be invited to think, discuss and to find ways of solving the problems. However, the lesson plan did not emphasise on student teachers justifying their solutions or explaining their reasons, therefore these could be missed and that would make the lesson less relational than it could be.

## Teacher College E

The research lesson by Teacher College E was on modelling multiplication of mixed numbers. The initial draft lesson plan was the only one of the five initial lesson plans that presented a relational understanding type of lesson. The lesson plan started by posing a problem; to model of  $3 \times \frac{1}{2}$ , for student teachers to do without giving them steps of procedure to follow. The lesson plan also included asking questions that would seek student teachers' understanding of mathematical reasoning behind the tasks. For example, they wrote: "Ask student [teacher]s to explain the meaning of  $3 \times \frac{1}{2}$ " and "Encourage student [teacher]s to demonstrate and explain their solutions." The whole research lesson was structured in four parts as follows: (i) introduction, (ii) posing the problem, (iii) individual problem solving and (iv) discussing student teachers' solutions. This might result in relational understanding lesson because students would be made to 'problem solve' and discuss their solutions, thus they would understand the strategies as well as the mathematical reasoning behind the strategies.

Comments from the knowledgeable others further encouraged the relational understanding type of lesson although not explicitly. For example in response to the lesson plan's point of evaluation that stated "Do students understand the meaning of  $3 \times \frac{1}{2}$ ", the knowledgeable others wrote: "How will the observers observe if the students understand? Through listening to discussions? Through analysing their written work?" This was suggesting that the teacher educators should be more specific in the activities that would display student teachers' relational understanding. However, there was no revised lesson plan from Teacher College E.

## Summary and conclusion

Table 1 summarises the type of lessons from the five teacher education colleges.

Initial draft plan	Final plan
4 (out of 5) research lesson plans mostly instrumental types of lessons and following the common general format: <ul style="list-style-type: none"> <li>- Teacher educator demonstrating example</li> <li>- Similar activity for student teachers</li> <li>- Class discussion</li> <li>- Conclusion</li> </ul>	All 4 lesson plans more relational types of lessons more focused on student teachers and their learning. General format changed towards: <ul style="list-style-type: none"> <li>- Teacher educator posing problem</li> <li>- Student teachers use their own methods to solve problems</li> <li>- Teacher educator observing student teachers</li> <li>- Student teachers discussing their solutions to problems</li> </ul>
One lesson plan of relational type of lesson: <ul style="list-style-type: none"> <li>- Problem solving approach</li> </ul>	Lesson plan not revised

**Table 1: Summary of type of lessons by the 5 teacher colleges**

Looking at all five teacher colleges, our analysis indicates that four of the five colleges initially had instrumental type of research lesson in their plans for the research lesson while only one college had a research lesson plan indicating a relational type of lesson. After comments and encouragement from the knowledgeable others to think about student teachers' learning and about how to make this learning visible in the research lesson, all the four lesson plans improved and became more relational type of lessons. This suggests that focusing on how to make student teachers' learning visible when planning research lessons can shift a lesson plan from an instrumental type to more relational type of research lesson. A relational type of lesson, which allows problem solving by the student teachers, enables student teachers' learning to be visible and therefore more appropriate for observation of student teachers' learning in lesson study. To plan such a lesson is however, challenging (Bjuland & Mosvold, 2015). The finding that the type of research lesson improved to make student teachers' learning visible suggests that lesson study has the potential to be a useful model for teacher educators' professional development in Malawi. . The study informs further work and other researchers in the field of lesson study the important role of knowledgeable others (Takahashi, 2013) for newcomers to lesson study and one important implication for future research would be to learn more about this role.

# How can we help teachers using guided discovery method, who have not used it before

Eszter Kovács-Kószó<sup>1</sup>, Katalin Gosztonyi<sup>2</sup> and József Kosztolányi<sup>1</sup>

<sup>1</sup>University of Szeged, Bolyai Institute, Szeged, Hungary; [k.k.eszter8@gmail.com](mailto:k.k.eszter8@gmail.com),  
[kosztola@math.u-szeged.hu](mailto:kosztola@math.u-szeged.hu)

<sup>2</sup>Eötvös Loránd University, Hungary; [kgosztony@caesar.elte.hu](mailto:kgosztony@caesar.elte.hu)

*Keywords: Guided discovery, group working, series of problems.*

## Introduction

In Hungary, there is a tradition of mathematics education focusing on problems and on mathematical discovery that we call Guided Discovery approach. This method was elaborated in the 20th century, first of all for the education of gifted students. Later the reform movement led by Tamás Varga in the 1960s and 70s developed a coherent general educational program for primary and lower secondary schools based on this approach (Pálfalvy, 2000). Although Hungarian specialists of mathematics education consider the approach actual and relevant until today, only a narrow circle of teachers follow it, and its large-scale dissemination remains problematic.

In my PhD research project, launched in September 2018, I would like to contribute to the elaboration of a more successful dissemination processes. In my analyses, I want to focus on one significant aspect of teaching by Guided Discovery: on the interactions between teacher and pupils, and amongst students. I plan to realize experimentations with teachers are willing to this approach and who want to discover it to improve their teaching practice. My purpose is to give an aid to teachers which could improve the number of “rich interactions” in their classroom.

## Experiments

I plan to follow two directions. The first one is based on my previous project held during my master studies, when I have tried to develop teaching projects based on group work. The second direction will be realized in collaboration with the members of the MTA-ELTE Complex Mathematics Education Research Group. A subgroup of this research project focuses on one of the specificities of Varga’s Guided Discovery approach: the planning of teaching trajectories in form of series of problems (Gosztonyi 2018). They examine the work with series of problems of expert teachers following the guided discovery approach, and they elaborate a commented collection of examples of series of problems to initiate other teachers into the approach.

In my experimentations first, I will analyze some lessons focusing on the interactions in both cases. Then I will try to help to the teacher to use one of the methods mentioned above and check the following lessons in the view of how the selected method could improve the quality of the teaching. Especially I want to answer the following question: Does the number of ‘rich interactions’ rise as an influence of the new way of teaching? If the answer will be ‘yes, it does’, I believe the quality of the teaching will rise also.

The project above has five parts. The first and most important element is the definition of ‘rich interactions’. If the number of ‘rich interactions’ and its ratio with all interaction is rising, it shows at least three things: students become more active and thinking more intensively about the mathematical content, realize more effectively what they have not understood yet and become braver about asking from the teacher or from another student.

Secondly, I will try to help the teacher to familiarize with the ‘new’ method. This will be different in the two threads of the project. In the first one, the teacher will get a complete plan for a period of teaching which will take about five to ten lessons. During this time group learning will dominate on the lessons which is unusual in Hungarian practice so the teacher will get a short, practical summary about how he or she should organize and control work.

In the second project the teacher will get a commented series of problems issued from the above-mentioned collection of the MTA-ELTE project. It is not necessarily connected with the following topic of the lesson, it is just an example. Then he or she will get time to measure it. The purpose is to help the teacher be able to create his or her own series of problems for his or her own class for the next period. During this he or she will have the opportunity to consult with one of the expert teachers mentioned above.

The third part will be the classroom realization. I will film the lessons and let the teacher work alone with the class.

After this, in the fourth part I will take an interview with the educator about how useful or efficient the experiment was in his or her opinion and I would be also interested in what he or she sees the most critical points of the lessons.

The last part will be the analysis of the data collected. The whole experiment will be repeated for three times in case of both versions. We hope this experiment will help us to support enthusiastic teachers to improve their method.

# Diagnostic competence of future primary school teachers hypothesizing about causes of students' errors

Macarena Larrain

Universität Hamburg, Germany; [mlarrainj@uandes.cl](mailto:mlarrainj@uandes.cl)

*Understanding students' thinking and learning processes is one of the main challenges teachers are faced to during teaching. This occurs in a process that includes perceiving relevant information, interpreting it and finally making pedagogical decisions. In particular, mathematical errors constitute a rich source of information about students' reasoning. In this paper, the diagnostic competence of future primary teachers in error situations is analyzed, focusing specifically in the process of interpreting the perceived information by hypothesizing about causes of students' errors. Results suggest that this competence can be fostered in teacher education and show that not only mathematical content knowledge but also practical experiences and beliefs are relevant for its development.*

*Keywords: Diagnostic competence, future primary teachers, errors analysis, mathematics teachers' competence.*

## Introduction

Effective teaching of mathematics in primary classrooms under a student-centered paradigm entails several challenges for teachers. In order to design and carry out effective teaching sequences that provide adequate opportunities for each student to learn, teachers need to enact several professional competencies that have been described and researched in the field (Shulman, 1986; Ball, Thames, & Phelps, 2008; Kaiser, Blömeke, König, Busse, Döhrmann, & Hoth, 2017). In particular, teachers' diagnostic competence has been regarded as a crucial component as students' thinking and understanding should be taken as the starting point for building further mathematical knowledge. Thus, teachers need to be able to understand students' thinking and adapt teaching strategies accordingly to promote learning.

Mathematical errors are unavoidable in the learning process and their educational potential has been widely acknowledged (Keith, & Frese, 2008) as they constitute an opportunity for teachers to look into students' mathematical thinking. Therefore, future teachers ought to learn about errors, their relevance and their underlying reasons, and start developing their diagnostic competence during teacher education programs.

This article focuses on future primary school teachers' diagnostic competence in error situations, particularly on the features related to their ability to hypothesize about causes of students' errors. On the one hand, aspects that may have an influence on future primary teachers' level of this competence are explored. On the other hand, the influence of an intervention in the frame of an university course on the development of this competence is investigated.

## Theoretical Background

### Teachers' professional competences

According to Weinert (2001), competences are composed by cognitive facets and affect-motivational facets. In teacher education, the cognitive facets can be associated with Shulman's (1986) categorization of teaching knowledge into subject-matter knowledge, in this context Mathematics Content Knowledge (MCK), General Pedagogical Knowledge (GPK) and Pedagogical Content Knowledge (MPCK). The affect-motivational facets usually include teachers' professional motivation and beliefs. Relevant studies such as the Teacher Education and Development Study in Mathematics (TEDS-M) and Cognitive Activation in the Classroom (COACTIV) have included these facets in their conceptualizations of professional competence (Döhrmann, Kaiser, & Blömeke, 2014; Baumert, & Kunter, 2011). Both specific cognitive abilities and affect motivation components are considered the main aspects of teacher professional competence.

Blömeke, Gustafsson and Shavelson (2015) suggest a situated model to assess teachers' professional competences that includes not only these cognitive and affect-motivational facets as disposition traits but also situation-specific skills, such as perception, interpretation and decision-making. These skills are key in the competence continuum that puts disposition traits in action in a particular classroom situation and therefore gives place to teachers' observable performance. In this model, the focus is neither on particular knowledge nor on the performance itself, but on the steps of the process in which resources activated and mediated by perception, interpretation and decision-making skills lead to performance as observable behavior in real-life situations.

### Diagnostic competence in error situations

Teachers' diagnostic competence is a relevant component in promoting learning mathematics in a learner-centered paradigm. Student-centered teaching requires teachers who are able to, during class, identify and comprehend each student's current level of understanding, make ongoing analyses of students' learning and make instructional decisions oriented towards building further skills and knowledge. In heterogeneous classrooms, teachers are faced to the challenge of identifying and understanding a wide variety of students' mathematical thinking that children may also communicate unclearly or incompletely (Radatz, 1979; Barmby, Harries, Higgins, & Suggate, 2007). In other words, teachers need to continuously 'diagnose students' achievements and learning processes during class' (Hoth, 2017, p. 2901).

In accordance with situated approaches, Prediger (2010) suggests that diagnostic competence has both a cognitive and an affective component. The cognitive element comprises the theoretical knowledge about mathematics concepts and mathematics learning required to analyze and understand students' thinking. The affective component includes teachers' beliefs, interest and curiosity about students' thinking, and an interpretative attitude that allows them to understand the underlying reasoning of students' thinking. Additionally, situation-specific skills, namely perception, interpretation and decision making skills, also affected by the cognitive and affective disposition traits, influence teachers' observable behavior. This suggests that diagnostic competence is a complex construct that cannot be assigned to a single component of Shulman's (1986) categorization

of teachers professional knowledge, but implies an integrated and situated understanding of teachers' competence.

This study focuses on diagnostic competence in particular class situations, where students' mathematical errors arise. It uses the definition of diagnostic competence in error situations by Heinrichs and Kaiser (2018) as

the competence that is necessary to come to implicit judgements based on formative assessment in teaching situations by using informal or semi-formal methods. The goal of this process is to adapt behavior in the teaching situation by reacting to the student's error in order to help the student to overcome his/her misconception. (p. 81)

The relevance of mathematical errors found in students' work or during teacher-student or student-student interaction in class relies on their potential as a source of information for teachers about students' erroneous conceptualizations or misconceptions (McGuire, 2013). Thorough comprehension of a student's understanding or misunderstanding and of where their knowledge and skills need further support is necessary for discerning what pedagogical resources should be provided to support students learning (Brodie, 2014; Radatz, 1979).

Students' errors that are not amenable to carelessness or a simple slip, are usually persistent and systematic and can be explained as the outcome of cognitive structures erroneously built, frequently connected to previous (correct) knowledge and experiences or by the overgeneralization of concepts or principles from other domains. Because there is an underlying reasoning explaining the erroneous ideas, they make sense for the student (Brodie, 2014). The eradication of this type of errors is difficult because involves complex cognitive restructuring. This represents a challenge for teachers, who need to design pedagogical strategies that support students in recognizing that their thinking is not correct and in reorganizing their knowledge. This also explains the relevance of teachers' diagnostic competence, as students' errors need to be considered and addressed during teaching (Smith, diSessa, & Roschelle, 1993; Brodie, 2014) not only because teachers need to understand student thinking in order to design and deliver appropriate learning experiences, but also because doing so is more effective than avoiding or ignoring them in the classroom (Keith, & Frese, 2008).

Considering different models describing teachers' diagnostic competence and error analysis knowledge, Heinrichs and Kaiser (2018) developed a model for future teachers' diagnostic competence in error situations, which is also used in this study. It consists of three phases. First, teachers attend to students' work and perceive the error, which is essential for the error to be dealt with. In the second phase, teachers interpret the error and hypothesize possible causes for that error in that specific situation. Finally, considering this hypothesis and aspects of students' knowledge that need further improvement, teachers design a strategy to deal with the error so misunderstandings can be overcome.

The study presented in this article focuses primarily on the second phase of this model and therefore, the following hypotheses are stated:

1. It is possible to foster the development of future primary teachers' competence to hypothesize about the causes of students' mathematical errors within a university course.

2. Future primary teachers' competence to hypothesize about the causes of students' mathematical errors is related to other features of their background, knowledge and beliefs.

## Methodological Approach

The aim of the main study in which this article is based is to investigate how future primary teachers' diagnostic competence in error situations can be assessed and fostered within a university course. Therefore, a university course and an online pre- and post-test assessment were designed. Future teachers in their third or fourth year of studies from 11 Chilean universities participated in the course and 131 answered both pre- and post-test questionnaires.

The course's goal was to foster the development of future primary teachers' diagnostic competence as used in error situations and it was designed on the basis of the model by Heinrichs and Kaiser (2018) described above. It consisted of four sessions in which prospective teachers made individual analyses and engaged in group discussions about primary students' mathematical errors.

During the sessions, videos and samples of students' written work were used to present the error situations, as has been argued for in similar studies (Hofmann & Roth, 2017). The usefulness of students' written work and videos of students working in class has been argued for as they constitute a good opportunity to generate discussions and analyses of students' thinking (Arcavi, 2016).

A set of questionnaires was applied to measure the impact of the course. In the first part, future teachers provided background information. In the second part, in order to collect data about their beliefs about the nature of mathematics and about mathematics teaching and learning, questionnaires from the Teaching Education and Development Study in Mathematics (TEDS-M) (Tatto, Schwille, Senk, Ingvarson, Peck, & Rowley, 2008) were used. Additionally, future teachers answered a multiple-choice Mathematical Knowledge for Teaching questionnaire from the MKT framework (Hill, Ball & Schilling, 2008) adapted and validated for Chile in the Refip project (Martínez, Martínez, Ramírez, & Varas, 2014).

Finally, in order to measure future teachers' diagnostic competence in error situations, a computer-based assessment was developed covering all three phases of the model by Heinrichs and Kaiser (2018) described above. Four different errors related to numeracy and arithmetic in primary school were chosen and assigned randomly, so that each participant worked through two errors before the course and other two errors after it. Students' errors were presented using video-vignettes together with information about the context, the students and the learning goals for the lesson. Future teachers were allowed to watch and pause the video multiple times but it was not possible to go back to the video once they started answering the items.

In particular, to assess the competence to hypothesize about possible causes of students' errors, which is the focus of this article, future teachers were asked to answer a set of close items based on the videos. In order to find the real cause for an error, teachers need to first think on a wide variety of reasons that may be leading to the error and then be able to discriminate between those that are possible in that particular situation and those that are not because of certain aspects of the circumstances. To evaluate this, future teachers were presented with eight statements with causes of the error in question and they had to decide, for each statement, whether it was a possible cause or

not. The plausibility of each of the causes was rated using experts' diagnoses. Mathematics teachers and academics working in the field of didactics of mathematics participated as experts. These dichotomous items were evaluated using methods of Item Response Theory (IRT). In particular, a one-parameter Rasch model (Wu & Adams, 2007) was used to determine the difficulties of the test items and the estimates for the latent abilities of every participant. The scaling showed an adequate fit (EAP Reliability = 0.65).

## Results

Future teachers' competence to hypothesize about the causes of students' errors showed a mean of 50 with a standard deviation of 10 in the pre-test. This competence was significantly improved at the second testing-time, when future teachers exhibited a mean of 52.6 (SD = 10). A paired samples t-test was conducted and a significant difference between these means was found ( $t(130) = -2.649$ ,  $p = .009$ ), with a small effect size (Cohen's  $d = .231$ ).

In order to test the second hypothesis, future teachers' competence to conjecture about the causes of error situations was related to their beliefs, knowledge and background prior to starting the course. In the beliefs questionnaires, they agreed with statements viewing mathematics as an inquiry process and the learning of mathematics as an active one. In other words, they revealed a tendency towards constructivist beliefs about the nature of mathematics and about the learning of mathematics. These constructivist beliefs showed a significant correlation of a medium-size effect with their competence to hypothesize about causes of students' errors ( $r = .378$ ,  $p = .000$  and  $r = .384$ ,  $p = .000$ , respectively).

It was also of interest to test the association between professional knowledge and the hypothesizing about errors' causes competence. Analyses indicated that better results in the Mathematical Knowledge for Teaching test are significantly correlated to a higher competence level for hypothesizing causes for students' errors ( $r = .307$ ,  $p = .000$ ). Similarly, a significant correlation was found between this competence and the number of mathematics or mathematics education courses that future teachers have finished within their university programs ( $r = .144$ ,  $p$  (one-tailed)  $= .050$ ).

Additionally, the link between future teachers' practical experiences and their competence to hypothesize about the causes of students' errors was explored. A significant, albeit small, correlation was found with the number of school practices future teachers have done within their university program ( $r = .164$ ,  $p$  (one-tailed)  $= .031$ ). Relatedly, the differences in the means on the competence level of future teachers who have no teaching experience in primary classrooms and those who taught primary students sometimes or frequently proved to be significant with a medium effect size ( $t(124) = -3.023$ ,  $p$  (one-tailed)  $= .001$ ,  $d = .543$ ). Moreover, when focusing on their experience teaching specifically mathematics in primary classrooms, a similar difference is showed between the groups with and without such experiences ( $t(129) = -2.297$ ,  $p$  (one-tailed)  $= .011$ ,  $d = .404$ ). Yet another kind of teaching experience was explored, namely private tutoring, as it is assumed to intensively expose future teachers to interpreting students' thinking and analyzing students' errors. Although no significant differences in the competence to hypothesize about the causes of students' errors of future teachers with and without tutoring experience for children of any age group was found ( $t(129) = -1.367$ ,  $p$  (one-tailed)  $= .087$ ), a significant difference was revealed in favor of future teachers who

have tutoring experience particularly with primary students ( $t(129) = -1.630$ ,  $p$  (one-tailed)  $= .052$ ,  $d = .284$ ).

Other aspects of future teachers' revealed no link with their competence to hypothesize about the causes of students' errors. For instance, no significant difference was found between participants enrolled in different types of teacher education programs ( $F(3,127) = 1.637$ ,  $p = .184$ ). Also, the semester of studies they were attending did not correlate significantly with this competence ( $r = .121$ ,  $p$  (one-tailed)  $= .084$ ).

Finally, multiple regression analyses were conducted including all variables with significant effects on the competence of hypothesizing about the causes of students' errors. The model that better predicts this competence ( $F(2,128) = 15.641$ ,  $p = .000$ ) includes only both beliefs variables, i.e. beliefs about the nature of mathematics as an inquiry process ( $\beta = .202$ ,  $p = .045$ ) and about the learning of mathematics as an active process ( $\beta = .291$ ,  $p = .004$ ). Together, both beliefs scales explain a 19,6% ( $R^2 = .196$ ) of the variance in the competence of hypothesizing about the causes of students' errors.

## Summary and Discussion

Teaching mathematics for understanding in heterogeneous classrooms requires teachers being able to provide individualized and differentiated learning opportunities to build further knowledge and skills. In order to do this, teachers need to understand individual student's thinking. Students' mathematical errors have been recognized as a rich source of information about their reasoning and, therefore, teachers' diagnostic competence in error situations has been regarded as pivotal for effective teaching.

When faced to an error situation, teachers are expected to work through a three-step model that includes perceiving the mathematical error, developing hypotheses about causes for that error in that particular situation and making a decision about how the error should be dealt with (Heinrichs, & Kaiser, 2018). This article focused particularly on the second phase of this model, i.e. on future primary teachers competence to hypothesize about the causes of students' errors. Factors influencing the level of this competence in future primary teachers, considering various aspects of their background, including specialized knowledge for mathematics teaching, beliefs and experiences were studied. Moreover, the possibility of fostering the development of this competence with an intervention within a university course was investigated.

The findings of the study reveal that constructivist beliefs about the nature of mathematics and about teaching and learning mathematics are related to higher levels of the hypothesizing competence. This means that, within this sample of future primary teachers, those who view mathematics as an inquiry process in which trying and discovering take place, and the teaching and learning of mathematics as an active and student-centered process, tend to have a higher ability to discriminate between plausible and not plausible causes for students' errors. These findings are in line to what has been found by Heinrichs (2015) in her study with prospective secondary teachers.

In addition, specialized knowledge for teaching primary mathematics was also found to be related to higher levels of the competence of hypothesizing about students' errors. Both a higher number of finished mathematics or mathematics education university courses and better achievements in the Mathematical Knowledge for Teaching questionnaire were related to higher competence levels on

hypothesizing causes for errors. This supports the view that dispositions traits such as knowledge and beliefs are relevant for professional competence.

Besides professional knowledge and constructivist beliefs, practical knowledge was also found to correlate with future primary teachers' competence of hypothesizing. It can be argued that targeted experiences displayed higher effects than general experiences. For instance, the number of school practices future teachers have participated in, revealed a significant but small effect correlation whereas teaching in primary classrooms exhibited a medium-size effect. Similarly, no significant difference was found between the groups with and without private tutoring experiences to children of any age but such a difference was found between groups with and without private tutoring experience particularly to primary-school students. This suggests that practical experiences make a significant difference when they are targeted to the same age group they will be teaching.

Concerning the impact of the university course, findings show that future primary teachers' competence of hypothesizing about students' errors can, in fact, be fostered within teacher education. However, as the intervention was quite time-limited and rather short its effects on the participating future teachers was apparently restricted. Taking these results together, an encouraging challenge is posed to teacher educators, as complex opportunities to learn need to be provided, in which practical experiences, beliefs and specialized knowledge are considered and interrelated.

### Introduction

This work is integrated in a teachers' training project, named SAM Culture Project<sup>1</sup>, that seeks to articulate the study of classroom culture in Mathematics with the professional development of teachers, in a perspective of interdependence between theory and practice.

We stand out three key aspects of this project: a) classroom culture considered as the system of relations and knowledge built in each learning community through the actions of both teacher and students (Goos, Galbraith, & Renshaw, 1999); b) learning from experience faced as a parallel between student learning and teacher development (Mason, 2010), facing the practice of teaching as a field of learning for the teacher himself (Doerr & Lerman, 2010; Leikin & Zazkis, 2010; Mason,

---

<sup>1</sup> The SAM Culture Project team consists of 2 mathematical educators and 9 teachers, all of them project trainers of the project and facilitators of the professional development sessions.

2010), and c) looking for ways to bring to training sessions teachers' classroom episodes using video as a means to access the classroom (van Es & Sherin, 2006; Cyrille & Sébastien, 2015).

Research conducted over the past decade suggests that video can be a powerful tool for facilitating teacher learning, allowing access to real classrooms situations and capturing teaching in all of its complexity while, at the same time, affording space and time for reflection (Tekkumru-Kisa & Stein, 2017). In the particular case of using videos made by teachers themselves, its role is recognized in the development of evaluation processes carried out in collaborative working modalities, highlighting the discussions about the videos of the participants' classes (Borko, Jacobs, Eiteljorg, & Pittman, 2008) and choosing the objectives of video viewing based on the learning goals (Cyrille & Sébastien, 2015). Videos produced by teachers own will, intended to be shared with peers and focusing a particular moment of the lesson, selected by the teacher himself, which we define as spontaneous videos can be the touchstone to discuss Mathematics classroom culture. Thus, this paper aims to discuss the role, contributions and limitations, of using video to reflect on Mathematics classroom culture, in a context of teacher training.

### **Theoretical considerations**

To think classroom culture in Mathematics in terms of classroom norms and practices led us to reflect on the social space of learning. This reflection focuses on various axes that characterize this culture, namely, the rules that establish it, the roles assumed by the various actors, the resources and mathematical tasks used, as well as the evaluation that regulates learning. Classroom culture constitutes a dynamic system, in permanent construction, which is why we intend to analyze these axes in interrelation (Cobb & Yackel, 1996). Some aspects of the complex relationship between these axes can be captured using mobile devices, which, for their simplicity, enable to save at any time a significant classroom episode to promote reflection on practice.

The use of authentic classroom videos in professional development sessions has been widely scrutinized and analyzed by international research (Cyrille & Sébastien, 2015; Tekkumru-Kisa & Stein, 2017). The videos need to be carefully selected, associated with reflection instruments, and used in ways to help teachers to notice and reason about important aspects of instruction and learning that occur in the video (Tekkumru-Kisa & Stein, 2017).

There are several reasons to use classroom videos of teachers participating in a professional development program (Borko, 2011; Borko et al., 2017). Teachers find videos from their own classrooms and the classrooms of colleagues to be more motivating and better support their learning than videos from classrooms of teachers they do not know. Using video from teachers' own

classrooms reduces the possibility of teachers dismissing what they see because “those kids are not the same as ours”. Using videos from classrooms where the teachers know each other requires a moderate amount of trust to view the student clips and a high degree of trust to watch the teacher clips. “To share their videos, teachers must feel that they are part of a safe and supportive professional community” (Borko et al., 2017, p. 5). This must be accounted for in the design of professional development sessions.

Combining the use of video from experienced teachers with the use of videos from the classrooms of teachers participating in a professional development program has been followed in many professional development programs. Roth et al (2017) followed this orientation in a long training program where professional development leaders model how to productively analyze these videos and they coach teachers in their analytical efforts at the same time they access to expertise models.

In addition to the cognitive aspects, research has also sought to know the motivational and emotional aspects present in the analysis of teachers’ classrooms videos in collaborative work environments (Kleinknecht & Schneider, 2013). These authors highlight the complexity of the network of cognitive, motivational and emotional dimensions involved in the analysis of videos of authentic situations, linking this analysis to the ways in which occurs and the role of professional development leaders. They demonstrate “the benefits of comparing teachers’ analysis of their own and others’ videos” and point out that “the individual analysis of one’s own and others’ videos results in differential effects on cognition, motivation, and emotion may not always be intuitive or easily observable in individual and group settings” (Kleinknecht & Schneider, 2013, p. 22).

One of the key aspects is leaders’ catalyst role to help teachers to notice and reason about important aspects of instruction and learning that occur in the videos (van Es & Sherin, 2006; 2017). Leaders use their experience to plan and facilitate productive discussions around carefully selected video clips to support teachers’ learning (Borko et al., 2017). One idea is to build tools to scaffold and streamline different video situations, supporting visualization and reflection in an interconnected way. The aspects to be observed, as well as the issues to be reflected during a small group discussion episode, are not the same as in a collective discussion episode. Different class moments require reflection scripts with specific characteristics. According to Borko, Koellner, Jacobs, and Seago (2011), a careful and intentional planning for video viewing and discussion can help ensure a critical, evidence-based, and meaningful analysis, performed with a proper language.

Jacobs, Seago and Koellner (2017) use a strategy for using the videos where teachers work on and discuss the same problem they will see later students working on during the video clip, in a way that teachers might make predictions about how students will solve the problem or what mistakes they

might make.

In summary, we can affirm that the potential of this learning resource for teacher learning is significant, but its use is complex, involving diverse risks and requiring multiple care.

## Methodology

This study follows a design-based research focused on professional development (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003; Cobb, Jackson, & Dunlap, 2016).

The option for this modality is justified by the interdependence between theory and practice that characterizes this professional development project. It allows to articulate two dimensions in which researchers and teachers collaborate: reflecting on the Mathematics classroom culture, through the analysis of their learning environment, and seeking to promote changes in the teaching practices.

The intervention includes a training workshop, entitled "Classroom Culture - Contributions for the learning of mathematics" with 26 hours. The first cycle was comprised with three editions of this workshop. We intend to construct and improve frameworks, theoretical based, to promote joint reflection on classroom culture and the consequent improvement of practices through the implementation of future cycles of intervention. The workshops involved 45 teachers from elementary school (grade 1 to 6), in Lisbon. Teachers enrolled voluntarily without knowing that the use of video would be privileged. The trainers of these workshops were researchers from the SAM Culture project.

Data were collected using the training team diaries (TD), trainers' reports (TR), and individual and anonymous assessment questionnaires, which were given to teachers at the end of each workshop (AQ).

Considering the potential of using video to reflect on Mathematics classroom culture, the training team organized an initial task involving a video and its discussion. It was a video of a moment from a collective discussion during a math task, recorded by an ordinary teacher, without previous preparation or editing. The training task intended to focus on aspects related to the axis of social and sociomathematical norms and to promote confidence on sharing spontaneous videos produced by teachers themselves to discuss classroom episodes. Throughout the three training workshops, the same anchor video and discussion script were used. It was intended that this video, used as an anchor video (Borko et al., 2008), would be an example, not a model to be followed, to motivate the production of spontaneous videos and their sharing in the context of the teacher training.

Thus, the access to the teachers' classrooms was planned through the use of spontaneous videos. This use had underlying design principles that sought to create conditions for teachers to (i) share

authentic situations in their classroom, (ii) collaboratively discuss classroom events with other teachers and (iii) acquire progressive confidence and predisposition for their learning.

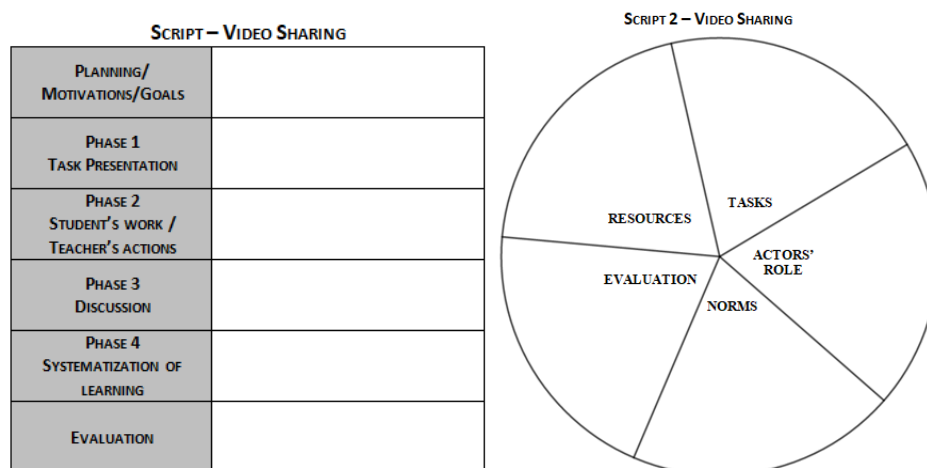

The preliminary analysis allowed the training team to make changes between workshops. At the end of the process, the retrospective analysis was carried out to revisit the data in order to identify opportunities and constraints of using videos to think about the culture of the classroom in Mathematics.

### **The use of video in a first design cycle**

In the first workshop, the use of the anchor video associated with the training task allowed, according to the trainer, to think about social and socio mathematical norms, emphasizing that "clearly it was something that they never had thought" [TD]. The awareness of aspects related to norms seems to have happened through the visualization of the video, as referred by a teacher "I became aware that sometimes we are not careful with this [norms] and other times we already do it and we do not know it" [TD]. However, the anchor video did not trigger the production of videos by teachers, as the trainer says "I realized that videos will not appear, despite my attempt to motivate" [TD]. The first video only appeared at the session before the last workshop session "breaking the ice" [TD] and leading to the production and sharing of two videos in the following session.

The reflection on the intention of sharing videos produced by teachers led to the re-thinking of the structure of the following workshops. In addition to performing the task that involved the use of anchor video, these workshops contemplated the creation of a moment of video sharing at the beginning of each session. This decision made teachers feel involved, from the first sessions, in the production and sharing of videos, as the trainers describe "teachers are truly committed to (...) collecting data from their experiences" [TD].

Having created the necessary confidence in teachers to share their classroom moments, the production and sharing of videos in all sessions became routine, as one of the trainers says, stating that "the initial fear was dissipating as the first trainees ventured, creating themselves at ease "[TR]. The difficulty in involving the trainees in the discussion of the videos triggered in the training team the need to create instruments to focus their analysis. One of these tools was an observation guide for shared videos structured according to the different stages of the development of a task in the classroom. Subsequently, another structured script was created in order to focus attention on the axes of the classroom culture (Figure 1).

**Figure 1: Scripts to support video sharing**

Regarding the data from the evaluation questionnaires of the three editions of the training workshop, all the teachers who answered (29 out of 45 participants) considered that the use of videos is appropriate to discuss aspects of classroom culture in Mathematics. In addition, all teachers also considered that the use of video is a way to bring the classroom itself to the discussion with a view to its improvement.

Although with little expression, constraints are identified with difficulties of producing videos during the class as "to record at the same time that I was exploring the task with the students" [AQ], referred by one of the teachers. Issues of student anonymity, such as "not being able to use student images", [AQ] are also cause for concern. However they do not constitute an obstacle to the production of spontaneous videos.

Opportunities offered by that use of videos are recognized by most teachers, particularly at the "Actor Roles" axis. Some teachers point out that video allows the "reflection and discussion of the role of the teacher as a mediator in learning" [AQ], contributing to "modify their methods of action [by observing their attitudes]" [AQ]. Regarding the role of students, teachers report that "the use of video made it possible to observe the reactions, behaviours, difficulties or facilities in explaining reasoning and how we can 'influence / direct' learning [AQ]. In addition, it is viewed as an important tool for "sharing student mathematical resolutions" [AQ]. The use of video is thus understood as an opportunity to revisit the classroom by "observing more than once" [AQ] moments of solving a task, allowing one to look at and discuss with others, in a "joint analysis of what happened in the classroom context "[AQ].

## Final remarks

Considering the use of videos to reflect on Mathematics classroom culture, teachers valued the use of spontaneous videos to discuss and reflect about teachers and students' role during whole class mathematical discussions. They recognized that the constraints associated with its production, namely the authorization to capture images and the dual role of teacher and video maker, do not constitute an obstacle to the production of spontaneous videos. From the motivational point of view, teachers were predisposed to the production and sharing of video episodes of their classrooms.

We highlight this way of producing videos, focused on the motivational and emotional dimensions (Kleinkrecht & Schneider, 2013), as a way to bring the classroom to the training process as was valued by teachers. Intentionally, the videos were analysed in a less directive way to promote the gain of confidence. However, this aspect reinforces the concern to create instruments to focus the visualization and discussion of the videos (Tekkumru-Kisa & Stein, 2017) in the axes of the Mathematics classroom culture.

The three editions of this workshop allowed us to identify the need to increase the design principles enunciated for the use of spontaneous videos. Thus, we add a new principle to create conditions for teachers to develop productive discussions supported by instruments of reflection constructed with them on a theoretical basis. From a perspective of continuity, the refined design principles will guide the next cycle of intervention.

In summary, the balance between promoting the emergence of spontaneous videos and their critical reflection, supported by guiding instruments, is an important aspect of teachers' professional development in order to think about Mathematics classroom culture. The search for this balance reflects the complexity of the relationships between the cognitive, motivational and emotional dimensions in the use of videos (Kleinkrecht & Schneider, 2013) for teachers' learning.

# Preservice teachers' learning about critical mathematics education

Camilla Meidell<sup>1</sup>, Diana Paola Piedra Moreno<sup>2</sup> and Georgia Kasari<sup>3</sup>

Western Norway University of Applied Sciences, Norway

<sup>1</sup>[came@hvl.no](mailto:came@hvl.no) <sup>2</sup>[dppm@hvl.no](mailto:dppm@hvl.no) <sup>3</sup>[geka@hvl.no](mailto:geka@hvl.no)

*Keywords: Argumentation for critical mathematics education, modelling, preservice teachers.*

## Introduction

We describe three PhD proposals that support the project Learning about Teaching Argumentation for Critical Mathematics Education (LATACME). The studies intend to explore how preservice teachers (PTs) include argumentation processes during their teaching practice in grades 1-7 within multilingual classrooms (MC). Argumentation for critical mathematics education (CME) in this case, is understood as a social production with multiple representations, such as oral and written expressions, gestures, and diagrams. In this production, contrasting, evaluating, and confronting the use of mathematical tools to understand social issues are essential for critical argumentation to take place.

## Intervention for multimodal argumentation with PTs in multilingual classrooms

The first study focuses on how multimodal argumentation processes are supported in multilingual mathematics classrooms. Multimodal argumentation in this case is seen in a translanguaging perspective (García, 2009) and, thus, will be investigated as a pedagogical context within which PTs can give equal opportunities for all students to participate in multimodal argumentation. For this reason, groups of PTs will be involved in interventions during the implementation of teacher education courses with a focus on modelling and Information and Communication Technology (ICT). The goal of the interventions is to consolidate with PTs and students an inclusive approach in language diverse classrooms that enables multimodality and CME. Thus, this study is connected to the following ones, through the multimodal and critical aspects of teaching and learning argumentation in both primary and teacher education level. After the data collection, a multimodal analysis of video-recorded classroom observations with the PTs will further look at how school students deploy and expand aspects of their communicative repertoires when they engage in critical argumentation processes. Finally, the study seeks to provide insights on how classroom members' diverse social, cultural and linguistic resources in the Norwegian school context empower them during the co-construction of meanings in multilingual-multimodal interactions.

## A case study of PTs' use of mathematical modelling to support students learning

The second project aims to explore how PTs support students to develop argumentation skills in mathematics and critical competence through mathematical modelling. The focus on how to expand students' argumentation skills connects to the previous project, but this one is centered on the context of modelling. This is explored by looking at how PTs argue for their didactical choices in the process of defining criteria for creating and implementing a mathematical modelling activity with the goal of promoting students' argumentation skills and critical competence in mathematics, as well as looking at how PTs support these goals in the classroom. The data will be gathered by following the process of one or two groups of PTs in relation to their work with a mandatory assignment in one of their

teacher education courses. The data will be analyzed with the use of the PTs' own definition on what they view as important aspects to include in modelling activities. Further, the ways by which PTs strengthen students' argumentation skills in mathematics will be analyzed by using Conner, Singletary, Smith, Wagner and Francisco's (2014) framework for teachers support of students' argumentation skills. This study expects to develop both theoretical and practical knowledge in relation to PTs knowledge and argumentation in relation to how to expand students' argumentation skills and critical competence in mathematics.

### **Possibilities for teacher education in CME**

The third project will identify elements that can be done in teacher education to let PTs explore activities of argumentation as open dialogues to do critical mathematics in multilingual school communities. The possibilities for teacher education in CME will be built in negotiation with different educational stakeholders (one PT, their colleagues, teacher educators, and school supervisors) in an effort of expanding the classroom practice towards a socio-political network of practices in mathematics education (Valero & Skovsmose, 2012). While some elements will be identified from a literature review in three teacher education dimensions for CME: modelling; ICT; and MC (which connects to both previous projects), others will arise from the educational stakeholders' considerations, the results of class observations, and collaborative problem-solving interviews with all the stakeholders. The data will be collected systematically when all stakeholders work together, which happens before, during, and after the PTs' practicum. This research will contribute to deep theoretical and practical knowledge by understanding the perceptions of diverse educational stakeholders about what "critical" argumentation in mathematics education can be as intended to students and teachers' practices. It will also analyze how PTs use argumentation as a characteristic of being critical teachers (Sánchez, et al., 2012) in the sense that it permeates not only their attitudes and reflections about the students work but also their own teaching practice. Finally, it will support ideas of teacher education in CME by developing connections between theory and practice.

### **Final note**

The poster was presented at the Eleventh Congress of the European Society for Research in Mathematics Education in Utrecht, the Netherlands. The digital version of the poster can be found at: [https://www.researchgate.net/figure/Poster\\_fig1\\_329338224](https://www.researchgate.net/figure/Poster_fig1_329338224).

## Retrospective competence assessment in a PD course on teaching statistics with digital tools in upper secondary schools

Ralf Nieszporek and Rolf Biehler

Paderborn University, Germany;

[Ralf.Nieszporek@math.upb.de](mailto:Ralf.Nieszporek@math.upb.de); [Biehler@math.upb.de](mailto:Biehler@math.upb.de)

*Recent changes in German national standards and curricula have made statistics including digital tools an inherent part of the final examination at upper secondary schools. In previous years, many teachers focused only on mandatory content like algebra or analysis and almost completely avoided optional stochastic content. Thus they are now facing the challenge to create and implement lessons for a topic in which they are inexperienced and feel insecure. The professional development course presented in this study has the aim to increase teachers' knowledge and competence in statistics, including the use of digital tools like graphic calculators and GeoGebra. A newly developed questionnaire was used to assess teachers' development during the course and led to preliminary findings concerning the knowledge and competence for advanced topics of inference statistics and the expertise of using digital tools in this field.*

### Design of the professional development course

There is a high demand for professional development courses on teaching statistics and the use of digital tools (like GeoGebra and graphic calculators) in Germany. Due to a recent change in the national standards (KMK, 2012), a new state curriculum was implemented in the German federal state of North Rhine-Westphalia (NRW) which made statistics including digital tools mandatory for the final exams (*Abitur*) in upper secondary schools. This obligation forced teachers to negotiate new and difficult challenges in their teaching practice. Many of them had not come into contact with statistics during their university education and they managed to also completely avoid this topic in their previous teaching practice. Therefore, content knowledge for teaching statistics or using digital tools in class is often missing (Batanero, Burrill & Reading, 2011). Teachers consequently feel insecure when teaching this topic. To meet the steadily increasing need for support, a professional development (PD) course was developed at Paderborn University. A team consisting of experienced facilitators, teacher educators, and practitioners revised an already existing course concept (Biehler, 2016) in the sense of *Design Research* (McKenney & Reeves, 2012). The improvements for the course were based on two foundations: on the one hand research on teacher education and proven ideas for designing teaching lessons (Biehler & Prömmel, 2010; Prömmel, 2013), and on the other hand concepts for PD course construction and research like the design principles of the German Center for Mathematics Teacher Education (DZLM) (Barzel & Biehler 2017) or the three-tetrahedron model for content-related PD research (Prediger, Leuders & Rösken-Winter, submitted, 2018).

The new state curriculum of NRW demands a wide variety of statistical topics to be covered in school lessons. It was possible to concentrate the essence of the curriculum in five PD attendance days (see Table 1 for the content of each day) distributed over half a year with opportunities for teachers to try

out the newly learned concepts in their lessons. In addition to that, the PD course also offers self-learning material so that teachers can deepen their knowledge on various topics like simulations with graphic calculators (GC), combinatorics, or the normal distribution.

Day	Topic	Content (examples)
1	Getting started in statistics and probability at upper secondary level, using GCs and simulation – in heterogeneous classrooms	Far-reaching and apposite examples for the law of large numbers and the $\frac{1}{\sqrt{n}}$ -law, introduction to digital tools (GeoGebra, GC) and simulations
2	Conditional probability, statistics independence, and expectation as basic concepts in stochastic modeling	Natural (absolute) frequencies in tree diagrams, complementing contingency tables with double tree diagrams
3	Modeling with probability distributions, particularly with the binomial distribution: suggestions for teaching in a content-related and process-oriented way	The binomial distribution dynamically visualized with digital tools, interconnecting insights from previous day by using the same examples, strengthen modelling critique
4/5	Teaching inference statistics (hypothesis testing) with the goal of understanding, with authentic examples for the binomial distribution	Hypothesis testing via p-values to predefined significance level, errors of the first and second kind, power function, choice of the null hypothesis

**Table 1: Topics covered in the five-day PD course**

The aim of our study is to implement and analyze a PD course with an emphasis on increasing participants' knowledge and competence in teaching statistics with digital tools. This excerpt of our larger study focuses day five which covers the field of teaching more advanced topics of inference statistics testing like:

- Interpretation of hypothesis testing results (with focus on didactics and language)
- Type I and type II errors
- Choice of null hypothesis
- Operation characteristics and power function

More information on the PD design, PD aims and the course content can be found in Biehler, Griesse & Nieszporek (to be submitted).

## Theoretical framework

The TPACK framework created by Mishra and Koehler (2006) expands the mathematical knowledge for teaching framework (MKT) by Hill, Ball, and Schilling (2008). In addition to *content knowledge* (CK) and *pedagogical knowledge* (PK), Mishra and Koehler enriched the model with elements of *technology knowledge* (TK). However, those knowledge facets and their intersections like *pedagogical content knowledge* (PCK) or *technology pedagogical content knowledge* (TPACK) are not sufficient as the only input for a PD course. It is essential for teachers and for their daily practice to acquire additional skills beside pure knowledge on the topic, as they are confronted with different classes or situations and have to constantly undergo planning activities. Planning activities can be performed with fictional classes where problems and difficulties have to be anticipated and adequate reactions must be found. Therefore, they can be implemented in PD courses rather easily to strengthen

the skills of the participants. In contrast to knowledge dimensions these skills were grouped as competences in regard to Weinert (2001). Table 2 illustrates some of the knowledge and competence dimension addressed in our PD course.

Knowledge	Content	I have content knowledge relating to the topic.
	Background of the content	I know the didactical and curricular background and the learning goals of the topic
	Ideas for implementation	I know ideas for the implementation of the topic in lessons.
	Approaches for digital tools	I know approaches for using digital tools / GCs in the context of the topic.
Competences	Handling misconceptions	I am capable of recognizing and reacting appropriately towards misunderstandings (...).
	Planning	I can create a lesson plan incorporating the goals of the topic.
	Teaching the content	I can teach the topic in a goal-oriented way.
	Integrating digital tools	I am capable of implementing the approaches for the use of digital tools / GCs (...) in school lessons in a didactically advantageous way.

**Table 2: Knowledge and competences addressed in the PD course, via statements to be rated**

### Teachers' heterogeneous knowledge and teaching experiences

For a long time, statistics and especially inference statistics have not been compulsory for upper secondary level, and were often neglected in university courses for teachers. This resulted in deficits regarding statistics knowledge of current in-service teachers, and some teachers might have mixed or mistaken content and horizon knowledge in some fields (Wassong & Biehler, 2010; Ball, Thames & Phelps, 2008). They are hardly able to simplify the content matter for class, which should also be taught in a PD course on statistics (Godino, Batanero & Font, 2007).

In addition to this deficiency, knowledge and competences towards digital tools are also demanded by new curriculum in NRW. GCs (or computer algebra systems, CAS) have also become mandatory in the final examination. Therefore, it is necessary to have at least a basic knowledge in programming, simulating or visualizing and interpreting distributions to fulfil the new demands. Due to the mismatch of teacher training and curriculum, this lack of experience must be addressed by a PD course, too.

### Research questions

We will address the following research questions:

1. *General assessment of course success from participants' perspective.* To what extent (from before until after the PD course) do participants report to have acquired knowledge and competence in reference to conducting lessons in advanced topics of inference statistics testing?
2. *Suitability of PD course in respect to the heterogeneity of teachers' previous experiences.* What differences concerning the self-reported development of knowledge and competence facets (from before until after the PD course) can be observed in different groups of teachers with comparable previous experience in teaching statistics and/or using graphic calculators?

Results for PD day 4 including a detailed description of the underlying theory, competence models and methodology can be found in Nieszporek, Griesse & Biehler (to be submitted). The procedures used in this article form the foundation for this paper and the analysis of the course success. Due to space limitations it is only possible to give a brief overview of the results for PD day 5 in this article.

## The ReCoS questionnaire

With reconsideration of the course concept and the corresponding theoretical background, the ReCoS questionnaire (see Figure 1) was developed to fulfill our needs. ReCoS is an abbreviation for **retrospective competence self-reports** which describes the questionnaire quite well. It combines the knowledge and competence dimensions presented earlier (Table 2) with the specific content facets of each day. The PD course participants rate their before and after level of the facets subsequent to each PD day. The self-reports were made via German school grades (1=excellent, 2=good, 3=satisfactory, 4=pass, 5=poor, 6=fail).

Item No.:	<b>I</b>		<b>II</b>		<b>III</b>		<b>IV</b>		<b>V</b>		<b>VI</b>		<b>VII</b>		<b>VIII</b>	
	I have content knowledge relating to the topic XXX.		I know the didactical and curricular backgrounds and the learning goals of the topic XXX.		I know ideas for the implementation of the topic XXX in lessons.		I know approaches for using digital tools/GC in the context of the topic XXX.		I am capable of recognizing and reacting appropriately towards misunderstandings and pupils' faulty reasoning regarding topic XXX.		I can create a lesson plan which incorporates the goals of the topic XXX.		I can teach the topic XXX in a goal-oriented way.		I am capable of implementing the approaches for the use of digital tools/GC in context of the topic XXX in school lessons in a didactically advantageous way.

Interpretation of hypothesis testing results																
Type I and type II errors																

Figure 1: ReCoS questionnaire matrix, see Table 2 for the content of the columns

Pre/post or knowledge test designs were not feasible measurement tools for our project. Reasons range from organizational difficulties (lack of time for a detailed knowledge test due to a tight PD course schedule) to ethical concerns or motivation on behalf of the teachers. There are also good reasons for a retrospective test instrument like ReCoS. On the one hand different effects like *response shift* or *practice effects* were prevented. On the other hand, there was no *sensitization* towards a specific aspect or topic of the PD (Willson & Putman 1982).

## Data collection and sample size

The ReCoS questionnaire matrix was adjusted to the topic of each PD day and distributed at the end of the respective day. A different questionnaire measuring individual experience levels via a six-point Likert scale (from *inexperienced* and *highly experienced*) was filled in by the participants at the beginning of the whole course. Individual anonymous codes were used to match the two questionnaires. 32 out of a total of 60 participants filled in both questionnaire types completely and thus only their data was used for further analysis.

Either SPSS 25 or R were used for statistical analysis like test for normal distribution (Kolmogorov-Smirnov), significance of competence increase (Wilcoxon signed-rank test) or building of scales of items and participants' groups.

## Results

The general success of the PD course is illustrated in Figure 2. The ReCoS matrix shows the mean increase for each item. First of all, every change between the before and after competence self-assessment is positive. The changes were significant ( $p < 0.001$ , Wilcoxon signed-rank test) and were around 1 which is equal to an increase of one school grade.

Item No.:	I	II	III	IV	V	VI	VII	VIII
	I have content knowledge relating to the topic XXX.	I know the didactical and curricular backgrounds and the learning goals of the topic XXX.	I know ideas for the implementation of the topic XXX in lessons.	I know approaches for using digital tools/GC in the context of the topic XXX.	I am capable of recognizing and reacting appropriately towards misunderstandings and pupils' faulty reasoning regarding topic XXX.	I can create a lesson plan which incorporates the goals of the topic XXX.	I can teach the topic XXX in a goal-oriented way.	I am capable of implementing the approaches for the use of digital tools/GC in context of the topic XXX in school lessons in a didactically advantageous way.
<b>Differences between before and after score means</b>								
Interpretation of hypothesis testing results	1.09	0.70	1.28	1.16	1.00	1.06	1.00	1.16
Type I and type II errors	1.09	0.80	1.25	1.32	0.97	1.09	1.06	1.22
Choice of null hypothesis	0.97	0.73	1.25	1.13	0.97	1.16	1.09	1.16
Operation characteristics and power function	1.61	1.18	1.64	1.52	1.22	1.48	1.30	1.41

**Figure 2: Mean differences between the before and after scores of each item, a difference of one positive point describes an increase by one school grade, sample sizes between 29 and 32**

Overall, the differences for each item do not vary much. Item II (*I know the didactical and curricular backgrounds and the learning goals of the topic*) is an exception. For almost every content facet the self-assessment increases less than 1 grade, which stands in contrast to the confidence in creating lesson plans (item VI) or teaching the topic (item VII). This might be a hint that teachers have insecure knowledge of the curriculum (a discussion of the curriculum was not part of the PD) or have difficulties understanding this specific item. Nevertheless, some scales within the questionnaire can be identified.

Content-specific facet	Knowledge	Competences	Technology
	$\alpha$	$\alpha$	$\alpha$
Before scores			
Interpretation of hypothesis testing results	0.910	0.982	0.897
Type I and type II errors	0.924	0.948	0.909
Choice of null hypothesis	0.933	0.979	0.927
Operation characteristics and power function	0.942	0.969	0.910
After scores			
Interpretation of hypothesis testing results	0.913	0.965	0.848
Type I and type II errors	0.906	0.947	0.930
Choice of null hypothesis	0.901	0.968	0.951
Operation characteristics and power function	0.925	0.965	0.898

**Table 3: Cronbach's  $\alpha$  for the different scales, separately for the before and after items, sample sizes between 29 and 32**

The theoretical framework of the course suggests a separation of the items into two scales *knowledge* (Item I – III) and *competences* (Item V – VII) for each content facet. Item IV and VIII form a separate

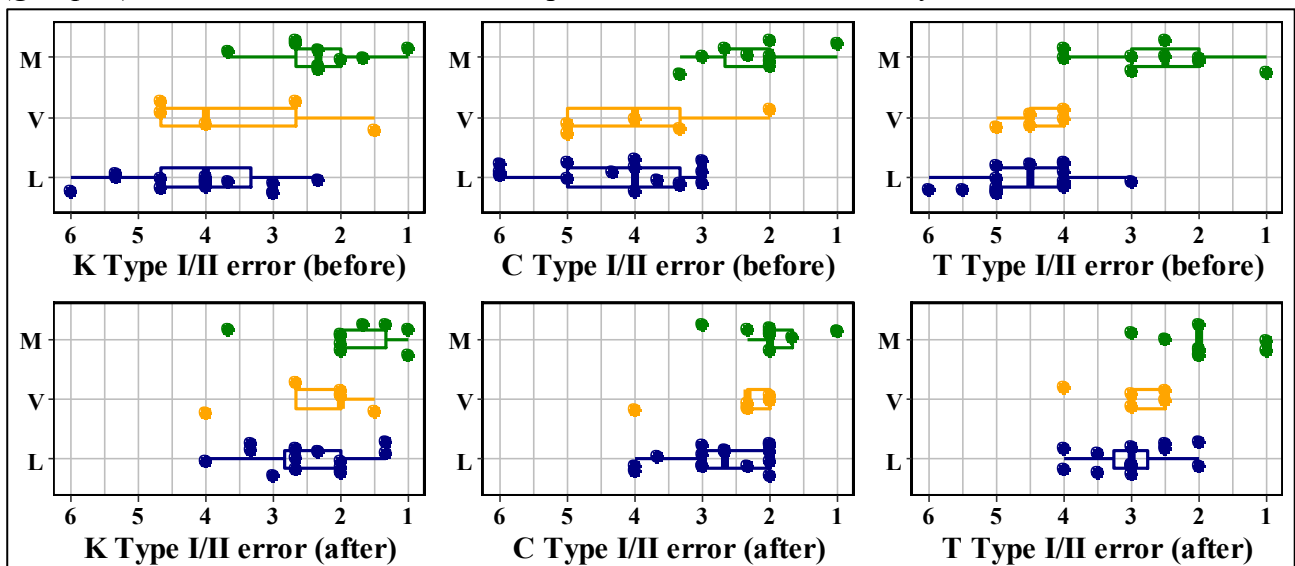

scale called *Technology*, because technology plays a big role in the PD course and the abilities for using digital tools in school differ from the content components combined within *knowledge* and *competence*. The theoretical considerations are supported by empirical results. As is presented in Table 3, the identified scales within ReCoS show good to excellent Cronbach's  $\alpha$ . In the following passages we will focus on the content facet *type I and type II errors*.

Table 4 shows the heterogeneity of experience among the teachers. The expertise reported in the field of teaching statistics and using the GC is not very high overall. It is striking that the participants were more unexperienced in handling digital tools ( $n=21$ ), even when tools like GeoGebra or GC are commonly used for topics like algebra or analysis. This lack of experience for statistics appears to be a singularity.

Experience in teaching statistics	Experience in using GCs in statistics		
	Low	Medium	High
Low	n = 15 (L)	–	–
Medium	n = 5 (V)	n = 9 (M)	–
High	n = 1	n = 1	n = 1

**Table 4: Distribution of participants in terms of self-reported experience in the use of GCs in statistics and in teaching inference statistics**

For obvious reasons, we will disregard the groups consisting of only one person here, and instead focus on the participants who had low experience in teaching statistics and using GCs (*group L*), those who had varied experienced in both fields (*group V*) and those who reported medium experience (*group M*). This selection reduced the sample size to 29 for further analysis.

**Figure 3: Jitterplots and boxplots of the three scale pairs *knowledge* (K), *competences* (C) and *technology* (T) for the content *type I and type II errors* (Type I/II error), group L: blue ( $n=15$ ), group V: orange ( $n=5$ ), group M: green ( $n=9$ ), scale range from 6=fail to 1=excellent, made with R**

The increase of the mean differences (Figure 2) can be rediscovered in the boxplots in Figure 3. This figure visualizes the development of the three groups (L, V and M) for the content facet *type I and type II errors*. The before scores of each group fit their previous experience on teaching statistics.

This means that the lowest experienced group (L) has the lowest before scores compared to the other two more experienced groups. Only group V, who also rated their experience in using digital tools low, shows equally low before scores in the technology scale. The after scores illustrate the huge increase of *knowledge*, *competence* and capability for *technology* reported earlier for the mean (Table 2). Even the most experienced group M rated themselves higher in all three scales after the PD course.

It is striking that there is a larger spread in the before scores of each group, which is remarkably reduced in the after scores of all three scales. Especially the participants of groups V and M rate their skills uniformly high. Only the lowest experienced group L shows a reduced but still high spread in the *knowledge* scale. There might be a ceiling effect at grade 2 (good) because only very few participants rated their skills higher with grade 1 (excellent). The rating system based on school grades might be the reason for that.

## Discussion and remarks

Overall, the PD course increased the knowledge and competences of the participants by a significantly high amount (Figure 2) and was a success. But at the same time there are some hints as to where the PD course can be improved in a future design research cycle. We expected that the participants would rate their *knowledge* higher than their *competence* level after the PD course, because they supposedly would need to test the new material and ideas for teaching in their classes. There is a small difference between the score levels, but the *competence* after scores were almost as high as the corresponding *knowledge* scores. The different opportunities in the PD course to test and discuss the new input (for more details see Biehler et al., 2018) seem sufficient to encourage the participants to cover *type I and II errors* appropriately in class. Participants also feel more capable of using digital tools not only for calculating purposes but also for its didactical opportunities in the learning process.

The distribution of the before scores of each group (Figure 3) supports our division of the participants via their pre experience level. For example, the group of varied experience (V) shows medium high pre scores in *knowledge* and *competences* but has low scores in *technology*. The three different groups vary significantly from each other in the pre scores. This difference is still apparent in the after scores but relatively smaller since the after scores of groups L and V are almost on the same high level as group M. Also, the heterogeneity within each group is reduced on all scales.

It is important to have in mind that ReCoS only provides self-reported data and also that the sample size of 29 is not a large one. Therefore, we plan to contrast our results with data from other PD days and to use data from different other sources (questionnaires, audio transcript) to validate our findings. The comparison of the results from day 4 and 5 seems to be satisfying.

## Acknowledgment

We would like to thank the Deutsche Telekom Stiftung who funds the DZLM and also the regional government of Arnsberg for cooperation and the opportunity to implement the course concept just as Birgit Griesse for the help in the development process of the methodology and evaluation of day 4.

# Learning through/about Culturally Relevant Pedagogy in Mathematics Teacher Education

Kathleen Nolan<sup>1</sup> and Lindsay Keazer<sup>2</sup>

<sup>1</sup>University of Regina, Regina, SK, Canada; [kathy.nolan@uregina.ca](mailto:kathy.nolan@uregina.ca)

*Keywords: Culturally relevant pedagogy, mathematics teacher education, teacher learning*

## Introduction

This presentation is grounded in self-study research by two mathematics teacher educators' (MTEs) as we taught courses in culturally relevant pedagogy (CRP) in mathematics and engaged in research conversations to discuss our learnings from students and from each other. The research is situated in the nexus between prospective and practicing teachers' (PTs) expectations for classroom 'tips & techniques' and MTEs' desires to disrupt dominant discourses in mathematics. We collected data from PTs through their projects and reflections on course content during offerings of CRP courses in our two institutions. We analyzed that data through a themes-based approach focused on MTE learning which was fostered by tensions and dilemmas stemming from students' responses to the disruption of dominant discourses. In this presentation, we describe our research contexts and the learning stimulated from listening to our PTs' thinking.

## Research overview

Dominant discourses of mathematics have been well-established through a history of being "culturally defined as objective, value-free, logical, consistent and powerful knowledge-based discipline" (Burton, 1994, p. 207). Efforts to disrupt these dominant technical-rational traditions in mathematics classrooms are evident in research on power, privilege and oppression. For instance, Willey and Drake (2013) indicate that subtle signs of power and privilege are manifested in, for example, "neglecting students' cultural and intuitive mathematics knowledge" (p. 62). They urge us, as MTEs, "to sharpen our sociopolitical lenses in order to notice and disrupt manifestations of privilege and oppression in mathematics education" (p. 68).

We draw on the work of Ladson-Billings (1995), who defines culturally relevant pedagogy as "a pedagogy of opposition... not unlike critical pedagogy but specifically committed to collective, not merely individual, empowerment" (p. 160). In mathematics education, Aguirre & Zavala (2013) state that culturally responsive mathematics teaching "involves a set of specific pedagogical knowledge, dispositions, and practices that privilege mathematical thinking, cultural and linguistic funds of knowledge, and issues of power and social justice in mathematics education" (p. 167).

In general, MTE research on their instruction has focused on what PTs learn from their instructional approaches, rather than on their own learning as they conduct research (Chapman, 2008). Chapman (2008) offers that MTEs should study their teaching by reflecting on the thinking of their students/PTs, examining the conflicts between intent, thinking, and behaviors, and using them to inform MTE instructional approaches. In line with Chapman's advice, this research taught us to listen to our students and their thinking about CRP in mathematics classrooms; to understand and work

through students' questioning and resistance that emerges when dominant discourses of mathematics are disrupted in teacher education courses. Our research situates our learning and development as we struggle, in designing and teaching CRP courses, with questions of who and what is considered 'relevant,' and as we analyze how students respond to CRP in mathematics.

## Discussion and results

Three themes emerged from our data that capture our learning as MTEs. The first is our need to clarify our own ideas about CRP. We found ourselves repeatedly questioning how to define and teach CRP, underscoring our belief that "[c]ultural responsiveness is not a practice; it's what informs our practice so we can make better teaching choices for eliciting, engaging, motivating, supporting, and expanding the intellectual capacity of ALL our students" (Hammond, 2015, p. vii).

A second learning theme is the need to negotiate understandings of CRP with PTs. We take seriously the warning of Aronson and Laughter (2016) to not turn CRP into "a buzzword or checklist of steps" (p. 198), that CRP must "be embraced more fully as a guiding ethos for every aspect of the classroom" (p. 198). As MTEs, we learned to be careful that we do not teach CRP courses which will merely make the dominant (technical-rational) mathematics more accessible, but that our courses are disruptive enough to make mathematics different in an enduring manner.

Finally, a third learning theme is the value of learning from others - from tensions created in our work with PTs, but also from each other, as MTE colleagues. This additional layer of collaboration fosters our growth and development as MTEs. Without the opportunity to discuss the tensions and dilemmas emerging in our practices, we would have remained isolated in our own individual contexts, struggling on our own with similar tensions and questions about CRP in mathematics.

# Using teachers' research to elicit professional development among pre- and in-service mathematics teachers: a qualitative meta-analysis of mathematics education in graduate programs

Tikva Ovadiya

Oranim Academic College of Education, Tivon; Jerusalem Academic College of Education, Israel;  
[tikvao@actcom.net.il](mailto:tikvao@actcom.net.il)

*This study used qualitative meta-analysis to analyze the professional development of 38 pre-service student-teachers who conducted a qualitative study in mathematics education as part of their learning requirements. The analysis of the teacher-researchers' (TRs) studies used qualitative meta-analysis and focused on learning through activity (LTA) (Simon, 2018). Analysis was based on a meta-model that was constructed to characterize the development of the TRs according to the following parameters: skill of mathematics instruction, pedagogical perceptions, pedagogical knowledge, and problem-solving methods. In this paper, I present and discuss the meta-model study of only the last parameter (problem solving).*

*Keywords: Professional development, teacher researchers, qualitative meta-analysis, learning through activity (LTA), problem solving.*

## Introduction

Professional development programs for pre- or in-service mathematics teachers or teacher educators generally include practice in conducting research, based on the perception that the short- and long-term goals of post-secondary and graduate teacher-education programs are to develop expert teachers, and that conducting original research is one way of obtaining expertise. Most teachers in college or university programs claim that they have developed professionally, and this study examines various aspects of their professional development as a result of research that they carried out in their practical teaching environments.

Aspects examined included the structure of their research tools, task design, data analysis, interpretation of results and data, and so forth. A meta-model was developed to incorporate all these elements and more. The model describes the main categories found in the studies: problem solving, theory, beliefs and attitude, assessment, and environment and setting. In addition, the model describes the catalysts for the TRs' professional development for each category examined, describes the study tracks, and illustrates whether the TRs followed a partial or complete pathway to their goal. The elements highlighted in the model are the LTA components identified as part of the TRs' research process.

## Theoretical background

### The teacher as researcher

Requiring pre- or in-service teachers to engage in research as part of their practical instruction moves their education away from the educator-centered model (where the educator “communicates” information toward the student) towards a more student-centered approach, thus shifting pre-service teachers from receivers of pedagogical knowledge from “higher” authorities (i.e., the educator) into creators of such knowledge (Cochran-Smith & Lytle, 2009). Allowing pre-service teachers to conduct their own original research offers not only an instructional tool for teacher educators to engage in student-centered, problem-posing pedagogy (Souto-Manning, 2012), but also offers a tool for the pre- and in-service teachers themselves to investigate any worries or problems of practice they may have in their classrooms and schools in the future (Baumann & Duffy, 2001). Knowing how to conduct proper research will become a tool that extends beyond the teacher-education classroom, allowing in-service teachers to continue their professional development after completing their formal coursework and providing them opportunities to improve teaching and learning (Lysaker & Thompson, 2013), explore questions of influence and social justice (Fecho & Allen, 2011), change their understanding of their own students’ understanding of the various concepts (Parkison, 2009), improve their skill in intervention (Christenson et al., 2002), improve and change their beliefs, and take action appropriate to their findings. Snow-Geron (2005) found that teacher-researchers (TRs) changed not only their classroom practices, but also their attitude towards teaching. Even small-scale research projects allow TRs to improve their understanding of the research process (Gray, 2013), their selected topic(s) of study (Goodnough, 2010), and even about themselves (Reis-Jorge, 2007).

Previous studies have found that conducting research leads teachers to professionally develop their teaching skills and to better understand their beliefs and attitudes toward themselves as teachers and toward their students/pupils as learners. In this study, I focus on teachers in the field of mathematics education. The goal was not only to examine the extent of professional development that the research project effected, but also to focus on the catalysts for development that emerged in the TRs’ research process.

### Learning through activity: theoretical framework

As the facilitator of the in-service teachers’ research projects, I utilized the learning through activity (LTA) theory as a strategy to investigate my students’ professional development. The LTA theory aims to integrate conceptual learning and instructional design. With respect to mathematics, LTA research is based on the questions: How do humans learn mathematical concepts? and How can instruction be designed to enlist these learning processes? Guided by these questions, LTA researchers have examined the design of mathematical concept study units and have developed a theory that simultaneously guides the work and derives from it (Simon, Kara, Placa, & Avitzur, 2018).

As defined by some of the studies on LTA, a “mathematical concept” is a researcher’s assumption used to characterize student knowledge. It does not represent what a student might actually say about her understanding but rather provides focus with respect to the learners’ *actions* and allows the researcher to recognize specific, higher-level actions that result when lower-level (current) actions are coordinated with the actions of the learning activity. This coordination of actions, along with

explanations to understand the concepts involved and reflective abstraction, becomes the source of a newer, more advanced concept (Simon et al., 2018). Based on this definition, theory designers also have defined specific “instructional” actions and procedures that promote conceptual learning. These may include hypothetical learning trajectory (HLT), guided reinvention, specific design steps, and use of computer applications, all of which can lead to a coherent process of building mathematical concepts.

## **Method**

### **Research goals**

The research goals were two-fold: 1) identify and characterize dimensions and aspects related to the professional development of teachers in the role of researcher in mathematics education, and 2) identify the catalysts that lead to this professional development.

To this purpose, the research questions were as follows:

1. What characterizes the professional development of TRs in the wake of the process of research on mathematics education?
2. Under what aspects does professional development takes place? What are the catalysts for professional development?

I narrowed focus onto two specific themes: “perceptions of concepts” and “conducting instruction.”

### **Population**

No direct population. The qualitative analysis was conducted by examining the research study projects carried out by undergraduate students. (These projects were presented as their theses). Fifty-six student studies were initially examined, but only 38 that met the three criteria – the research involved mathematics education, the findings were qualitative, and the TR’s or mentor’s journal were available – were chosen for the meta-analysis (8 teacher educators, 18 elementary school teachers, 12 high school teachers).

### **Meta-analysis**

Meta-analysis studies act as a guide for prospective research by qualitatively analyzing studies in a specific field to comparatively identify similarities and differences between them (Çalık & Sözbilir, 2014). This present meta-analytical study is aimed at systematically analyzing in-service teacher research on a variety of subjects in mathematics education so as to identify any professional development that occurred thereby and to determine any deficiencies and gaps therein.

### **Data analysis**

The research process involved hermeneutic and dialectic aspects: hermeneutic to do justice to the original primary findings and dialectic to compare and contrast them with each other.

The first stage consisted of an initial reading of all the papers to familiarize myself with the subjects, methods, data analyses, findings, and results of each study. Next, at the second stage I formulated sub-questions that I attempted to answer during rereading. They were: What characterizes the topics that teachers choose to study? What do teachers ask in studies about student learning? What do teacher educators ask about their associate teachers? What do teachers ask about themselves? What

characterizes the process by which teachers build the research structure? What do teachers learn from the definition of intervention principles? How do teachers analyze data as researchers? Where and for what reason do teachers note in their work or journals the difference between being teachers and being researchers? Do teachers eventually indicate changes in their perceptions or beliefs?

In the third stage, I constructed a number of meta-models based on the answers to the above questions. These included meta-models pertaining to research subjects and populations, classification of research questions and research methods, application of theories, and the TR's skills and perception of mathematics instruction.

In the fourth stage, the meta-model was expanded based on LTA theory so as to recognize which TR actions complied with the theoretical predictions. The categories that evolved were "problem solving," "theory," "beliefs & attitudes," "assessment," and "surroundings". At this stage, I built the framework of the expanded model. I chose random events from the studies and examined them based on the categories in the extended model and, as a result, was able to refine the model.

### **Triangulation**

I supplemented the qualitative meta-analysis with three types of data: the final versions of the papers the TRs submitted, the journals they submitted to me, and the notes that I, as facilitator, wrote throughout the procedure.

### **Findings**

The meta-models constructed revealed five main categories that fell under "mathematics instruction, skills perceptions, and knowledge" and that involved project mechanisms unique to teachers' work in the research milieu. I then narrowed it down to the "sub-meta-model" of "problem solving" (see Figure 1 as part of an entire model) to provide a detailed analysis of the professional development of the TRs as it occurred during the research process.

### **Meta-model research: mathematics instruction, skills perception, and knowledge**

As mentioned above, all the studies chosen for analysis included some form of "conceptual learning" and "instruction" and could be described through meta-model analysis. All the categories and subcategories in the meta-model can be divided into actions, thoughts, perceptions, or catalysts, and the four categories that pertain to the LTA instructional design framework. In constructing the meta-model, I analyzed events and attempted to identify these four components (shaded elements, Figure 1). Thus, it was possible to identify in which cases the process of teaching and intervention promoted perception of mathematical concepts and those that did not.

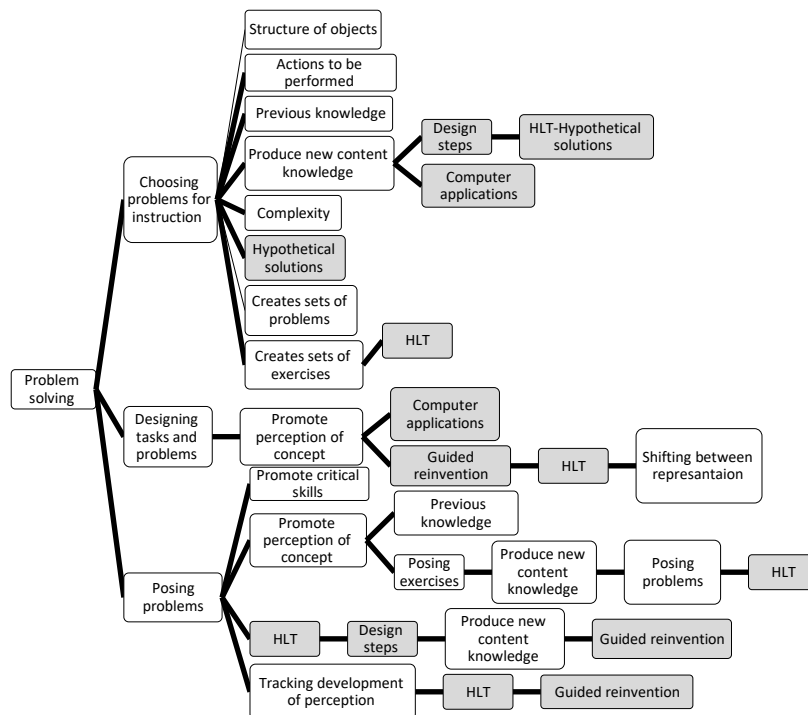

### **Professional development in problem solving**

In the meta-model, "problem-solving" includes any new action, skill, or perception of problem-solving instruction that occurred during the TRs' research. The TRs did not use standard problems from textbooks or online per se, but selected exercises or problems suitable for the topic at hand. In addition, where changes in perception were observed, they redesigned tasks and imagined the solution their population might hypothetically give. Their design of their study tools evolved and changed if they recognized that their hypothetical path did not suit their population, as for example, they had

fifth-grade material but were teaching a third-grade class (for which no appropriate problem sets were available).

### Identification of catalysts

Using LTA theory helped me define and recognize the intervention processes constructed by the TRs. If I recognized them as one (or more) of the four components of instruction that promote development of a mathematical concept, I examined the events to pinpoint the elements (i.e., catalysts) that led to this development. Catalysts included the following: assessing and analyzing solutions according to personal or theoretical interpretation, research questions that focus on identifying the development of concepts or actions, research questions that focus on changing the learning environment, and teaching and intervention.

**Figure 1: The “problem solving” component of the meta-model research**

Below are three cases that illustrate the professional development of the TR with a focus on the catalysts.

#### Example 1: Designing tasks and problems to promote graphic representation

Rachel, a 12<sup>th</sup>-grade teacher, wanted to help her students solve calculus problems through graphic drawings. She found a problem online and adapted it to the non-computer environment. After analyzing the students’ solutions, she realized that her students did not yet have sufficient knowledge to solve the problem. She then chose problems from the textbook, redesigning them to encourage a graphic representation of the solution. However, she discovered that most students solved the problem algebraically; only a few applied graphic representations. She therefore proceeded to design two tasks: drawing the derivative of a given logarithmic function, and graphing the original function of a derivative presented as a denominator. She specifically chose functions where the students would have to consider many aspects of the “derivative” concept. At this point, she wrote some hypothetical (correct and incorrect) solutions, and made a hypothetical list of aspects of perception related to the

understanding of the original function and its derivative. In her journal, Rachel reflected how preparing the list of hypothetical solutions in advance helped her understand how her students might perceive the two concepts. From this stage on, Rachel worked as follows: 1) She chose a set of problems which, combined, developed understanding of the mathematical concept in the context of graphic representation and offered a multiplicity of examples and graphical solutions to problem. 2) She redesigned textbook problems to fit her research goal (fostering understanding of graphic representations of functions and shifting from one graphic representation to another). At each stage, she prepared a list of hypothetical solutions and implemented “guided reinvention”. She also posed questions to enhance her understanding of the solution process based on her analysis of each lesson.

Rachel is an example of a formative teacher who posed problems in accordance with the goal: developing a perception of graphs in calculus. LTA follow-up (HLT, guided reinvention, design steps, and computer application) enabled analysis of the stages of development and their identification. The catalyst was her investigation of the students’ solutions whereby she concluded that the original problem did not invite a graphic solution, leading her to design her own problems that focused on her research goal. By posing problems, she learned new mathematics content knowledge.

### **Example 2: Designing tasks and problems to promote transfer of learning**

Betty, a grade-2 teacher, wanted to promote her pupils’ perception of the multiplication operation by solving problems involving tessellations. Her research goal was to promote transfer of learning from tessellation problems to multiplication problems and vice versa. Her research paper and journal indicated that she focused on the problem-solving aspect as follows: First, she found problems in the textbooks and redesigned them into a set appropriate for second graders. After analyzing her pupils’ solutions, she concluded that they understood the three basic properties of tessellation. Next, she posed tessellation problems using the categories she had created and introduced multiplication questions. At each stage, Betty wrote hypothetical solutions in advance and then analyzed the actual results to ascertain how her pupils perceived multiplication and tessellation. Also, at each stage, she focused on the dual purpose of posing problems whose solution reflects a perception of multiplication expressed through tessellations, and vice versa, which was supposed to reinforce each.

Betty’s professional development in problem solving was two-fold: 1) while posing the problems she refreshed the multiplication concept by creating different tessellations not necessarily with geometrical polygons; and 2) she considered the generic process of designing and posing problems: setting a learning goal, formulating steps to achieve it via specific concepts, posing appropriate problems, writing hypothetical solutions, analyzing the problem, and posing new problems accordingly. The catalyst was her unique study linking these two concepts and the fact that she had to design assessment rubrics to identify the development of the concepts.

### **Example 3: Designing tasks and problems to identify teachers’ perception of division by fractions**

Sofie is a teacher facilitator. Her research focused on teachers’ perception of division by fraction, a concept that is sometimes confusing even to in-service teachers. She had previously experimented with the concept of the addition and subtraction of fractions, but she strongly suspected that teachers had difficulty posing problems that clearly taught the nature of division by fraction. She composed a

set of division exercises illustrating different aspects of division by fractions. Her plan was to interview teachers and ask them to pose a word problem for each exercise. She believed that how the problems were formulated would reveal the teachers' perceptions. Sofie first formulated and solved a set of hypothetical problems herself to determine if her chosen exercises were suitable and if they encompassed all aspects of division by fraction. Sofie's professional development was expressed in two ways: 1) Based on theories she had learned and papers she read, she composed and recomposed the set of exercises five times until she deemed them satisfactory. (She thus showed that she had learned to compose exercises as a series so as to develop various aspects of fractional division.) 2) Sofie learned how to convert the exercise into "realistic problems" so that the concepts of dividing by fractions were reflected in the formulation of the problem. Thus, her own concept of division by fractions developed and deepened. In addition, her research led her to construct a path for teaching the subject so that her students would develop a broad, coherent perception of the action. Sofie's catalyst was her exceptional interview structure that obliged her to overhaul exercises to solve the appropriate problem. An additional catalyst was reading studies and theories regarding the understanding of division by fractions. She tried to examine the perception of teachers against the perception of students.

### **Discussion and implications**

In this brief article, I have presented a general model of the main and sub-categories that indicate the professional development of in-service teachers who conducted research. I then elaborated on the "problem-solving" category. This present article augments previous papers that discuss similar aspects (Baumann & Duffy, 2001; Cochran-Smith & Lytle, 2009; Goodnough, 2011; Fecho & Allen, 2011; Friedrich & McKinney, 2010; Labaree, 2003; Lysaker & Thompson, 2013; Moran, 2007; Souto-Manning, 2012; Vetter, 2012).

Three major findings emerge from the analysis of these studies in which TRs were required to deal, on their own and perhaps for the first time, with formative assessment at every stage of their research, using intermittent results to (re)build and improve their research tools and intervention actions. First, it is clear that such assignments support the coherent perception of mathematical concepts and processes and support the TRs' own skills in constructing a lesson to promote the development of their own coherent perceptions. This finding is consistent with the LTA theory (Simon et al, 2018). Second, it supports the general model of the skills and actions of the TR, which illustrates the catalysts in the sub-categories. (For example, what and when do teachers learn from theory?) Identifying catalysts and understanding their role in each category may help facilitators design studies with a higher potential for enabling the professional development of the TRs. Third, enhancement of the TRs' mathematical content was a central goal (and outcome) of this study. At the outset of their projects, the TRs considered themselves quite knowledgeable about the subject that they had decided to study, but, while building their research tools, they realized that there was a need for them to deepen their content knowledge.

Because this study was conducted using qualitative meta-analysis research, it presents a summary of findings from all the TR studies. This method is effective because it generates a comprehensive result that includes many aspects of the phenomenon (McShane, & Böckenholt, 2017). Thus, the "problem-solving" meta-model can be used to create a pathway that describes each of the studies individually.

If a particular path lacks some necessary component(s), e.g., “step design” or HLT, this indicates that the TR progressed less than one who did employ all the components.

Finally, the complete model can assist the facilitator in guiding TRs in designing research structure, making sure that they include activities with the potential to develop and promote mathematical “knowledge.” A paper regarding the use of the complete model is currently in preparation.

# A quasi-experimental impact study of a professional development course for secondary mathematics teachers in South Africa

Craig Pournara and Patrick Barmby

Wits School of Education, University of Witwatersrand, South Africa;

[craig.pournara@wits.ac.za](mailto:craig.pournara@wits.ac.za); [patrick@nomoremarking.com](mailto:patrick@nomoremarking.com)

*We report on the impact of a mathematics professional development course on teachers' mathematical knowledge for teaching and their learners' attainment. Teachers' scores on a mathematics test improved significantly. Using a quasi-experimental design we examined the learning gains of Grade 9 learners (N=991) from nine secondary schools taught by teachers who had attended the course. We compared these results with those of learners (N=988) in the same schools taught by teachers who had not participated in the course. The intervention group learners made larger gains but these were not statistically significant. The teachers who had done the course had far fewer years of teaching mathematics at senior secondary level than their colleagues. This highlights the importance of a matched comparison teacher sample in impact studies.*

*Key words: Learning gains, mathematics teacher knowledge, impact of professional development.*

## Introduction

There are attempts across the world to improve teachers' mathematical knowledge in order to raise learner attainment. In South Africa, despite a wide variety of programmes costing many millions of Rand, there is little evidence that these interventions have had much impact on learners' performance in mathematics. The impact problem is frequently attributed to teachers' poor mathematical knowledge (Carnoy *et al.*, 2011; Taylor & Taylor, 2013).

In 2010 the Wits Maths Connect Secondary project (WMCS) set out to develop models of professional development for secondary mathematics teachers that would improve learner attainment in Mathematics. In 2012 the Transition Maths 1 (TM1) course was offered for the first time to a small group of teachers in one district in the broader Johannesburg area. In 2013 the Learning Gains I impact study showed that learners taught by teachers who had attended the course out-performed learners in the same schools taught by teachers who had not attended the course. The results were treated as "evidence of promise" since the sample was small, the gains were small and the variation within the treatment and comparison groups was large (Pournara, Hodgen, Adler, & Pillay, 2015). The notion of *learning gains* was employed as a measure of learner attainment where the gain is the change in test-score from pre- to post-test over one academic year. It is a useful notion in the context of impact studies because it enables us, to some extent, to attribute learning gains to the teaching received from a particular teacher in a given year. We are well aware of a range of interventions that are taking place in secondary schools and so we make all claims with caution, knowing that no individual intervention at the level of the teacher can account entirely for improvements in learner attainment.

The TM1 course has been revised and refined annually since 2014, and has now been offered to four more cohorts of teachers across the Gauteng province of South Africa, totaling approximately 150 teachers. A follow-on impact study, Learning Gains II, commenced in 2016 to extend the Learning Gains I study with a more robust instrument and a larger sample of teachers, learners and schools.

The key question the study seeks to answer is, “What is the effect of teachers’ participation in the TM1 course on their learners’ attainment in Mathematics?”

We begin with a brief review of the literature on teacher knowledge, mathematics professional development and the impact of these on learner attainment. Thereafter we provide a description of the TM1 course, giving the reader some insight into the mathematics and teaching components of the course by means of specific examples of tasks.

## **Teacher knowledge and learner attainment**

Shulman’s (1986, 1987) distinctions between subject matter knowledge (SMK) and pedagogical content knowledge (PCK) have provided much impetus for a great deal of research on teacher knowledge. While it is widely agreed that the knowledge teachers need for teaching mathematics is more than sound content knowledge of mathematics itself, the elaboration of the detail takes different forms. Some refer to the additional knowledge as PCK (e.g., Krauss, Baumert, & Blum, 2008) while others (e.g., Ball, Thames, & Phelps, 2008) distinguish sub-categories of SMK as common, specialised and horizon content knowledge, and further sub-categories of PCK such as knowledge of content and students, curriculum and teaching. While we find the SMK-PCK distinction useful, the boundaries between them are too blurred to be useful as analytical constructs. We therefore choose to speak of “mathematics-for-teaching” (MfT) (Adler, 2005; Adler & Davis, 2006) as an amalgam of mathematical and teaching knowledge. MfT includes both subject content knowledge and mathematics-specific pedagogical knowledge.

Elsewhere (Pournara *et al.*, 2015) we have argued that in contexts where teachers’ mathematical knowledge bases are poor, proxy measures such as state certification, number of post-school maths/maths education courses taken and years of teaching experience may be relevant predictors of learner attainment in secondary mathematics. However, these proxy measures alone are insufficient as measures of teachers’ mathematical knowledge.

Attempts to measure teachers’ mathematical knowledge have taken various forms across the world. In some instances, teachers have been given the same/similar test items to the learners they teach. Harbison and Hanushek (1992) and Mullens, Murnane, and Willett (1996) found that primary teachers’ scores on such tests were good predictors of learner performance. In South Africa, Taylor and Taylor (2013) reported the poor performance of Grade 6 teachers and learners on items in the SACMEQ III study, thus implying a link between (poor) teacher knowledge and (poor) learner performance. More sophisticated measures have been developed in Germany and the United States (Baumert *et al.*, 2010; Hill, Ball, & Schilling, 2008; Krauss *et al.*, 2008). These studies have both found associations between teacher knowledge and learner attainment.

While teacher knowledge is key in all contexts, it is particularly crucial in contexts of poverty and low achievement. Nye, Konstantopoulos, and Hedges (2004) and Krauss *et al.* (2008) have shown that variances in learning gains attributable to teaching are higher in low socio-economic status (SES) schooling contexts.

## **Professional development and learner attainment**

The impact of professional development is a concern across the world. Based on a literature survey in English publications, Adler, Ball, Krainer, Lin, and Novotna (2005) reported a predominance of small-scale qualitative studies. The review of studies of professional development relating to school mathematics by Gersten, Taylor, Keys, Rolfhus, and Newman-Gonchar (2014) showed that very few

of the initiatives which met acceptable standards of rigour also led to positive effects on learner attainment. Sample-McMeeking, Orsi, and Cobb (2012) reported the effects of a middle school intervention in the US where teachers took university summer courses in mathematics lasting two to three weeks. They reported an effect size of 0.20 (Hedge's  $g$ ) on learner attainment for teachers who had attended two courses but there was no discernible effect size for those who had attended only one course. Further work is clearly required to carry out rigorous studies on the impact of teacher professional development on learner attainment in mathematics, and this study makes a contribution in this regard.

### The Transition Maths 1 course

The TM1 course is underpinned by the assumption that focusing on teachers' MfT will lead to better teaching which will in turn translate into improved learner attainment. It is targeted at teachers currently teaching in Grades 8 and 9 (first two years of secondary school in South Africa), and aims to address the transition from mathematics in the Senior Phase (Grades 7–9) to mathematics in the Further Education and Training (FET) phase (Grades 10–12). Teachers are typically nominated by their school or district to attend the course. They are then required to write a selection test before being accepted. The course was offered free of charge to teachers. While it is an officially recognized Short Course of the University, it does not carry accreditation towards a qualification but does carry Continuing Professional Development (CPD) points.

The course consists of eight two-day contact sessions over a ten-month period and focuses on mathematics content (75%) and aspects of mathematics teaching (25%) – a similar ratio to the course described in Sample-McMeeking *et al.* (2012) mentioned above. The mathematical content of the course includes algebra, number, functions, Euclidean geometry and trigonometry. Teachers submit seven assignments and write two tests which include mathematics content and tasks related to teaching.

We approach the learning of MfT through *revisiting* known mathematics (Pournara, 2013) and learning new mathematics. When working with familiar mathematics, a revisiting approach frequently draws on extreme cases and problematizes taken-for-granted aspects to deepen teachers' knowledge rather than merely redoing known mathematics to improve procedural fluency (Kilpatrick, Swafford, & Findell, 2001). For example, in working with linear functions we provide teachers with five representations (verbal, table, function machine, equation and graph) of the same function, say  $y = 2x + 1$ . We then invite them to consider questions about each representation, including some that are likely to be new and unusual, for example: “Where is *double* in the graph?”; “Where is *double* in the table?”; and “When the input is  $-1$ , the output is also  $-1$ . Is there another output-value that is the same as the input-value?”

We extend teachers' knowledge beyond the mathematics they currently teach so that they can teach Grade 10 (and possibly beyond) in the future. We therefore deal with Grade 11 curriculum content in algebra, functions and trigonometry, paying attention to common procedures in the senior secondary years such as completing the square, which we approach algebraically and geometrically. We reinforce connections between representations and between procedures by asking teachers to solve quadratic equations using three methods (factorizing, quadratic formula and completing the square) for typical examples such as  $3x^2 - 5x - 2 = 0$  and unusual cases such as  $k^2 = 5$ .

The focus on mathematics teaching is built around the notion of teachers' *mathematical discourse in instruction* (Adler & Venkat, 2014) which is operationalised through what is known as the

Mathematics Teaching Framework (MTF). Here we focus on key elements common to all teaching practices: identifying and articulating a lesson goal; designing and selecting example sets; selecting representations; selecting and designing tasks; producing explanations and justifications; and, building opportunities for meaningful learner participation in lessons. Each of these aspects is sufficiently close to teachers' current practice and hence possible to implement and then to work on so as to become more skillful at each one. We illustrate the teaching focus through an example from a session on explanations where we deal with the pervasive error of conjoining in algebraic simplification. Teachers are asked to produce an explanation that will convince Grade 8 learners that  $4p + 5 \neq 9p$ . This typically leads to a range of responses from teachers such as those illustrated in figure 1.

- 1) *Numerical approach using a single case*: The letter stands for an unknown number. So, let's try  $p = 2$ . If  $p = 2$ , then what is  $5p + 4$ ? Is it the same as  $9p$ ?
- 2) *Appealing to everyday life using letter as object*: We can think of  $5p$  as 5 pencils, but 4 is just a number. When we add, we won't get 9 pencils.
- 3) *Appealing to everyday life using letter as specific unknown*: We can think of  $p$  as a box with a number of sweets, but we don't know how many sweets are in the box. Is  $5 \square + 4$  the same as  $9\square$ ? i.e., Is 5 boxes of sweets plus 4 more sweets the same as 9 boxes of sweets?
- 4) *Comparing different algebraic expressions using principles of variation*: Let's compare different algebraic expressions. What is the same/different about the following expressions: a)  $5p + 4p$       b)  $5p + 4m$       c)  $5p + 4$

**Figure 1: Four possible responses to explain  $4p + 5 \neq 9p$**

We then ask teachers to study these responses and to evaluate each explanation in the light of its mathematical correctness, its generalizability and the extent to which it is appropriate for Grade 8 learners. While we have not yet researched teachers' responses to this kind of task, anecdotally we have noticed that they are not aware of the limitations of the *letter as object* (Küchemann, 1981) explanation. We therefore highlight the important yet subtle distinctions between explanations (2) and (3), showing why (3) is more productive for making sense of algebraic symbols later in algebra. We recognize that explanation (4) shows evidence of teachers' take-up of ideas of variation (Marton & Tsui, 2004; Watson & Mason, 2006), which we explicitly teach in the teaching sessions.

## Research design and methods

We adopted a quasi-experimental design to assess the effect of the TM1 intervention on the participating teachers and on the attainment of their learners. We describe the sample of teachers taking part in the TM1 course in 2016 and the methods used to analyse their gains in MfT during the course. We then examine a sample of Grade 9 learners during the 2017 school year to assess the impact of the TM1 course in the first year after teachers' participation in the TM1 course.

Forty teachers completed the TM1 course in 2016. The gains in their MfT were assessed by means of tests, administered at the start and the end of the course. The test at the end of the course was more cognitively demanding than the test at the start and covered more topics. Both tests were developed by the project team.

Eleven teachers, in 9 schools, were invited to participate in the study because they were teaching Grade 9 Mathematics in 2017 and 15 of their colleagues, also teaching Grade 9 Mathematics, agreed to be part of the comparison group. In terms of analysis, a repeated measures t-test analysis was used to compare the mean test scores at the start and the end of the course. This was carried out only for the 11 teachers in the study.

At the same time, we tracked 991 Grade 9 learners taught by TM1 teachers over the 2017 school year. We refer to these as the TM1 learners. We also tracked 988 Grade 9 learners from the same schools but taught by teachers who had never participated in the TM1 course. These learners are referred to as the comparison group. A test was administered to both groups in February and September 2017.

The learner test, designed by the project team, tested key aspects of number, algebra and functions. Most items were typical curriculum items at Grade 8 and 9 levels. The test was designed to contain a spread of items across difficulty levels. It was piloted in 2016 with Grade 9 and 10 learners in schools similar to those participating in the study. A Rasch analysis showed that the test was fit for the purpose of testing learning gains at Grade 9 level although there were a few too many items that were difficult for many learners.

Each test response was marked as *correct*, *wrong* or *missing* with only 1 mark being allocated for a correct response. Therefore a learner's test mark simply indicated how many items s/he had answered correctly. There was no consideration of partially correct responses.

A repeated measures ANOVA analysis was carried out to see whether the interaction between pre/post gains in the learner assessment and the learners' group (control vs TM1 group) was statistically significant.

## Results

We first present the quantitative results and analysis from the TM1 tests for teachers, and then the results of the learner test.

Looking firstly at the TM1 maths tests, the mean test scores for the teachers before and after the TM1 course were compared. The mean pre-course test mark was 57.3% and the mean final test mark was 72.1%. A repeated sample t-test analysis showed that this increase was statistically significant at the 5% level ( $t = 3.67$ ,  $df = 10$ ,  $p < 0.05$ ). We therefore concluded that the course had a significant impact on the teachers' MfT. Given that the final test was more cognitively demanding and covered more topics, the statistics may under-report the impact of the course on teachers' MfT.

The results of the Grade 9 Learning Gains test scores were as follows: for the TM1 group the mean score increased from 13.2% to 19.5% from pre- to post-test. By contrast the comparison group's mean scores increased from 13.9% to 19.7%. The TM1 learners made greater gains, closing the gap between the two groups. However, using a repeated measures ANOVA analysis, the interaction between pre/post-test and learner group was not found to be significant (Wilks' Lambda = 1,  $F(1, 1975) = 0.91$ ,  $p = 0.34$ ). We therefore concluded that there was no statistically significant difference in the gains in the learner test scores pre to post between the comparison group and the TM1 group.

The teachers' levels of teaching experience provide a possible explanation for the apparent lack of impact of the intervention. We compared the TM1 teachers and the comparison group teachers on their number of years of teaching Mathematics (in general) and on their number of years teaching Mathematics in each of Grades 8 to 12 (Table 1). We report on all 11 TM1 teachers but only on 12 comparison teachers because the biographical data for the remaining 3 teachers was incomplete.

	N	Years of Maths Teaching	Grade 8	Grade 9	Grade 10	Grade 11	Grade 12
<b>TM1 teachers</b>	11	14.6	7.0	9.6	3.6	1.9	1.1
<b>Comparison teachers</b>	12	13.3	4.5	5.8	4.1	4.3	4.0

**Table 1: Teachers' average years of experience of Mathematics teaching per grade**

The data shows that both groups had, on average, been teaching mathematics for a similar number of years although within each group there was a wide range of years of experience. While on average the TM1 group had more experience teaching at Grade 8 and 9 levels, the comparison group had considerably more experience teaching in Grades 11 and 12. This suggests that participation in the TM1 course does not make up for years of teaching experience at senior secondary level, particularly beyond Grade 10. However, based on the learner results, it could be argued that participation in TM1 enabled the teachers to do “as good a job” in teaching Grade 9 Mathematics as their colleagues who have more experience in teaching higher grades.

Given that the teachers in the comparison group are the “more senior” teachers with respect to mathematics, it is not surprising that the TM1 learners did not significantly outperform the comparison learners. If it can be assumed that teachers teaching higher grades have stronger mathematical knowledge for teaching, then the overall findings of this study fit with the underlying assumptions behind TM1 – that paying attention to teachers' mathematical knowledge for teaching is a necessary condition for improving teaching.

## Discussion and implications

As noted above, proxy measures of teachers' knowledge may have some predictive power in contexts where teachers' mathematical knowledge is generally poor. Based on the data presented, the proxy measure “number of years of mathematics teaching” needs to take into account the levels at which teachers are teaching within the secondary school. Secondly, as Clarke (1994) has argued, the impact of professional development programmes on teachers' practice is delayed. Therefore, attempts to measure the impact of teachers' participation in TM1 on their learners should not be undertaken in the first year after completing the course.

Impact studies, irrespective of whether or not they report statistically significant results, do not provide insights into the mechanisms which enable or constrain the desired change. Based on the data reported here, little can be said about why the gains were small for both the TM1 learners and the comparison group. Further research is necessary to unearth possible reasons for the continued low performance of learners in Grade 9 Mathematics. A related qualitative study is underway to investigate the nature of learners' errors and the extent to which these errors may change between pre- and post-test. Such changes in the nature of learners' errors cannot be picked up by a coding system that does not make allowance for partially correct responses. This points to the need for mixed methods impact studies where quantitative impact analyses are complemented by qualitative studies such as those that attend to learner error.

In terms of research design, particularly in the context of secondary mathematics in South Africa, the above finding on teacher background and learner attainment shows the importance of matched sampling in the teacher group. This will likely expand the size, cost and complexity of the study since it is seldom possible to find comparison teachers, within the same schools, who have similar years of experience in Grades 8 and 9 but have not participated in TM1. Inevitably this means the inclusion

of new comparison schools, which potentially strengthens the findings of the study. However, experience has shown that schools such as those participating in this study are not in a position to confirm which teachers are teaching in each grade until early-to-mid February by which stage data collection for a study such as this has already commenced. Consequently the matching of teachers is likely only possible after the pre-test learner data has been collected. This leaves some of the matching of teachers up to chance as the researchers have little control over these matters.

*Keywords: Mathematics teaching practices, problem solving, collective discussions, challenges.*

## Theoretical framework

Currently, there is a wide agreement concerning the idea that students' understanding of mathematics, their ability and confidence to use it to solve problems, and the development of a fruitful disposition toward mathematics, are shaped by the teaching they encounter in the classroom (NCTM, 2000; Smith, & Stein, 2011). Besides, researchers agree that “within mathematics classrooms, the nature and character of the discourse that students and teachers engage in has a profound impact on students’ opportunities to learn mathematics, and it shapes their identities as mathematical knowers and doers” (Cirillo et al., 2014, p. 141).

If we intend to support and foster students’ “mathematical proficiency” (Kilpatrick, Swafford, & Findell, 2001, p. 5), it is essential that the mathematical discourse that occurs in the classroom takes as a starting point the students' exploration of cognitively challenging tasks; it is also crucial that they actively engage in whole-class discussions of the strategies they used to solve these tasks. In fact, research has shown that whole-class discussions with these characteristics and in which the teacher, relying on what the students say and do, moves them towards a more powerful, efficient, and accurate mathematical thinking, are a resourceful context for learning mathematical ideas and processes (Lampert, 2001).

Even though these collective discussions rooted in students’ thinking and work and about relevant mathematical tasks can provide important opportunities to learn mathematics, to orchestrate “a productive mathematical discussion (...) turns out to be an extremely demanding and intricate task. The role of discussion coordinator is particularly difficult” (Sfard, 2003, p. 375). Even experienced teachers face difficulties and challenges that would not exist if the control of the classroom discourse was mainly in their hands. These challenges, well documented in the literature (for example, Boavida, 2005; Lampert, 2001; Smith, & Stein, 2011), increase when the teachers who try to conceive and implement mathematical teaching practices which emphasise productive whole-class discussions based on problem solving, are prospective teachers.

## The research: aim and results

This presentation relies on two studies developed by two prospective elementary mathematics teachers (Prata, 2017; Silvestre, 2017). Both of the studies aims to understand how they could develop teaching practices focused on the orchestration of mathematical collective discussions and to analyse the challenges that these practices pose to a future teacher. From a methodological point of view, the

studies fit into an interpretative paradigm. During the last year of their teaching training programme, the two prospective teachers conceived and carried out, in primary schools and over about five weeks, pedagogical interventions in which several problems related to selected mathematical concepts were proposed. Over this period they acted both as researchers and teachers. The empirical data were collected mainly by participant observation and documental analysis.

The results of the studies illustrate that the five-practices model proposed by Smith and Stein (2011) has helped the prospective teachers to manage better the orchestration of collective discussions around problem solving strategies generated by the students. Besides, they highlight the importance of selecting challenging tasks that foster the emergence of several solution strategies and which context is close to the students' experience. The main challenges experienced by the prospective teachers are related to help the students to understand that errors are valuable "ways of thinking" preventing, at the same time, that those who have failed feel themselves in a vulnerable position; to support their reasoning without telling "what to do" to get the right answer; to change the pattern of interaction from "funneling" to "focusing"; and to honor students thinking while assuring that the mathematical ideas that are in the heart of the teaching agenda remain prominent.

# Pre-service mathematics teachers interpret observed teachers' responses to students' statements

Sigal Rotem, Michal Ayalon and Shula Weissman

University of Haifa, Israel; [sigal.h.rotem@gmail.com](mailto:sigal.h.rotem@gmail.com)

*In this paper, we will present and exemplify a three-level category scheme used for categorizing the depth of interpretations pre-service mathematics teachers offer for teachers' responses to students' mathematical thinking in observed critical events. The category scheme is a result of top-down literature analysis and bottom-up analysis of 38 critical event reports submitted during one academic year within a clinical preparation context. This category scheme may help teacher educators to gain a better understanding of PTs' interpretations of teachers' responses, and therefore to plan field-based training programs that help PTs to broaden their theory-practice connection.*

*Keywords: pre-service mathematics teachers, critical events, noticing, reflection.*

## Introduction

Reflection has had a growing role in teacher education over the past four decades (e.g., Zeichner, 1981) and is considered to lie at the heart of teachers' professional practice (Clarke, 2000). Teacher educators argued for the integration of reflection with field-based preparation, in order to help pre-service mathematics teachers (PTs) learn how actions connect to particular purposes in context and to support PTs' ability to link theory with practice (e.g., Ball & Forazani, 2009; Zeichner, 1981). In this research we follow Karsenty and Arcavi's (2017) definition of reflection, which is "analytical and careful observation of 'what was done' in order to attempt to understand intentions, plans, actions and utterances" (p. 435). A common use of reflection in teacher education (in-service and pre-service) is asking teachers to analyze classroom situations (e.g., van Es et al., 2017). However, research indicates that when PTs are merely asked to reflect on situations that they observed, their reflection may focus on aspects of teaching that are irrelevant to building further mathematical instruction (e.g., Santagta & Guirno, 2011). This suggests that a structured framework for reflection is needed. Recent research indicates that *professional noticing framework* is an appropriate framework for structured reflection (Jacobs et al., 2010). In this research we built on Jacobs et al. framing of professional noticing framework, which requires PTs to: (1) identify a critical event (2) interpret the mathematical thinking of the student/s in the critical event, and (3) offer an alternative response as if they were the teacher responding to the critical event. This framework is used here to analyze authentic mathematics classroom situations that PTs observed in their clinical preparation program. We refer to these situations as *critical events*. In this study we built on Stockero and Van Zoest (2013) and Goodell (2006) definitions and define critical events as moments in the classroom that if pursued by the teacher may enhance students' mathematical learning, and therefore provide the teacher with an opportunity to reflect and thus to learn about teaching.

In most studies PTs are asked to focus on the student's mathematical thinking as it is expressed in student-teacher interactions (e.g., Jacobs et al., 2010; Simpson & Haltiwanger, 2017). This study takes a slightly different approach, and seeks to focus not only on the student but on the teacher as well. The premise is that an analysis of teacher responses is an inseparable part of the critical event

analysis and that focusing on the relationships between the student's statements and the teacher's responses in the given event will contribute to reflection. In addition, research shows that PTs struggle when it comes to offering an alternative response as if they were the teacher in critical event (e.g., Jacobs et al., 2010). Although not in the scope of this paper, we began looking for ways to support PTs to base their alternatives for teaching on the students' mathematical thinking as expressed in the event. A possible approach for achieving this aim is to direct the PTs to focus their attention to the teacher's response. The current paper takes a first step in building a characterization for the PTs' interpretations for the teachers' statements in the observed events.

This paper presents an analysis of PTs' written interpretations for a teachers' responses in critical events which were submitted during a clinical training program. We analyzed 38 reports submitted by the PTs. The reports contain PTs' analysis of the critical event according to the three elements of the professional noticing framework (Jacob et al., 2010) plus analysis of an observed teacher's response to the student. Our analysis of the reports was conducted bottom-up together with adaptations of some existing frameworks to construct a three-level rubric to assess the depth of PTs' interpretations of a teachers' response in observed critical events. This rubric may help teacher educators to gain a better understanding of their PTs' interpretations of an observed teacher's response, and therefore, may help to plan field-based training programs for teachers.

## **Literature review**

In correspondence with the importance specified above of offering interpretation to the teachers' responses in critical events, we built mainly on three bodies of research: (a) reflection, which we ask PTs to perform in the context of their clinical training; (b) critical events as a construct for reflection; and (c) teachers' professional noticing which is the basis of our structured reflection framework.

Reflection, as in analytical articulation of instructions and teaching actions in order to understand consideration that led those actions (Karsenty & Arcavi, 2017) is, according to Clarke (2000), "not just an option pursued by good teachers; rather, to teach is to reflect." (p. 201). Karsenty and Arcavi (2017) offered a bottom-up characterization for different aspects that in-service teachers attended while reflecting on observed mathematics lessons. Potari and Jaworski (2002) looked at teachers' reflection using the teaching triad framework, which perceives teaching practice as an integration of management of the lesson, being sensitive – cognitively and affectively – to the students and managing the mathematical challenge of the lesson. Teachers' reflection has been found to be a productive tool to link practice with mathematics teaching theories (e.g., Jacobs et al., 2010). Additionally, recent research suggests that teachers' involvement in deep reflection and analysis of teaching strategies and intentions may hold opportunities to learn from such examination new ways of instruction, insights and horizons (Karsenty & Arcavi, 2017). In this research we ask PTs to reflect on critical events they observed during their clinical training classroom observations. The theoretical base for critical events is cases which are descriptions of events that represent a broad pedagogical phenomenon or a dilemma with theoretical aspects (Shulamn, 1986) and which exhibit unexpected moments that are valuable in regard to students' learning (e.g., Stockero & Van Zoest, 2013). In the research literature critical events also appear as ordinary teaching-learning situations that make teachers question their practice and, through reflection, provide a gateway for the teacher to improve

his/her teaching (Goodell, 2006). As our use here of critical events is meant to promote PTs' learning about teaching mathematics, we define critical event as moments in the classroom that if pursued by the teacher may enhance students' mathematical learning, and therefore provide the teacher with an opportunity to reflect and thus to learn about teaching.

But just asking PTs to reflect on observed critical events is not enough; there is a need to teach PTs how to reflect on teaching in disciplined and structured ways (e.g., Santagta & Gurino, 2011). Therefore, the third body of research that informed this study is the teachers' professional noticing framework (Jacob et al., 2010) which is defined as: (1) attending to student thinking within student-teacher interactions; (2) interpreting student understanding based on these interactions; and (3) offering a response based on this analysis. For example, deciding when to ask students for more clarification or to follow up on a student's statements requires the teacher first to attend to the student's statement, then to interpret its mathematical meaning and then to formulate an immediate response. Therefore, these skills are considered core elements of teaching practice that should be practiced in teacher training programs (Ball & Forzani, 2009). Research focusing on cultivating these skills among PTs indicates that PTs struggle when asked to offer alternative responses for the teaching reflected in a critical event (e.g., Jacobs et al., 2010). For example, Rotem and Ayalon (2018) found that even when PTs offered a rich interpretation for the students' statements in the critical event, interpretations for the teacher's response and the suggested teaching alternatives were general in their nature and detached from the interpretation they offered for the students' statements. To date, most researchers have focused on assessing the interpretation teachers ascribe to students' statements in the event (e.g., Simpson & Haltiwanger, 2017). Interpretations for the teachers' statements were seldom in the focus of research. An exception for this is van Es et al.'s (2017) study, which investigated the development of PTs' noticing of ambitious mathematics pedagogy in the context of a video-based course designed to foster PTs' skills of interpreting classroom interactions. They used the term 'making thinking visible' to capture the extent to which the PTs attended to the teacher's role in making student thinking visible. Van Es et al. (2017) identified three levels of skill: (a) not paying much attention to the teacher's strategies making student thinking visible, but rather to management and arrangement of the students and class; (b) identifying the teaching strategies and judging their effectiveness; and (c) inferring the ways the teacher made student thinking visible, and how they influenced on student thinking and learning. For the study presented in this paper, we built on van Es et al.'s three levels of skill to develop a three-level category scheme for categorizing the depth of interpretations PTs offer for teachers' responses to students' mathematical thinking in observed critical events. Consequently, our research question is: *What are the main characteristics for the levels of interpretations PTs offer to a teacher's response in a critical event, which they identified?*

## **Research context: ACLIM-5 clinical training program**

The study took place in the context of ACLIM-5 (a Hebrew acronym meaning "clinical training for unique 5-unit (high track) mathematics teaching"). ACLIM-5 is a large university's three-year training program designed to support the development of high track mathematics pre-service teachers. Due to the limited space of this paper we will not elaborate regarding the program. We will note, however, that this study focused on the first year of the program, in which PTs study for their teaching

certificate. PTs participated in a course on critical events in which they were required to submit a critical event reports based on lesson observations. The reports consisted of four main parts: (a) prompts for describing the critical event that was identified during classroom observation, the mathematical context, and the student-teacher interaction. (b) prompts for interpreting the students' statements. (c) prompts for interpreting the teacher's response, E.g. "offer interpretations for the teacher's actions. What was going through his mind? What was it based on?" and (d) a request for alternative ways of responding, other than the teacher's response. Sections (a), (b) and (d) of the report resonance Jacobs et al. (2010) framing of professional noticing. Here, PTs' answers for (c), served as the data source for this study.

## **Data collection**

The data for this paper was taken from the critical event reports submitted in the first year of the first ACLIM- 5 course. In the course participated one male and 12 female. Five studied toward a dual degree in Mathematics and Education, and eight graduated with a B.Sc. from the university's department of Mathematics. The data consist of 38 critical events reports describing real-life classroom events from PTs' observations, submitted during the academic year.

## **Data analysis**

Data analysis was conducted in three phases. First, we used bottom-up characterization for PTs' answers within (c) section. Then we searched for compatibilities between the bottom-up characterization and research literature that was mentioned above (e.g., Potari & Jaworski, 2002; van Es et al., 2017). Finally, we built the coding scheme, using both the bottom-up and literature-based characterization.

## **Findings**

Our analysis of 38 critical reports resulted in a three-level scheme for categorizing the depth of interpretations that were assigned by PTs to the teacher's response in critical events. Van Es et al. (2017) three-level framework for analyzing PTs' attention to the teacher's making student thinking visible, served us as a base ground for developing the scheme, while using a bottom-up approach to allow other characteristics for each level of interpretation to emerge. Eventually, we have received a refined coding scheme for level of interpretation, as presented in Table 1.

**Table 1: Coding scheme for level of interpretation**

Levels of interpretation of teacher's response	Characteristics of level of interpretation
Descriptive/affective	Participant describes the teacher's response in general terms while attending to affective aspects of the students or to the management and arrangement of the students and class;
Semi interpretation	Participant points out the teaching strategies that the teacher used when responding to the students' statements; and/or judges the effectiveness of the strategies.
Full interpretation	Participant details the teaching strategies that the teacher used when responding to the students' statements and proposes considerations that may have led to the teacher's response and judges the effectiveness of the strategies.

### Low level of interpretation to teacher's response- descriptive/affective interpretation

The results of the bottom-up analysis indicated that when asked to interpret teachers' statements, PTs tended to describe teachers' statements while attending to the management and arrangement of the students and class without offering an explanation for the considerations behind the teacher's statements. This echoes van Es et al. (2017) low level of interpretation - attending mainly to management and arrangement of students and class. Some PTs interpreted the teacher's actions or statements as aiming to motivate the students by addressing their affective needs. For example, in a critical event which was described by Faith and in which the teacher asked a student to share with the class an original way of drawing the graph of  $f(x) = \sin(2x - \frac{\pi}{3})$  within the segment  $[0, \pi]$  without analyzing the function, but through transforming the basic *sin* function, Faith interpreted the teacher's response as:

- 1 He [the teacher] gave the student a positive feeling
- 2 and she [the student] felt that she had deep and beautiful thinking [...]
- 3 and this provided an opportunity for other students to think differently.

Faith started by attending to the teacher's intentions (line 1) and then she offered her interpretation of the student's feeling as result of the teacher's response (line 2). Together, lines 1-2 could imply that Faith sees the teacher's response as an expression of his attention to the student's affective aspects. Line 3 could imply either that Faith considered the teacher's response to be a way to motivate other students in the class or a way of promoting students' awareness to the different ways to solve the problem. However, Faith's interpretation is very general in the sense that it can be assigned to various lessons (not just mathematics) and it is disconnected from the specific critical event that was observed. Her general interpretation can be characterized by attending to teacher's affective sensitivity to students (Potari and Jaworski, 2002)

### Medium level of interpretation to teacher's response- Semi interpretation

The bottom-up analysis indicated that at this level PTs tended to point out at the teacher's teaching strategy and sometime judged its effectiveness but still without regarding considerations behind the teacher's statements. This echoes van Es et al. (2017) medium level of interpretation - "identifies teaching strategies and choices the teacher makes in the lesson to make thinking visible; and/or judges the effectiveness of strategies."

Vanessa observed and reported on the same critical event as Faith. Vanessa's interpretation was as follows:

- 1 The teacher enjoyed the student's response,
- 2 and shared it with the rest of the students
- 3 to see whether she was correct or not, and asked them to apply it.
- 4 When he shares the response with the class, and discusses it
- 5 it means she is going in the right direction [...]
- 6 It encourages the student to think more deeply while answering other questions.
- 7 The teacher wants to encourage students to think analogously while analyzing functions
- 8 and not just to rely on rules, so he shares the student's response with the class to discuss.

Here, in lines 2-4 Vanessa point out the teacher's strategy in the critical event - the teacher made the student's solution a focus for a whole classroom discussion. From line 3 it may follow that Vanessa sees the teacher's strategy as aiming to evaluate the student statement "to see whether she was correct or not". The effectiveness that Vanessa sees in this strategy may be seen as: (I) a way to acknowledge the student's solution (line 5); (II) a way to encourage the student to "think deeper" when approaching other questions (line 6); and (III) a way to motivate the class to adopt a different kind of approach to function analysis, one that is based on function transformation (line 7-8).

### High level of interpretation to teacher's response- Full interpretation

The characteristics of this category - *Participant details the teaching strategies that the teacher used when responding to the students' statements and proposes considerations that may have led to the teacher's response; and judges the effectiveness of the strategies* - are similar to those of the medium level of interpretation, with two modifications. First – the participant details the teaching strategies - and second - they propose considerations that may have led to the teacher's response. This characterization is meant to keep the overall language of the levels of interpretation while also echoing our purpose in interpreting teachers' responses, which is to attempt to understand the intentions, actions, statements and considerations that led to the response. This level differs from van Es et al. (2017) high level of interpretation as in this category the emphasis is on the consideration that PTs ascribe the teacher's response. An example of high-level interpretation of a teacher's response can be found in Adel's critical event interpretation. In the critical event two students, one after the other, asked the teacher whether E is the orthocenter of the triangle (the mathematical task that was at the center of the critical event is presented in figure 1).

In the isosceles triangle ABC ( $AB=AC$ ), E is the bisectors intersection point.  
When the line AE is extended, it intersects the base of the triangle at point D (see the figure).  
Given that:  $\angle ABC = \alpha$ ,  $AE=m$ .  
(a) using  $m$  and  $\alpha$  express the length segment ED.  
(b) using  $m$  and  $\alpha$  express the radius of the circumscribed circle to triangle ABC.

**Figure 1: The mathematical task that was presented in Adel's critical event.**

The teacher answered the first student privately and then, when the second student asked the same question, he facilitated a discussion with the whole class. Adel's interpretation of the teacher's response was as follows:

- 1 When the first student gave a wrong answer,
- 2 the teacher explained to him privately why what he said was wrong.
- 3 The teacher explained to the student that E is not the orthocenter of the triangle,
- 4 but rather the bisectors meeting point.
- 5 After a second student gave the same answer,
- 6 the teacher thought that there was something wrong with his [the teacher's] explanation,
- 7 and perhaps the rest of the students had also misunderstood.
- 8 So, the [teacher] asked the class: was what the student just said correct? [...]
- 9 The discussion was an effective way to understand the mistake
- 10 and for the teacher to understand why they [the students] think their answer is correct.

In the beginning of her interpretation Adel repeats the course of events (line 1-5). Then Adel offers her idea regarding what led to the teacher's response: because more than one student had this confusion the teacher might have thought that his instruction was not clear enough (line 6-7). In line 8 Adel goes back to the critical event and articulates the teacher's strategy: making the students' statements public within a whole class discussion. Adel reflects about the effectiveness of the response. She sees this strategy as a way that might help the teacher to understand his students' thinking (line 10).

Applying this three-level analytic framework to the 38 critical event reports, we found that 58% of PTs' critical event interpretations for teachers' responses were low-level, 26% of PTs' critical events interpretations were of medium level and 16% were high-level. These findings raised several thoughts regarding ACLIM-5 clinical training programs as well as theoretical insights which are elaborated in the next section.

## Discussion

Our bottom-up analysis of critical event reports together with inspiration drawn from van Es et al. (2017) rubric allowed us to categorize coding scheme for depth of levels of interpretation to an observed teacher in a critical event, which does not appear in the literature so far. The first level has a descriptive/affective nature, the second level indicates that the PT tries to interpret the teacher by pointing out the teaching strategy the teacher used and its effectiveness. In the third level, the PT offer considerations that may have led to the teacher's response in the critical event.

From a practical standpoint this scheme will guide our further research regarding the ACLIM-5 clinical preparation program, to investigate whether there is a change in the level of interpretation as PTs become in-service teachers. Furthermore, to investigate whether there is a connection between in-depth interpretation of a teacher's response in a critical event and offering a teaching alternative to that is based on the students' mathematical thinking as it is interpreted by the PT in the critical event. From a theoretical standpoint, a connection between in- depth interpretation for a teacher response in a critical event and suggested teaching alternatives, could serve as a basis for further conceptualization of the professional noticing framework by adding a subprocess - interpreting the teacher response in the student-teacher interaction - in the gap between student interpretation and suggested alternative (e.g., Jacobs et al., 2010).

## Acknowledgment

# Using Concept Cartoons in future primary school teacher training: the case of problem posing and open approach

Libuše Samková<sup>1</sup>

<sup>1</sup>University of South Bohemia in České Budějovice, Czech Republic; [lsamkova@pf.jcu.cz](mailto:lsamkova@pf.jcu.cz)

*The contribution focuses on an educational tool called Concept Cartoons from the perspective of problem posing activities of future primary school teachers within the framework of the open approach to mathematics. It introduces Concept Cartoons, the open approach to mathematics, and a small qualitative empirical study conducted with future primary school teachers. The aim of the presented study is to observe how open might be problems posed by future primary school teachers in the Concept Cartoon form. The results of the study confirm that Concept Cartoons can be successfully employed in problem posing activities and that they have a potential from the perspective of the open approach to mathematics.*

*Keywords: Concept Cartoons; elementary school teachers; mathematics education; open approach to mathematics; preservice teacher education.*

## Introduction

The study presented here reports about an educational tool called Concept Cartoons, and about the way how the tool can be employed in future primary school teacher training. In particular, it will focus on the possibility to use Concept Cartoons during problem posing activities and observe the posed Concept Cartoons from the perspective of the open approach to mathematics. The study follows up the contributions of me and my colleagues from previous CERME and ERME conferences, as it discusses mathematics problems of a given structure and their employment in future teacher training (Tichá & Hošpesová, 2015), problem posing of future teachers (Tichá & Hošpesová, 2010), and future teachers facing or composing potential pupils' misconceptions in the Concept Cartoon form (Samková & Hošpesová, 2015; Samková, 2017; Hošpesová & Tichá, 2017). The issues of teachers posing problems and teachers facing potential pupils' misconceptions are the topics that have been broadly discussed at CERME and ERME conferences in TWGs related to teacher professional development, e.g. by Malaspina, Mallart and Font (2015), Milinković (2017), Kuntze and Friesen (2017). The topic of Concept Cartoons is close to the concept of polyvalent math tasks presented at CERME by Hellmig (2010).

In the following text, I will introduce the idea of Concept Cartoons and my experience with them, and the open approach to mathematics. Then I will describe an empirical qualitative study addressing the following research question: “*How open are problems posed by future primary school teachers in the Concept Cartoon form?*”

## Theoretical background

### Concept Cartoons

An educational tool called Concept Cartoons appeared in Great Britain more than 20 years ago (Keogh & Naylor, 1993), in order to support discussion and involvement of primary school pupils during science lessons. Later the tool also expanded to other school subjects and school levels.

Concept Cartoon is a picture showing a situation familiar to pupils from school or everyday reality, and several children discussing the situation in a bubble-dialog. Each bubble presents an alternative viewpoint on the pictured situation. The alternatives might be correct as well as incorrect; the correctness also might be unclear or conditioned by circumstances not mentioned in the picture. Sometimes the picture includes a blank bubble with just a question mark, to indicate that there might be other alternatives not presented in the picture yet. For a sample see Fig. 1.

**Figure 1: An original Concept Cartoon with three correct bubbles, one incorrect bubble, and a blank bubble; taken from (Dabell, Keogh, & Naylor, 2008: 4.11)**

When working with Concept Cartoons in the classroom, pupils are asked to decide which children in the picture are right and which are wrong, and justify the decision. In that setting, it turned up that the lack of agreement amongst the pictured children encourages the pupils to join the discourse and defend their opinions (Naylor, Keogh, & Downing, 2007).

Besides the original classroom use, we started to consider each Concept Cartoon as an educational model of a contingent situation (Samková & Hošpesová, 2015), and more widely as a representation of practice oriented on diagnostic purposes (Samková, 2018b). In that sense, Concept Cartoons do not cover all aspects of school practice but might be regarded as a result of a decomposition of practice according to Grossman et al. (2009). Following this line, I created my own set of Concept Cartoons and accompanied them by a list of indicative questions focusing more deeply on conceptions and misconceptions probably hidden behind individual bubbles (Samková, 2018b). We included these Concept Cartoons as a diagnostic tool in future primary school teacher training, and conducted several studies: on aspects of pedagogical content knowledge (Samková & Hošpesová, 2015; Samková, 2018b), reasoning on selected topics (Samková & Tichá, 2017), or comparison between information on mathematics content knowledge that can be obtained through Concept Cartoons and through word problems in standard written tests (Samková, 2018a). In this paper, I will focus on Concept Cartoons within the framework of open approach to mathematics.

## Open approach to mathematics

Open approach to mathematics is a method of mathematics teaching that employs problems called open. These problems have multiple levels of grasping (i.e. their starting situation is open), multiple correct ways of solving (i.e. their process is open), multiple correct answers (i.e. their end products are open) and/or multiple ways to transform the problem into a new one (i.e. ways to develop are open) (Nohda, 2000; Pehkonen, 1997). Such problems allow us to perceive mathematics in all its diversity. For samples see Table 1. Also Concept Cartoons themselves may be considered as open problems, since they present various alternatives (of grasping, solving, solutions) in their bubbles.

There are 4 beds of seedlings in a forest nursery, each of them having 5 rows with 240 seedlings. How many seedlings are there?	starting situation is open (it is not clear whether 240 is the amount for each of the rows, or altogether for all 5 rows);  process is open (for the first case above: we may count the number of rows in all beds and multiply it by 240, or count the number of seedlings in one bed and multiply it by 4);
90-minute tickets in Prague cost 32 crowns; 24-hour tickets cost 110 crowns. How much will Ivan pay for the tickets on a weekend trip?	starting situation is open (we do not know how much or how often will Ivan travel around the city, how long the trip will last: less than 24 hours? more than 48 hours? how much more? ...);  end products are open (there are 13 different solutions, from minimal pay of 0 crowns, to maximal pay of 330 crowns).

**Table 1: Samples of open problems (left), with their open-approach characteristics (right)**

Open problems that have multiple solutions of different levels of difficulty while every pupil is probably able to find a solution appropriate with his/her actual knowledge are called polyvalent (Hellmig, 2010). The Concept Cartoon from Fig. 1 might be considered as polyvalent, since it has three different correct bubbles, and each of the them requires a different level of knowledge to justify its correctness: the easiest is the bottom left bubble where the discounts are in the same order as in reality in the shop; the top right bubble deserves an additional knowledge that changing order of discounts does not change the final price; the bottom middle bubble is the most difficult, it is the only one with some other calculations behind. The incorrect bubble (top left) deserves another type of knowledge – that a combination of discounts cannot be solved by their addition.

## Design of the study

### Participants

Participants of the research were 29 future primary school teachers – full time students of the 5-year teacher training program at our university. They had already finished all mathematics content courses of the program, and in the time of the study they were attending the course on didactics of mathematics. During the mathematics content courses the participants had several times worked with Concept Cartoons, discussing them in the classroom or responding in written form to various sets of questions related to them, i.e. they got familiar with the format of Concept Cartoons.

## Course of the study

In the data collection stage, the participants were asked to create their own Concept Cartoon that could be assigned to primary school pupils during a mathematics lesson. They worked on the task individually, in the form of a compulsory written homework where they introduced the Concept Cartoon, and gave a short explanation of the task and the bubbles.

During data analysis I searched for answers to the research question “How open are problems posed by future primary school teachers in the Concept Cartoon form?”. I processed collected data qualitatively, using open coding and constant comparison (Miles & Huberman, 1994). During open coding I focused on the composition of the Concept Cartoon, on its mathematical correctness, and on displays of openness in relation to Nohda’s definition of open problems (2000). For better arrangement, some of the codes were denoted by plus or minus sign to distinguish between positive and negative aspects (correct or incorrect format, open or non-open parameters of the task, etc).

The following code categories appeared as relevant for my study:

- A. the format of the Concept Cartoon (this category included codes *proper format, improper format, no bubbles, no alternatives, each bubble solves a slightly different task, independent bubbles, conditional bubbles*, etc.);
- B. grasping of the task in the picture and its levels (codes *unique, multiple, unclear, too open to be comprehensible, various parameters, diverse interpretations of the assignment*, etc.);
- C. ways of solving the task in the picture (codes *unique, multiple, diverse procedures offered in bubbles*, etc.);
- D. number of solutions and their interpretations (codes *unique solution, multiple solutions, unique interpretation, multiple interpretations of unique solution*, etc.);
- E. difficulty and smartness of the posing process (codes *detailed preparation needed, smart pre-calculations made*, etc.).

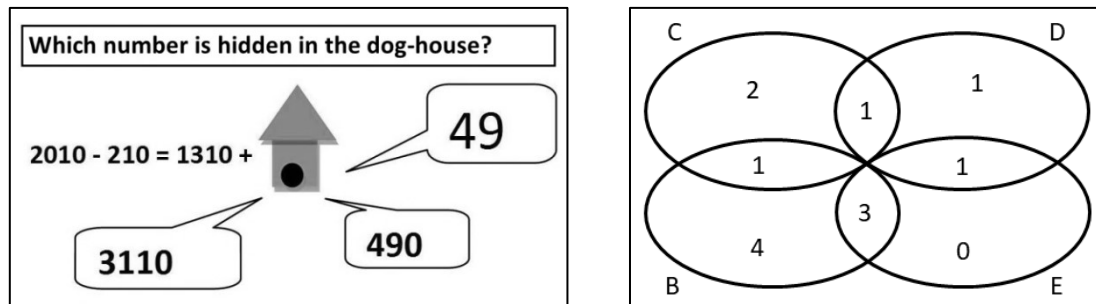

Subsequently, I analysed the codes and categories in order to divide the participants into groups according to the level of openness provided in their Concept Cartoons. Since each Concept Cartoon that is properly formatted might be considered as an open task, the participants who were not able to pose their Concept Cartoon in a proper format were assigned to the lowest level group named LL. The other participants were assigned to groups named L#, where # stands for a number from 1 to 4 denoting in how many code categories of B to E did the individual participant cause positive codes.

## Findings

### Improper vs proper format of the Concept Cartoon (category A)

Three of the participants composed their Concept Cartoon in an improper format; they form the LL group. These participants offered either a picture without bubbles or a picture with bubbles that discussed diverse situations not much related to the picture.

Thirteen of the participants composed the Concept Cartoon in a proper format but with no other openness: they prepared a task with a unique solution, grasped it unambiguously, and did not considered multiple correct ways of solving (see Fig. 2a). These participants form the L0 group.

**Figure 2: The Concept Cartoon posed by Beata, translated from Czech (left); numbers of participants displaying particular open aspects in their Concept Cartoon (right)**

### **Openness of the Concept Cartoon with proper format (categories B to E)**

The other participants composed a properly formatted Concept Cartoon that can be considered as open: seven of them caused positive codes in one of the categories B to E (they form the L1 group), six of them caused positive codes in two of the categories B to E (they form the L2 group). The distribution of the participants among the code categories with positive codes is shown in Fig. 2b, a detailed description of particular open aspects is given in the following text.

### **Multiple levels of grasping the task in the picture (category B)**

Eight of the participants presented in their bubbles various ways how the pictured task might be grasped. For instance, Francis prepared a task about clocks (Fig. 3), and contrasted various possible ways of grasping the term "most hours". Her Concept Cartoon provokes many questions: "What does it mean most hours?", "Shall we take the biggest number in the notation, or the latest hour?", "Is 10 in the morning the same as 10 in the evening?". Annie prepared a task about 30 candies in a bag, and contrasted relative and absolute meanings of numbers (see Fig. 10 in Samková & Tichá, 2017). Morris prepared a practically based task about part-time job offers, and contrasted three different ways to make money (weekly wage, monthly wage, and daily task wage; see Fig. 8 in Samková & Tichá, 2016).

**Figure 3: The Concept Cartoon posed by Francis, translated from Czech**

### Multiple correct ways of solving the task (category C)

Four of the participants posed tasks that allow multiple correct ways of solving; e.g. Viola offered in her bubbles two diverse ways of solving a task about Easter eggs (see Fig. 4).

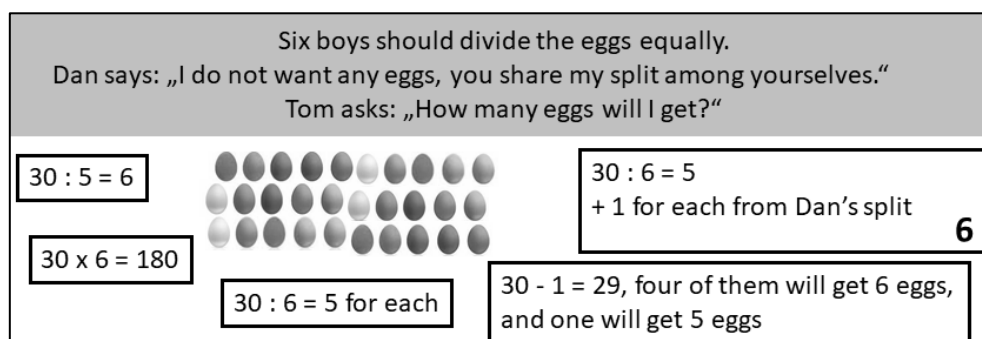

Figure 4: The Concept Cartoon posed by Viola, translated from Czech, graphically adjusted

### Multiple correct answers to the task (category D)

Only two of the participants posed tasks with multiple solutions. Tammy prepared a wordless Concept Cartoon based on a geometric task with two different solutions (see Fig. 7 in Samková & Tichá, 2016), Diana prepared a task with eight different solutions (see Fig. 6 in Samková & Tichá, 2016). In each of these Concept Cartoons, the particular solutions of the task are of the same difficulty, based on a common idea, i.e. these Concept Cartoons cannot be considered as polyvalent.

One of the participants (Helen) posed a task with a unique solution but interpreted the solution in multiple ways. In her bubbles she described various properties of the solution.

### Difficulty and smartness of the posing process (category E)

Four of the participants presented Concept Cartoons that required detailed preparation of the content of bubbles and smart pre-calculations; all of them belong to L2 group. For instance, Morris in his Concept Cartoon about part-time jobs prepared five bubbles based on diverse wage conceptions but the diverse calculations hidden behind particular bubbles lead to numbers that are almost the same. Since the aim of his task is to compare the jobs and find the most suitable one, such an arrangement makes the task open for wide discussions. Ruth in her task about who is the fastest runner assigned that Rex ran 10 rounds in 3 min 20 sec, Punt'a ran 7 rounds in 2 min 27 sec, and Max ran 5 rounds in 1 min 50 sec. One of the misconceptions in her Concept Cartoon originated in an erroneous conversion of the times into decimal notation (e.g. 3 min 20 sec converted to 3.20 min). She prepared the numbers in the assignment so smartly that with that erroneous conversion the order of the runners differs from the order in the correct solution.

### Conclusions

The presented study hopefully enriched the puzzle on *“How can we meaningfully employ Concept Cartoons in future teacher education”* by another piece of knowledge, by studying the tool during problem posing activities within the framework of the open approach to mathematics and by looking for answers to the research question *“How open are problems posed by future primary school teachers in the Concept Cartoon form?”*.

The results confirmed that Concept Cartoons can be successfully employed during problem posing activities, and that they have a potential also from the perspective of the open approach to mathematics. Although for the participated future primary school teachers it was the very first opportunity to create their own Concept Cartoons, almost all of them were able to compose a properly formatted Concept Cartoon, and almost half of them were able to compose a Concept Cartoon that positively displayed openness in one or two of the following aspects: multiple levels of grasping the pictured task, multiple correct ways of solving the task, multiple number of solutions and their interpretations. Some of the participants also proved their ability to thoroughly think about the task they pose, and presented Concept Cartoons that required detailed preparation and smart pre-calculations.

The described results of problem posing activities of future primary school teachers also illustrate how Concept Cartoons may help to elaborate a wide range of pedagogical content knowledge: authors of the Concept Cartoons had to pose an appropriate mathematical problem, present at least one of its correct solutions and several possible pupil misconceptions, and combine them into one complex bubble-dialog task.

Such results are in accordance with the recent research showing the importance of implementation of mathematical problem posing activities into future teacher education (Singer, Ellerton, & Cai, 2015).

<sup>2</sup>University of Kassel, Germany; [borromeo@mathematik.uni-kassel.de](mailto:borromeo@mathematik.uni-kassel.de)

*As part of the PRONET project of the University of Kassel<sup>1</sup>, the further development of teacher training through the "implementation of a coherent professionalisation concept" is being investigated. The aim of the subproject is to combine mathematical-didactic knowledge with pedagogically relevant and cognitive-psychologically anchored concepts, including the "desirable difficulties". The generation effect is one of the four best-known "desirable difficulties" and aims to ensure that knowledge is not merely predetermined but is generated to a certain extent from one's own knowledge. In order to achieve this, we have developed for the first time generation tasks on mathematical-didactic topics of a basic lecture for mathematics teachers at their study beginning. The generation tasks and first results are part of this paper and are complemented by the basic theory of "desirable complications".*

*Generation effect, mathematics didactics, desirable difficulties, mathematical-didactic knowledge, teacher education*

## Theoretical Background

The focus of this contribution lies on the generation and is reflected approach by the university students. For this reason Generation and generation tasks in mathematics didactics training of future teachers are illustrated more detailed.

### Desirable difficulties of learning

One possible encouragement of sustainable knowledge building is the concept of 'desirable difficulties' (Bjork, 1994, 2011; Lipowsky et al., 2015). The term "desirable difficulties" is a cognitive psychological concept and a didactic procedure that makes learning more difficult in the short term, but sustainable with the goal to a better retention of the learning content (ibid.). Desirable difficulties include such popular techniques as the testing effect, the distributed learning, the generating effect, and the interleaving practice (Bjork & Bjork, 2011).

### Generation effect

The generating effect appears, when the information is generated from own knowledge (e.g. Salmecka & Graf, 1978). The focus of our research is on the generation effect. This effect has been recognized, reproduced and characterized as extremely stable within controlled learning environments and with simple learning content (e.g. word pairs) (Slamecka & Graf, 1978; Bertsch

---

<sup>1</sup> The project is financed as part of the PRONET project from the "Quality Initiative for Teacher Education" programme of the Federal Ministry of Education and Research in Germany.

et al., 2007). Chen et al. (2015) have shown that the generation effect is more distinctive if very less is dictated by the task itself or by solution examples and teacher interference. They also found that this increase and stabilisation of the generation effect depends on the type of task. While learners benefited more from the generation in simple tasks, the learning outcomes in complex tasks through guided learning were higher (ibid.). In the field of mathematics, the generation effect is only within the framework of multiplication tasks (cf. McNamara & Healy, 2000) but is not researched with reference to mathematical-didactic knowledge. It becomes clear from the previous studies that generation tasks can extend beyond word pair formation, but that the complexity should not be increased immeasurably, otherwise there is a danger that there will be no more lasting learning effect.

### **Generation and generation tasks in mathematics didactics training of future teachers**

Generation in mathematical didactics means therefore to stimulate the cognitive thought processes of the students and to have new information generated from themselves by means of suitable generation tasks. The self-dependent generation of knowledge takes place within the framework of mathematics didactic generation, for example by linking to previous experiences, for example by generating examples. Another possibility is the creation of individual memory aids in which students use their personal thinking structure to memorize new knowledge. In particular, it should be noted that the generation tasks developed include the basic, recurring contents of mathematics didactics on the one hand and are not too complex in terms of the task and the focus of content on the other. In addition, it must be taken into account that the prospective teachers can build on their own knowledge, although the "new knowledge" cannot be presented to them in advance, otherwise there is no generation effect. Therefore, the above-mentioned lecture contents were chosen which are simple enough to dispense with illustrated examples and complex enough to serve as a basis for further study and structural (mathematical-didactic) expertise (Borromeo Ferri & Schäfer, 2017).

### **Research questions**

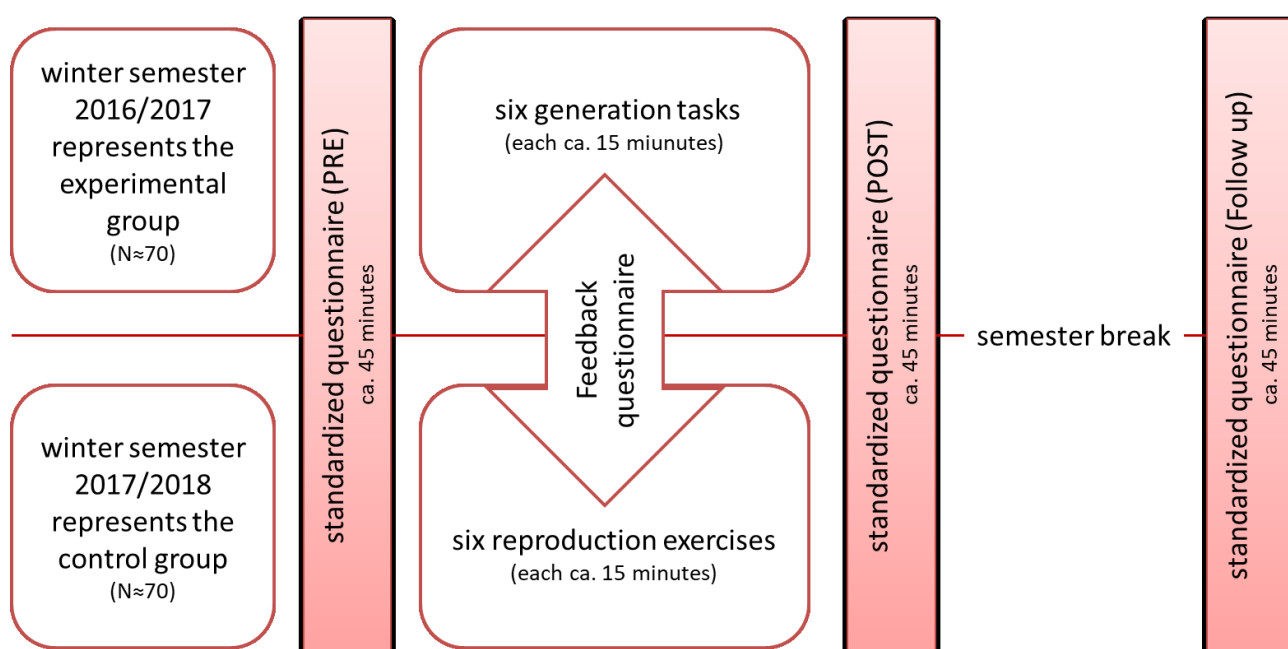

On the basis of the theoretical background to the generation effect, it was shown that the specific generation can be regarded as a research gap in mathematics didactics. It is to be examined whether and how the generation effect is shown by the use of generation tasks with a mathematical-didactic focus and how effectively the knowledge thus acquired is consolidated among the students. An all-encompassing answer to this main question is not yet possible at this point in time, as the statistical data could not yet be fully evaluated. Therefore, in this paper we limit ourselves to demonstrating what marked generation tasks and highlight the following two research questions:

1. Are there any differences between the generation and reproduction cohort regarding the perception of the learning process?
2. Are there any differences between the generation and reproduction cohort regarding the perception of the tasks?

## Methodology

The study is conceived as a prospective and hypothesis-generating comparison of two cohorts attending the mathematics didactic basic lecture at the University of Kassel, Germany. The cohort of the winter semester 2016/2017 represents the experimental group and works on the generation tasks. The control group is represented by the cohort of the winter semester 2017/2018 and works on the reproduction tasks. The teacher training students attend the lecture for the first time and are on average in the 1st to 3rd semester. The semester differences are due to the fact that the lecture is attended by various teacher training courses (secondary school, grammar school and vocational school). In order to ensure the comparability of the two cohorts, both the lecture contents and their sequence are held identically by the same professor in both years. Likewise, all questionnaires, feedback forms, the subject areas of the tasks used and the survey times are identical. The study design is graphically illustrated below (Fig. 1).

**Figure 1: study design**

Due to the fact that this paper has put the emphasis on generation tasks, an insight into what generation tasks are will now be given. The aim of these tasks, as explained above, is to move students of teaching professions to generate their own knowledge out of themselves in a mathematics didactic basic lecture. What does it mean to generate knowledge and how should this be done? Producing knowledge out of them means nothing other than that the teacher training students open up new fields of mathematics didactics for them with little input. For example, the general mathematical competences will be addressed within the framework of the lecture. This is followed by a generation task, which calls for a memory aid to be considered in order to memorize these six competencies. The desirable difficulty for the teacher training students now consists in using a useful memory aid for them without knowing the deeper theoretical contents of the competences. The theoretical contents of the mathematical competences are discussed after the

generation task. In this approach, the main difference to reproduction tasks also becomes clear, since these are always carried out after a theoretical input and usually allow this to be summarised. An exemplary comparison of generation and reproduction tasks in the field of general mathematical competences is given in Table 1. A total of six grading tasks have been developed and applied for use in the mathematics didactic basic lecture. These deal with basic mathematical-didactic content on the topics (1) mathematical educational standards, (2) general mathematical competences, (3) mathematical competence: mathematical modelling and the modelling cycle, (4) mathematical competences: solving problems mathematically, (5) mathematical thinking styles and (6) psychology of mathematics.

**Table 1: Example Generation and Reproduction Task<sup>2</sup>**

generation task
<p>The general mathematical competences of the lower secondary level are:</p> <ul style="list-style-type: none"> <li>• argue mathematically</li> <li>• solve problems mathematically</li> <li>• mathematical modelling</li> <li>• use mathematical representations</li> <li>• to deal with mathematics symbolically/formally/technically</li> <li>• communicate mathematically</li> </ul> <p>Create a personal memory aid to memorize general mathematical skills.</p> <p>Explain (briefly) your procedure and briefly justify your choice of memory aid.</p>
reproduction task
<p>Julia, Stefan, Sarah, Carsten and Nadine take the school bus to school every morning. Since they get on at the first stop, they always manage to sit in the five seats of the last row. One day Julia remarks: "The school year takes about 210 days. Is it possible that we five always sit in the last row in different ways?"</p> <p>What is the guiding idea behind the task? Which mathematical competence(s) are relevant to answer the question?</p>

In order to answer the research questions underlying this paper, we have developed, used and evaluated a feedback questionnaire that students of teaching professions can use with regard to their perception of the learning process and their perception of the tasks questioned. The perception of

<sup>2</sup> Translation of the German original by the authors.

the learning process questions whether there has been in-depth information processing or whether students have perceived it as in-depth information. This scale comprises four items, an item example is here: "I have succeeded in developing my own thoughts and ideas on this subject". The perception of the tasks questions to what extent the students come to the conclusion that the respective task was meaningful, helpful, stimulating or similar. This scale comprises five items, an item example for this is "The task used in the pre-presentation illustrates the benefit of the learning content". The two perceptions were recorded using a 6-stage, end-point-based scale. The scale ranges from the negative endpoint "Does not apply at all", which is rated one in the evaluation, to the positive endpoint "Fully applies", which is rated six. In order to analyse the differences, a grouping variable was first created that distinguishes between the cohorts and their tasks in generation tasks and non-generation tasks (reproduction tasks). Subsequently, a scale was introduced for each perception and each task, so that in the end 12 scales were created. Six scales for the perception of the learning process and six scales for the perception of the tasks. These 12 scales were checked for their one-dimensionality by means of a main component analysis (PCA), which turned out to be given for all of them. The scales for the perception of learning process show a reliability of  $0.85 \leq \alpha \leq 0.90$ . The scales for the perception of the tasks show a reliability of  $0.76 \leq \alpha \leq 0.87$ . All items can be described as selective in their respective scales. Due to the sample size of  $N = 117$  student teachers, the verification of the normal distribution has been recorded. For this reason, a T-test for independent samples is performed to investigate the differences and Cohan's  $\delta$  is calculated manually to determine the effect strength<sup>3</sup>.

## Results

1. Are there any differences between the generation and reproduction cohort regarding the perception of the learning process?

When the mean values and the standard deviation are considered for the first time, the first differences can be seen purely descriptively on all task scales with the exception of the scale for the fourth task. These descriptive mean differences are checked by means of a T-test for independent samples. It turned out that two of the six task scales for the perception of the learning are a significant difference in the mean value in favor of the cohort that worked with the generation tasks. This significant mean difference is reflected in the tasks three and five. Task three is the generation task that deals with the mathematical competence of mathematical modeling and the modeling cycle. This is a medium effect ( $\delta = 0.63$ ). Task five contains the three levels of representation according to Bruner (enactive, iconic, symbolic) (Brunner et al., 1971). This is an almost medium effect ( $\delta = 0.48$ ).

Table 2 below gives an overview of all mean values, standard deviations, sample distribution, significance level and effect strength for the respective task scales one to six.

---

<sup>3</sup> Cohan's d is calculated using the online calculation tool: <https://www.psychometrica.de/effektstaerke.html> and to the rehearsal again with <http://www.soerenwallrodt.de/index.php>.

**Table 2: table of results for the perception of the learning process**

	perception of the learning				level of significance	Effect strength Cohan's $\delta$
task number		<i>N</i>	<i>MW</i>	<i>SD</i>		
1	GA	73	4,03	0,86	p=0.204	
	NGA	35	4,25	0,81		
2	GA	65	4,19	0,86	p=0.720	
	NGA	35	4,25	0,72		
3	GA	73	4,63	0,68	p=0.003	0.63
	NGA	35	4,16	0,90		
4	GA	65	4,06	1,05	p=0.961	
	NGA	35	4,07	0,82		
5	GA	65	4,40	0,75	p=0.023	0.48
	NGA	35	3,99	0,98		
6	GA	66	4,10	0,76	p=0.086	
	NGA	35	3,81	0,82		
GA = generation tasks and NGA = non-generation tasks						

2. Are there any differences between the generation and reproduction cohort regarding the perception of the tasks?

The second question dealt with the question of whether differences in the perception of the tasks of the two cohorts were recognizable. Here, too, the first mean value differences could be seen purely descriptively on all six scales. A T-test for independent groups was also performed to test the significance of the differences. It was found that the performance of the cohorts in two tasks differed significantly. These significant differences were seen in the scales for tasks three and four. Task four dealt thematically with the graduated aid according to Zech (1996). It is striking that the significant effect was only in the case of task three in favor of the cohort that worked with the generation tasks. This is a medium effect ( $\delta = 0.52$ ). In the case of task four, the effect in favor of the not yet generation group is significantly positive, although this is only weak ( $\delta = 0.38$ ).

Table 3 below gives an overview of all mean values, standard deviations, sample distribution, significance level and effect strength for the respective task scales one to six.

**Table 3: table of results for the perception of the tasks**

task number	perception of the tasks				level of significance	Effect strength Cohan's $\delta$
		<i>N</i>	<i>MW</i>	<i>SD</i>		
1	GA NGA	73 35	3,92 4,29	1,08 0,77	p=0.078	
2	GA NGA	65 35	3,91 4,31	1,10 0,94	p=0.071	
3	GA NGA	73 35	4,67 4,25	0,80 0,92	p=0.014	0.52

6	GA NGA	66 35	3,86 3,52	1,06 0,86	p=0.103	
GA = generation tasks and NGA = non-generation tasks						

## Conclusion

The differences determined in the course of the T-test provide initial indications of a possible effect of the generation tasks, as these are assessed by the students as being much more meaningful. They acknowledge the in-depth information processing and the value of the transfer and assess it positively. As part of a further study, we also analyse the extent to which students have gone through a "generational process". In order to be able to work this out, the generation tasks and interviews are evaluated with regard to the solution process and reflection. The first interview and task analyses showed that the experimental cohorts were able to reproduce the contents of the generation tasks better than the control cohorts were able to reproduce the contents of the reproduction tasks. Furthermore, an initial analysis has shown that no appreciable proportion of self-reflection is discernible in the context of reproductive tasks. In contrast, there are different approaches to reflection in the solutions of the generational tasks. On the one hand, individual solution steps are reflected and corrected if necessary. On the other hand, the individual participants reflect the entire solution process. In particular, the reflexion-in-the-action (Korthagen et al., 2002) is very pronounced in the generation tasks. One possible reason may be that the generation tasks address deeper cognitive structures, similar to problem-solving tasks, and thus their contents are anchored more sustainably in the memory. So far, however, the results are purely indicative, as only a few interviews and task solutions of the teacher training students have been evaluated so far. For this reason, it is necessary to deepen the analyses in the upcoming research process. For this purpose it is planned to develop a detailed coding manual for the analysis of the generation tasks and interviews on the one hand and to evaluate the questionnaire and the knowledge tests on the other hand. Further evaluations then compare the cohorts and include other factors such as choice of

subjects, motivation (MOLAMA), learning strategies, mathematical thinking, study satisfaction or mathematical convictions.

*The study described in this paper accompanies a three-year R&D project that is currently in its final year. Participants are 25 high school mathematics teachers, of whom 14 have started their 2<sup>nd</sup> year and 11 are currently in their 3<sup>rd</sup> year of integrating Mathematical-News-Snapshots in their classes. This study examines the effect of integrating these snapshots in the ordinary high school curriculum on the development of several components of Mathematical Knowledge for Teaching. The findings indicate that teachers perceive the integration of Snapshots of contemporary mathematics as contributing to the development of their Specialized Content Knowledge, Knowledge of Content and Students, and Horizon Content Knowledge.*

*Keywords: Specialized Content Knowledge, Knowledge of Content and Students, Horizon Content Knowledge, Mathematical News Snapshots (MNSs).*

## Theoretical background

### Knowledge of mathematics teachers

Over the past few decades, the mathematics education research community has become interested in characterizing the required knowledge for mathematics teaching. Shulman (1986) recognized that the required teacher's knowledge is unique and suggested two main types of knowledge teachers required, not necessarily in mathematics: Subject Matter Knowledge (SMK) – a deep understanding of the subject matter, and Pedagogical Content Knowledge (PCK) – a repertoire of representations, analogies, models, explanations, and demonstrations.

Relying on Shulman's work, Ball & Bass (2003) attempted to distill the knowledge required from mathematics teachers. They defined the term "Mathematical Knowledge for Teaching" (MKT) as knowledge that crosses areas and levels of school mathematics, knowledge that supports connected ideas of the mathematics teacher, and emphasizes the ability to plan, evaluate, integrate and manage appropriate mathematical content for teaching. Following this work, Ball, Thames & Phelps (2008), presented six different components of mathematical knowledge for teaching. Three of them are particularly relevant to this study:

- Specialized Content Knowledge (SCK). This component includes the mathematical knowledge and skills unique to teaching that is not typically needed for purposes other than teaching, such as searching for student errors, intelligent integration of examples during instruction;
- Knowledge of Content and Students (KCS). This component combines knowing about students and knowing about mathematics, namely, knowing how students think, what may confuse them, what kind of mathematical task may be easy or difficult for them, and more. This kind of knowledge requires an interaction between specific mathematical understanding and familiarity with students and their mathematical thinking;

- Horizon Content Knowledge (HCK). “Horizon knowledge is an awareness of how mathematical topics are related over the span of mathematics included in the curriculum” (ibid p. 403).

Ball & Bass (2009) suggested a more detailed definition of HCK:

“knowledge as an awareness – more as an experienced and appreciative tourist than as a tour guide – of the large mathematical landscape in which the present experience and instruction is situated. It engages those aspects of the mathematics that, while perhaps not contained in the curriculum, are nonetheless useful to pupils’ present learning, that illuminate and confer a comprehensible sense of the larger significance of what may be only partially revealed in the mathematics of the moment.” (Ibid ,2009, p. 5).

They present four components of HCK: A sense of the mathematical environment surrounding the current “location” in instruction; major disciplinary ideas and structures; key mathematical practices; core mathematical values and sensibilities.

There is a strong connection between MKT components and mathematical quality of instruction (Hill et al., 2008; Ma, 1999). Teachers with a strong MKT can present their students with rich mathematical links, representations and examples beyond what is given in most textbooks. These teachers are familiar with the curriculum and with ways to relate students to various subjects. In contrast, teachers with a poor MKT have a limited arsenal of examples to cater to diverse student needs.

### **The Mathematical News Snapshots project**

Mathematics is a dynamic field that is developing constantly. The current number of publications in the mathematical reviews database is presently over three million, and over 80,000 additional reviewed papers are added to the database each year (American Mathematical Society, 2018). However, school mathematics curricula generally do not reflect this dynamic nature nor the constant struggle of mathematicians to discover new results. As a result, high school graduates often graduate while erroneously perceiving mathematics as a field in which all questions and answers are known in advance, and there is little space for further research (Amit & Movshovitz-Hadar, 2011). In some countries, this situation has led to a decline in enrollment to mathematically intensive academic studies, and even developed into an economic, social, and national concern (Noyes & Adkins, 2017).

The Mathematical News Snapshots (MNSs) project, in which the current study is situated, was set up to provide a better perspective of the nature of contemporary mathematics by introducing high-school students to current frontiers in the rapidly growing area of mathematics (Movshovitz-Hadar, 2008). The chosen method was to prepare high school teachers to interweave snapshots of mathematical news in their teaching on a regular basis. Each MNS is developed in the form of a PowerPoint presentation, with three main characteristics (Amit & Movshovitz-Hadar, 2011): (i) A new mathematical result published in the professional literature in the past few decades; (ii) Exposition of about 25 minutes focusing on the new result, elaborating on its history, the main underlying ideas, and the people involved in the field; and (iii) Taking into account students’ limited background, preferably linking it to some topics in the mandatory curriculum, without harming the progress in their teaching.

The current study focuses on one question – *how do high-school mathematics teachers perceive the contribution of integrating MNSs (in their mathematics lessons) to the development of their*

*Mathematical Knowledge for Teaching?* This study is part of a larger research program that examines the experiences of teachers as well as of students participating in the MNS project.

## Method

**Setting:** Mathematics teachers participating in the MNS project attend a dedicated three-year professional development program. This program involves both face-to-face meetings and online meetings in which teachers are getting acquainted with seven MNSs each school year (Grades 10-12) and hold discussions about the mathematical, historical, and innovative contents of the MNSs. Following the implementation of each MNS in their classes, teachers are required to document their experiences (e.g., their own reflections and their students' responses) into an online database via a dedicated proprietary software called "Ramzor" (lit. Traffic Light). These reports often entail information regarding students' comments and classroom atmosphere, as well as suggested accompanying activities, recommended videos, and questions regarding possible mistakes in the presentation. The project staff provides ongoing one-on-one support for each participating teacher. To date, we have completed two and a half (out of three) years of our longitudinal study.

**Sample:** The participants are 25 high school mathematics teachers who volunteered to participate in the MNS project: 14 teachers have integrated MNSs for one year ("beginning teachers" – Group A), and 11 teachers have integrated MNSs for two consecutive years with the same students ("continuing teachers" – Group B). (They are continuing this year, but the data is restricted to the 2<sup>nd</sup> year).

**Research instruments:** Three data collection instruments are used in this study: Teacher questionnaires, teacher interviews, and field notes.

Teacher questionnaires. At the beginning of the first year (prior to the students' first introduction to the MNSs) and at the end of each school year, each participating teacher is asked to complete a questionnaire. The questions involve three types of items: 5-level Likert-type scale items, multiple-choice items, and open-ended items. The intention was to trace the development of teachers' MKT following the integration of MNSs in their lessons. The questionnaires were constructed with, and validated by, a team of mathematics education experts.

Participants' interviews. We conducted an informal semi-structured interview with each teacher at the end of each school year, in the form of a friendly conversation conducted online via video chat. The interviews dealt with the considerations that guided the teacher in integrating the MNSs.

Field notes – Analysis included all (and only) comments made by teachers on the proprietary software and during conversations with the project staff.

**Data analysis:** We utilized a qualitative research paradigm, implementing a process of open and axial coding, to identify the main categories and sub-categories (Corbin & Strauss, 2008). At the first stage, the teachers' responses to the questionnaires were analysed, to generate preliminary categories. In the second stage, the data analysed from the observations and interviews in order to identify and map the initial categories. We identified a correlation between the reports received from the final evaluation questionnaire and the knowledge obtained from the interviews that supports the findings (Miles & Huberman, 1994). In the third phase of the analysis, while reviewing the findings of the first and second stages, we focused on the data related to the development of key components of MKT.

## Findings

The integration of the MNSs introduced teachers to diverse and innovative mathematics contents, in a systematic and structured manner. The teachers' experience in integrating the MNSs led to the development of various teachers' knowledge components, as they perceived it. Some of which are presented below.

### Teachers' perceptions about Integrating MNSs as a lever for the development of their mathematical knowledge

In each end-of-year questionnaire the teachers were asked to relate to the contribution of the integration of the MNSs to their mathematical knowledge, both in the context of school curriculum and beyond the curriculum. Table 1 presents the distribution of teachers' degree of agreement with the statement: To what extent did the integration of MNSs in your mathematics lessons contribute to the expansion of your mathematical knowledge?

Teachers		Degree of Agreement				
		Very Large	Large	Medium	Little	Not at all
Group A (N=14)	Curricular context	14.29	14.29	7.14	57.14	7.14
	Extracurricular	28.57	28.57	28.57	7.14	7.14
Group B (N=11)	Curricular context	9.09	0	36.36	45.46	9.09
	Extracurricular	18.18	27.27	36.37	18.18	

**Table 1: Teachers' grading of their mathematical knowledge development, according to groups and type of knowledge (in percentage)**

Here are a few quotes (translated from Hebrew to English) from group A teachers' testimonials about the expansion of their mathematical knowledge: "*The MNSs helped me understand, and present in class the distinction between proofs and refutation*"; "*I realized that there are proofs of impossibilities, such as the impossibility to trisect an angle*"; "*I learned about the existence of notions such as Mersenne number*". As can be seen from Table 1, both groups perceived the contribution of integrating the MNSs to their mathematical knowledge beyond the curriculum was greater than its contribution to knowledge related to the curriculum itself. Group A teachers maintained that: "*I was exposed to mathematics theorems such as Fermat's last theorem and Kepler's theorem*"; "*I became familiar with interesting mathematical subjects that I did not know, like the connection between guarding an art gallery and mathematics*". Similar to Group A, Group B teachers reported that: "*My mathematical knowledge was expanded, through integrating MNSs for example I learned from the MNS about Efron cubes that the transitive rule does not always holds*"; "*Through integrating MNSs, I learned with my students a lot about contemporary mathematics*"; "*There are many mathematical contents I was not familiar with. For example, the frequency of the digit 1 as a leading digit*". The findings from the interviews with the teachers reinforced the findings from the questionnaires. They indicated that all the interviewed teachers (Seven out of seven) perceived an expansion and deepening

of their mathematical knowledge. *"It was new to me that nowadays mathematicians employ technology not only for proving theorems but also for validating proofs"*. In addition, the teachers were exposed to the protracted work of proving mathematical theorem: *"I did not know that to prove the Fermat Last Theorem it took 300 years"*; *"I am happy to learn new things in mathematics, as the MNSs power point presentation there are many references, to mathematical background materials and applets"*.

### **Teachers' perceptions about integrating MNSs as an attribute for their recognition of the importance of exposing students to contemporary mathematical subjects beyond the curriculum**

Table 2 presents the distribution of teachers' degree of agreement with the statements: To what extent integrating the MNSs contribute to your recognition of the importance of exposing students to contemporary mathematical subjects beyond curriculum?

Teachers	Degree of Agreement				
	Very Large	Large	Medium	Little	Not at all
Group A (N=14)	21.43	50	21.43	7.14	
Group B (N=11)	18.18	63.64	18.18		

**Table 2: Teachers' grading of their recognition about the importance of exposing students to contemporary mathematical subjects beyond curriculum (in percentage)**

The teachers in Group A reported that their recognition about the importance of exposing the students to the content of the MNSs motivated them to join the project to start with, and to carry on their participation in it. In addition, teachers in Group A, reported about their desire to change the students' image about mathematics as a dynamic, and constantly evolving field: *"The exposure of the students is very significant to their image of mathematics"*; *"It's important for me that my students really recognized that mathematics is an ever-growing field"*. The teachers in Group B added: *"It is important that students recognize the world of mathematics beyond matriculation exam"*. The teachers' awareness of the importance of exposing students to MNSs also related to an opportunity to deal with the fears of students from math: *"One of my goals in integrating MNSs in my class is to try to remove fear of mathematics and try to develop a love for mathematics"*. In addition, integrating MNSs helped teachers emphasize the use and the connection of mathematics to daily life: *"It was very important to me at every MNSs presentation to note the fact that mathematics connects to science, which has many uses and is constantly evolving"*. The teachers' interviews strengthened the findings from the questionnaire. Five out of seven interviewed teachers reported that they chose to participate in the project to expose themselves and their students to mathematics as a field of constant development: *"Mathematics is perceived by students, as frozen and unchanging"*. Integrating MNSs enabled teachers to present mathematics in an orderly, interesting and exciting way: *"the integration of MNSs gave me an opportunity as a teacher to present a story after story of things that can ignite students' imagination"*. With integrating the MNSs *"I can open to my students horizons for what is*

*happening in mathematics. I did not have the ability to connect things together without participating in this project"*

### **Teachers' perceptions about integrating MNSs as a way to deepen teachers' knowledge about the relationships between mathematics, and its applications to science and society.**

Table 3 shows the distribution of teachers' degree of agreement with the statement: To what extent integrating the MNSs contribute to your knowledge about the relationships between mathematics and its applications to science and society?

Teachers	Degree of Agreement (in percentage)				
	Very Large	Large	Medium	Little	Not at all
Group A (N=14)	14.29	35.71	42.86	7.14	0
Group B (N=11)	18.18	36.37	27.27	18.18	0

**Table 3: Teachers' grading of their recognition of the relationships between mathematics and its applications to science and society**

The teachers in Group A, reported on important knowledge from integrating MNSs in their lessons, which links mathematics to its uses: *"It is Important as a teacher to have the knowledge beyond the curriculum that connect mathematics to other fields such as: agriculture, the connection to taxes, music, world maps"*. Group B teachers also reported a rich expanse of examples illustrating the relationship between mathematics and science through integrating MNSs: *"I was amazed to discover the connection between origami folds and the development of science and medicine"*. All the interviewed teachers reported about the contribution of the MNSs to their knowledge of the relationship between mathematics, sciences and society. The integration of the MNSs has given teachers the exposure, and understanding, the relationship between mathematics and scientific phenomena around them: *"for example, soap bubbles were very interesting. Why the bubble is round, and it has to do with both science and mathematics, I knew that the Hungarian cube knew has math around it, but now I did deepen my knowledge about it. The MNSs enriched my knowledge, opened my horizons, and the integration of the MNSs in students instruction forced me to understand it more deeply"*. In addition, all the interviewed teachers reported the contribution of integrating MNSs, to their knowledge about the relationship between mathematics and computer science. An example of teachers report: *"The fact that the computer becomes a significant player in the stages of proof is very impressive, such as the color of the map"*. The teachers reported a deepening of the relationship between mathematics and phenomena occurring in nature: *"For example, in the Fibonacci series, I was very excited by the physical explanation of the series' shows in the flowering mechanism. MNSs help me to understand why, and the explanation took me a few steps forward"*.

## **Discussion**

The present study focused on high-school mathematics teacher's perceptions of the contribution of integrating MNSs to various component of their MKT during the first two years. The findings as appeared above in Tables 1, 2, 3 indicate that teachers perceive the interweaving of MNSs in their mathematics lessons, as a catalyzer for the development of at least three components of their MKT.

This goes hand in hand with the claim by Shulman (1986) and Ball et al (2008) that this is the unique mathematical knowledge required for teaching mathematics.

Teachers also expressed their perceptions that by integrating MNSs in their mathematics lessons, they developed their SCK as well as their KCS. By intelligent integration of MNSs during instruction teachers perceived that they deepened their knowledge about the connection between mathematics and other field, about different ways for proof theorems, hence they have expanded their SCK. By introducing various ways in which students' curiosity can be stimulated, and identified topics in which students were interested in the curriculum and beyond, teachers have expanded their KCS.

Another component that the findings illuminate is the HCK as defined by Ball et al. (2008). The findings indicate that teacher's perceptions the significant contribution of integrating MNSs on their MKT component, related to HCK (Ball et al. 2008). By exposed to the MNSs, they strength and deepen their awareness of the dynamic, lively and ongoing mathematics development. The teachers found out about the connections between the development of mathematics and the development of science and society. According to HCK, defined by Ball & Bass (2009), by integrating MNSs in their mathematics lessons, the teachers reflected in the various HCK components: They developed a sense of the mathematical environment surrounding the current "location" in instruction, by identified links between topics taught in the mathematical curriculum to topics outside the curriculum. They were exposed to major disciplinary ideas and structures such as various possibilities of mathematical theorem, to the logical structure of mathematical content. Finally, the teachers stated they appreciated being exposed to core mathematical values such as, collaborative work and persistence, as expressed in the MNSs, with the description of mathematicians work with their colleagues in other fields.

In conclusion, this study will continue in examining more components as the third year of this study unfolds.

*The problem solving approach to teaching and learning mathematics has for some time been the focus of professional development (PD) programs. This paper discusses a case study of an elementary school teacher who participated in such a program. We apply the lens of figured worlds when analyzing her pedagogical and classroom discourses to reveal which aspects of explorative figured worlds penetrate her discourse. Findings indicated that the teacher adopted some aspects of explorative figured worlds but resisted others. The lens of figured worlds can help us, as teacher educators, to plan continued PD.*

*Keywords: Figured worlds, explorative instruction, professional development.*

## Introduction

Although there is a consensus among researchers and teacher educators regarding the benefits of what may be called explorative instruction (i.e., inquiry-based, student-centered, and cognitively demanding instruction) (Schoenfeld, 2014), studies have shown that teacher-centered, ritual instruction is still very prominent in many classes (e.g., Resnick, 2015). Resistance to explorative instruction may even be found amongst teachers who have taken part in professional development specifically promoting this type of instruction (Heyd-Metzuyanim, Munter, & Greeno, 2018). One way to explain this phenomena is by viewing it through the lens of ‘figured worlds’ (Holland, Lachicotte, Skinner, & Cain, 1998). Figured worlds are based on one’s interpretation of situations and may be revealed through discourse.

This paper presents a case study of one teacher, Yifat (a pseudonym), and analyzes her pedagogical and classroom discourses after participating in a professional development (PD) program centered on problem solving and explorative instruction. Through the lens of figured worlds, we analyze her discourses and examine which aspects of explorative instruction she adopted and which were missing.

## Theoretical background

This section begins by offering some background on the notion of figured worlds and how it relates to mathematics education. It continues by describing the problem solving approach to teaching mathematics. Finally, as this paper analyzes the teacher’s pedagogical and classroom discourses, the section ends by presenting how discourse is understood in the commognitive approach.

A figured world is defined by Holland and her colleagues (Holland, et al., 1998) as “a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (p. 52). People ‘figure’ out who they are through the activities of their world, in relation to the social types that populate these figured worlds, and in social relationships with the people who perform in these

worlds. In addition, artefacts and signs are attributed meaning that might differ from how those outside of the figured world interpret them. To sum up, the people within the figured world take on roles that come along with responsibilities, and in addition, certain actions, outcomes, and objects are valued more than others.

Relating figured worlds to mathematics education, Boaler and Greeno (2000) pointed out that the difference between ritual and explorative instruction may not just be a matter of certain teaching techniques or forms of classroom organization, but a matter of widely different figured worlds. They defined the problem-solving, group-work mathematics instruction found in some secondary schools as a “connected knowledge” figured world. In contrast, the more common teacher-centered instruction was conceptualized as a figured world based on “received knowledge”. Ma and Singer-Gabella (2011) showed that it was difficult for prospective teachers to move from the “traditional” figured world (in which they supposedly studied at school) to the “reform” figured world of mathematics instruction, supported and enacted in their training program.

Over the years, evidence has shown that the “connected knowledge” figured world is fruitful for mathematics learning (Schoenfeld, 2014). In particular, Hiebert and Grouws (2007) highlighted two significant aspects of such teaching: Explicit Attention to Concepts (EAC), and Students’ Opportunity to Struggle (SOS). These two aspects are part of the problem-solving approach to teaching mathematics (Hino, 2015). This approach emphasizes meticulous planning of detailed mathematics lessons that include implementing rich problems in such a way that students are active participants who explore mathematics. The teacher’s role is to create learning opportunities that support students’ conceptual understanding through problem solving, as well as supporting student agency and authority (Schoenfeld, 2014). Relating to all of the above, Shabtay and Hed-Metzuyanin (2018) described the figured world of exploration as one where students are free to struggle, mathematics is at the center, and the teacher and students share responsibility for the learning process.

Learning, including learning mathematics, may be seen as the process of becoming a full participant in a certain discourse (Sfard, 2008). Such participation may be characterized as lying on an axis between ritual and explorative participation (Viirman, 2015). In Sfard’s commognitive framework (Sfard, 2008), a basic assumption is that doing mathematics means engaging in mathematical discourse. Discourses, according to Sfard, are different types of communication “set apart by their objects, the kinds of mediators used, and the rules followed by participants, and thus defining different communities of communicating actors” (p.93). While these discourses are not stable or distinct, but rather overlapping and constantly developing, it still makes sense, within a given context, to see them as “distinct enough to justify talking about discourses [. . .] as reasonably well-delineated wholes” (p. 91). Regarding the classroom as a community, Tabach & Nachlieli, (2016) defined a pedagogue, as a person who assumes the role of the leading participant in the discourse. Thus, pedagogical discourse is a discourse about teaching and learning (Shabtay & Heyd-Metzuyanin, 2017). Similar to any other discourse, it is made up of certain key words, narratives, and meta-rules that dictate what to teach students, how to teach them, and who can learn (or not learn). This view is based on Sfard’s (2008) view of mathematizing as participating in a discourse about mathematical objects. The pedagogical (the how and for whom) is closely intertwined with the what (Shabtay & Heyd-Metzuyanin, 2017).

Through the lens of figured worlds, this study examines which explorative narratives may be found in a teacher's classroom discourse and in her pedagogical discourse, after participating in a PD program focused on the problem solving approach to teaching mathematics.

## Methodology

Yifat is an elementary school teacher with a B.Ed. degree and a specialization in mathematics. At the time of the study, Yifat had 11 years of experience teaching mathematics to fourth and fifth graders (10-11 years old), and was the mathematics coordinator in her school. This case was chosen because it illustrates the gap between a teacher's classroom and pedagogical discourses. In addition, Yifat consented to be part of the study, and agreed that her lesson and interview be recorded.

Yifat participated in a PD program for mathematics teachers centered on designing and implementing lesson plans according to the problem-solving approach (Hino, 2015). During the program, teachers engaged in cognitively demanding tasks, viewed videoed lessons demonstrating the problem solving approach, discussed the pedagogical gains and mathematical ideas that emerged from those lessons, and designed lesson plans modeled on the problem-solving approach. The PD program took place over a period of eight months, and included 10 sessions. In addition, each teacher met with the PD educator three times on an individual basis, receiving personalized instruction and advice for planning and implementing mathematics lessons using the problem-solving approach in their specific classes.

Relevant to the present study, the seventh meeting of the program dealt with the construction of prime and composite numbers. During that meeting, teachers, including Yifat, engaged with a cognitively demanding task that involved representing different prime number with different signs, and composite numbers with an appropriate combination of prime number signs. For example, a card representing the number 2 had a circle on it, the card for 3 had a triangle, and the card for six had both a circle and a triangle (see Figure 1 for the symbols which represented the numbers from one to ten). During the session, teachers also viewed a Japanese lesson, demonstrating how this activity may be implemented as part of a problem-solving teaching approach to learning these new concepts. At the end of this session, Yifat invited the teacher educator to come to her fourth grade class and observe her teaching this exact lesson. Yifat expressed her belief that she “finally understood the problem-solving approach,” and that she felt students would enjoy the lesson and experience meaningful learning.

**Figure 1: Cards with symbols representing the numbers from 1-10**

## Data collection and analysis

Yifat was interviewed both before and after the observed lesson. The first interview dealt mainly with the goals of the lesson, the main mathematical ideas, and the planned pedagogical processes. The post-teaching interview revolved around achievement of goals, class-driven processes, and the mathematical ideas that emerged from students and the teacher during the discussions. Each interview was audio-taped and transcribed. The lesson was video-taped and transcribed.

Relating back to the theory of figured worlds described previously, a qualitative analysis was carried out on all transcriptions searching for four dimensions of figured worlds: characters, valued actions, outcomes, and artifacts. The characters, in this case the teacher and students, play roles that involve responsibilities. Thus, when analyzing characters, we analyze the roles Yifat plays and those she refers to during her interviews. Noting the value that Yifat places (or does not place) on these four dimensions, we describe Yifat's figured world and compare it to an explorative figured world.

## Findings

In the transcripts below actions are underscored with one line, outcomes with a double line, and roles and responsibility are indicated with a broken line. Artifacts are in bold.

The first interview took place in the teacher's classroom, during the recess prior to the mathematics lesson. Yifat was anxious, and yet proud, to show the teacher educator what she had prepared.

Interviewer    What's new?

Yifat            Hi. (Yifat is preoccupied with **a bag of flashcards**).

Interviewer    Do you need help?

Yifat            Look. I made these **symbols**. **These (she places the flashcards on the table)**.

Interviewer    Okay.

Yifat            You'll see. I will arrange it for them after they sort them like this. (She arranges the cards as in Figure 1. She has more cards that have not been arranged yet.) Then we will discuss the topic. That's okay, isn't it?

Interviewer    What are you going to try to achieve today? How would you describe your objective?

Yifat            Uh ...That they know what a prime number is, and what a composite number is.

Interviewer    Hmm...and how did you plan the lesson?

Yifat            You'll see. I planned it just like the teacher in the clip. Don't worry (she is busy with the flashcards, putting them back into the bags)...I need the sticky stuff so that I can stick them on the board (gets up to get the glue).

From the lines above, we see Yifat's preoccupation with the flashcards, signifying their value in her eyes. Yifat also states her intent to emulate the teacher in the film. Emulation is an action that might indicate her tendency towards being a ritualistic learner, i.e., she watched a documented lesson during a professional development meeting, and would like to replicate the lesson. Thus far, it seems that Yifat has chosen an appropriate problem, and has brought along appropriate props (cards) that will help her achieve the goal of students "knowing" (Yifat's term) what prime and composite numbers are. Note that she does not relate to explorations and discussions as objectives, or valued outcomes.

The observed lesson was 47 minutes long. The teacher began by randomly sticking the cards on the board and telling the children to decide how the cards could be sorted. Yifat proceeded to spend 30 minutes listening to various suggestions of how to sort the cards, calling on different students to

demonstrate their method on the board. Finally, she arranged the cards on the board in ascending numerical order as represented by the symbols, in accordance with her lesson plan (see Figure 1).

For the next 12 minutes, she again led a whole-class discussion, this time relating to the arrangement of the cards on the board. Yifat tried to steer the discussion towards explaining the arrangement of the cards, as depicted below.

- Yifat            Let's make things clear. You (meaning the class) said skip by twos, and Noa just said even numbers (referring to the cards with circles on them). Let's check everything. Imagine that I have more and more cards. And there's always a shape. There's a circle, and another shape, and a circle and something else, and a circle and something else. (Pause) And what's here?
- Student A       (something unintelligible)
- Yifat            Here is another circle. And something. I am skipping on purpose. What do you say? Yoav, do you agree with what she said?
- Yoav            Yes.
- Yifat            Daniel, do you agree?
- Daniel          Yes.
- Yifat            So wait a second. Let's make some sense out of this so we can understand what's going on. Michal said (referring to the circles) that 2 and 2 and 2 and other items were added. And Roni says ... (referring to the triangles) it skips by 3.

In the above segment of classroom discourse, Yifat takes the lead, saying “Let’s make things clear.” Although she takes the lead in the discourse, her use of the word “let’s” hints at her inclusion of the students in the process of making sense of the symbols. She also turns to different students and asks them if they agree, sharing with them the responsibility for learning. Yet, Yifat’s questions are closed yes or no questions. She does not ask those students to expound on their thoughts. Finally, her valued outcome is that we will “understand what’s going on.” During the last five minutes of the lesson, Yifat wrote down the numbers from 1-10 under each of the symbols and introduced the notions of prime and composite numbers. It was only during those five minutes, that mathematics was at the center of the discourse.

In the interview following the lesson, Yifat talked about the differences between this particular lesson and her regular lessons:

“Look, this was a really different type of lesson. They haven't learned composite or prime numbers at all. So, it's the first level of acquisition. And also, it's...the first time that I...gave a lesson like this, when the whole lesson is...um...only the one problem. It's different from what we usually do. They always have a lot of practice, exercises... Here (pointing to the **cards**) ... they are just symbols that you have to categorize...and understand.”

The actions mentioned by Yifat are student actions. In the past, they practiced; in the present, they categorized. Most interesting are the outcomes she values. The outcome of her lesson plan is the

“different” type of lesson she perceives as having enacted. The outcome for her students is that they will “acquire” the first level of understanding. The terminology Yifat uses gives us a mixed message regarding her figured world. On the one hand, she consciously attempts to break with her former lesson style. She chooses to implement a cognitively demanding task. Yet, she resorts back to words such as “acquisition,” and “giving a lesson,” that remind us of a traditional figured world.

Asked if she has achieved her goals for this lesson, the following exchange ensues:

- Interviewer    Okay. So, in your opinion...did you achieve your goal?
- Yifat            Of course. Look, it's only the beginning, and [so] I had to explain...so...yes.
- Interviewer    Um...what was your objective?
- Yifat            That they would know what a prime number is and what a composite number is.  
That they would know how to differentiate between the two.
- Interviewer    Okay. How do you know that they have, in fact, made that distinction?
- Yifat            Because, look. I told them. They also said that there are **cards with one symbol and there are cards with a number of symbols.** ...I'm sure that most of them understood. And whoever didn't, I will sit with them in a small group and explain it again. You know, it's only the beginning. Look. They can't arrive at it by themselves. My job is...I have to explain it to them and that's how they'll know. They would never get to it by themselves.
- Interviewer    Why?
- Yifat            Because it's too complex. Later, when things are clarified, I'll be able to let them come up with symbols for 13 or 17, and construct 12 or 18.

The actions Yifat values for herself (e.g., explaining, telling), go hand-in-hand with how she describes her “job”, or role, as an “explainer”. Although during the classroom discourse Yifat did ask students to share their ways of sorting the symbols, during the interview she ascribes a passive role for her students, claiming unequivocally that they would not be able to arrive at the mathematical conclusions on their own. This interview offers evidence that Yifat’s figured world is mostly traditional.

Referring to the main characteristics of the problem-solving approach, Table 1 summarizes the similarities and differences between Yifat’s figured world and the explorative figured world. Yifat does choose to present a cognitively demanding in her class. She perceives this lesson as being quite different from those she usually teaches. Additionally, Yifat led a discussion concerning the task she presented to her pupils. These are all part of the explorative figured world. However, Yifat did not offer enough of an opportunity for her students to struggle with the problem. Recall that after she randomly stuck the symbols on the board, she immediately began to call on students to share their ways of sorting, without giving them time to think about it. When she finally arranged the cards in order, she still had difficulty shedding her central role as the teacher who explains, and where the students are attentive. These are elements of a more traditional figured world. In other words, Yifat is struggling between two worlds.

	Explorative figured world	Yifat's figured world
Teachers select cognitively demanding tasks	+	+
Students present their own ideas	+	+
Collaborative group discussions	+	+/-
Shared mathematical authority	+	+/-
Students are offered opportunities to struggle	+	-
Explicit attention to concepts	+	-

**Table 1: A comparison between Yifa's figured world and an explorative figured world**

## Discussion

The aim of this study was to investigate what explorative narratives enter into a teacher's classroom and pedagogical discourses after attending PD focusing on a problem-solving approach to teaching. From the first, we get mixed messages. Yifat is very enthusiastic about the task, yet is preoccupied with the artifacts (the cards). Though not entirely insignificant, the cards are actually mere props, to be used in the ultimate aim of having students engage with the concept of prime and composite numbers. Yet, during the lesson, more time is spent discussing the artifacts than on the mathematical concepts they were supposed to elicit; not enough time is allowed for exploring the possible significance of the symbols and how they might be related to mathematics (Hiebert & Grouws, 2007). This is also reminiscent of Henningsen and Stein (1997), who argued that a teacher must not only select and appropriately set up worthwhile mathematical tasks, but must proactively and consistently support students' cognitive activity. In addition, although her classroom discourse shows her attempts at sharing authority, her second interview contradicts this view. These findings are in line with Sfard's approach (2008), that discourses are not stable, but rather overlapping and constantly developing.

While acknowledging that discourses may be overlapping, as teacher educators, we attempt to move teachers toward a more explorative discourse. Sfard (2016) suggested that for teachers to be explorative in their teaching, they must have experienced explorative mathematics learning for themselves. Yifat had limited experience with this type of learning, most of which stemmed from the PD program. Indeed, Yifat explicitly states that her aim is to imitate the teacher in the filmed lesson. She does not say that her aim is to offer the students the same type of experience she has recently had in the program. From paying attention to her discourse, we might infer that additional time must be given for teachers to experience for themselves explorative learning.

By focusing on characters, actions, outcomes, and artifacts, we can see what parts of a figured world a teacher adopts, and which seem to be restricted. As teacher educators, we can utilize this lens to listen to teachers' discourses and identify aspects that perhaps need more attention. Yifat is ready to adopt appropriate tasks, and willing to listen to her students. At this point, we would say that more attention could be paid to authority, while at the same time placing the mathematics at the center. Insight into a teacher's figured world, can help teacher educators plan appropriate professional development.

*We report on a study of preservice teachers' eliciting performances in a scenario in which a student has made a mistake and, if sufficiently probed, is able to recognize the mistake and revise their work. Our findings reveal the skills and capabilities of one group of preservice teachers at the start of a teacher education program.*

*Keywords: Teacher education-preservice.*

## Student responses in teaching

Mr. Chinn, an experienced sixth grade teacher, is circulating in his sixth-grade mathematics class as students work independently on a set of problems involving operations with fractions, including mixed numbers. He pauses by Chloe and notices that she has arrived at an answer for a subtraction problem with “mixed numbers” that looks wrong. By mixed numbers, we mean numbers that combine integers and proper fractions. Chloe’s work, shown in Figure 1, has resulted in an incorrect answer.

$$\begin{array}{r} 2 \phantom{0} \cancel{3} \frac{2}{5} \\ - 1 \frac{3}{5} \\ \hline 1 \frac{9}{5} \end{array}$$

**Figure 1: Student work, the student makes a mistake**

Mr. Chinn decides that he does not want to assume what Chloe was doing and so he asks her some questions about her work: “Chloe, what did you notice when you started to work on this problem?” Chloe responds, “I was trying to take three-fifths away from two-fifths but I didn’t have enough so I needed to borrow.” Mr. Chinn nods and follows up, “Where did you borrow from?” Chloe responds, “I borrowed from the 3 and then the two-fifths become twelve-fifths.” Mr. Chinn wonders whether Chloe is overgeneralizing “borrowing” from work with subtracting multi-digit numbers or if she has made a bookkeeping error. He asks some more questions and presses Chloe to explain the value of the “little one” in fraction notation and Chloe pauses, and then says softly, “I think I made a mistake.” Mr. Chinn asks her what she thinks is a mistake and to articulate why she thought she did it. Through this interaction, he learns that Chloe believes she was just “working too quickly” and that she forgot that she was borrowing “five-fifths.” Then, Mr. Chinn asks Chloe to solve the problem again. When

Chloe changes the “two-fifths” to “seven-fifths,” Mr. Chinn asks Chloe how she knew to write seven-fifths and why the mixed number can be re-written as “three and seven-fifths.”

In this episode, Mr. Chinn encounters a regular problem of practice in mathematics teaching. A student is doing something when solving a mathematics problem that misaligns with the lesson’s mathematics goal of accurately computing the difference. The processes of teaching and learning often involve such mismatches between goals and the current status of students’ performances. For example, students might use an approach that is not familiar to a teacher. Or a student may make what Bass (personal communication) terms a “bookkeeping” error. Radatz (1980) refers to such an error as a mistake, an isolated and unrepresentative mis-executions of an algorithm (a careless move) as opposed a systematic and persistent mis-execution that reflect a conceptual or procedural misunderstanding. Chloe’s response reflects a book-keeping error. Another possibility is that student’s work might reflect a misunderstanding that results in an incorrect answer. Of course, other sorts of mismatches happen in teaching that are crucial, such as when teachers favors/expects a particular approach or route of reasoning and a student treads an alternative path. In a broader sense these mismatches illustrate a broader categorization of students’ actions/productions that are “*not what the teacher is looking for.*” This is not about anticipation as teachers may very well anticipate that students might produce some of these responses. This is more about the need for teachers to have generative responses when there is a mismatch between what the teacher prefers/hopes to see and the variability in what students produce in the course of learning mathematics.

Interactions around student responses that are not what the teacher is looking for can be powerful sites of learning for both teachers and students (Borasi, 1994; Hiebert et al., 1997). When the answer is incorrect, the joint sense-making required to interpret student thinking goes beyond the identification and correction of mistakes/errors into the conceptual analysis of why the mistake/error was made (Borasi, 1994; Kazemi, & Stipek, 2001). The information that teachers can uncover by eliciting students’ thinking can then guide their pedagogical response. This is not to say that all student responses that are different from the responses that teachers are looking for have the same potential for being a site for learning. For example, one could argue that a bookkeeping error has less potential to support learning for the teacher and the student compared to an instance in which a student’s work reflects a misunderstanding that results in an incorrect answer. While the importance of interacting with students around incorrect answers is well-documented, research suggests that practicing teachers vary greatly in their attention to and treatment of errors and mistakes in classroom discussion (Bray, 2011; Santagata, 2005; Silver, Ghouseini, Gosen, Charalambous, & Strawhun, 2005). Less is known about the ways in which preservice teachers (PSTs) elicit student thinking when they see answers that are not the answers that they want students to produce. This matters for several reasons. For one, when students do something that the teacher is not looking for, this indicates a place where the teacher could learn something about the student and/or about mathematics. Both of which merit being able to leverage the opportunity. For another, when students make what seem to be mistakes, asking questions may reveals understandings that are not evident from their written work.

In this study, we examine PSTs’ skills around asking questions to learn about student thinking (eliciting student thinking) when a student has an incorrect answer. We explored a case in which the student makes a bookkeeping error, a mistake, in their arithmetic process and will recognize the

mistake if asked specific questions about their reasoning. The context is challenging for many PSTs. It has significant implications for students because teachers' understanding the basis of student's mistakes is necessary for responsive instruction. In other words, teachers need to know the degree to which a mistake reflects underlying understandings in order to ascertain how to move a student's understanding forward. Specifically, we sought to analyze the extent to which PSTs' (a) elicited the full process used; (b) elicited the student's understanding of the process, and (c) elicited the student's mistake, including the reason for the mistake and their revised process. We illustrate how knowledge of this kind of skill can be gathered through the use of a simulation in which a PST interacts with a teacher educator who is taking on the role of a student, what such findings reveal about PSTs in one teacher education program, and the implications of these findings.

### **Focusing on PSTs' skills at the beginning of teacher preparation**

There has been increasing focus on preparing PSTs for the work of teaching by focusing on specific instructional practices (e.g., Ball, & Forzani, 2009; Ball, Sleep, Boerst, & Bass, 2009; McDonald, Kazemi, & Kavanagh, 2013). In "practice-based teacher education," learning goals for PSTs are tied to developing skills in carrying out specific teaching tasks. To help PSTs develop skill, it would be useful to know what they bring with them to teacher education, so as to be able to design the program in ways that capitalizes to their prior ways of acting and interacting. Prior research provides knowledge of some of the orientations and assumptions that PSTs bring to teacher preparation and their knowledge of subject-matter content. Research on particular teaching practices often focuses on the utility of the approach, composite parts of the teaching practice, and/or challenges in learning to enact particular teaching practices. Such knowledge is useful for the design of teacher education; however, it is insufficient. Needed is knowledge of the skill with which PSTs can enact particular teaching practices upon entry to a teacher education program.

We build on a prior study which examined the skills with eliciting student thinking at the start of a teacher education program (Shaughnessy, & Boerst, 2018a). PSTs elicited the thinking of a student who arrived at a correct answer to a multi-digit addition problem using a method that was likely to be unfamiliar to PSTs. That study revealed skills with eliciting student thinking that could be built on (e.g., eliciting the student's process), needed to be learned (e.g., eliciting the student's understanding), and needed to be unlearned (e.g., directing the student to use a different process). However, the case of eliciting when a student has made a mistake is different. We wondered whether PSTs would learn that the student had made a mistake and what understandings underlie the mistake.

### **The practice of eliciting student thinking**

In teaching, "teachers pose questions or tasks that provoke or allow students to share their thinking about specific academic content in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students" (TeachingWorks, 2011). Eliciting student thinking makes the nature of students' current knowledge available to the teacher. Such information is essential for engaging students' preconceptions and building on their existing knowledge (Bransford, Brown, & Cocking, 2000). In actual practice, eliciting student thinking is often done in conjunction with interpreting student thinking and responding to student thinking in ways that support students in building on their current understandings (Jacobs, Lamb, & Philipp, 2010).

Because of the crucial nature of the practice and the need to teach PSTs to do this work, it is necessary to specify the work involved in eliciting student thinking. We conceive of the work of eliciting student thinking in the context of a mathematics problem as asking questions to bring out the student's process and the student's understanding of key ideas underlying the process (Shaughnessy, & Boerst, 2018b). Students are at the center of this work. It is their thinking which is sought and intended to be understood, and the work is situated in mathematical context that focus dialog, shape interaction, and influence follow-up questions. Throughout this paper, we use "skill with eliciting student thinking" to refer to the degree to which PSTs are able to engage in this work.

## **Studying skill with eliciting student thinking**

Since 2011, we have used teaching simulations to study PSTs' skill with eliciting student thinking. A simulation serves as an "approximation of practice" (Grossman, Hammerness, & McDonald, 2009). Simulations have been used in many professional fields such as medicine and more recently in the preparation of teachers (Self, 2016). In these simulations, a PST interacts with a "standardized student" (a teacher educator taking on the role of a student using a well-defined set of rules for responding) around a specific piece of written work. This form of assessment has advantages over field-based interviews to assess skill with eliciting student thinking (Shaughnessy, Boerst, & Farmer, 2018). Field-based interviews leave the particular student thinking being elicited to chance and can be highly variable. The teaching simulation uses highly specified protocols that enable us to control key aspects of the student's process, understanding, and demeanor. This leads to comparable eliciting contexts for all of our PSTs and facilitates fair and more nuanced assessment of PSTs' eliciting skill.

We design teaching simulations to have a consistent three-part format (Shaughnessy, & Boerst, 2018b). First, PSTs are provided with student work on a problem and given 10 minutes to prepare for an interaction. Second, PSTs have five minutes to interact with the standardized student, eliciting the student's thinking to understand the steps they took, why they performed particular steps, and their understanding of the key mathematical ideas involved. Third, PSTs are interviewed about their interpretations of the student's thinking. In total, the assessment takes approximately 25 minutes.

We designed this simulation to be one in which the student uses non-standard process (meaning a process other than the standard US algorithm) for solving multi-digit subtraction problems and makes a mistake. The process we selected is sometimes referred to as "Expand and Trade" (see the student work in Figure 2). The process involves writing the value of the minuend and subtrahend in expanded form and making any necessary trades. When used correctly, the user would then subtract the numbers place-by-place in expanded form. This student correctly applies the expanding and trading process, but mistakenly adds values by place instead of subtracting. This student has conceptual understanding of expanded form, the meanings of addition and subtraction, and when, how, and why to make trades. In this instance, however, the student loses sight of the fact that they are solving a subtraction problem due to the addition symbols in the expanded form. This is a bookkeeping error. During the interaction, the student will change their mind when pressed to: make and evaluate an estimate for the original problem, represent their process with a picture, talk about the meaning of the operation, explain why trades were made, solve another multi-digit subtraction problem, or re-solve the original problem. The student is trained to only reveal the mistake if pressed by the PST on one of these specific points.

$$\begin{array}{r}
 583 \rightarrow 500 + 80 + 3 \\
 - 295 \quad 200 + 90 + 5 \\
 \hline
 600 + 260 + 18 = 878
 \end{array}$$

**Figure 2: Student work, the student makes a mistake**

## Methods

Thirty PSTs enrolled in a university-based teacher education program in the United States participated during the first week of the teacher education program. The simulations were video-recorded. In this paper, we focus our analysis on: (a) eliciting the student's original process, (b) eliciting the student's understanding of the process, (c) eliciting the student's mistake, including the reason for the mistake and the revised process and solution. For each of these components, we identified specific "moves" and tracked their presence or absence in each performance. We used the software package Studiocode© to parse the video into talk turns. Then, we identified "instances," which contain a question posed by a PST and the student's response to that question. Two independent coders applied all of the relevant codes to each instance. Disagreements were resolved through discussion and by referencing a code book.

## Findings

### Eliciting the student's original process

The student's process had five steps: expanding both the minuend and subtrahend, comparing the numbers in each place, trading, adding (rather than subtracting) numbers by place, and adding the partial sums to arrive at the answer. The highest rates of eliciting occurred around the expansion (70%), the comparison of the numbers in each place (90%), and the trading steps (80%). In fact, 65% of PSTs elicited all three of these steps and 90% of the PSTs elicited two or more. However, only 53% of the PSTs elicited that the student added numbers by place in the expanded form after trading. This was surprising given that it was the point where the mistake occurred. The smallest percentage of eliciting occurred around the adding of the partial sums (10%). This was not surprising given that (a) it occurred after the point where the student made the mistake and may have not been relevant if the PST had asked questions that resulted in the student revealing that they had made a mistake, and (b) it could be easily inferred from the written work. Given that these PSTs elicited some, but not all, of the student's steps, we concluded that they brought skills relevant to eliciting a student's process that may be leveraged and built upon in the teacher education program; however, there was also a need for these PSTs to work on identifying and actively asking about steps that are particularly important to understand in the context of the problem.

### Eliciting the student's understanding of the original process

We coded whether PSTs elicited the student's understanding of six mathematical ideas underlying the process. The highest percentages of eliciting of understanding occurred around the operation in the problem (27%), why the student expanded (37%), and why the student traded (27%). The lowest percentages occurred around the equivalence of expanded form and the "original" number (7%), the

reasonableness of the answer (7%) and what trading means (0%). This suggests that limited eliciting of understanding of mathematical ideas occurred. However, when we looked across the set of ideas, we found that 67% of PSTs elicited the student's understanding of one or more idea. Thus, we concluded that this 67% of PSTs brought skills relevant to eliciting the student's understanding in this scenario, but note that their eliciting does not show discernment of which understandings are more important to focus on and/or more relevant to subsequent instruction.

### **Eliciting the student's mistake, including the reason for the mistake and the revised process**

We coded the extent to which the PSTs elicited the student's mistake, including their understanding of why they made the mistake. We found three foci in PSTs' performances: eliciting the student's realization that a mistake had been made (47% of PSTs), pointing out the mistake and getting the student to admit a mistake without first eliciting the mistake from the student (20% of PSTs), and only asking questions that were not focused on the mistake (33% of PSTs). In other words, 67% of the PSTs uncovered the mistake either by eliciting it or asking the student to confirm that they made a mistake; 33% percent did not learn about the mistake through questioning.

We now turn to the 47% of the PSTs who elicited the student's realization that a mistake had been made. These 14 PSTs elicited the mistake in different ways. The most common way, used by 11 PSTs, was to ask about the operation involved in the problem and to press on how the operation in the problem (subtraction) differed from the operation that the student had used (addition). Another two PSTs posed another problem for the student to solve or asked the student to redo the original problem. The student profile specifies that the student should correctly apply the Expand and Trade method if prompted to solve another problem. A third approach to eliciting the mistake was to ask about why the student had made the trades. One PST leveraged this to ask why the student had added.

We next turn briefly to the 20% of the PSTs uncovered the student's mistake by pointing it out themselves and getting the student to admit the mistake. Often, PSTs made statements about what it appeared the student had done based on the written work. For example, one PST stated her impression that that expansion and trades were executed correctly and that the student had added instead of subtracting. This exchange took place after the PST had elicited the steps of the student's original process through the trading step. In the exchange, the idea that the student mistakenly added instead of subtracted is introduced by the PST, not elicited from the student. The student merely confirms what the PST has stated. We see this approach to uncovering the mistake as qualitatively distinct from eliciting the mistake through asking questions.

To explore what PSTs did after learning the student had made a mistake, we considered the 20 cases in which PSTs uncovered the student's mistake either by eliciting the student's realization that a mistake had been made or pointing out the mistake. Twelve of the 20 PSTs did not ask any further questions about the mistake. These PSTs need to learn to ask additional questions once a student recognizes a mistake. Of the 8 PSTs who followed up about the mistake, 5 made statements based on their own inferences about how and/or why the student made the mistake and got the student to agree. The remaining 3 PSTs asked questions to learn about how and/or why the mistake was made. These findings suggest that these 8 PSTs bring skills relevant for eliciting a student's mistake, but may need to learn reasons and strategies for eliciting how and why a mistake was made.

## Discussion

Understanding the skills with teaching practices that PSTs bring to teacher education is key to designing experiences that are responsive to the needs of PSTs (Shaughnessy, & Boerst, 2018a). This study examined the ways in which PSTs at the beginning of a teacher preparation program elicited the thinking of a student who made a mistake when solving a subtraction problem. Learning about the reason for a mistake is important for teachers to accurately assess and respond to student thinking. For example, a student who has made a mistake due to misunderstanding about ideas underlying the process would need different instruction than a student who has made a bookkeeping error when carrying out a well-understood process. However, at the start of their teacher education program, these PSTs focused more on eliciting the revised method and/or solution than asking about why the mistake was made. We hypothesize that there might be multiple reasons that this pattern occurred. Some PSTs might refrain from directly asking the student why they made the mistake because they are fearful of embarrassing the student by asking them to talk about it. For other PSTs, limitations in their content knowledge for teaching might impede being able to identify important mathematical ideas related to the process. Still other PSTs might not have been able to formulate a question that could be used to elicit evidence of the student's understanding.

The data suggest several directions for continuing research. First, these PSTs were in their first week of a teacher education program. In what ways do their skills with eliciting student thinking develop over time? Second, what course activities might effectively cultivate an inclination to elicit how and why students make mistakes? Third, the assessment itself involved a mistake where the student was using a “non-standard” approach to solve the problem. Anecdotally, we have reason to think that some PSTs were discounting the student's reasoning because they believed that the student should be using a different method to solve the subtraction problem. A future study could compare skills in eliciting around a mistake with a “standard” and an “alternative” algorithm.

# Beliefs and expectations at the beginning of the bachelor teacher training program in mathematics

Evelyn Süss-Stepancik<sup>1</sup> and Stefan Götz<sup>2</sup>

<sup>1</sup>University College of Teacher Education, Lower Austria, Austria; [evelyn.stepancik@ph-noe.ac.at](mailto:evelyn.stepancik@ph-noe.ac.at)

<sup>2</sup>University of Vienna, Austria; [stefan.goetz@univie.ac.at](mailto:stefan.goetz@univie.ac.at)

*Keywords: Beliefs, expectation, student teachers, mathematical training, factor analysis.*

## Introduction

Since 2016/17, a new bachelor teacher training program has been implemented in a cluster of four tertiary education institutions in the North East of Austria to provide a common secondary level teacher training program. The education of future maths teachers in mathematics as a science is separated from the program for other maths students. The first compulsory lecture for future maths teachers is an introduction to university mathematics. It offers mathematical terminology, parts of the mathematical toolbox and methods of proving. Thus the students' beliefs, which are already developed due to their school experience, are faced with mathematics at university level.

## Contextualising our study in the field of belief research

In the field of mathematical belief research, the pivotal work of Grigutsch, Raatz, and Törner (1998) is well known. It deals with maths teachers' beliefs and shows that the beliefs of mathematics teachers represent four main dimensions: scheme, formalism, process and application. Rach, Heinze, and Ufer (2014) also follow that conception, but they focus on specific expectations of students in terms of relevant learning opportunities. They found that students' expectations are mostly realistic and have a small influence on the students' success. In our approach, we incorporate both the beliefs and expectations of future math teachers. We define the following research questions:

1. Which beliefs and expectations do student teachers hold at the beginning of their maths study?
2. Which significant changes can be observed between the beginning and the end of the first term?

## The inquiry instrument and a description of the setting

We developed a questionnaire similar to Grigutsch et al. (1998) and "Mathematics teaching in the 21st Century (MT21)" (Schmidt, 2006, Part C). It is divided into two parts: the first 41 statements deal with the personal view of mathematics; the second part consists of 19 statements to investigate subjective expectations. In both sections, different four-point Likert scales are used to measure the level of agreement with the given statements. The first one spans from *strongly agree* (1) to *strongly disagree* (4), the second one from *fully* (1) to *not at all* (4). An example of the first part is: *If one doesn't know the correct procedure to solve mathematical tasks, then one is lost.* And from the second part: *My mathematical education qualifies me to learn prospective and unknown content of the subject curricula on my own.* We surveyed students before and after attending their first mathematical course in 2017/18 (winter term) using the same questionnaire. 374 students participated in the pretest, 186 in the posttest. The paired sample has a size of 150 participants.

## Evaluation process

An exploratory *factor analysis* was carried out to get an insight into the beliefs of the young student teachers. The data from the paired sample were tested by the *Wilcoxon test* for significant differences (caused by the attended lecture) between the data of the pretest and posttest. Finally, *frequency distributions* were generated for each factor regarding the pre- and the posttest in order to explain the detected differences. Data analyses were conducted using SPSS.

## Results

From three relevant factors, two should be mentioned here. The first one contains 16 items (Cronbach alpha 0.869, explained variance 11.990 %). This factor contains items like: *My mathematical education empowers me to follow mathematical in-service trainings*. It can be interpreted as, “Autonomy concerning the subject teaching design”. This shows that future maths teachers have specific expectations concerning their mathematical training at the beginning of their study. It seems that the conviction of becoming experts in mathematics made a considerable shift ( $p = 0.027$ ): from *fully expect* (69.51 % to 55.67 %) to *expect partially* (29.27 % to 41.24 %). Although the relative frequency of *hardly expect* is small, it increases by a factor of more than 2.5.

The other factor refers to mathematics without practical utility (two items, Cronbach alpha 0.817, explained variance 3.697 %). One statement with negative loading is given for illustration of this belief: *Many aspects of mathematics have practical relevance*.

## Discussion

Regarding the first factor, the results indicate that the first maths lecture, “Introduction to mathematics”, cannot fully answer the students’ expectations. The originally strongly anticipated expectations of getting more mathematical autonomy had decreased. In the light of Shulman’s (1987) conceptualisation of content knowledge, the described changes are hardly conducive.

# Preservice teachers' geometrical discourses when leading classroom discussions about defining and classifying quadrilaterals

Gry Anette Tuset

Western Norway University of Applied Sciences, Norway; [gry.tuset@hvl.no](mailto:gry.tuset@hvl.no)

*In this paper I use Sfard's commognitive framework to investigate four geometrical discourses, as they appeared when preservice teachers (PSTs) were leading classroom discussions about defining and classifying quadrilaterals in authentic lower secondary school classrooms. Their tryouts are part of a broader learning teaching project in a practice-based teacher education course in Norway. The focus is on mathematical problems PSTs address in learning-teaching situations, with students and geometrical discourses, in their efforts to promote hierarchical relations between quadrilaterals using pre-constructed dynamic figures in Geogebra. The analysis shows that PSTs create opportunities to talk about hierarchical relations. However, they struggle to move between static and dynamic ways of talking about geometrical objects when needed and it seems challenging to build appropriately on students' prototypical and partitional contributions.*

*Keywords: Commognitive framework, Defining and classifying quadrilaterals, Preservice teachers*

## Introduction

The most challenging work preservice teachers (PSTs) face in enacting current reforms is to orchestrate classroom discussions that use students' responses in such ways that they advance the mathematical learning of the whole class (Lampert, Beasley, Ghouseini, Kazemi, & Franke, 2010). The PST is expected to execute skilled ways to support and challenge students when they are presenting their ideas, and build upon them by contrasting, comparing and connecting their ideas to accepted disciplinary ideas (Stein, Engle, Smith, & Hughes, 2008). For students, age 13-15, it could mean helping them move from using visual recognition or informal properties check when identifying and comparing geometrical shapes, to using definitions and state logical arguments to justify claims about these shapes (Sfard, 2008; Moss & Sinclair, 2012).

Defining and classifying quadrilaterals contribute to the development of geometrical thinking and mathematical argumentation and proof (Fujita & Jones, 2007). Research reports, however, that PSTs and students find it difficult to understand and accept hierarchical relations of geometrical shapes (e.g., Fujita & Jones, 2007; Millsaps, 2013). A significant reason is their reliance on prototypical images. Hershkowitz (1990) describes prototype examples as the subset of examples that have all the necessary properties and, in addition, other specific (none-necessary) properties that have strong visual characteristics. Prototype images often lead to what de Villiers (1994) calls partitional definitions, which exclude, for instance, rectangles from being parallelograms. In mathematics, hierarchical definitions, which includes rectangles as parallelograms, are preferred because they are more economical and useful. Consequently, defining and classifying quadrilaterals are highly interrelated activities (de Villiers, 1994).

Leading classrooms discussions is a complex and situated activity (Stein et al., 2008). One way of looking at this complexity is to see teaching as an activity of problem solving and problem posing (Lampert et al., 2010). These problems arise in establishing and maintaining relationships between the teacher, students and the mathematics because of the constraints and possibilities the

participants generate during instruction (Lampert et al., 2010). For instance, the way the teacher creates and exploits opportunities for mathematics learning can constrain or promote the kind of mathematics students can engage in (Sfard, 2017). Similarly, students and the mathematics can both constrain and open up what the teacher can do to teach. To solve these problems of practice, the teacher needs to deal with a wide range of issues across social, temporal, and intellectual domains. This paper focus on mathematical problems PSTs address in situations, with students and mathematics, in their efforts to promote hierarchical relations between quadrilaterals using shape makers (i.e. pre-constructed dynamic figures in Geogebra). For this purpose, I use Sfard's (2008) commognitive approach to examine the geometrical discourses that developed in four whole-classroom discussions led by PSTs in authentic classrooms. The framework enables me to make claims about PSTs' geometrical discourses in terms of how they communicate when teaching (Sfard, 2017). In the following, I will first briefly outline key concepts from the commognitive framework related to characteristics of geometrical discourses. Then I will introduce the context of the study and illustrate identified mathematical problems with excerpts from the discussions.

## Theoretical background

The movement towards a geometrical discourse that includes hierarchical definitions are, by Sfard (2008, p. 256) called meta-level development, because the rules that governs the participation change and words are used differently than colloquial discourses. Taking a participationist view, these changes must be mediated by an experienced participant in the desired discourse (Sfard, 2008, p. 254). I therefore argue, as Sfard (2017, p. 55), that being able to capture mathematical problems PSTs address in their attempts it is necessary to go into the finest details of the geometrical discourse offered. From a commognitive perspective (Sfard, 2008, p. 93), this means the use of *words* (e.g., parallelograms) and *visual mediators* (e.g., shape makers created for the sake of communication) to surface how geometrical objects are perceived and the construction and substantiation of *geometrical narratives* (stories about geometrical objects) to characterize the *routines* (e.g., how to identify shapes) employed in the classroom.

Sfard (2008, p. 228) describes orders of geometrical discourses, where each subsequent discourse is a meta-discourse of the former and geometrical objects typically arise as a result of *saming* lower order objects. Drawing on Sfard's work, Sinclair and Moss (2012, p. 31) present three orders of geometrical discourses relevant for school. In first and second discourse, identification routines rely on a continuous transformation of a figure into a prototype and some informal properties check of necessary and specific properties. The words are mainly used as proper names of concrete objects or as family names of exclusive classes of concrete objects. In the third geometrical discourse, transformability is no longer the official identification routine. Here, recognition needs to be followed by a discursively mediated procedure, such as, checking if the conditions described in a definition holds or not. The set of properties listed in a definition are seen as necessary and sufficient conditions for determining membership in a category. This means that the new routine opens up for the possibility to call a figure by several names (Sinclair & Moss, 2012).

Studies (e.g., Millsaps, 2013; Sinclair & Moss, 2012) report that dynamic environments are helpful to move towards more sophisticated geometrical discourses. It is especially the actual witness of

continuous transformations of shapes when dragging a figure that is promising because students flex their prototypical range of shapes they are ready to call the *same* (Sinclair & Moss, 2012). However, according to Sinclair and Yurita (2008), the transitions between dynamic and static media are challenging, because the transitions influence the talk about geometrical objects. For instance, in dynamic geometry, identification routines become time-dependent and human-based operations that invite students to act on the figure. In addition, Millsaps (2013) found that PSTs struggle to move between the two discourses when they explore shape makers that embody hierarchical definitions.

## Methods

The PSTs in this study are undertaking a one-year mathematics course as part of a four-year Norwegian teacher education program for lower secondary school teachers. They were provided opportunities to move back and forth between campus and practicum to collaboratively prepare for, enact and reflect on their teaching. In their preparation, the PSTs investigated seven shape makers. See Figure 1. Each maker generates a category of shapes with all necessary properties of specific quadrilaterals. The PST rehearsed discussions about these makers where they all acted, in turns, as teachers and students. Afterwards, four practicum groups planned a lesson using Stein et al.'s (2008) framework to prepare for classroom discussions in authentic classrooms. One PST taught the lesson. Others video recorded the activity.

**Figure 1: Four of the seven Shape Makers of specific quadrilaterals**

The videos and transcripts of the enactments and the rehearsals are data in this paper, as well as PSTs' portfolios about the tryouts. The focus is the geometrical discourses that surfaced in four classroom discussions with students. In addition, the rehearsals and the portfolios provide a window to PSTs' geometrical discourses before and after the enactments in the classroom.

The transcriptions of the classroom discussions were first organized into mathematical episodes that encompass the whole discussion around a claim about the shape makers. 55 episodes were identified and categorized in three groups; 1) 17 episodes about necessary and specific properties; 2) 18 episodes about the naming process; 3) 10 episodes addressed hierarchical relations. Since classification is closely related to definitions (de Villiers, 1994), I analyzed all episodes focusing on the use of words and routines related to orders of geometrical discourses (Sinclair & Moss, 2012). I looked especially for instances in the talk that seemed to constrain or promote the geometrical discourse in order to capture mathematical problems the PSTs address in these complex settings.

## Findings and analysis

The analysis shows that the four PSTs, called by pseudonyms Andy, Fay, Joy and Lisa, manage to create opportunities to talk about hierarchical relations in their discussions. However, PSTs struggle to address the problems that arise in the learning-teaching situations.

### **The problem of moving between dynamic and static ways of talking about geometrical objects**

This problem arises in almost all of the hierarchical episodes, which resonates with what Sinclair and Yurita (2008) and Millsaps (2013) report in their studies. For instance, in Lisa's, Joy's and Fay's first hierarchical episode they ask students if the diagonal angles are perpendicular in Figure B (the rectangle maker). The students answer "no." In contrast to squares, perpendicular diagonals is a specific property in rectangles. The PSTs exploit the opportunity offered and similar problems arise. However, they address them differently as illustrated by excerpts from Joy's and Lisa's discussion.

In Joy's discussion, another student disagrees and says; "yes, you can make the diagonals perpendicular. If you make it into a square. Just take it in"[19]. The student uses the terms "make it" and "take it in" to describe the dynamic movement involved in dragging the rectangle maker until it looks like a square. Joy acknowledges the suggestion and demonstrates the transformation-based routine on the smartboard.

Joy: Then it is not a rectangle anymore, it is a square. But a square is also the same as a rectangle. (3s) It can be a rectangle, but a rectangle cannot be a square. (2s). [20]

Joy reinforces the dynamic, exclusive way of talking about a rectangle becoming another shape, a square, in the first sentence (Millsaps, 2013). Then she contradicts this statement using an inclusive way of talking. Finally, she concludes with a dynamic and incorrect way of talking about the asymmetric relation between a square and rectangle. In the rehearsals, Joy's group addressed the same problem using the words "can be" and "cannot be" to express these asymmetric relations as well. In contrast, they used "can be" appropriately ("A rectangle can be a square, but a square cannot be a rectangle"). This shows that Joy struggles to articulate hierarchical relations when she moves between dynamic and static ways of talking about figures. Joy does not address these contradictory statements and she avoids hierarchical episodes in the rest of the discussion.

Lisa was in the same rehearsal group as Joy. In her discussion with students, she manages to use the term "can be" appropriately when she explains why diagonals "can be" made perpendicular in Figure B. She states the following inclusive narrative: "This is because a rectangle also can be a square"[43]. However, Lisa does not address the opposite asymmetric relationship, as Joy did. Nor does she verify the claim by using the hierarchical definitions she introduced to the students in the beginning of the lesson. In the other hierarchical episodes, Lisa repeats the same narrative, replacing "rectangle" with "rhombus" and "parallelogram." To conclude, the way the PSTs' address the problem of moving between dynamic and static ways of talking about geometrical objects seems to constrain the kind of mathematics students can engage in during the discussions.

### **The problem of building on students' prototypical and partitional contributions**

In Fay's and Andy's discussions, another problem surfaced. Namely, the problem of building on students' prototypical and partitional contributions. I use excerpts from Fay's talk about parallelograms (Figure D) to illustrate how students' contributions and the mathematical discourse seem to constrain and open up what PSTs can choose of possible solutions during the discussion.

*Diagonals “can be” perpendicular:* Fay’s first hierarchical episode surfaced in the discussion about perpendicular diagonals being a specific property in rectangles. Fay drags the rectangle maker to show that it is possible to make the diagonals perpendicular. When Fay asks if it can be named anything else than rectangles [50], a student suggests that it can “if we take it in”[51]. Fay reinforces the dynamic, exclusive way of talking about shapes when she uses the terms “become” and “could it” in her following questions; “what had it become then?”[52] and “could it be a square?”[54]. A student confirms and Fay concludes by saying “But, then the sides are of equal length, right?”[58].

*Diagonals “are not” of equal length:* After the discussion about squares and rectangles, Fay asks a student about the diagonals in Figure D (the parallelogram maker). “Are they not of equal length?”[61], a student replies. Fay asks if “they look equal?”[62]. The student revises his answer (“no, no, just kidding”[63]). Fay replies “OK” and concludes with a prototypical claim that diagonals “are not equal”[64]. Equal and perpendicular diagonals are specific properties to parallelograms and necessary properties to rectangles and rhombs, respectively. There are therefore many possible solutions and Fay has to make a decision which one to pursue. In this situation, Fay does not use dragging to explore these “can be” possibilities as she did in the discussion about rectangles “becoming” a square. She chooses to follow the path of “not equal diagonals.”

*Figure D is a parallelogram because it is “slanted:”* Fay reinforces the idea that Figure D is different from Figure A and B because the lengths of the diagonals are not equal (“OK, but we have just had two shapes where they (*diagonals*) were equal, so this must be something else then?”[66]). A student suggests that it is a parallelogram [69]. Fay prompts for an explanation why.

- |    |          |                                                                                                                                                         |
|----|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 77 | Student: | No, eh well. It is slanted.                                                                                                                             |
| 78 | Fay:     | It is slanted. (2s) What do you think? Do you think it has something to do with the angles maybe? ( <i>Points at figure D shown on the smartboard</i> ) |
| 79 | Student: | Yes                                                                                                                                                     |
| 80 | Fay:     | Yes. In a parallelogram. Will this be 90 degrees? ( <i>Points at an angle</i> )                                                                         |
| 81 | Student: | Heh?                                                                                                                                                    |
| 82 | Fay:     | Will this be 90 degrees? ( <i>Points at another angle</i> )                                                                                             |
| 83 | Student: | No                                                                                                                                                      |
| 84 | Fay:     | No. Will this be? ( <i>Discovers that she can use her finger to drag the figure</i> )                                                                   |
| 85 | Student: | You can pull it together.                                                                                                                               |
| 86 | Fay:     | Yes. If I do this? ( <i>She drags and figure D looks like a slanted rhombus.</i> )                                                                      |
| 87 | Student: | No                                                                                                                                                      |

In this situation, the student contributes with a prototypical and partitional claim about parallelograms (Hershkowitz, 1990). Fay repeats the student’s narrative and draws attention towards the angles in the vertices [78]. The phrasing of the questions has changed from the dynamic “could this be” to a static “will this be” 90 degrees. However, the student’s suggestion in [85] provides Fay with an opportunity to search for counter examples where the angles “can be” 90 degrees and therefore flex the student’s prototypical claim (Sinclair & Moss, 2012). She follows the student’s suggestion but drags the figure so that the diagonals become perpendicular, not the

vertices [86]. The potential opportunity provided by the student therefore becomes a confirming example, which is not sufficient to substantiate that the vertices “will not be” 90 degrees nor to convince the student that not all parallelograms are slanted. Fay does not address this problem in the discussion, but uses the dragging experience to verify that figure D cannot be a square, at least [93].

*In parallelograms, the diagonals are not equal, the vertices are not 90 degrees, and the diagonals are not perpendicular:* Fay drags the parallelogram maker back to a prototypical parallelogram.

- 95 Fay: Okay, we say that the diagonals are not of equal length, and the vertices are not 90 degrees. Are these 90 degrees? The angles inside here? (*Points at the diagonal angles*).
- 96 Student: No
- 97 Fay: Not 90 degrees? Yes, maybe this is a recipe for a parallelogram?(2s) Maybe.
- 98 Student: Maybe
- 99 Fay: Yes, because this is the only one we have seen until now that have different lengths on the diagonals. (*Points to the diagonals*)

During the discussion, Fay has shifted from talking about necessary properties used as conditions for determining membership in a category of specific quadrilaterals, such as squares and rectangles, to talking about conditions that exclude membership in a category of parallelograms. Fays advocates a “recipe”[97] where excluding conditions, such as “diagonals are not equal” and “vertices are not 90 degrees,” are sufficient conditions for naming a figure a parallelogram, because parallelograms “is the only one” they have seen that have different length of diagonals [99]. Furthermore, she claims that diagonal angles are not 90 degrees in parallelograms, despite the fact that she recently presented a counter example (the slanted rhombus). Thus, the dynamic perspective is absent when Fay talks about the properties of parallelograms, which I believe happened when she decided to follow the path of “not equal diagonals”[64] instead of the dynamic “can be” talk she promoted earlier. The other critical learning-teaching situation was when Fay decided to build on the prototypical claim about parallelograms being slanted [77]. I have tried to show how these decisions changed the inclusive talk that started in the first hierarchical episode where rectangles could become squares, and ended as a static and exclusive talk where rectangles and squares are excluded as parallelograms. These problems, I believe, affected the conflicting geometrical discourses that surfaced in the final hierarchical episode in Fay’s discussion.

*Parallelograms cannot be a rectangle, but a rectangle is a parallelogram:* In her final hierarchical episode, Fay recalls a peer PST’s teaching some weeks ago to sum up and end the discussion.

- 109 Fay: He talked about a rectangle that could be a parallelogram and the opposite. (.) Or, can parallelograms be a rectangle? (7s) Can it? (2s) Can this be a rectangle? (3s) (*Points at the parallelogram maker*) If I say to make this a rectangle, it must be 90 degrees at the angles here. (*Points at the vertices*) Can it?
- 110 Students: No
- 111 Fay: No, but can this (*Points at the rectangle maker*) be a parallelogram?
- 112 Student: Yes
- 113 Fay: Yes. Why?

- 114 Students: Because the opposite sides are parallel.
- 115 Fay: Yes, they are parallel and they are parallel. Right, this and this. (*Points to the pair sides in the rectangle*) They just go upwards and will never intersect each other. Yes. (2s) Figure B, it is in fact a parallelogram as well, but it can also be a rectangle.

In this episode, Fay asks students to compare rectangles and parallelograms. First, she asks if parallelograms can be a rectangle [109]. She waits for 7 seconds and there is no response. Fay simplifies the question by drawing attention to the vertices in the slanted parallelogram in Figure D and recalling that in rectangles they must be 90 degrees [109]. Several students reply no, which is correct according to visual recognition and the offered partitional definition that excludes rectangles from being parallelograms. Then Fay prompts for the opposite relation between rectangles and parallelograms asking if a rectangle “can be” a parallelogram [111]. The student claims yes, and she uses the lengths of the opposite sides as a necessary and sufficient property to determine membership in parallelograms [114]. The student uses the definition of parallelograms that most students in lower secondary school know. Fay acknowledges the contribution and she demonstrates what sides are parallel [115]. Fay ends up with two conflicting narratives, which are both endorsed using “accepted” definitions of parallelograms by the class community. The first uses the vertices not being 90 degrees to exclude rectangles from being parallelograms [109]. The second uses the opposite parallel sides to include rectangles as parallelograms [115]. Both suggestions are based on student’s contributions and Fay’s attempt to build on them. Fay does not identify the problem, which resonates with Millsaps’ (2013, p. 38) study that reports on PSTs being capable of holding two conflicting claims about hierarchical relations when they are moving between dynamic and static geometry.

## Concluding remarks

Several studies have used interviews or questionnaires to examine PSTs’ hierarchical reasoning and they report that PSTs struggle even though they have taken geometry courses as part of their teacher education program (e.g., Fujita & Jones, 2007; Millsaps, 2013). It is therefore no surprise that PSTs in this study meet similar challenges when they are trying to lead classroom discussions about defining and classifying quadrilaterals in authentic classrooms with students. However, what challenges and how they tackle them in this setting has not been sufficiently investigated.

The analysis show that the PSTs are in their early process of individualizing hierarchical relations between quadrilaterals. They manage to create opportunities for students to engage in hierarchical relations. However, none of the PSTs use hierarchical definitions in their reasoning about the shapes. This resonates with Fujita and Jones (2007) reporting that PSTs prefer to rely on specific examples when identifying shapes, even though they know definitions. When PSTs need to step in and out of dynamic and static discourses, they struggle to connect and articulate hierarchical relations as illustrated in Lisa’s and Joy’s discussions. Millsaps (2013, p. 38) reports on similar challenges where experiences with shape makers actually can reinforce some aspects of existing partitional definitions. She therefore highlights discussions about the use of classification narratives to support the transformation from partitional to hierarchical definitions (Millsaps, 2013, p. 40). Trying to interpret and build on incomplete contributions from students is challenging for PSTs

(Lampert et al., 2010). I believe Fay's discussion illustrates how difficult it is for PSTs to balance between honoring students' participation and promoting mathematical discourse in classrooms. Especially when the discussion requires a sensitivity to step in and out of geometrical discourses when needed and provide opportunities for students to engage meta-level development (Sfard, 2008).

*Uruguay is a country with an extensive government policy providing all teachers and students laptops and connectivity. In order to carry out new professional development programmes for teachers of mathematics to use digital technologies in classrooms, we developed a qualitative study, collected data, and analysed teachers' concerns and needs for classroom-based technology use, identifying a set of guidelines to assist teachers. The programme was designed to offer teachers key experiences that can help them to achieve their didactical goals. As traditional courses and assessment did not address the detected needs, game components were incorporated into the teacher training programme. Gamification contributed to the solution of several problems such as formal assessment, certification, passing grades, adaptive content and self-evaluation. This paper reports and links two studies about identifying teachers' needs and the impact of a gamified professional development programme developed in Uruguay.*

*Keywords: Teacher education, professional development, gamification, technology uses in education.*

## Introduction

Uruguayan schools were transformed in the past decade, because of the utilisation of digital technologies for educational purposes. *Plan Ceibal*, a government policy that has provided a laptop to each student and teacher in public schools for more than a decade now, as well as connectivity all over the country, significantly changed classrooms in Uruguay (Plan Ceibal, 2017).

The new presence of digital technologies was challenging for teachers, who had to face these changes on their own, or supported by special, but often ineffective, professional development programmes. Such transition for teachers was not easy, especially because of some characteristics of Uruguayan teachers of mathematics: most of them have multiple jobs (60% teach in at least two schools), there is an important deficiency in their training (only 1 out of 3 of those who are teaching mathematics at middle schools finished their basic teacher's training) and they do not have enough time for attending professional development activities (paid hours are only for teaching) (INEEd, 2017; González, González, & Macari, 2013).

Consequently, professional development was required by teachers and strongly encouraged by authorities and supervisors. Nevertheless, as Assude, Buteau, and Forgasz (2010) state and our research confirmed, these activities did not significantly impact teachers' everyday lessons. The problems of identifying professional development programmes' long-term impact and promoting their sustainability have been analysed in several contexts (Loucks-Horsley, Stiles, & Hewson, 1996; Zehetmeier & Krainer, 2011; Zehetmeier, 2017).

Teachers and their supervisors agree about the minimal impact of existent professional development programmes on technology transition. Thus, we carried out a first qualitative study to identify the key

aspects that should be addressed in these programmes to assist mathematics teachers to utilise didactical advantages of digital technologies on a regular basis.

This paper summarizes results of the first phase of this study and reports on subsequent research: after designing and implementing a professional development programme according to the key aspects we found, we analysed its impact based on teachers' perceptions. The unexpected appearance of gamification elements when designing the programme resulted in an interesting and challenging contribution.

## **How to assist teachers of mathematics to improve their technology-based lessons?**

The first part of this study suggested two key aspects of professional development, as follows.

### **Research design and methods**

The major research question of this phase was: What key aspects should be addressed in a professional development programme for mathematics teachers in Uruguay to assist them to utilise didactical advantages of digital technologies on a regular basis?

Experts who were interviewed suggested that this question had been discussed by national supervisors and trainers, but they provided unclear answers. We wanted to investigate teachers' concerns and difficulties, but letting other relevant key elements emerge as well. Thus, we decided to design a qualitative study based on a Grounded Theory approach (Glaser, & Strauss, 2009). Experts, teachers and their supervisors participated in (13) semi-structured interviews. Participants were asked about their and trainees' concerns; the obstacles teachers encounter while trying to use technologies in their classrooms; and also about their personal experiences of learning/teaching with technologies.

Data were processed using TAMS Analyzer (Weinstein, 2015), identifying emerging concepts through coding and recoding the interview transcriptions. This process let us also detect topics participants addressed spontaneously, which were not directly asked by the researchers. We can assume that if certain subjects show up regularly, even with no explicit questions, they might be closely related with our study aims (Cohen, Manion, & Morrison, 2015).

In order to offer more comprehensive answers to the research question, scientific literature was reviewed and integrated (e.g., Assude, Buteau, & Forgasz, 2010; Fullan, 2016; Loucks-Horsley, Stiles, & Hewson, 1996; Zehetmeier & Krainer, 2011).

### **Findings, first set: Obstacles and concerns**

Interviewees were asked about the obstacles teachers encounter while they try to use digital technologies in their teaching. We detected four main obstacles: (a) a lack of *resources*: teachers say that devices do not work as expected, there are technical issues, connectivity fails, and it is not true that every student has a functioning computer because they are often broken; (b) a lack of *time*: teachers point out that it is very difficult to plan different lessons, as they do not have enough time to do so; (c) a lack of *feedback*: teachers say that they need to be encouraged by principals and supervisors to change their ways of teaching, otherwise they feel that they might not be working as they should; and (d) a lack of *confidence*: teachers are taken out of their comfort zones, so they might need assistance and encouragement to believe in their own teaching skills in technology-assisted environments.

We also investigated teachers' interests and concerns regarding training topics. The data showed that teachers' concerns evolve gradually. Inexperienced and untrained teachers usually belong to the first step, and experienced trainers are placed in the top one (Figure 1). Each teacher recognizes other steps; nevertheless, they point out that the most concerning one is their own. Those who are at the top of the stairs declare that they have been in the previous stages before, but thanks to experience and training their concerns evolved. Steps are represented in Figure 1 and explained below.

**Figure 1: Teachers' concerns**

*Usage:* teachers think that they need to be skillful at using software to be able to use it in their classrooms.

*Potential:* teachers understand that knowing what is possible to do with computers is more important than knowing how to do it.

*Pedagogy:* teachers are concerned with how technologies could help students to understand mathematical concepts.

*Adoption:* using technologies in classrooms on a regular basis is even more important, because otherwise learning is not as meaningful as it could be.

*Benefit:* teachers are focused on students and their learning outcomes, and they think that if everything else does not help you achieving the main goal then that is not important.

Teachers usually recognize the steps that they already went through, but they do not clearly visualize themselves in the higher stages. According to supervisors and experts, teachers should be assisted to be raised to higher steps as quickly as possible, because that means important improvement in their skills.

These findings are also consistent with previous research in the same topic (Biehler & Nieszporek, 2017; Liu & Huang, 2005; Loucks & Hall, 1979).

### **Findings, second set: Collaboration and leadership**

One of the unexpected results of this phase was the importance of collaboration among teachers. Even when teachers were not asked about it, they expressed that being part of a team and being able to discuss pedagogies was a condition to improve their skills and learn how to use technologies in their lessons. Every interview suggests that it is not possible to evolve without teamwork.

Schools' leadership style also arose unexpectedly as a key aspect. Flexible rules, less bureaucracy and principals' good will are necessary conditions for teachers to improve their technology-assisted teaching skills.

### **Findings, third set: Innovation and motivation**

In addition to the findings from the gathered data, we should also pay attention to the scientific literature on pedagogical innovations. Teachers adopting technologies on a regular basis arose as an important educational change in several aspects (Berman, 1981; Fullan, 2016). In order to assist teachers in this process, the complexity of every innovation should be carefully monitored.

Using multiple resources to keep and raise teachers' motivation at a high level is also essential, because the Uruguayan educational system does not offer them significant rewards for attending professional development programmes.

### **Preliminary conclusion: A set of guidelines, a set of experiences**

We can summarise the previous findings in the following set of guidelines, which describe the key aspects of a professional development programme that should facilitate teachers' development with technology:

(1) Assist teachers to face the typical obstacles by teaching them particular solution strategies; (2) offer them various topics during courses according to each step of concerns (Figure 1) and try to guide them to be raised to the subsequent step, this should be done individually considering teachers' specific needs; (3) encourage them to collaborate, we discovered that it is a crucial aspect for their development; (4) guarantee schools' support to teachers (principal and supervisors should agree with the courses, computers must be available, etc.); (5) remember that the patterns of every innovation apply; and (6) keep motivation level as high as possible through various strategies (discussed in previous papers in detail).

It is important to point out that, according to interviewees, teachers' learning is associated with certain vital experiences in their teaching careers, but maybe not to traditional courses. If a traditional course makes a change in participants, it means the course promotes these key experiences (i.e., it includes collaborative planning, observing lessons, being observed, discussing pedagogies and results, etc.). As Loucks-Horsley, Stiles, & Hewson (1996) state, it is necessary to provide teachers with opportunities to develop knowledge and skills, but it seems that courses with a traditional format are not sufficient.

### **A pilot programme from a new perspective**

The first part of this study highlighted that professional development activities for Uruguayan mathematics teachers do not fully satisfy their needs; thus, they are not completely sufficient for their development. Experts, teachers and their supervisors expressed that courses are interesting and you can learn because of them, but they only slightly affect their pedagogies.

Through the comparison of courses and guidelines, we can detect that numerous training conditions were satisfied, such as supporting innovations' characteristics and helping teachers to tackle common obstacles. Missing points are detected: course syllabi are rigid and therefore they do not care about individual concerns, and the formal structure of a course does not guarantee the crucial experiences like collaboration, team planning, lesson observation and discussions, etc. Even when collaboration was encouraged in best-rated courses, assessment was based on traditional methods, such as tests, examinations, writing or presenting. As Zehetmeier & Krainer (2011) recommend, "Considering and facilitating these fostering factors (and at the same time avoiding the hindering factors) when

designing and implementing professional development projects is one important step on the journey to sustainable in-service teacher professional development”.

One of the main challenges for professional development programmes seems to be reassuring teachers that they will experience what is needed for them to learn, and also taking those experiences as valuable components of the certification process. We designed a pilot professional development programme, which implemented every guideline and we tried it in different courses. We outline here the main characteristics of that programme.

In order to increase teachers’ motivation and help them to overcome the common obstacles, agreements with schools and training institutes were signed. Schools would guarantee adequate conditions for teachers (fully working devices, availability of computer laboratory, flexibility with teacher to observe colleagues’ lessons) and the training institute would issue certificates.

The basic structure was a traditional online course (because teachers do not have time for face-to-face workshops), four months long. 16 participants began the course and 4 of them finished, which is a more than acceptable ratio for an online free course. Through detecting teachers’ interests (by questionnaires and analysis of forum posts), the moderator assigned special materials and tasks to each participant, addressing personal concerns and expectations.

Assessment was designed to oblige teachers to go through the key experiences, so it was mandatory to work together, observing lessons, welcoming someone else into his/her classroom, giving feedback, etc. A multi-dimensional credits system was designed to establish the passing point, thus key experiences were not avoidable. From the very beginning, teachers knew how many credits of each kind they needed to be able to pass the course. Nevertheless, there was also a minimum total amount of credits they had to collect; getting the minimum of each type would not be enough, they had to go deeper and obtain more credits in any aspect they preferred.

This assessment and certification system led us to a complex set of rubrics; it was accurate and let us achieve our goals, but it could be confusing for teachers, hindering motivation and transparency. This led to the emergence of gamification components in the study.

We represented the credits with colourful stars (one colour for each dimension), so the goal was to collect as many stars as possible. We designed a personal dashboard (Figure 2) for each participant, in which you could see how many stars you have, which colours are missing and how to obtain them.

In this case, game elements are not changing the essence of the design, but they only make it nicer. As Stott & Neustaedter (2013) explain, most of what gamification, in the sense of Deterding *et al.* (2011), implies is already recognized and utilized in school, although under different designations.

**Figure 2: Personal dashboard and definition of credits**

### Research design and methods

The second part of this study intends to answer the following questions: To what extent can this course design address teachers' needs and expectations? What is the contribution of game elements in this professional development programme?

A case study was designed to understand participants' evolution during the course (Yin, 2003; Cohen, Manion, & Morrison, 2015).

An online platform (learning management system) was used, and forum posts and interactions were analysed. Questionnaires (to identify main participants' concerns regularly and detect evolution), several interviews and lesson observation were carried out before, after and during the course. All data was transcribed and processed with qualitative data analysis software (Weinstein, 2015). Most of these data were used during the course to adapt contents to participants' concerns.

### Preliminary findings

The analysis showed that teachers were pleased with the flexibility of the programme; they enjoyed that content was adapted to their concerns and they actually tried out in their classrooms what they learnt. All teachers expressed that this experience changed the way they think about teaching; suggesting that an important modification in their perceptions happened, that can be associated to a progress in the concerns model. They found the opportunity in this programme to develop their skills and knowledge (Loucks & Hall, 1979). They also expressed that assessment was a bit overwhelming at the beginning, but afterwards the funny stars and the dashboard made it easier, motivating them and eventually they were not worried about certification. Game elements helped them in terms of self-assessment and motivation.

## Discussion

We began thinking about the contribution of gamification in teacher training as a necessity to motivate teachers and change the environment of the teacher-training course. Understanding gamification as the utilisation of game components in non-game contexts (Deterding et al., 2011), using game elements like collection of stars and personal dashboards helped us to deal with the complexity of the course's design. We cannot assume that the presence of gamification elements is the reason for the course to be successful (Dicheva et al., 2015), we need further measurement of changes (Stott, & Neustaedter, 2013). There are also drawbacks in the integration of gamification in education (Hanus & Fox, 2015), but based on our experiences and this study there are good prospects for further developments.

This study confirmed that it is possible to design a professional development programme for teachers, which has serious assessment and certification, but is based in key personal experiences, adapted to different concerns and expectations (Loucks & Hall, 1979). Traditional methodologies should be modified to achieve this goal, but it can be done as demonstrated above.

Gamification arose as an unexpected ally, simplifying assessment, enhancing motivation and offering new opportunities for adaptive content. Thus, we believe that teacher training courses with gamification elements should be designed and further researched.

# Action research as a potent methodology for improving teaching and learning in mathematics

Eda Vula

University of Prishtina, Faculty of Education, Kosovo; [eda.vula@uni-pr.edu](mailto:eda.vula@uni-pr.edu)

*This paper represents an effort of the author to better understand teachers' perceptions of their experiences during their engagement in the action research process. In completing their action research projects, teachers not only learned how to conduct research themselves but, also, they shared some of their experiences. The course structure has had the effect of encouraging teachers to try new methods in their teaching, to use new resources and to improve the communication outside class in order to improve their teaching and their students' performance in mathematics. Further, it was discussed about the possibility of involving teachers, both, pre-service and in-service, in the action research studies and the possibility of support for them from the university and the government as an initiative for the successful implementation of education reforms.*

*Keywords: Action research, teachers, perceptions, improvement, teaching.*

## Introduction

During the last two decades, the system of education in Kosovo underwent several reforms in order to respond to social, cultural and political developments in the country and broader societal aspirations for integration in European and global processes. Along with ongoing reforms, special attention was paid to the development of education programs for quality teacher training in line with common European principles for teacher competencies and qualifications. Unfortunately, the results from the Programme for International Student Assessment (PISA), conducted in 2015 and in which Kosovo participated for the first time, were quite discouraging. (OECD, 2016). Until recently, the teachers' qualification programs for subject teaching, as well for mathematics were mainly based on subject knowledge, being developed in the academic unit of the University of Pristina. Because the relationship between "academic" and "professional" courses was mostly "bloodless" and teacher training in Kosovo was mainly academic and heavily subject-based (Vula, Saqipi, Karaj, & Mita, 2012, p. 38), the Ministry of Education and Technology in Kosovo made the decision in 2012 to reform the study programs for subject teachers' qualification according to the consecutive model. Thus, all teachers should complete 3 years of academic studies for the respective subject in the relevant academic programs at Bachelor level and 2 years at Masters level at the Faculty of Education, where they have specific training in subject pedagogy and practice teaching. These programs have started to be implemented for the first time in the 2016/2017 academic year. Students enrolled in these programs are those who have no experience in teaching (prospective teachers), but also those who are already mathematics teachers in grades 6-12 and want to advance their qualification at Masters level. Last academic year, the action research course was offered as an elective course, and all of the enrolled students were already teachers. As a course instructor (author), my objective was not only to review the action research projects conducted by teachers but also to better understand the teachers' perceptions in terms of their benefits, experiences as a researcher and their students' benefits during the action research process.

## Literature review

Action research is a method used for improving educational practice (Koshy, 2010). Considered as a powerful tool for change and improvement at the local level (Cohen, Manion, & Morrison, 2007), it is any systematic intentional inquiry conducted by teacher-researchers to improve their practice and students' outcomes (Mills, 2013; Cohran-Smith & Lytle, 1993). It is a study process of a real situation in a classroom which assists in teacher education through linking theory and practice (Stenhouse, 1975). According to Elliott (1991), the theoretical understanding of education, knowledge, learning, and teaching are derived from curriculum practices and teachers. Thus, two of the most essential purposes for doing action research are the improvement of the quality of activities or teaching practice and the development and testing of the practical theories that guide one's own practice (Feldman, Altrichter, Posch & Somekh, 2018). According to Koshy (2010), action research is "a constructive inquiry in which the researcher constructs his/her knowledge on specific issues through planning, action, evaluation, refining and learning from experience" (p. 9). It is one of the most essential motives for teachers to improve the quality of their actions and a potent methodology for educational reform (Somekh & Zeichner, 2009). Action research is intended to support teachers with the challenges and problems of practice and carrying through innovations. Somekh and Zeichner (2009) focused on the remodelling of action research theories and practices in response to local cultures. They presented five variations of action research: in times of political upheaval and transition; as a state-sponsored means of reforming schooling; co-option of action research by Western governments and school systems to control teachers; as a university-led reform movement; and as locally-sponsored systemic reform sustained over time. According to Somekh and Zeichner's analyses, a common feature in these variations of action research is the importance each demonstrates of working towards a resolution of the impetus for action with the reflective process of inquiry and knowledge generation, to generate new practices (2009). Improving teaching practice and generating new ones is very important for teachers' everyday work, but action research has impact also on increasing teachers' self-confidence for their role as researchers and fostering collaboration amongst peers in their school environment (Vula & Saqipi, 2015). Action research should be part of both preservice and in-service teachers' professional development programs. Examining the curriculum of action research for teachers' education requires a critical appraisal of the ways in which preservice teachers think critically and creatively about their practical experience to know and understand research and teaching, as well as how they craft their own pedagogies (Capobianco & Ní Ríordáin, 2015). On the other hand, action research curriculums used by in-service teachers are focused on the teachers' own situations, training to validate their own teaching practice. Krainer & Zehetmeier (2013) present an example of a national initiative for fostering mathematics and science education. They have introduced the "lessons learned" from a project that promoted teachers' investigation into their own work. In that project, teachers were key stakeholders in innovation and research. The authors provide exemplary research results for the teachers' critical stance towards innovation and inquiry as an important basis for disseminating inquiry-based learning. The individual and the social dimensions, as well as actions and reflections, should be part of the professional development programs (Zehetmeier, Andreitz, Erlacher, & Rauch, 2015). In addition to the individual engagement of the teacher researchers, it has been shown that teachers are successful and can achieve tremendous results when they co-operate with their colleagues and are supported by the university teachers (Altrichter, Posch & Somekh, 1993). Other researchers have shown that teachers' perceptions on action research

are related with an opportunity for them to deepen their knowledge of the content they provide, to strengthen the pedagogical aspect of the classroom, increase sensitivity to the affective concerns of students and place themselves as creators of knowledge and researchers (Sardo-Brown, 1995; Goodnough, 2011; Vula & Saqipi, 2015). Bonner (2006), in her study of professional development of two teachers, has shown that throughout action research projects, both teachers acquired “richer knowledge” of how to teach mathematics, and “new ways of thinking” about learning about their students, and about themselves (p. 40).

This study aimed to reveal the perceptions of mathematics teachers on the impact of the action research projects on their teaching and students’ learning, as well as the benefits of the process itself.

## **Method**

Eleven teachers attended the action research course offered in the spring semester of the 2017/18 academic year. The course was offered to the master degree program for mathematics teaching at the Faculty of Education, University of Prishtina. The course participants (teachers) attended 15 weeks of action research course instructions, applications, and action research methodology. During the course, the teachers were expected to think about a problem or issue they encounter in their classrooms. As part of the course assignment, each teacher was asked to conduct his/her own action research project based on his/her individual classroom students’ needs. First, the teachers worked on their research problem, purpose, methodology and literature review. Then, during class discussions, the instructor and the teachers were “critical friends” in regards to the teacher project ideas, the development and implementation of the systematic plan, serving as a validation group for action research projects. They established trusting relationships, which became the grounds for giving and receiving feedback on the validity of the evidence (McNiff & Whitehead, 2009). Later, the teachers conducted their research in their classrooms, where they collected the data, analyzed and further discussed their findings as a final report paper, part of their assignments.

After completing the course, a questionnaire with three open-ended questions was sent to them via email. The questions were related to teachers and students benefits on conducting the action research project, as well as their experiences as a researcher-practitioner. In this paper, only four teachers who responded fully to the open-ended questions have been reviewed and discussed. The participants are mathematics teachers with diverse teaching experiences: Egzon has three years of teaching experience in a non-public middle school; Isuf has ten years of teaching experience in a rural middle school; Qendresa and Besmir have five years of teaching experience in a secondary school.

As a lecturer for the action research course, I played the role of a facilitator helping the teachers carry out their own action research. The teachers’ action research reports, my notes during class lectures, discussions, and the written responses to the open-ended questions used to conduct the research are presented in this paper. A qualitative content analysis research methodology (Cohen, Manion and Morrison, 2007) was used to identify major themes related to the three questions on the impact of the action research process: What are you and your students’ benefits of doing an action research study? What are some of your key experiences as a researcher? What advice would you give to colleagues about action research study?

## Findings

All teachers inquired into different aspects of their teaching by defining research questions of relevance to their everyday situations, by collecting data, interpreting, drawing conclusions and writing down their findings in the research reports. The summaries of the action research projects, which are described below, are taken from the four teachers' reports.

### The descriptions of teachers' action research reports

In his action research project, Egzon explains the reason why he was concerned with students' poor engagement in doing their homework in mathematics. As a mathematics teacher in a middle school, he had reviewed numerous sources about the importance and effect of performing homework, but he was more concerned about managing this process. In other words, he wanted to see if using the online platform would efficiently link the relationship between performing homework and observing or controlling their performance by students. Thus, in order to conduct his project on the online platform he involved the parents, strengthening the communication between parents, students and himself. Since the school where Egzon works is non-public and learning is conducted in English, he has been able to use the internet and other resources needed for the project. The engagement of Egzon in an action research project influenced not only an increase in the level of performance of the homework and the improvement of communication between parent, student and teacher but also the enhancement of quality in understanding the mathematics concepts and time management efficiency in carrying out the homework.

Isufi is another middle school mathematics teacher who works in a rural school. His concern was related to students' difficulties understanding fractions. Even though fractions are taught in primary education, according to the curriculum, in the sixth-grade students expand their understanding of fractions and continue learning fraction operations. As a mathematics teacher, Isufi was concerned with his student's preconceptions of fractions. Most students were confused about the concept of fractions, so he decided to explore more on teaching methods that could facilitate students' learning. He decided to use not only physical manipulatives but also virtual manipulatives. Similar to many schools in Kosovo, the school where Isufi works deals with a lack of labs and not all teachers know English. However, he planned to use ten computers that the school had so that each student would have the opportunity to use them. Isuf expressed that using new methods in the class was a challenge for him, especially when resources are not in the native language. But it is worth trying when such an action raises the students' interest and improves their learning.

Isufi had hypothesised that teaching his students how to use manipulatives, both physical and virtual, would improve their understanding of the fractions concept. Thus, after he collected data from several action research projects, he found that nearly all of his students improved their knowledge of fractions.

How to motivate and encourage students to learn mathematics? was one of the questions that Qëndresa, a mathematics teacher in the secondary school, often asks herself. She was concerned that her students spent most of their time using smart phones on social networks, so she thought of exploring if their phones could be of use to learn mathematics. Thus, she decided to engage students with IXL's interactive mathematics platform and to systematically evaluate if the students can improve their results in solving quadratic inequalities. She engaged her 32 students to use the

interactive platform for the period of a month. The students were enthusiastic and curious to use the platform, she observed. Although it was challenging, Qëndresa noted a change in students' behaviors. After completing her research, Qëndresa concluded that:

Practising online tasks specifically of the IXL Math platform, makes all students active, more responsible problem solvers and more focused on tasks to cover the gaps and understand concepts by having fun and testing themselves.

Another action research study has been done by Besmir in secondary school. Unlike the previous action research studies, he put his effort into attempts to arrive at conceptual understandings of probability, which be considered problematic when students are asked to connect with everyday problems. Previously, Besmir reviewed the different studies in the field of probability teaching and was inspired by the findings of Zhonghe Wu's study *Using the MSA model to assess Chinese sixth graders' mathematics proficiency*. He adapted the MSA Model for his teaching of probability. His action research was based on quantitative data. He used a quasi-experimental design in order to assess the impact of the MSA model. For the intervention, he has developed learning plans based on the MSA model. This model shows the conceptual understanding, presenting a strategy that demonstrates the procedural steps for problem-solving and application or creating a similar word problem in a realistic situation. For implementing his study, he has separated all students into two groups, experimental and control group. In the experimental group, the teaching was based on the MSA model, whereas in the control group it was with traditional methods. A t-test analysis of scores from pre- and post-tests indicated that the experimental group performed significantly better than the control group.

### **The teacher's perceptions on the action research process**

All of the teachers have shown that the benefits of an action research study were numerous. Some benefits mentioned by the teachers were related to the innovations in their teaching and their commitment to using various resources to improve the performance of their students. Below, are some of the thoughts shared by the participants:

The action research conducted in my classroom was a new experience for me, it was quite challenging. First, I had to analyze many research studies that have treated the same problem. I had to examine not only the theory that we have learned in other courses but also the different practices of teachers which helped me to improve the pedagogical aspect of my teaching and also to strengthen the academic components. (Besmir)

Teachers had observed that the carrying out of their action research projects in their classes increased the engagement of the students as well. The use of class activities that were not used earlier in the classrooms was one of the factors that stimulated students to be more active in mathematics class.

Self-confidence, passion for math, dealing with success and failure, accepting similarities and differences in problem-solving methods, giving and receiving help in group work were some of their characteristics that I didn't notice before. (Qëndresa)

My experience with action research had two effects. First, it has changed my habits and the second, I have changed my expectations for my students. I see action research as a stimulus

not only for changing my teaching but also as a stimulus for students' engagement in the learning process. (Egzon)

Action research is a methodology that also helps us as teachers to turn the attention to ourselves, to understand our teaching methods, to find out what would be the best way to present different mathematical concepts to students, to measure our knowledge and supplement them if needed. (Besmir)

As a result of doing action research, teachers also shared some key experiences. The problems that arise in classrooms are often overlooked. For them, action research has increased their responsibility to deal more in detail with students' needs. Through action research, the teachers gained a lot of information during their literature reviews. The literature review has helped them find models and examples, which were later used in their teaching, practicing the new pedagogical methods. However, because there is limited research in mathematics education in the Albanian language, for some of them using the resources in English was a bit challenging. Thus, an important impact of the action research studies was not only to supplement gaps in the teachers' pedagogical knowledge and subject knowledge but, also to practice and improve their English.

Action research can be considered as a tool to make changes in our classrooms. Each step we make towards a change by adapting to today's time and student preferences can be successful. Therefore, I recommend all math teachers to consider action research as the method that gives them the answer every time they have a dilemma to reach out to their goals. (Isuf)

In addition to the benefits, the teachers have also presented some of the difficulties during the action research process. Difficulties in access to relevant documents, the understanding of the English language during the literature review, the data analysis and the limited time to complete the research by the end of the semester.

As I found it harder during the research process, I had a look at the literature. Lack of access to academic sites, or the cost of access to documents or relevant literature has been the most difficult part of the research. (Egzon)

However, due to the many benefits, they proposed that action research studies be a compulsory course for all preservice teachers, as well as a professional development program for all in-service teachers.

## **Discussion and conclusion**

This paper aimed to explore how teachers formulate their own research problems and conduct their action research projects. Also, this paper examined the teacher's perceptions of their experience when they carry out action research as novice researchers. From the action research reports and the teacher's perceptions, it has been shown that there were different topics to which teachers oriented their research, but all of them were concerned about the effectiveness of their 'new teaching activities' and their impact on students' outcomes. The teachers' reports on the impact of their action research show that these are consistent with other studies on how action research contributes positively to their development and professional autonomy by improving their teaching and increasing the students learning (Cohran-Smith & Lytle, 1993; Krainer & Zehetmeier, 2013).

The cases presented by teachers in this paper confirmed the finding from Capobianco and Ní Ríordáin (2015) that although their efficacy as mathematics teachers is sometimes difficult, through action

research, difficulties can be recognized, accepted, and addressed in a positive and productive manner. The case of Egzon indicates that action research helped him to look for new ways of collaboration with parents and students in order to improve students' engagement in doing homework. Isuf and Qëndresa indicate that action research encourages teachers to use technology in their class even when it is challenging for them. On the other hand, the case of Besmir shows that action research encourages him to analyze different sources, to examine the literature related to his field of interest and stimulates him to experience new methods in his classrooms that for others have been successful.

Teachers' experience with action research has shown that they are able to do research in their classrooms successfully and that they can achieve remarkable results when the opportunities are given, especially if they are supported by the university teachers. Action research provides more opportunities for them to be responsible for improving their basic content knowledge, as well as for gaining knowledge and skills in research methods and applications (Altrichter et al., 1993; Loucks-Horsley et al., 2012). Thus, including action research in the study programs for teacher training for both preservice and in-service teachers will help them to create trust as an important conducive factor for generating new ways for learning (Krainer & Zehetmeier, 2013).

Action research in Kosovo can be approached as a potent methodology for educational reform. Action research engages teachers to investigate and teach through analyzing deeply the content and pedagogical issues needed for their teaching. Furthermore, action research challenges teachers to carry out changes, which are necessary for the implementation of mathematics curricula for pre-university education and to align them with international standards. Thus, universities need to consider including action research as a core unit in all teacher preparation degree programs (Hine, 2013) and stimulate collaboration with their students, in-service teachers, and schools, in order to conduct action research studies in mathematics classes as well as in all other subjects.

We started as a small-scale effort involving a few teachers to conduct research in their classrooms aiming to grow into an important part of school-based professional development. The effort for a university-led reform movement (Somekh & Zeichner, 2009), supported by the government as a national initiative, could be a possibility for fostering mathematics education. Ultimately, as cited by Krainer and Zehetmeier (2013), teachers should be key stakeholders in innovation and research, as well as in all educational reforms. This paper suggests that such an effort to prepare teachers to take the role of teacher-researchers is one of the possibilities to answer their concerns about teaching and learning in mathematics.

*Since its birth in the aftermath of CERME10, discussions in TWG19 concentrated on identifying its research territory and on creating opportunities for collaboration among the participants beyond the conference sessions. These discussions led to shifting the focus of the group on mathematics teaching and teacher practice (s) and to an initiative of working on shared data that fueled fruitful explorations related to conceptualizations and theorization of mathematics teaching. The participants' contributions and the work carried out during CERME11 sessions challenged further the core ideas of how mathematics teaching can be defined and studied while an emerging distinction between teaching as an activity and teaching as work stimulated further the group's discussions.*

### Introduction

Thematic Working Group 19 (TWG19) emerged as a result of the splitting of a TWG called “From a study of teaching practices to issues in teacher education” into three sub-groups after CERME8. One of the new groups targeted teacher education and professional development (TWG18), another focused on teacher knowledge, beliefs and identity (TWG20), and TWG19 targeted “Mathematics teacher and classroom practices”. Since its conception, TWG19 has been in a process of developing its identity. In discussions, core concepts have been taken for granted, without explicit or shared definitions. This became apparent at CERME10, where participants called for a development of common grounds — or at least for efforts to increase awareness about differences in conceptualizations, theories and methods, and of the implications of these differences. After CERME10, two changes have been made to move forward TWG19's work: 1) the name of the working group has been adjusted, and 2) an initiative of offering sets of shared data for analysis and use in the working group has been initiated.

This introductory paper discusses the ongoing development of TWG19's identity and where the continued development appears to be heading. Due to a large number of submitted papers, the group split into two (TWG19a and TWG19b) for CERME11, but we tried to maintain a sense of community by having three common sessions, and by discussing the same overarching questions in split sessions. In the final session, team leaders shared reports to the whole group and facilitated a concerted discussion around these questions. This joint introduction to TWG19a and TWG19b testifies to these

efforts. There are three main sections in this introduction. The first section discusses emerging issues and critical considerations as reflected in the section name. The second section reports from the joint activity around the initiative of analyzing and using shared data, and the third section discusses patterns and trends in the individual papers that were presented. The introductory paper concludes with a discussion of the collective efforts made to deal with the emerging issues and some reflections on the way ahead.

### **Emerging issues to pursue: some critical considerations**

After CERME10, the name of TWG19 changed from “Mathematics teacher and classroom practices” to “Mathematics teaching and teacher practice(s)”. The change of wording is intentional and deserves elaboration. First, the change from teacher to teaching signals that the group targets teaching rather than teachers and their characteristics; teacher knowledge, beliefs and identity are the focus of TWG20. This shift reflects a development that Skott, Mosvold and Sakonidis (2018) described and reflected upon in their recollection of research on classroom practice, knowledge, beliefs and identity over ten biannual CERME conferences and corresponds with a general shift of focus in research on teaching. Although the shift from teachers to teaching has emerged over several decades, conceptualizations of teaching appear to be underdeveloped in our field. While discussing the problem of theorizing teaching, Jaworski (2006, p. 188) suggests that “the big theories do not seem to offer clear insights to teaching and ways in which teaching addresses the promotion of mathematics learning”. Furthermore, Jaworski suggests that one of the problems lies in how learning and teaching are connected with practice, and this relates to a second change in the name of TWG19.

The shift from classroom practices to teacher practice(s) signals that the primary focus of the research in TWG19 is on practices of teachers and teaching rather than on any practices in classrooms. Use of the term practice has changed over the years. Jaworski (2006) discussed “teaching as learning in practice”, whereas Schön and DeSanctis (2011) consider teaching to be a reflective practice. The former suggests conceiving teaching as a social practice in which teachers are practitioners, whereas the latter offers a view of how teachers “act in the classroom as informed, concerned professionals and about how they continue to learn” (Lerman, 1998, p. 33). The discussions by these authors imply some of the different meanings that might be attached to the term practice. Lampert (2010) distinguishes between four different meanings of the word practice, and three of those are relevant for TWG19. First, practice might refer to what teachers do in contrast to theory. Second, the word is used to describe a collection of practices, some of which might be more core or high-leverage than others. A third use is to consider teaching as a professional practice, like the practice of law or medicine. The word practice in the new name of TWG19 might encompass all three meanings.

The first joint session of TWG19a and TWG19b at CERME11 was devoted to discussing some of these foundational issues, and attempts were made to contribute to the discussion of the underdeveloped conceptualizations and theorization of mathematics teaching. To introduce the discussion, two of the presented papers drew on different theoretical foundations. In the first presentation, Watson drew on developments in cognitive psychology, neuroscience and ontology to provide a theoretical account of teacher decision making and how this influences practice. He argued that the momentary decisions influence the character of the lesson and proceeds to focusing on

algorithmic reasoning, a conscious process making use of heuristics and pre-established routines and processes to reduce the demand on working memory. In mathematics teaching, in-the-moment decisions have to be immediate and thus well-practiced. The algorithmic mind quickly accesses routines and procedures that are learnt through participation and provide well-rehearsed and culturally-embedded approaches to respond to situations in the classroom. Watson concluded that it is important to further study teachers' decision making, to better understand the affective dimensions, the culturally embedded routines and strategies acquired through participation in the professional community. In the second paper, Sakonidis argued that mathematics teaching tends to be seen today as a professional practice shaped by the expectations and norms of the learning settings where is exercised. Sociocultural theories provide useful lenses for the relevant research and three of them appear to readily lend themselves to this direction: the theory of learning participating in a community of practice, Cultural-historical activity theory, and Skott's (2013) patterns of participation theory. Sakonidis concluded by highlighting the need for dynamic perspectives to disentangle and understand the ever-evolving outcome of individual and communal acts of meaning-making (by both teachers and students) characterizing the practice of mathematics teaching.

Following the presentation of these two papers, Hoover and Mosvold presented their reflections on the developments in the field of research on mathematics teaching. They started by reflecting on the different meanings of teaching, and how the field has proposed dichotomies like pedagogic versus didactic, art versus science, ambitious versus conventional, and profession versus occupation. Based on these initial reflections, they proposed a distinction between teaching as *activity* and teaching as *work*. The first interprets teaching as activities done by teachers, whereas the second considers teaching to be work to be done. Each of these understandings has different implications for studying teaching. Studies of teaching as activity tend to seek empirical descriptions of what teachers are doing, and they study methods of expert teachers in order to improve teaching. On the other hand, studies of teaching as work tend to investigate the demands of instruction by applying conceptual analysis, and they conceptualize professional practice for teacher education as a means to improve teaching. This distinction was taken up by participants in the group and stimulated productive discussions.

### **In search of answers to the emerging issues in a joint research activity**

As another effort to move the group forward, TWG19 decided to prepare sets of shared data for CERME11. These shared data sets were made available for analysis and use in participants' papers, and they were also available for use in presentations and as a common reference point for discussions in the group. Four sets of data were prepared and uploaded to a secure server that all participants in TWG19 were given access to. Three of the data sets contained videos of mathematics teaching, whereas one data set contained transcripts only. Each data set was accompanied by a document that laid out policies for sharing and reuse, and a document with information about the person or institution that shared the data as well as with permissions and limitations for usage.

Videos are extensively used in research on teaching. In a presentation to the group about sharing data, Mosvold, Hoover and Suzuka suggested that study of a complex phenomenon like teaching requires good data, and that video data provides access to nuances in communication and interaction. Videos also provide more detail about context. While adding value, video data also introduce some

challenges — including practical as well as ethical concerns. Sharing and reusing video data provide benefits like better utilization of data, access to high-quality data, saved costs, as well as increased quality and scope of analysis. However, successful sharing and reuse of video data demand careful considerations around issues of usability and reuse of data. Many find the challenges entailed in sharing and reusing data so severe that they are reluctant to get involved. Engaging in this initiative has provided us with useful experiences that we hope might help us as a field move forward towards overcoming the anticipated difficulties.

Having multiple eyes look at the same data opens up for richer and more nuanced interpretations. For instance, five papers analyzed a Norwegian video where a teacher facilitates a group of students' presentations of their solutions to a problem of figuring out when the king of Norway was born, given that he celebrated his 80<sup>th</sup> birthday on that particular day. Some participants focused on how the teacher was moderating the dialogue, how he elicited students' mathematical thinking (Drageset), and how he positioned students as mathematical authorities whose thinking were put on public display and collectively analyzed (Bass & Mosvold). Others emphasized how the teacher's use of revoicing might interrupt and even prevent further development of the discourse (Kleve, Solem, & Aanestad), and Nic Mhuiri followed up by observing that student interactions were always funneled through the teacher and never developed into discussions in whole class. Whereas most papers applied particular frameworks or theories in their analysis of this video, Hoover and Goffney used conceptual analysis to identify aspects of mathematics teaching that might disrupt patterns of inequity.

Another frequently analyzed video displays Deborah Ball teaching fractions on the number line. From his analysis of turns in the conversation, Drageset noticed how the teacher often requested students to ask questions instead of entering a traditional pattern of initiation-response-evaluation. He also discussed how the teacher moderated the discourse while simultaneously guiding students' participation and attending to norms. Mosvold and Bjuland also mentioned attending to norms of participation in their use of the data set to unpack the role of positioning in the work of teaching mathematics. A couple of papers also observed how assigning students with agency and authority becomes visible in this instance of mathematics teaching (Bass & Mosvold; Nic Mhuiri). Again, the nuances provided by the sum of the analyses exceeds the contributions of each individual paper.

Engaging in analysis of shared data prompts some new questions: Why do we see different things when analyzing the same data? Can we reach agreement of some kind in our analyses? Is agreement even a goal? After all, our efforts to analyze and discuss these shared data sets did not lead to a shared understanding of mathematics teaching, but they stimulated productive discussions about different conceptualizations of teaching.

### **In search of answers to the emerging issues in individual participants' research**

The papers reporting on studies of mathematics teaching and teacher practices that did not use the shared data sets can be placed in three groups: 1) teachers' practices, actions and resources before or during daily instruction; 2) teachers' implementation of teaching practices and actions developed in the context or in the aftermath of a particular purposeful professional development (PD) activity; 3) developing tools or practices of monitoring classroom instructional activity. Emerging issues from these groups of papers are discussed below.

Papers reporting on issues related to daily teaching practices, actions and resources apply established theoretical or conceptual frameworks to examine their functionality and effectiveness. For instance, Pericleous used cultural-historical activity theory to investigate how the activity of proving was constituted in a primary classroom. She analyzed tensions that arose for the teacher and identified points of contradiction between the classroom micro-system and elements of the macro-system, such as curriculum context. In a series of focus group interviews, Grundén used critical discourse analysis to interrogate teachers' planning practice(s) in mathematics. The results described how teachers construct their own discourse of mathematics teaching in resistance to the official discourse of the National Agency of Education. Grundén contended that critical discourse analysis is useful for attending to the complexity of mathematics teaching. Rudsberg, Sundhäll and Nilsson inquired into teachers' monitoring of students' meaning making. To this purpose, they adopted a framework of epistemological move analysis and a pragmatic perspective on learning to analyze lesson transcripts. The results suggested that epistemological move analysis might enhance our understanding of the relationship between students' meaning-making and the related actions of teachers.

Stouraitis and Potari studied a prospective secondary school teacher's first field experiences. Using activity theory, the authors focused on emerging contradictions considering prospective teachers' planning and enactment of a lesson plan, as well as what led to such contradictions and how contradictions could potentially influence prospective teacher learning. Calor et al. examined teachers' use of a model based on small-group work, drawing on socio-cultural notions such as collaborative learning and scaffolding as well as on cognitive ideas like Janvier's approach to representation systems. The analysis of a pre- and post-test on mathematical level raising shows that more mathematical level raising occurred in the small-group than in the control condition. Olsson and Teledahl described an investigation into how principles of feedback might be used by a mathematics teacher to encourage students' creative reasoning. Their analysis illustrates the challenges that this presents for teachers and highlights associated issues such as the existing classroom norms for interaction, as well as teachers' beliefs about the object of teaching.

Andrews explored what happens mathematically when teachers and learners engage in between-desk-teaching across different mathematics topics. From a multiple case study, he focused on the case of one teacher who used between-desk-teaching practice with a strategic purpose that could potentially support student understanding. Taylan and Esmer used the instructional actions framework to examine a novice teacher's instructional actions in response to unexpected classroom moments. Analyzing lesson planning meetings and observations as well as teacher interviews, they found out that responses to unexpected moments include both supporting and extending actions. Kayali and Biza studied a teacher's use of the available resources in relation to their teaching aim. Based on the 'Knowledge Quartet' (Rowland, 2010), their analysis highlights different aspects of a teacher's classroom work and leads to suggesting replacing code 'instructional materials' to 'resources' and expanding the Knowledge Quartet by adding a code named 'connection among resources'.

The submissions related to teachers' implementation of instructional practices and tools developed in professional development contexts aim at providing rich mathematical classroom activity for all students. In particular, Büscher focused on teachers' designed tasks during a professional development course to reconstruct their categories of differentiation for percentage problems. The

results show that teachers tended to differentiate in ways that exclude low-achieving students from conceptually rich learning opportunities due to their partitioning of their envisioned ideal-typical solution paths. Psycharis, Potari, Triantafillou and Zachariades investigated how secondary school teachers attempted to balance mathematical challenge and differentiation in whole class settings in the context of a professional development program which aimed to support teachers in engaging all learners while teaching challenging tasks.

Klothou, Sakonidis and Arsenidou used a multiple case study approach to investigate the use of learning trajectories in teaching fractions by three primary teachers participating in a PD project. The analysis shows that all teachers tended to view learning trajectories primarily as a way of organizing mathematical content more than as an elaboration of the possible development of student thinking. The study by Medová, Bulková, and Čeretková was conducted in the context of a professional development program focusing on inquiry-based learning in upper secondary mathematics. Results indicate that students' independent learning was observable more often in the inquiry-based lessons than in regular lessons, whereas teachers played a more dominant role in the regular lessons. Maugesten explored Norwegian lower primary teachers' views about good mathematics teaching by using a focus group interview with teachers after a two-year school-based professional development. The results reveal that teachers focused on communication in classroom and use of representations, student thinking in and about the subject of mathematics, and resources, textbooks, and tasks that are related to everyday mathematics.

Finally, the papers related to developing tools or practices of monitoring classroom instructional activity concentrated on cognitive as well as social determinants of this activity. Thus, Nowińska reported on the development of a rating system for analyzing metacognitive activities: Metacognitive-discourse instructional quality. This is illustrated with examples of how one can identify different parts of metacognition related to planning, monitoring, and reflection. She emphasized that such a rating system needs to identify patterns that are stable across lessons and practice. Arnesen and Grimeland also presented an investigation of teachers' planning. They asked teachers to identify the mathematical ideas they would focus on and use Bloom's Taxonomy to classify the learning goals teachers had identified for lessons. Findings indicate that higher-order cognitive process categories were poorly represented in the learning goals and teachers' descriptions of mathematical ideas were vague or absent.

The study by Mellroth and Boesen provides a proposal for teachers to help them notice mathematically highly able students by illuminating aspects of students' problem-solving processes. The paper of Ableitinger, Anger and Dorner is unique in its efforts to attend to student voice. Student feedback was collected in post-lesson interviews and quantitative and qualitative methods were used to compare students' and researchers' choice of significant events in mathematics lessons. The analysis indicates differences between students' and researchers' choices of significant events. Even when both groups identified the same event as significant, different reasons were given for this choice.

Summarizing, all papers presented above highlight challenges of accessing interesting data in consistent ways within or across instructional settings. The adopted theoretical frameworks view teachers as professionals coordinating the instructional activity aiming at rich learning environments

and maximum participation. These frameworks offer analytical tools and sometimes provide — combined or coordinated — new theoretical lenses allowing useful insights into various aspects of mathematics teaching and teacher practice(s). The accompanying methodologies are mostly qualitative. Although these methodologies vary, they tend to concentrate on examining instructional routines, actions, tools and practice(s) by analyzing teachers' designs, classroom implementations or classroom excerpts and so on.

### **Towards a collective effort to deal with the emerging issues**

Discussions in TWG19 at CERME11 often revolved around the core questions of what we mean by teaching and how we study it, and the distinction between teaching as activity and teaching as work was discussed frequently. The majority of participants in TWG19 tend to consider teaching as what teachers do, but there is considerable variation in this view of teaching as activity and how it is studied. Some consider teaching as what teachers do, but they also include teachers' thinking and emotions (e.g., Watson). Others focus more squarely on teacher actions and study patterns of such actions (e.g., Sakonidis). Yet others emphasize that teaching is a communicational activity (e.g., Nachlieli et al.). Among the papers viewing teaching as activity, many were concerned with the connection between teaching and learning (e.g., Ayan; Grundén, Serrazina et al.). Some consider the teacher as an agent who shapes new classroom practices (Nic Mhuiri). Others consider the teacher as a facilitator or an orchestrator (Baldry), who provides students with opportunities to explore (e.g., Pericleous). Yet others consider the teacher as a transmitter of knowledge (Ableitinger et al.). Teachers' use of feedback is supposed to influence student learning, and Olsson and Teledahl investigated development of productive feedback practices.

Other papers lean towards a conceptualization of teaching as work to be done. A couple of papers are explicitly directed towards such a conceptualization of mathematics teaching (e.g., Hoover & Goffney; Mosvold & Bjuland), whereas others point in this direction implicitly. For instance, Nachlieli et al. studied tasks that teachers are faced with, and Santos et al. investigated demands of teaching mathematics. It is also worth noticing that some papers appear to study what teachers do, but they still make claims about the work to be done (e.g., Baldry).

Having the distinction between teaching as activity or work out there seemed to fuel the discussions. People started engaging with questions about the purpose of distinguishing between teaching as activity and teaching as work, and how the conceptualization of one might be independent of the other. The discussion of papers often targeted foundational questions about implications of our views on teaching, of applying different theoretical frameworks to analyze teaching, and about how different methods and types of data might or might not inform us about teaching and the demands of teaching. The effort of introducing and using shared data was another initiative that seemed to stimulate productive discussions in the group. Some reflected on how seeing different things in the same data must prompt careful reflection about use of different theoretical frameworks, whereas others suggested that seeing different things might be fruitful and provide a broader and more complete image of teaching.

## Conclusion

TWG19 is still developing its identity, but the group is taking some important steps forward. The name change stimulated some important foundational discussions about conceptualizations of teaching and methods of studying teaching. The distinction between teaching as activity and teaching as work was useful, but further conceptual work is needed. The participants' contributions, despite the polyphony identified in their attempts to conceptualize mathematics teaching as well as in the theoretical lenses and the methodologies employed to study its classroom manifestations, somehow highlight the issues to consider and the questions to pursue in the way ahead.

The initiative of sharing data was also interesting, and several participants were interested in contributing to and using such data sets in upcoming conferences. Sharing and reusing data provide opportunities for richer analysis, but it also appears to be a productive space for developing shared understandings and possibly also better consensus about the object of study. However, further efforts are needed to investigate what kinds of (video) data are most suitable for joint analysis of mathematics teaching, how to organize an even more productive space for such joint analysis, and how such analysis might be scaled up. It is also imperative to investigate ways of organizing analysis of shared data in order for it to be more than an interesting exercise in data analysis.

*Considering the learners' perspectives on classroom teaching is central in our project 'AmadEUs', in which we work together with 79 students of four school classes in Austria and 23 pre-service teachers. In a first stage, we interviewed these students about significant events in math lessons they had just attended. In this paper, we analysed what kinds of events our students have mentioned and chosen and compared them with our (researchers') choice of significant events. While different groups of students tended to choose similar events, we observed differences between students' and researchers' choices of significant events. In a qualitative analysis, we tried to identify the characters of most commonly selected events by students in contrast to the teachers' and the researchers' selections.*

### Introduction

Mathematics education is a complex network with several players involved, such as students, teachers, researchers and teacher educators, who prioritize different aspects of quality and therefore attach importance to different events during math lessons. Hence, one can understand and optimize teaching practice only through research that takes into account various perspectives, and particularly those of the learners as an essential part (see Clarke, Keitel, & Shimizu, 2006). Through giving students the opportunity to articulate their opinions, thoughts and feelings, valuable insights into their attitudes towards mathematics can be gained. Hence, listening to their voices has the potential to influence educators and policy makers (Mok, Kaur, Zhu, & Yau, 2013). This so-called Student Voice approach and some related studies will be further discussed in the theoretical framework.

One aim of our study is to explore which events of math lessons students consider as significant. The results do not only inform us about what kinds of events students consider as important for their learning, we might also get a clue about which events actually stay in their mind and in which events they might pay more attention to. This knowledge has the potential to influence and improve teaching practices (Huang & Barlow, 2013; Lee & Johnston-Wilder, 2013).

By comparing the choice of students to our own (researchers') choice of significant events (by that we mean short sequences of approximately 2-5 minutes) of the math lessons, we want to detect blind spots of typical researcher's views on mathematics education on the one hand. Through contrasting the two perspectives, we expect to maintain student-specific choices of concrete situations in the learning process, which can help teachers in their prospective lesson planning (McIntyre, Pedder, & Rudduck, 2005). On the other hand, it is also interesting to discover events that are significant to

researchers but not to students (and vice versa). For this, our study may give hints, where and in which way crucial points of lessons need to be made explicit to students, in case they do not attach importance to these points sufficiently by themselves.

## Theoretical framework

Our study takes the perspectives of students into account. Such “Student voice” approaches have been of growing interest in the past two decades. Early work that has been conducted on the voice of students (e.g. McCallum, Hargreaves, & Gipps, 2000; Pollard & Triggs, 2000; Fielding, 2001) revealed the potential of listening to students in order to understand teaching and learning and making it more effective. In the course of this development, Robinson and Taylor (2007) aimed at theorizing student voice, carving out core values of student voice work. Flutter and Rudduck (2004) analysed different student voice initiatives and derived potential benefits to students, teachers and schools, including the potential to improve learning (as the participation of students might have a positive impact on their meta-cognitive development) as well as teaching (as teachers and researchers are provided with valuable insights).

As Allen (2003) pointed out, it took some time until students have been consulted to articulate their views about mathematics teaching and learning, but meanwhile several studies have been conducted in this field (e.g. Taylor, Hawera, & Young-Loveridge, 2005; Sullivan, Tobias, & McDonough, 2006; Lee & Johnston-Wilder, 2013; McDonough & Sullivan, 2014). While some studies concentrate on what students attach importance to in math lessons in general (e.g. Wilkie & Sullivan, 2018), only few studies deal with significant events of certain experienced math lessons. Of interest is the Learner’s Perspective Study (LPS), which has been designed to analyse and compare practices of mathematics classrooms around the world (Clarke, Keitel, & Shimizu, 2006). Within LPS, Huang and Barlow (2013) compared important events selected by students and teachers. They examined 15 videotaped consecutive mathematics lessons of one teacher, the corresponding lesson plans, teacher interviews and 30 student interviews. During the teacher interview, he described his intentions in the lesson, the important events from his point of view as well as his actions, thoughts and feelings during the important events. The two researchers analysed the data set in order to verify whether the important events identified by students coincided with the teachers’ intended important events within the lessons.

Using a slightly different research design than LPS, we seek answers to the following research questions:

*What kinds of events of math lessons are significant for students and/or researchers?*

*By what criteria do students and researchers select these events and in what way do these criteria differ from each other?*

## Method

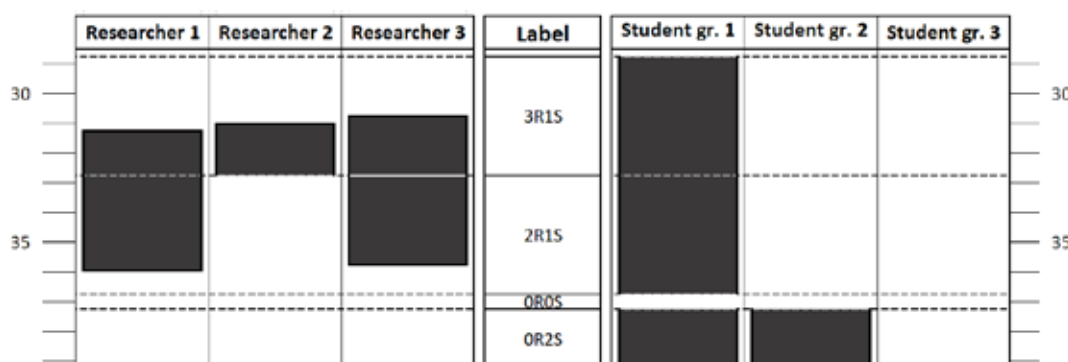

*Teaching units:* Four school classes (79 students) who visited our University were taught by pre-service teachers in the following topics: Percentage calculation (6<sup>th</sup> grade), introduction to probability theory (10<sup>th</sup> grade), combinatorics (11<sup>th</sup> grade), application of the differential calculus (11<sup>th</sup> grade). Each class was divided into two groups. These 8 lesson sequences have been videotaped.

*Identifying significant events of the math lessons:* Right after each lesson, interviews were conducted and recorded among all students (groups of 2-4) to ascertain events that seemed significant to them (we used the German word “wichtig”). We do not predetermine the term “wichtig” as a survey construct, because we do not aspire to infer causal relationships to other constructs. In fact, we seek to learn more about what is important to students when reflecting on their attended math lessons. We thus chose the word “wichtig” out of a group of words with a similar meaning (such as “wesentlich”, “markant” or “maßgeblich”, which all translate to significant or important, respectively) for its easy comprehensibility and its openness for all kinds of aspects that could be meaningful to the students. “Wichtig” expresses that some aspect is of essential relevance (Duden, 2016).

We decided to use semi-structured interviews (Galletta, 2013) to reveal significant events from the students’ point of view. Our interview protocol consists of three segments: For the opening segment, we formulated two open-ended questions that stimulate students to talk about the math lesson they just experienced. The middle segment consists of more specific and structured questions directly related to our research that should jog the students’ memories as well as help them to reflect on different aspects of the lesson. These questions cover the scope of our intended meaning of important/significant events. In the concluding segment, students have to come to an agreement about the five most important/significant events.

In addition, we (as researchers) watched the complete video material (because we did not attend the lessons) and took notes of significant events. At the end of this process, each of us had to choose the five most significant events from his/her own point of view.

In order to conduct an analysis, assistants fragmented each lesson sequence into short scenes due to certain criteria (e.g. change of teaching method, change of subject, presenting or discussing a new example, etc.). Altogether, this procedure led to 221 scenes (for all lesson sequences). After our own selection of events (the researchers’ choice) had been completed, we evaluated the audio material of the student interviews in order to mark their significant events. Each scene was then labelled according to the number of selected events that coincide with that scene (at least partially). For example, the scene label 2R1S means that two (out of three) researchers and one of the three groups of students selected significant events that occurred during this scene (see Figure 1 for a short extract of one lesson sequence). At this stage, we were able to analyse the data quantitatively and qualitatively respectively.

**Figure 1: Scene labels according to selected significant events**

## Results

### Differences in significance between students and researchers

In order to measure the disparity between researchers' and students' selection, we determined the difference of the number of researchers' and students' marks for each scene. While the difference is at most 1 in 75% of all scenes ( $n=221$ ), we observed 15 scenes (7%) which have been found significant by either all researchers and no group of students, or vice versa. These scenes are of great interest. 85 scenes (38%) are marked solely by either students or researchers. We must mention that 42 of these 85 scenes are labelled as significant by only one group of students or one researcher, respectively.

In more detail, 23% of all scenes are significant for at least one group of students, but not for any researcher. The majority of these scenes belong to student-centred learning phases. Furthermore, students but not researchers highlighted many events assigned to group work phases and games (due to their active participation) as well as summaries. Students have predominantly chosen events in which they had fun, events that suited them as well as events in which they could easily follow, irrespective of the professional or didactical quality.

On the other hand, 15% of all scenes are significant for at least one researcher, but not for any group of students. Such scenes often contain mathematical errors of the teachers or didactical mistakes (e.g. confusing explanations, explanations that might lead to misconceptions, etc.) and have been commonly chosen by us due to the revealed lack of (pedagogical) content knowledge of the acting teacher. A small part deals with interesting procedures of the teachers that have been either considered as appropriate or inappropriate by us.

### Qualitative analysis of a particular scene

For the following scene (which all researchers and students marked as significant), we go more in-depth into the corresponding justifications stated by students and researchers.

*Combinatorics (11<sup>th</sup> grade), minute 63–68*

*Description of the scene:* The teachers use this scene to sum up the content of the lesson. The graphic shown in Figure 2 is drawn on the blackboard to help students identify combinatorial problems as either a variation, permutation or combination and to repeat the associated formulas which have been taught in this lesson. During that scene, one teacher confuses variation with combination and gets corrected by his colleague.

**Figure 2: Decision tree**

*Perspective of students:* All groups of students appreciated the summary as a ‘helpful overview’ and identified that scene as a key point. They described the provided graphic as ‘very good’, ‘well-structured’ and ‘easy to follow’. It also helped them to solve problems they had to work on after that scene. Furthermore, they liked that the teachers helped and corrected each other and got the feeling that errors are permitted.

*Perspective of researchers:* We observed several inaccuracies and errors. The teachers define the permutation solely by choosing all elements of a certain set. They do not mention whether order matters or repetition is allowed and even indicate once that the order does *not* matter:

Teacher: If I cannot deduce from the task that the order matters or that a subset is chosen, then it is always a permutation.

In their graphic, combination and variation only differ in the matter of the order. It is neither mentioned that combinations are without repetition nor that repetitions are allowed in variations. By saying, “We choose  $k$  out of  $n$  elements”, the teacher indicates that  $k$  cannot be greater than  $n$  in variations. A correct and thoroughly overview must include those two aspects (order and repetition) for each counting problem.

Further, the scene indicates a highly syntactical approach:

Teacher: No selection occurs; I just take all elements. I’ve only got an ‘ $n$ ’.

Student: I see. This is a permutation.

Teacher: Yes, this is a permutation, because we do not have a ‘ $k$ ’ [...] because I simply need one number.

Without being able to verify the criteria of a permutation, students give the correct answer, knowing that the formula of permutations (out of the three presented formulas  $n!$ ,  $n$  choose  $k$  and  $n^k$ ) is the only one that consists of one parameter.

*Comparison and discussion:* While all groups of students looked upon that scene favourably, we chose that scene due to the syntactical approach and inaccuracies/errors showing a lack of (pedagogical) content knowledge. As students do not know any other counting problem apart from those three presented in that lesson, the given overview is sufficient to distinguish between them, although misconceptions might result (e.g. that  $k$  cannot be larger than  $n$  in a variation). As the whole topic is new to them, they trust in the expertise of the teachers and are not able to identify errors. Thus, they focus on the use of the summary (e.g. repeating the formulas), whereas we focus on the content quality. We agree that a summary of counting problems is a good idea, but the poor implementation has been decisive for our selection.

## Discussion and conclusions

The results have demonstrated that the difference of the number of researchers’ and students’ marks for each scene is at most 1 in 75% of the cases, however, the reasons for choosing certain scenes are quite different, as we have shown in the above mentioned example.

While we focused on events that deploy the didactic strategies of the teachers or revealed existing or missing (pedagogical) content knowledge, the students concentrated on student-centred learning phases, summaries, quizzes and games. This emphasis on student-centred learning phases is in line with the findings of Huang and Barlow (2013) and Mok et al. (2013). Their interviewed students attached importance to seatwork and group work. Wilkie and Sullivan (2018) illustrated that students wish among others more such phases in their math lessons. In the present study, students described teacher-centred phases as ‘conventional instruction’, which could be a reason for choosing student-centred events. Being active is more meaningful and therefore more memorable to them. The findings of Lee and Johnston-Wilder (2013) confirm the importance of quizzes and games for students. In their study, students explicitly demand more interactivity, games and creative tasks. The significance of such events might issue from feelings of success (discover connections, find solutions to certain problems and so on) or emotional involvement. According to Huang and Barlow (2013) and Mok et al. (2013), students valued review and feedback parts as important. Those findings are also in line with our study: Students have chosen summaries as significant and valuable events (as has been shown in the qualitative analysis). However, our data reveals that the researchers did not mention summaries unless they included mistakes or highlights.

Contrary to our expectations and to the results of Mok et al. (2013), students barely talked about teacher explanations. This even holds true for some appalling explanations by the teachers that were not even mentioned by the students during the interviews, although some questions focused on teacher explanations. We conclude that the students did either not remember those scenes or did not attach any importance to them. In a certain way, their focus on methodical aspects of math lessons is understandable, due to students’ less developed meta-cognitive skills and the fact that highlights during classes are kept in mind more strongly. These findings are in line with the study of Waldis, Grob, Pauli and Reusser (2010), who compared student ratings with class observer ratings of math classes and found differences between these two groups when rating cognitively activating instructions and the structure of math classes.

In cases where students and researchers selected the same events, different reasons were decisive. This is similar to the result of Huang and Barlow (2013), who obtained differences in students’ and teachers’ interpretations in such match cases. We presented an example, where students described the visualisation and the associated explanation as well-structured while we as researchers valued it as confusing and identified several content-related mistakes. This may be due to a certain inability of students to detect mistakes or to think about alternative approaches to particular concepts (Lee & Johnston-Wilder, 2013) while still being involved in the learning processes and not being able to oversee the topic as a whole. Some statements expressed by students during the interviews hypothesise that they tend to evaluate the quality of explanations according to how easily they are able to solve corresponding tasks. This implies that their self-assessment relating to their mathematical understanding depends on (amongst other aspects) the tasks they need to solve.

For mathematics teaching practice, we can deduce that students obviously and understandably depend on the teachers’ knowledge and the way content is dealt with in class. We have seen that they did not mention several inconsistencies or misleading actions of the teachers, which were obvious to us as researchers and teacher trainers, respectively. Hence, teachers cannot fully rely on students’ feedback

concerning content-related or didactical inappropriateness, they should – beside asking students for regular feedback – see to get feedback from experienced mathematics teachers or teacher educators (e.g. through job shadowing) in order to gradually improve their teaching practice.

It is essential for the learning process that students are aware of essential content points of the lesson (e.g. phases where concept formation and the development of basic mathematical ideas are in the centre of interest), but our study reveals that they hardly mentioned them nor valued many of them as important. According to Huang and Barlow (2013), the agreement on the importance of such events between students and teachers is necessary for effective learning. We deduce from our results that teachers have to emphasise these essential content points on a meta-level to be sure that the students value these events appropriately. Teacher training has to do its duty at this point by calling the teachers' attention to this problem.

What we can learn from the students' choices of events and the associated justifications is that teachers indeed should make an effort to include more student-centred and methodically varied learning phases into their math lessons (as they do have the potential to motivate students and to enhance their activity as well as their attention). However, it is crucial that there has to be a strong focus on the quality of the content promoted in these phases. As we have seen in our data, games and quizzes are popular among students, but it is difficult to get any content-related feedback to these events from them on the spot, even in cases where we have chosen the same scene out of misleading or confusing aspects. Hence, entertaining elements have the potential to inspire students and to stay in mind. However, they must not cover the content and the learning goals of the lesson.

Teachers can gain useful insights into their students' learning by knowing what classroom events they perceive as important, as they are then able to adjust their teaching practice in order to catch their attention and draw it to essential content points. In addition, a lot can be learned from students' justifications of their selected events as this has the potential to reveal – through further analysis – certain predispositions students have towards math lessons in general.

## **Between-desk-teaching as a deliberate act of making content available: The case of Bernie teaching ratio**

Nick Andrews

University of Oxford, UK; [nicholas.andrews@education.ox.ac.uk](mailto:nicholas.andrews@education.ox.ac.uk)

*Between-desks-teaching is recognised as a feature of mathematics classrooms across the world. Previous studies have sought to describe the range of purposes of this lesson event within a lesson and have been concerned with the orchestration of the classroom. Yet there has been little attention given to the role of between-desks-teaching beyond a single lesson, such as its contribution to how mathematical content is made available to learners over time. The current study explores what is happening mathematically when teachers and learners engage in between-desks-teaching across a topic. There is a particular focus on one case in which this lesson event features extensively. This case reveals how between-desks-teaching can have a strategic purpose and has potential to be used deliberately when teaching a topic.*

### **Introduction**

In this paper I focus on between-desk-teaching and how it can be distinctive in terms of its purpose when teaching a topic over a series of lessons. To do so, I draw on data from a wider exploratory study of four cases of classroom practice over a series of lessons. I then focus on one particular case in order to understand better the distinctive contribution of between-desks-teaching to how subject matter is transformed and connected over time in this context. This study therefore, in common with previous CERME papers (Skott, Mosvold, & Sakonidis, 2018), brings to the surface a specific act within mathematics teaching and discusses how it provides opportunities for learning.

Between-desk-teaching has been identified as a feature or “lesson event” of mathematics classrooms across the world (O’Keefe, Xu, & Clarke, 2006, p.73). It is a distinct event from ‘classwork’, which might include teacher exposition and whole-class discussion, but is a sub-set of ‘seatwork’, which is when “students work individually or in small groups on assigned tasks” and “talk is mostly private — teacher-student or student-student” (Stigler & Hiebert, 1999, p.67). It is this mostly private teacher-student talk, while students work on assigned tasks, which defines between-desk-teaching, although O’Keefe et al. (2006) also point to instances where this talk becomes more public. Inoue, Asada, Maeda, and Nakamura (2019) describe how between-desk-teaching offers learners individual support when problem solving, while Jakonen (2018) states that teacher actions during this lesson event are ‘occasioned’ in that they are sensitive to the learner’s present situation. Yet between-desk-teaching is often ‘repetitive’ in that the teacher addresses the same issue both with multiple learners and also potentially multiple times with the same learner (Jakonen, 2018).

O’Keefe et al. (2006) discuss both the monitoring and guiding functions of between-desk-teaching. Providing feedback, including references to learning goals (Svanes & Klette, 2018), or observing learners working serve a monitoring function. The guiding function can be associated with either

‘extending’ or ‘enabling’ teacher prompts (Roche & Clarke, 2015). Extending prompts are typically discussed in the literature with reference to challenge and questioning (e.g. Svanes & Klette, 2018), while enabling prompts may involve telling, modelling or offering hints (Svanes & Klette, 2018), or referring to prior learning or suggesting alternative approaches (Inoue et al., 2019).

While between-desk-teaching can be analysed as a distinct lesson event, or as an event within a lesson (Inoue et al., 2019), O’Keefe et al.’s (2006) study emphasises that in order to understand its purpose consideration needs to be given to the events that surround it and whether these events are classwork or seatwork. In terms of how content is made available to learners, between-desk-teaching can be seen as a bridge between independent-of-the-teacher seatwork and classwork, or vice versa. When the flow is from seatwork to classwork, the purpose of between-desk-teaching is more likely to be ‘monitoring student activity’ (O’Keefe et al., 2006) in order to inform the precise nature and focus of the classwork to follow, whereas when the flow is from classwork to seatwork the purpose is more likely to be ‘guiding student activity’ and making connections between the assigned task and the whole-class teaching the preceded it (Inoue et al., 2019). This emphasises how these lesson events mutually influence each other, but that there is a pedagogical choice regarding their sequencing.

The previous studies of between-desks-teaching discussed above focus particularly on the nature of teacher-learner participation during this lesson event rather than how the subject matter is being transformed and connected through these interactions. My own work however has focused on how subject matter is made available to learners over the course of teaching a topic (Andrews, 2017), through the actions of the teacher. I use the term ‘manifestation’ of a mathematical concept to refer to the form of content I observe the teacher offering learners at any moment in time, and a manifestation may be categorised as visual, technical, functional, or a combination of these. Visual manifestations often include diagrams or forms of imagery, technical manifestations often relate to methods or symbolic manipulation, and functional manifestations include worded problems and applications of methods.

In order to connect the sequencing of manifestations with opportunities for learning, I draw on a theory of growth in mathematical understanding (Pirie & Kieren, 1989; Pirie & Kieren, 1994). This constructivist theory proposes a progression of levels, each of which represents a reorganisation of knowledge structures, from ‘primitive knowing’, through ‘image having’ and ‘formalising’, to ‘structuring’ and beyond (Pirie & Kieren, 1989). I associate visual, technical and functional manifestations with opportunities to focus learners’ attention on image having, formalising and structuring respectively. I associate visual-functional, visual-technical and functional-technical manifestations with opportunities to shift the focus of learners’ attention, captured by Pirie & Kieren’s (1989) terms ‘image forming’, ‘property noticing’ and ‘observing’ respectively.

In a recent paper I highlight mathematical differences between what is addressed during classwork and seatwork in each of the four cases studied (Andrews, 2018). One pattern in practice revealed in this paper is a flow from classwork to seatwork within lessons and also across lesson series, with greater foregrounding of visual manifestations during classwork and functional manifestations during seatwork. This analysis suggests a degree of alignment in these cases between how content is made available to learners over time and the underlying progression proposed in Pirie & Kieren’s theory.

The current study builds on this recent paper and explores ways in which between-desk-teaching might support this progression.

From the range of purposes of between-desk-teaching identified above, I focus particularly in this paper on the guiding function and references back to prior learning (Inoue et al., 2019). Pirie and Kieren describe growth as “levelled but non-linear” (Pirie & Kieren, 1994, p.166) and use the term ‘folding back’ to describe returning to a previous level “in order to extend one’s current, inadequate understanding” (Pirie & Kieren, 1994, p.173). I associate teacher references during between-desk-teaching to prior learning with offering explicit opportunities for learners to ‘fold back’ to a previous level of understanding in order to come to understand the assigned task at hand. In such a situation the between-desk-teaching will not, in terms of manifestation, align to the assigned task but rather more closely to what has been offered previously (for example through classwork). The current study explores therefore whether during seatwork between-desk-teaching aligns with the assigned task, or is more associated with opportunities for folding back. Addressing this question over a series of lessons on a given topic rather than an individual lesson affords exploring patterns in practice, which in turn reveals if between-desk-teaching is being deployed as a strategic act for transforming and connecting the subject matter of a topic.

## Methodology

A summary of the approach taken to address the current research question will be offered here. A methodological paper detailing the range of approaches taken in the wider study is being worked on separately, and this will in due course provide fuller details and justifications of methods employed. The approach is an analysis of the text of what the teacher is seen to offer learners over the course of a series of lessons on a single mathematical topic. By text here I mean the literal text of teacher-talk during lessons, whether that be public or privately to individual learners, and also the tasks, video clips, simulations, physical resources and other teaching media that the teacher makes available.

A quantitative approach is taken in order to detect differences in manifestation over periods of time through applying what I call a *tri-polar analysis*. The relative stressing of the three elements of the triad {visual, functional, technical} in the ratio  $v : f : t$  and satisfying the condition that  $v + f + t = 1$  can be succinctly represented by the Barycentric co-ordinate  $(v, f, t)$ .

How the teacher makes content available to learners is conceptualised as having two elements: teacher-talk and given-tasks. Teacher-talk may be public (for example, during periods of classwork) or private (during seatwork). Given-tasks are only present during seatwork and are the prompts that initiate subsequent activity in a lesson rather than that activity itself. The combination of teacher-talk and given-task during an individual between-desk-teaching event may serve to alter what is offered to learners when compared to what would have been available through the given-task alone. Therefore the effect of between-desk-teaching is revealed in any differences between what is offered during seatwork through considering both teacher-talk and given-task in unison to what would have been offered over the same time period through the given-task alone.

For the current study, the text of each lesson series is parsed into 30-second intervals, each of which is then qualitatively coded for manifestation. Each manifestation category is associated with a Barycentric co-ordinate. The quantitative code for teacher-talk for the interval is the mean of the

Barycentric co-ordinates of all of the manifestation categories present in the teacher-talk in that interval (or (0, 0, 0) if there is no teacher-talk), and the quantitative code for given-task for the interval is determined similarly. The overall quantitative code for the interval (referred to as the interval centre) is either the co-ordinate for teacher-talk if there is no given task, the co-ordinate for given-task if there is no teacher-talk, or the mean of the teacher-talk and given-task co-ordinates. Each 30-second interval is also coded as either seatwork or classwork. The seatwork centre for the lesson series is then the mean of the Barycentric co-ordinates of all the intervals coded as seatwork, and the classwork centre is similarly defined. The given-task centre is the mean of the quantitative codes for given-task of all the intervals coded as seatwork. A statistical analysis of the visual co-ordinates for each interval using the Wilcoxon rank-sum test (Wilcoxon, 1945) allows the stressing of visual manifestation between classwork and seatwork, and between seatwork and given-task to be compared quantitatively (reported here using an effect size), and a similar analysis is conducted on the functional and then the technical co-ordinates. The extent of differences is represented by the effect size, and an effect size greater than .3 is treated as a material difference. By this I mean that the difference is large enough to infer systematic differences in how content is made available associated with strategic differences in teacher action.

The current paper initially reports on four lesson series taught in local secondary schools in England with students aged between 13 and 16. One of the teachers, Ashley taught a series of five lessons on geometrical constructions. Bernie was at the same school as Ashley and taught a series of four lessons on ratio with one class and three lessons on linear equations with another. Courtney was at a different school and taught a series of four lessons on linear equations. In each case, the teacher determined the topic and the teaching approach. The four cases are used to address the question of whether there are mathematical differences in what the teacher makes available through between-desk-teaching when compared to the underlying given-task alone. A closer analysis is then conducted of Bernie teaching ratio in order to understand better between-desk-teaching in this case.

## Cross-case findings

Table 1 sets out the seatwork and given-task centres for the four lesson series studied. For each case the statistical significance of any differences between seatwork and given-task are given. The number ( $n$ ) of 30-second intervals given over to seatwork is also given in each case.

The seatwork and given-task centres are descriptive statistics, and so comparisons between them only indicate where there are differences. It is the statistical analysis that quantifies these differences. The Barycentric co-ordinates highlight differences in each case between the seatwork and given-task centres, which indicate that during between-desk-teaching teacher-talk did not always align mathematically with the given-task. Instead this form of teacher-learner participation changed the mathematical nature of the activity. The greatest misalignment between seatwork and given-task was in the case of Bernie teaching ratio, and as this is an extreme case it has been selected for further analysis below. As this difference was material, the inference is that between-desk-teaching was being deployed as a strategic act for transforming and connecting the subject matter of a topic in this case.

**Table 1: The seatwork and given-task centres of the four lesson series**

Case		Seatwork	Given-task
Ashley teaching geometric constructions	<i>n</i>	410	
	Centre	(0.24, 0.27, 0.49)	(0.24, 0.32, 0.44)
	Difference	**	
Bernie teaching ratio	<i>n</i>	301	
	Centre	(0.06, 0.29, 0.65)	(0.00, 0.39, 0.61)
	Difference	MAT	
Bernie teaching linear equations	<i>n</i>	208	
	Centre	(0.20, 0.02, 0.78)	(0.18, 0.02, 0.80)
	Difference	NS	
Courtney teaching linear equations	<i>N</i>	270	
	Centre	(0.17, 0.09, 0.74)	(0.15, 0.12, 0.73)
	Difference	NS	

*N.B. Difference indicators show whether differences between the centres were material (MAT), statistically significant at the 1% level (\*\*), or not statistically significant at the 1% level (NS)*

### The particular case of Bernie teaching ratio

The lesson series was concerned with translating part-to-part relationships into part-to-whole relationships, such as dividing quantities in a given ratio. Inspection of the statistical analysis of differences between the classwork, seatwork and given-task centres (see table 2) indicate that the visual and technical components of manifestation were stressed more during classwork. This underlying pattern in practice is triangulated by the narrative account of the lessons that follows.

**Table 2: The classwork, seatwork and given-task centres for Bernie's lesson series on ratio**

Case		Classwork	Seatwork	Given-task
Bernie teaching ratio	<i>n</i>	82	301	301
	Centre	(0.14, 0.11, 0.75)	(0.06, 0.29, 0.65)	(0.00, 0.39, 0.61)
	Difference	MAT	MAT	

*N.B. Difference indicators show whether differences between the centres were material (MAT), statistically significant at the 1% level (\*\*), or not statistically significant at the 1% level (NS)*

In the classwork event of Lesson 1 Bernie displayed the problem “share £20 in the ratio 2 to 3” on the interactive whiteboard and learners were tasked with solving it individually. The problem was presented along with twenty circles representing the twenty £1 coins that were to be shared between the two people. After allowing a brief period for individual consideration, Bernie led a whole-class sharing of ways to solve this problem. As part of this, Bernie demonstrated how the 20 coins might be shared in the ratio two to three by counting them out two, then three, then two, then three, and so on. This classwork phase of the lesson was categorised as featuring visual and technical manifestations as Bernie offered a visual representation of an enactive method of sharing the money

in the given ratio. Building on Lesson 1, Bernie provided an opportunity for the whole class to recap methods for sharing quantities in a given ratio at the start of Lesson 2. The first example offered was: “share £140 in the ratio 3 to 4.” Three methods were suggested by learners, the third of which was a simple integer ‘scaling up’ method:  $4 : 3 \equiv 40 : 30 \equiv 80 : 60$  and  $80+60=140$ . The limitations of this method were revealed by the second example: “share £45 in the ratio 2 : 3 : 7.” Following this, Bernie endorsed a single method, the first step of which was dividing the quantity by the total of the parts. Thus there was an emphasis placed on formal methods in this introductory classwork phase to the lesson, with technical manifestation foregrounded.

Technical and particularly functional manifestations were emphasised in the given-tasks assigned to learners during seatwork. For example, in Lesson 1 learners were provided with the opportunity to practise sharing quantities of money in given ratios, for example: “divide £20 in the ratio 4 : 1”, and “divide £10 in the ratio 3 : 2.” The given-task here was categorised as technical. In each of the following lessons students were set problems that required sharing in a given ratio, but increasingly these became worded, contextual problems. Thus functional manifestation was more emphasised over time.

The effect of between-desk-teaching was that overall seatwork was materially different to the assigned given-task, with visual manifestation emphasised more and functional less. This can be largely attributed to Bernie drawing on the image of ‘moneybags’ when between-desk-teaching in order to represent a unitary share, such as in Lesson 1:

In effect you've got 3 bags of money and 2 bags of money, which altogether is 5 bags of money. If you share your £10 equally into those 5 bags you'll have £2 in each bag won't you? That person gets 3 bags [and] that person gets 2 bags, yes? (Bernie, Ratio Lesson 1)

Between-desk-teaching in Lesson 2 also referenced moneybags and included four separate conversations with different students over a period of 10 minutes in which Bernie offered essentially the same explanation of the solution to the same problem. It is interesting to note that while Bernie used a particular visual method for dividing in a given ratio during classwork in Lesson 1, the visual method offered when between-desk-teaching was equivalent but not identical. Lesson 3 continued to include between-desk-teaching in which Bernie made reference to moneybags, but not Lesson 4. This suggests a progression from Lesson 3 to Lesson 4, as in Lesson 4 there was less recourse to the imagery of moneybags in Bernie’s between-desk-teaching.

My reading of the between-desk-teaching actions across Lessons 2 and 3 was as a return to more familiar-to-the-learner manifestations of ratio, which I associated with offering learners explicit opportunity to ‘fold back’ (Pirie and Kieren, 1989) to a secure level of understanding. In Lessons 2 and 3, this secure level of understanding was inferred to be a visual method for sharing quantities in a given ratio. Whereas in Lesson 4 Bernie was heard to return to more technical manifestations of ratio when between-desk-teaching, which I associated with offering learners explicit opportunity to fold back from an inadequate contextual understanding to a more secure understanding of a method for sharing in a given ratio.

## Discussion

There are indications in this lesson series that between-desk-teaching was a lesson event foregrounded by Bernie in the context of teaching ratio to this class. Firstly, in total 52% of lesson time across the series was given over to between-desk-teaching compared to 27% to independent-of-the-teacher seatwork and 21% to classwork. Secondly, I have offered examples of Bernie repeating the same explanation on multiple occasions through between-desk-teaching when an alternative choice could have been to explain once to the whole class. This was an instance of the repetition effect noted by Jakonen (2018).

Furthermore I infer from the statistical analysis that between-desk-teaching was being deployed strategically as a way of making content available to learners. Non-linear opportunities were offered for growth in understanding (Pirie & Kieren, 1994) that were sensitive to the needs of individual learners (Jakonen, 2018). Teacher explanation at the start of the lesson series emphasised visual methods for solving ratio problems, while technical and increasingly functional components of manifestation were emphasised in the given-task that were subsequently assigned. While the methods of problem solving offered through between-desks-teaching in Lessons 2 and 3 were not identical to the methods seen at the start of Lesson 1, there was a clear intention to offer visual representations of problems in order to facilitate their solution, and for these to remain available throughout the lesson series. By Lesson 4 it can be inferred that visual representations were no longer needed, but symbolic representations of contextual problems were being offered through between-desks-teaching by this stage. In summary, whether through conscious deliberation or out of habit Bernie's actions aligned in this context with choosing to use between-desks-teaching in order to offer learners explicit opportunities to fold back to a secure level of understanding from earlier in the lesson series.

## Conclusion

Previous studies have considered between-desks-teaching as an isolated event or as an event within a lesson (e.g. Inoue et al., 2019), but the current study has taken the lesson series as the unit of analysis. There is stronger evidence of Bernie's between-desks-teaching being a deliberate act because this phenomenon was explored across a series of lessons. A further affordance of this research design is that through the analysis of teacher-talk and given-task it supports making sense of the contribution of between-desk-teaching to the way content is made available to learners over time. The lesson series is a unit of time over which teachers typically plan, and while the role of between-desks-teaching at this grain size may not be an issue they (and researchers) currently attend to, it could be. The two case studies involving Bernie reported in this paper offer an ideal example of when it might be appropriate for a teacher's attention to be drawn to this. In the case of Bernie teaching ratio, as we have seen, between-desk-teaching was used extensively and strategically. Yet in the case of teaching linear equations it was not used in this strategic way at all. Such contrasts in the practice provide in my experience powerful prompts for teacher reflection.

# Teachers' learning goals for a mathematics lesson

Kristin Krogh Arnesen and Yvonne Grimeland

Norwegian University of Science and Technology, Norway; [kristin.arnesen@ntnu.no](mailto:kristin.arnesen@ntnu.no)

*Due to current policy, including a curriculum that is managed by objectives, it is common that Norwegian mathematics teachers specify a learning goal for each lesson they teach. This study aims to identify characteristics of such goals. To this end, we analysed 50 learning goals with the revised Bloom's Taxonomy. A main finding is that there is an emphasis on students' understanding; however, the cognitive process categories Analyse, Evaluate, and Create were poorly represented in our data. Moreover, we asked the teachers to identify mathematical ideas (related to the learning goal) they would focus on in the lesson. In our data, the stated mathematical ideas were vague, and many teachers did not state any mathematical ideas at all. We discuss possible reasons for this.*

*Keywords: Learning goals, identifying mathematical ideas, revised Bloom's Taxonomy*

## Introduction

To plan lessons with the intended learning outcome (in this paper called a “(learning) goal”) as the point of departure is an old tradition. Tyler's influential model for planning (Tyler, 1949) is described by John (2006) as linear, meaning that you start with identifying a goal for the lesson, and then choose activities, assessment, and other elements that fit the goal. More dynamic models (see e.g. John (2006)) also include specifying goals. In one framework for learning how to teach (Hiebert, Morris, Berk, & Jansen, 2007), specifying the learning goals for an instructional episode is listed as the first item of the framework. Moreover, learning goals are closely linked with theory on assessment for learning, where one principle is that students should understand the learning intentions, including an understanding of what would count as success criteria (Hodgen & Wiliam, 2006). Thus, goals are typically not only a part of a teacher's planning process, but also present in the classroom. For instance, it is common in Norwegian schools that pupils get a goal for the week/day/lesson in every subject (Vikan & Buland, 2014). Another influence on the use of learning goals in Norway is that the education system is managed by objectives. The practice of using learning goals in teaching is probably similar to what is found in other countries where the education system is managed by objectives, e.g. Denmark (see Hansen, 2016). In Denmark, a study has shown that visible learning goals implicitly lead to a focus on skills and performance instead of mathematical competence (Hansen, 2016). A Norwegian Master's thesis investigating the mathematical competences present in five 8<sup>th</sup> grade teachers' learning goals (as they appeared in teaching) found that most of the goals had a short-time horizon and mostly focused on procedures, rather than on understanding (Selling, 2017).

In mathematics teaching, deciding upon a goal is closely connected with identifying a particular mathematical topic to discuss (Superfine, 2008). This identifying process can be linked with Askew's term “precision” (Askew, 2008). Being precise, including about the mathematical knowledge at stake, is one of the key elements in his framework for mathematics subject knowledge for teaching. It is suggested in a study by Sullivan, Clarke, Clarke, Farrell, and Gerrard (2012) that teachers tend to concentrate on activities and general aspects of pedagogy rather than on content objectives when planning mathematics lessons. In the study, Australian teachers were asked “what is the most

important idea that you will focus on for [the next mathematical topic you plan to teach]?”. Only half of the teachers in the study could describe the important ideas with a level of precision “likely to assist them in their planning” (Sullivan et al., 2012, p.478). In the conclusion to the study, the authors write that “it seems that teachers may need support in articulating the ‘important ideas’ on which they will focus and the sequencing and interrelationship of these ideas” (Sullivan et al., 2012, p. 478). Our study is based on the assumption that identifying mathematical ideas, or relationships between them, is intrinsic to producing adequate learning goals. It is therefore of interest to gain more knowledge about teachers’ identification of ideas underpinning the goals. To this end, our research questions are:

*What characterises teachers’ mathematical learning goals for mathematics lessons?*

*What characterises teachers’ identified mathematical ideas behind the learning goals?*

With the above stated assumption in mind, there is a hypothetical outcome where the two research questions gain similar results (a mathematical learning goal may be referring to a mathematical idea). However, for the first question, we aimed to analyse the learning goals given explicitly to students, and there could be pedagogical reasons not to give the mathematical idea to students in advance. Thus, the second research question will give more insight into the teachers’ practices regarding learning goals. In order to answer the research questions, we designed a questionnaire, which was answered anonymously by 51 teachers from primary and lower secondary school. In the subsequent analysis, we used two frameworks: The revised Bloom’s Taxonomy (Krathwohl & Anderson, 2001) and a framework from the already mentioned paper by Sullivan et al. (2012).

As the study is set in Norway, we provide the reader with some contextual background. In Norway, the non-linear “didactic relation model” for lesson planning (Bjørndal & Lieberg, 1978) has become part of the Norwegian “pedagogical canon”, as it is used in a number of textbooks in teacher education (Engelsen, 2006). In this model, six (originally five) elements are shown as mutually interplaying, with “goal” being one of them (Bjørndal & Lieberg, 1978). However, although goals are not the typical starting point for lesson planning in Norway, they are an important part of teachers’ practices. More precisely, “[g]oals are visible in a variety of ways; in the weekly plans, when teachers write goals on the blackboard and when they discuss goals orally in class” (Vikan & Buland, 2014, p. 17). The current curriculum, implemented in 2006 (Ministry of Education and Research, 2016), is written in terms of goals. For all school subjects, there is a subject curriculum, which consists of a list (ordered by year) of so-called *competence aims*, and the students are assessed by whether they have achieved these competence aims.<sup>1</sup> As an example, the curriculum for mathematics lists that after year 4 (aged 9–10), a student should be able to “make estimates of and find numbers by means of counting in one’s head, using counting aids and written notes, making estimates by calculating with simple numbers, and assessing answers” (Ministry of Education and Research, 2010). The competence aims are further decomposed, ultimately by the teacher(s) when planning a lesson.

## Theoretical frameworks

One of the most well-known models for analysing goals is Bloom's Taxonomy (Bloom et al., 1956). We build our analysis of the learning goals on the revised Bloom's Taxonomy (Anderson & Krathwohl, 2001), in which the original taxonomy has become a two-dimensional model, with one dimension focusing on the cognitive aspect of the goal, the other on the knowledge at stake. Unlike the original taxonomy, the revised version does not stress a rigid hierarchical structure – that is, a goal in a given category in either dimension is not necessarily “better” or “more demanding” than a goal in the previous category in that dimension. On the other hand, the revised taxonomy is meant as a tool to, among other things, “help educators consider the panorama of possibilities in education” (Anderson & Krathwohl, 2001, p. 35). As such, it is most common among educators, but it is also used in research (see e.g. Hansen, Herheim, & Lilland, 2017). We chose the revised Bloom's Taxonomy because it would give an overview of the learning goals, suggesting some characteristic features and some features that do not appear among the goals.

We explain here how we have interpreted the categories of the revised Bloom's Taxonomy. The four categories of the knowledge dimension are interpreted as follows: *Factual knowledge* means terminology and conventions. *Conceptual knowledge* consists of mathematical concepts, ideas, and models. *Procedural knowledge* includes everything related to *doing something* (Anderson & Krathwohl, 2001): computing, algorithms, strategies. *Metacognitive knowledge* is knowledge about cognition, including meta-knowledge of strategies. Moreover, the six categories of the cognitive process dimension are interpreted as follows: *Remember* is about memorising things (like definitions, terminology, or the steps of an algorithm). The *Understand* category is for goals including verbs like “learn”, “know”, “explain” and others listed by Anderson and Krathwohl (2001) (in our data, it is hard to identify the category in other ways). The *Apply* category is for doing something of a non-algorithmic nature. Note that this differs slightly from Anderson and Krathwohl's description, as we would classify performing a given algorithm to a standard problem as *Remember procedural knowledge* rather than *Apply procedural knowledge*. *Analysing* means breaking something down to look at relationships, while *Evaluate* is to test or detect something based on given criteria. Finally, *Create* means to produce something new, like a hypothesis or an argument.

To analyse the teachers' stated mathematical ideas, we use a framework introduced by Sullivan et al. (2012). The framework consists of five categories, which we have interpreted as follows: For *A mathematical idea within the topic*, the mathematical idea/relationship is clearly specified. For the second category, *An element of a hypothetical learning trajectory*, the mathematical idea/relationship is underlying the response, but not explicitly stated – instead, the focus is on the students' discoveries or activities. The third category, *A sub-topic of the larger mathematical topic*, is characterised by keyword-style answers. The two final categories have self-explanatory titles: *A statement which could apply to most other topics and not specifically an important idea tied to the particular topic* and *A statement which describes aspects of pedagogy and does not particularly address content*. We did not intend to connect the two frameworks. Instead, it was our aim to treat the two research questions separately, and then use the second to shed light on the first, as the goals are our main topic of interest.

## Method

The research questions require data in the form of teachers' mathematical learning goals, together with information on what the teachers regard as the mathematical idea underpinning the learning goals. To obtain this, we designed an anonymous questionnaire for teachers, introduced by the request "base your answers on the next mathematics lesson you give". The questionnaire and the quoted responses are translated from Norwegian by the authors. The questions relevant for the research questions treated in this paper are Q2: "What is the content-related learning goal of the lesson?"; Q4: "Is there a particular mathematical relationship or idea within the learning goal you want to especially focus on in the lesson? If yes, what?"; Q6: "Do you as the teacher have any other content-related or pedagogical goals for the lesson, that are not made known to the students? If yes, what?" Additionally, we asked about the overall topic of the lesson, the age of the students, and whether the goal would be made explicitly known to the class.

We piloted a first version of the questionnaire among a group of in-service teachers taking a course given by the first author. In the discussion with the pilot respondents, we were made aware that the terms "mathematical relationship/idea" could be hard to distinguish from "content-related goal". As suggested by the pilot respondents, we changed the order of some questions, intending to make this distinction clearer. Yet, we chose to keep the terms used, as this would be in line with the terms used in the theoretical frameworks of the study. Nevertheless, this suggested confusion could indicate that the validity of the study is not optimal, as we will comment further upon in the discussion.

In-service teachers supervising school placement of student teachers were chosen as the cohort because we had easy access to them via the university's digital learning management system (LMS). In general, supervisors have not taken more mathematics courses than other teachers have. The respondents are called "teachers" throughout this paper. We posted information of the study in the digital LMS, and additionally issued individual messages to all teachers, with a link to the digital questionnaire. Later we sent two reminders to all the teachers. In this period, we obtained 29 digital answers. To get more data, the second author visited a meeting for supervisors hosted by the university the following term, distributing paper copies of the questionnaire (as well as link to the digital version). At the meeting, 22 completed questionnaire sheets were handed in. Thus, the data in this study consists of 51 questionnaire answers (29 digital and 22 on paper). It makes sense to assume that most teachers answering in the first round had access to their actual planning notes, while most teachers answering in the second round did not. Yet, we have treated the answers from both rounds as one data set, because the teachers at the meeting had the option of answering digitally later, which they chose not to do (so we can assume they considered that they remembered the details sufficiently). Some teachers might have answered the questionnaire twice (once in each round); this has not been taken into consideration during analysis, as we cannot identify them in the data material. The teachers work in primary or lower secondary school, and the majority (37 teachers) teach grades 4-7. One teacher in the cohort did not state a goal when answering Q2; thus, 50 goals were analysed.

After collecting all the data, the first author coded the replies to Q2 and Q4 with the revised Bloom's Taxonomy and Sullivan's framework for mathematical ideas, respectively. Then the coding was discussed with the second author. We used the revised Bloom's Taxonomy as follows: First, we coded

by the knowledge dimension, subsequently by the cognitive process dimension. Not all goals were easy to reliably classify by the framework. For instance, it is sometimes unclear whether a goal belongs to the *Remember* or the *Understand* category, in particular for goals in the *Procedural* knowledge category. In these situations, we used the replies to additional questions (in particular Q4) to look for indicators on how to classify the goal. We also intended to use Sullivan's framework to analyse goals given as replies to Q6, but here the replies were (with very few exceptions) either blank, or belonging to the last of the five categories (general aspects of pedagogy). Thus, we concluded that this question did not shed light on the research question, and we include no analysis of the replies.

Because of the methodological weaknesses in the study, we need to be careful when addressing the data. Nevertheless, we can view the results as preliminary results, initiating discussions and indicating directions of future research.

## Results

The complete results of the analysis are presented in Table 1 (Q2) and Table 2 (Q4). From the analysis of Q2 (the goals), the most prominent findings are *a focus on understanding* and *a lack of higher-level goals*. Regarding Q4 (the mathematical ideas), the analysis reveals a *vague/missing description of mathematical ideas*. All teachers except two state that they would present the goals to their students before the class.

The knowledge dimension	The cognitive process dimension					
	1. Remember	2. Understand	3. Apply	4. Analyse	5. Evaluate	6. Create
A. Factual knowledge	2					
B. Conceptual knowledge	1	10	2			
C. Procedural knowledge	6	13	6			
D. Metacognitive knowledge		4				
Other	6					

**Table 1: Revised Bloom's Taxonomy table. Number of goals in each intersected category**

### A focus on understanding

Of the 50 goals that were analysed, 27 goals – more than half of the goals – were found to belong to the *Understand* category. Examples include “understand fractions as a part of a set” (*Understanding conceptual knowledge*; the knowledge at stake can be identified as the set model for fractions) and “The students should learn addition with regrouping” (*Understanding procedural knowledge*; the respondent states in reply to Q6 that no algorithm will be given, but that the work builds a fundament for a later understanding of the standard algorithm). In contrast, there are few goals identified in the *Remember* category.

### A lack of higher-level goals

By “higher-level”, we mean the three upper categories in the cognitive dimension; *Analyse*, *Evaluate* and *Create*. No goals were found to fit within these categories. The “highest” category we found

examples of in our analysis were C3, *Applying conceptual knowledge*. In this category, any method mentioned for the given procedure is subject to the students' exploration, or there is no method given at all. One example, with a given method, is "that the students should get experience with using strategy with 'friendly numbers' in computing". With a particular idea highlighted in the reply to Q4, this goal could belong to category C4, but no such idea is stated.

Category	Number of replies
1. A mathematical idea within the topic	8
2. An element of a hypothetical learning trajectory	8
3. A sub-topic of the larger mathematical topic	7
4. A statement which could apply to most other topics and not specifically an important idea tied to the particular topic	12
5. A statement which describes aspects of pedagogy and does not particularly address content	3
Missing	11
Uncategorised	1

**Table 2: Sullivan et al.'s framework. Number of replies in each category**

### **Vague/missing description of mathematical ideas**

As Table 2 shows, only 16 of the 50 analysed replies fall into the two top categories in Sullivan et al.'s framework. Eleven of the teachers do not state a mathematical idea at all. Examples of category 1 and 2 include "the relationship between division and multiplication" and "understanding that decimal numbers consist of parts that are less than one whole" (category 1); "strategy thinking – how to find fourths and eights – focus on halving" and "converting to correct unit of measurement before computing" (category 2). Examples from category 3 are "friendly numbers" and "the decimal number system". In category 4, we find "focus on exactness and using a sketch figure", in category 5 "more than one way leading to the target". The uncategorised reply is "show a way to do it ['it' is division by one digit numbers]", where we do not know whether the "show" regards the teacher or the students.

### **Discussion**

We can assume from the preliminary findings that many teachers intend to teach for understanding, judging by their use of verbs like "understand", "learn", "see" and so on (the verbs attributed to the *Understand* category in Bloom's Taxonomy). This is in contrast to Selling's findings, where the goals were dominated by a focus on procedures and not understanding (Selling, 2017). One reason for this difference can be that we have analysed learning goals from the teachers' lesson planning, while Selling analysed goals that appeared – explicitly or implicitly – during lessons. Nevertheless, the teachers' focus on students' understanding is an uplifting finding. As terms like "understand" and "learn" are ambiguously used in pedagogics and mathematics education research, more information is needed in order to get a more detailed picture of the teachers' use of such words. Yet, it is tempting – from the researchers' point of view – to connect the idea of "understanding" to a focus on the

mathematical ideas underpinning what is to be understood. Here, we note an intriguing discrepancy between the emphasis on understanding in the learning goals and the vague/missing description of mathematical ideas.

When discussing the teachers' seemingly disappointing reports on mathematical ideas, it is necessary to return to the methodological problem we encountered when wording Q4 in the questionnaire. Because we wanted to elicit information about the teachers' view on mathematical ideas, we ended up using a term – mathematical idea – that seemed unfamiliar and confusing to the pilot respondents. As mathematicians, we may have assumed that the meaning of the term is evident. However, a brief search in literature reveals that very few papers using the term (or similar terms, like “big idea”) actually define it. An exception is the in the German-speaking tradition, where mathematics educators use “fundamental ideas” to guide their mathematics teaching (see Vohns, 2016), but this is – from our experience – not familiar to the Norwegian mathematics education community. Interestingly, we find traces of a similar problem in Sullivan et al.'s paper (2012). In their study, they asked the teachers “what is the most important idea that you will focus on for that topic”, assuming that the teachers would interpret “idea” as “mathematical idea”. When the responses showed that this was not always the case, the authors conclude that “[t]he fact that the important idea in the teaching of a forthcoming mathematical topic in the mind of a teacher might not be mathematical is revealing in itself” (Sullivan et al., 2012, p. 468).

Following this discussion, we infer that we cannot conclude whether we have found a problem with the teachers' level of precision (cf. Askew, 2008), with the teachers' own mathematical competence, or with the use of a term that is understood differently by the researchers and by the teachers. To ensure the validity of further studies, such terms should be avoided. Other approaches (like interviews) can help to distinguish the teachers' mathematical focus when writing learning goals.

When it comes to the third finding, the lack of higher-level goals, there is also a potential explanation due to the same issue. The teachers' replies to Q2 were partly analysed based on their reply to Q4. Thus, it is possible that some goals were misjudged due to our use of the term “mathematical idea”. At the same time, many goals were easy to analyse without the need to consider Q4. Based on this, the preliminary findings indicate the same trend that has been found in Denmark, i.e. that the focus on visible learning goals can lead to more focus on skills and less on competences (Hansen, 2016).

*The purpose of this study is to explore how a mathematics teacher contributed to a classroom design research and how this contribution promoted student learning and the establishment of students' mathematical practices of linking composite units and iterating linked composites, which is the basis for proportional reasoning. In this classroom design research study, a classroom learning trajectory and related instructional sequence were formulated based on the theory of Realistic Mathematics Education and implemented by the teacher. Findings showed that the teacher contributed to the design research in each phase, and her contributions promoted students' mathematical practices regarding linking composite units and iterating composite units.*

*Keywords: Realistic mathematics education, proportional reasoning, classroom design research.*

### **Introduction**

Proportional reasoning lies at the heart of many mathematical structures, especially those included in the primary and middle school mathematics curricula (Lesh, Post, & Behr, 1988). However, several studies reported students' difficulties and misconceptions in proportional reasoning. These difficulties are said to have stemmed from the fact that proportional reasoning instruction is superficial and limited since it is conventionally referred to as solving missing-value problems with procedural algorithms, such as cross multiplication (Lesh et al., 1988). Thus, it is clear that there is a need for improved instruction for proportional reasoning.

Simon (1995) was a pioneer in proposing the development and use of Hypothetical Learning Trajectories (HLT) for improving instruction in such a way that lessons are designed in line with related research findings on student thinking and learning. Stephan (2015) introduced the construct of a classroom learning trajectory, which is referred to as anticipated classroom mathematical practices that might evolve over the course of an instructional sequence. Using Stephan's approach, we conducted a classroom design research project, in which we formulated a classroom learning trajectory and related instructional sequence for ratio and proportion for seventh grade based on the theory of Realistic Mathematics Education (RME) since working in realistic contexts can be an instructional aid for meaningful learning and reinventing mathematical ideas (Gravemeijer, 1994). While the larger study concentrates on these issues, we particularly focus on the teacher's role in classroom design research for the big ideas of linking composite units and iterating linked composites in this paper. The research questions addressed are:

1. How does a seventh-grade math teacher participate in the preparation/design phase of a classroom design research study? How does this contribution promote the emerging and establishment of mathematical practices regarding linking composite units and iterating linked composites?

2. How does a seventh-grade math teacher support the emerging and establishment of mathematical practices regarding linking composite units and iterating linked composites through the implementation of the instructional sequence?

## Methods

Design research studies have gained importance in the last two decades and have been conducted for various goals in educational research area from designing and examining innovations, such as activities, institutions, interventions, or curricula (Design-Based Research Collective, 2003). This study is a classroom design research in which an instructional sequence is formulated, tested, and revised by a research team including teachers and university members (Stephan, 2015). A classroom design research cycle entails three phases as design, implementation, and analysis (Stephan, 2015).

This classroom design research study was conducted in a seventh-grade classroom in a public school located in a rural area in the capital city of Turkey. Hence, most of the students had low socioeconomic statuses. The students had been instructed on calculating the ratio of two quantities and finding different values of the quantities that are directly proportional in sixth grade. They had not been instructed on ratio and proportion in seventh grade prior to the study. The teacher was female with 10 years of experience in teaching in seventh grade. She was selected since she adopted student-centered teaching practices and was willing to cooperate with the researchers in every part of the study. Even though she had not been trained specifically before the study, she was informed about the purposes of the study and the literature on proportional reasoning, RME, and HLT.

## Instructional Sequence

The approach that undergirds the design of the proportional reasoning instructional sequence is RME. The roots of RME are based on the idea of mathematics as a human activity. Freudenthal (1968) stated that people need to see mathematics not “as a closed system, but rather as an activity, the process of mathematizing reality and if possible even that of mathematizing mathematics” (p. 7). Within the context of RME studies, students are guided to reinvent mathematical ideas through organizing realistic contexts that are didactically rich (Gravemeijer, 1994). In addition, students are encouraged to create and reason with models and mental imagery associated with the physical tools, inscriptions, and tasks they employ.

In the instructional sequence, which was developed for the students in the USA, the instruction begins with a story about a bad dream in which aliens were chasing the teacher and a bar of food was enough to satisfy three aliens. In this way, students were encouraged to link together one food bar with three aliens and knew that if this relationship was broken, there would be an alien attack. As students solve problems, they are encouraged to organize their pictures or numbers, and eventually a ratio table is introduced as an efficient way to keep track of how the two quantities may scale up or down. For the purposes of this paper, we will not describe the remainder of the instructional sequence because we focus our analysis only on the first part, *linking composite units and iterating linked composites*. For more information of the sequence and the materials themselves, see <https://cstem.uncc.edu/sites/cstem.uncc.edu/files/media/Ratio%20T%20Manual.pdf>

A small part of the HLT that is related to this study can be seen in Table 1 below. The Big Idea column describes the learning goal for that portion of the instruction, and the Tools/Imagery column outlines the specific inscriptions and/or notations that are intended to support the corresponding learning goal. The third column, Possible Topics of Discourse, is meant to guide teachers in the types of questions or mathematical conversations that are important for that section of the sequence. The HLT for the entire proportional reasoning sequence can be reached via the same link.

Big idea	Tools/Imagery	Possible Topics of Discourse
Linking composite units	Connecting pictures of aliens to food bars	If the rule is 1 food bar feeds 3 aliens, the rule can't be broken if we add more food bars
Iterating linked composites	Informal symbolizing (e.g., tables, two columns of numbers, pictures of aliens and food bars)	How students keep track of two quantities while making them bigger

**Table 1: A small part of the HLT related to linking and iterating**

### Data collection

Cobb, Confrey, Lehrer, and Schauble (2003) stress that the units of analysis in a design research are the key elements of a learning environment and these are:

the tasks or problems that students are asked to solve, the kinds of discourses that are encouraged, the norms of participation that are established, the tools and related means provided, and the practical means by which classroom teachers can orchestrate relations among these elements. (p. 9)

Therefore, in this study, it is crucial to analyze the teacher's contribution to each phase of the study and how her contribution had an impact on the emerging and establishment of students' mathematical practices of linking and iterating. The related data were collected through the videotapes of class sessions, audiotapes of teacher interviews and research team meetings, and analysis of student work.

### Data analysis

The teacher's contribution to the design research was documented by an analysis of the written transcripts of her interviews and of the design team meetings. These qualitative data were analyzed by an interpretative framework and a related analytic approach that focuses on the "meanings made both by the social actors and by the researcher" (Miles & Huberman, 1994, p. 8). Students' mathematical practices were analyzed using Stephan and Rasmussen's (2002) adaptation of the Toulmin's (1969) argumentation model. After classroom argumentation process was coded as claim, data, or warrant, the ideas that emerged were noted. The criteria by Stephan and Rasmussen were used in order to see what mathematical ideas became taken-as-shared (or established) by the classroom community. For the last part of the analysis, these taken-as-shared ideas were organized around common mathematical activities, which were later named as classroom mathematical practices. Seven mathematical practices were obtained in the larger study; however, we focus only on the first mathematical practice in this study.

## Findings

Findings are presented by describing the teacher's contribution to each phase of the study with specific examples. In addition, the first classroom mathematical practice regarding linking composite units and iterating linked composites is explained with details in order to reveal how the teacher's contribution to the design phase was realized in the classroom and had an impact on the establishment of students' mathematical practice of linking composite units and iterating composite units.

### Teacher's contribution in the preparation/design phase

The initial phase of the classroom design research is mostly about reviewing literature, finding a realistic and engaging context, and hypothesizing a classroom learning trajectory. Literature review was conducted by the design team on teaching and learning of ratio, proportion, and related concepts and instructional activities and tools. In addition, the teacher was interviewed regarding her experiences on the learning and teaching of related topics and curriculum. Even though an already developed and tested trajectory was available, a number of adaptations and modifications were needed for Turkish students. For instance, the context was changed from alien-food bars to fish-food bars in order to make it more experientially real for Turkish students. Moreover, pictures were added to some of the questions, and quantities in some of the problems were changed in order to improve the sequence and the HLT. While deciding on these changes, the design team was engaged in anticipatory thought experiments in which they tried to imagine possible classroom mathematical discourse, which were helpful in shaping the design and coming up with conjectures about the teaching and learning of the topic. Even though the teacher had an active role in all of this process, we represent below a number of substantial teacher suggestions in order to reveal the unique value of her contribution to this phase. To begin with, the teacher suggested that pictures of food bars and/or fish were included for some problems in order to visually support students' processes of linking units and iterating composite units. In addition, she suggested that some values in the questions should be altered in a way that it was possible to make connections between questions. For instance, the question "how many fish can be fed with 5 food bars?" was followed by "how many fish can be fed with 9 food bars?" and "how many fish can be fed with 10 food bars?" in order to support the use of build-up strategies.

### Teacher's contribution to the implementation phase

The teacher launched the trajectory with the adapted version of the bad dream story in which her fish were making noise and attacking her since they were hungry. The teacher, then, asked students if they had pets and how they fed their pets. Students suggested that pets had to be fed with a certain amount of food each day: if they were underfed they would be hungry and if they were overfed they would get sick or even die from overfeeding. This was an on-action (unplanned) instructional move that laid the ground for students to make sense of why the rule could not be broken.

In the first problem in the sequence, seven fish and four food bars were given, and the rule was one food bar for three fish. The question asked whether or not there were enough food bars for those fish. The sequence started with simple whole number ratio situation with pictures of both food bars and fish in order to help students link the composites concretely. Even though those questions were easy for the students, starting with those questions made it possible for the teacher to capitalize on taking

three fish as a unit and linking this unit with one food bar. This was also helpful for students to group the three fish and link them with a food bar with arrows as given in Figure 1 below.

**Figure 1: Linking units by with arrows**

In the later problems, pictures of either food bars or fish were provided as suggested by the teacher. Whereas some students drew the pictures as in Figure 2a, some of them just wrote the corresponding number of fish numerically as in Figure 2b. Therefore, it was inferred that the teacher's suggestion was helpful for students to make pictorial, numerical, and mental linking and iteration.

**Figure 2a: Linking units by grouping**

**Figure 2b: Linking units with numerical values**

After a few problems through which this link was established, scaling up problems were posed (e.g. How many fish can be fed with 5 food bars? with 10 food bars?). Pictures were not included in the problems in order to help students create mental images of composite units and the link. In their solutions, a number of students drew pictures of food bars and/or fish, and some used numerical build up strategies as illustrated in the figures 3a, 3b, and 3c below. This gave us evidence that the students reasoned with models and mental imagery, and associated those with the physical situation.

**Figure 3a: Drawing pictures and linking with numbers**

**Figure 3b: Drawing pictures and linking with numbers**

**Figure 3c: Numerical build-up**

After finding the answer for the number of fish that can be fed with nine food bars as 27, a student answered the following question that asked the number of food bars for feeding 10 fish immediately as 30 by building up on nine and 27. He explained his reasoning as "We found that nine food bars could feed 27 fish in the previous question. So, I added three to 27 and found that 10 food bars can feed 30 fish since the number of fish goes up by three...since one food bar can feed three fish." Therefore, the teacher's suggestion regarding changing numerical values helped students make connections and improve their understanding of the link between the number of food bars and fish.

Later on, after all the students explained their answers with pictorial and numerical strategies, the teacher took the opportunity to introduce a long ratio table in order to keep track of students' iterations, organize information, and make calculations more easily. By using long ratio tables, students were able to make such interpretations as "When the number of food bars goes up (or down) by one, the number of fish goes up (or down) by three". In the following instances, students started to use abbreviated build-up strategies where they did not add values one by one; instead, they made interpretations of the type "when the number of food bars is doubled (or tripled, quadrupled etc.) the number of fish is also doubled (tripled, quadrupled etc.)" as in Figure 4 below.

13. Yukarıdaki kurala göre yem ve balık arasındaki ilişkiyi gösteren tabloyu doldurunuz.

Yem (Kutu)	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Balık	3	6	9	12	15	18	21	24	27	30	33	36	39	42	45

**Figure 4: Representation with abbreviated build up strategies**

After the one-to-three relationship was established among the classroom community, the instructional sequence was continued with different rules (e.g. 2-4, 2-3). When the rule was two food bars for four fish, a couple students used the given rule, whereas most of the students discovered that they could change the rule to one food bar for two fish. Below is a conversation in which students discussed about changing the rule when the question asked the number of food bars needed for feeding 12 fish:

Student 1: Six food bars are needed for 12 fish [claim] because I divided 12 by two. [data]

Teacher: Why did you divide 12 by two? [challenge]

Student 1: Because four fish can be fed with two food bars. [warrant]

Student 2: Then you have to divide by four, right? [challenge]

Teacher: Why do you think you have to divide by four? [challenge]

Student 2: (Draws 12 circles to represent 12 fish and groups each four fish by a bigger circle) I grouped [the fish] by fours and obtained three groups [of four fish]. I know that I need two food bars for each group. So, I multiplied three by two [data] and obtained six. [claim]

Student 3: We changed the rule. If two food bars feed four fish, then one food bar feeds two fish. [warrant] So we divided each value by two. [data]

Teacher: What does everyone think about this?

Student 4: It is easily seen with the pictures (Linking one food bar with two fish as in Figure 5). It is easily seen that one food bar feeds two fish. It is easier to use this rule. We can group fish by twos after we change the rule. [warrant]

**Figure 5: Changing the rule while preserving the link between the number of food bars and fish**

As deduced from the figure and the dialogue, students changed the rule while preserving the link and the invariant relationship between the number of food bars and fish, which was an evidence of the strength of the link between food bars and fish. On the other hand, even though she did not use the term, Student 4 also referred to the concept of unit rate and how using unit rate makes calculations easier. Therefore, it could be deduced that including the pictures of fish and food bars as suggested by the teacher helped students to make sense of the ideas of equivalent ratios and unit rate.

Following the above activities, problems with a non-integer ratio (i.e. two food bars for three fish) were included in order to strengthen students' linking and iterating processes. At some point in the instruction, the teacher needed to communicate with the first researcher (participant observer in the classroom). While the students were filling in the table using the rule two food bars for three fish, a student asked if she had to fill in the table by building up by ones or by twos and threes. The teacher communicated with the researcher, and they decided that the tables had to be filled by building up by twos and threes. The teacher asked the student which way made more sense for her. The student replied that filling in the tables by twos and threes was meaningful since there would be decimal values while building up by ones and decimal values for the number of fish would not make sense.

### **Teacher's contribution to the analysis/revision phase**

Design research includes ongoing and retrospective analysis. As part of the ongoing analysis process, the teacher participated in the daily/weekly design team meetings that focused on how students were engaged with the tasks and the required revisions, which helped the teacher see whether or not the intended learning goals and practices emerged. The retrospective part of the analysis was conducted by the university members since they were trained in this area.

### **Discussion and Conclusion**

The power of design research is that it blends theory, research, and practice. It is reported that teachers can benefit from classroom design research in such a way that they would be up-to-date research-wise and experienced in developing/adapting tasks that would help students learn meaningfully (Stephan, 2015). The findings of our study have further shown that the teacher could contribute to classroom design research aiming at developing an instructional sequence and classroom learning trajectory for linking composites and iterating linked composites.

The teacher contributed to the study and the establishment of students' mathematical practices regarding linking units and iterating composite units by implementing the activities and the HLT in the pre-planned ways. The findings obtained by Toulmin analysis related to students' participation behaviors of claiming and providing data/warrants for their claims and the documentation of mathematical practices showed that she contributed to the establishment of the mathematical practice of linking units and iterating linked composites. What is more, the teacher made a few on-action instructional decisions and communicated with the researcher in the implementation phase. Apart from implementing the instruction, the teacher contributed to the design research in the design/development phase by making suggestions on the necessary adaptations to the tasks and the HLT. However, it might not be obvious how substantially the teacher contributed to the design phase in this study. It should be noted that the analysis included the teacher's contribution only in the first part of the HLT and the instructional sequence, which were the anchor that laid the ground for the

rest of the activities. Since it was the anchor activity it was well developed, and the teacher did not need to make big modifications. It is anticipated that the teacher's contribution to the design phase would be more substantial in the rest of the activities. Still, we claim that teachers can be valuable sources in designing instruction since teaching plans should be informed by students' mathematics (Steffe, 1991) and teachers are supposed to know their students. Lastly, the teacher contributed to the analysis phase by participating in the daily/weekly design team meetings that focused on enhancing student learning and required revisions. Engaging teachers more in classroom design research that focuses on a variety of mathematical topics could give more information about the contributions of the teachers to each phase of the studies.

# A comparison of the treatment of mathematical errors arising from teacher-initiated and student-initiated interactions

Fay Baldry

University of Leicester, UK; [fb128@le.ac.uk](mailto:fb128@le.ac.uk)

*This paper explores teachers' treatment of errors as they occur both within and outside of Initiate-Response-Evaluate (e.g., Cazden, 1988) interactions. Data are drawn from a classroom-based video study in England, involving three participating secondary mathematics teachers and six classes. This paper focusses on one of those teachers, whose lessons contained the widest range of treatment of errors. This included facilitating extended peer-to-peer turn-taking and bald negative evaluation of student contributions; the latter appeared to be atypical, both in relation to the other teachers in this study and the wider literature. Analysis showed, for this teacher, indirect evaluation of errors was associated with teacher-initiated interactions, whereas bald negative evaluation was associated with student-led exchanges. Here, consideration is given to the interactional patterns related to the treatment of errors, and the potential impact on learning opportunities for students.*

*Keywords: Classroom norms, errors, mathematics education, misconceptions.*

## Introduction

Patterns of classroom talk vary, but Lefstein and Snell (2011), amongst other, report that in Anglo-American schools whole-class talk is typically controlled by the teacher. Moreover, a large proportion of interactions are in Initiate-Response-Evaluate (IRE) format, that is to say these are initiated by the teacher asking a question, which is followed by a student response and concluded with another teacher-turn, in which the mathematical validity of the student contribution is evaluated (Cazden, 1988). The role and treatment of mathematical errors has been reported in previous studies (e.g., Steuer, Rosentritt-Brunn, & Dresel, 2013), but the ubiquitous nature of IRE interactional patterns means that many of these discussions draw on evidence from this type of turn-taking exchange. Other types of interaction patterns, such as talk initiated or led by students, are less common in many classrooms (Edwards-Groves, Anstey, & Bull, 2014), but a move away from univocal teacher talk has been associated with enhancing learning opportunities (Alexander, 2004; Edwards-Groves et al., 2014). This paper focusses on one secondary school teacher in England and the shifts in turn-taking patterns that are seen when he teaches two classes. In particular, this study analyses the treatment of errors as they arise in IRE exchanges and student-initiated turns, with the aim to explore the leverage of errors to develop productive talk in different types of interaction.

## Theoretical Framework

The use of 'error' varies between studies; some use the term to indicate anything treated as such by the teacher (e.g., Ingram, Pitt, & Baldry, 2015), whereas others use 'error' when they identify an issue with a mathematical contribution (e.g., Heemsoth & Heinze, 2016), although it is supposed there is considerable overlap between these two conditions. Whilst research has highlighted the role errors can play in providing learning opportunities (Bray, 2011), there is evidence a productive use of errors is not a routine part of many teachers' pedagogical practice (Ding, Li, Piccolo, & Kulm,

2007). The potential conflict between errors being seen as learning opportunities and the notion that errors should be avoided has been discussed. For instance, Swan (2001) argues some teachers avoid errors because they believe students might be confused by the discussion and erroneously remember the error rather than the correct solution. The notion that errors are embarrassing has been used to justify the avoidance of errors and to explain why both teacher and students take mitigating actions when they do occur (Pekrun, 2009). However, work by Steuer et al. (2013) has shown that the classroom climate and students own goal orientations have a significant effect on the affective reaction of students to errors.

Questions permeate most aspects of whole-class talk and hence are often the precursor to mathematical errors. In many classrooms, IRE sequences dominate whole-class interactions, being described as the ‘default’ setting for many teachers (Resnick, Michaels, & O’Connor, 2010). Whilst questions can play a variety of roles, from developing student understanding through to a tool for drawing attention to mathematically important features (Mason, 2000), within IRE interactional sequences the questions asked are often more limited in scope (Edwards-Groves et al., 2014). Teachers frequently ask questions that have a single expected response, with a shared understanding that the teacher knows the answer and that they will evaluate the accuracy of the student’s response in the third turn. Within this type of turn-taking, correct solutions are usually acknowledged immediately by the teacher, whereas errors are rarely directly acknowledged as such (Ingram et al., 2015). When errors do occur in student responses, the negative evaluation in the third turn is often communicated indirectly, through teachers’ pedagogical actions, such as redirecting the question to another student, asking follow-up questions or other actions to draw attention to the nature of the problem. Indeed, the pedagogical moves taken to avoiding direct evaluation are often directed towards allowing students to undertake additional mathematical work in subsequent turns, including self or peer correction of the error (Ingram et al., 2015). However, whilst there are examples of learning opportunities being created after an error has been identified in an IRE sequence, there is also evidence that teachers tend to reduce the mathematical load in subsequent turns and may ‘funnel’ students towards particular solutions (Jones & Tanner, 2002), thereby limiting the learning opportunities made available. From a conversation analysis perspective, the avoidance of direct negative evaluation would imply that errors are embarrassing and should be avoided (Seedhouse, 1997), but Steuer et al. (2013) argue that the lesson context is more complex, with students’ engagement shaped by their reading of the error climate of the classroom.

This study seeks to contribute to the understanding of the treatment of errors through the exploration of their occurrence in different patterns of whole-class interactions.

## **Methodology**

This paper draws on data from a classroom-based video study in England. As part of a qualitative case study in the interpretative tradition, eighteen secondary mathematics lessons have been observed and recorded by this author. Three teachers participated and for each teacher two classes with different attainment profiles were observed. Lessons were recorded with two static video cameras and lesson artifacts, such as students’ work, were collected. Semi-structured interviews were conducted with the teachers before and after each lesson and lesson planning documents were

obtained. Audio data from each lesson was transcribed and collated with copies of mathematics written or projected in the shared space of the class whiteboards. The initial coding of the transcripts classified activities as either mathematically relevant or not, with episodes in the former category being subject to further scrutiny. As part of the wider study, the Orchestration of Mathematics Framework (OMF) has been developed to capture teachers' pedagogical moves and the potential impact this has on the mathematics made available to learners (Baldry, 2017). The further analysis of the mathematically relevant episodes involved an iterative process of coding interactions against this conceptual framework and cross-referencing with other data sources, such as teacher interviews and student work.

A key element of the analysis was the nature of interaction patterns in class-level talk, including the treatment of errors, although it is acknowledged that the interpretation of interactions is predicated on understanding the classroom culture (Larsson, 2015). The notion of classroom norms (Cobb, Stephan, McClain, & Gravemeijer, 2001) has been drawn on to establish whether interactions are typical or atypical, and thereby allow inferences beyond the particular occurrence, but this is limited to what is discernible at a whole-class level. This paper focusses on one teacher, Sam, and four lessons from two classes, selected when the analysis highlighted distinct patterns of interaction in relation to errors. These have been chosen because they do appear to be atypical, both in relation to the other two teachers in the study and the wider literature. Here, 'errors' are taken to be students' contributions that include a mathematically incorrect statement, but these occurrences were also all treated as errors by Sam. The practices of one teacher cannot be generalized to others, and indeed it could be argued that the analysis of a limited number of lessons in a study of this size may not provide a sufficiently representative picture to allow comparisons (Staub, 2007). However, I believe that a consideration of these more atypical behaviours has the potential to contribute to our wider understanding of the relationships between interactional patterns of whole-class talk, the treatment of errors and the learning opportunities for students.

## Findings

Across all lessons, whole class-level talk represented about one third of the lesson time, and IRE interactional patterns accounted for at least two thirds of this talk. Most questions asked by Sam had a limited range of appropriate mathematical responses and about 20 percent were 'simple', that is to say students should have been able recall the answer immediately and without effort. About 75 percent of IRE exchanges were positively evaluated, a rate that was relatively stable across the lessons. The majority of the remaining exchanges were coded as containing negatively evaluations, although there were a few ambiguous cases. The interactional patterns in IRE exchanges across both classes were very similar. For example, when discussing the rules of indices, the following IRE interactions occurred, but similar exchanges were regular occurrences in all lessons:

- 30 Sam: What does two to the power four mean
- 31 Student 1: Sixteen
- 32 Sam: What does it mean
- 33 Student 1: Oh it means two times two times two times two
- 34 Sam: Excellent (.) good

⋮

- 53 Sam: So two the power five times two to the power four (.) what's that
- 54 Student 2: Two to the power nine
- 55 Sam: Two to the power nine (.) OK (.) what is (.) three to the power four times two to the power three (...)
- 56 Student 3: Is it six to the power seven
- 57 Sam: (..) what we can't do (.) really easily (..) we just can't add those powers this time (..) Tom

### Extract 1: Positive and negative evaluation in IRE sequences

Most questions asked by Sam had a limited range of appropriate mathematical responses (e.g., line 53) and when the questions were more ambiguous his reaction in the third turn indicated a particular response was sought (e.g., line 32 and 34). Acceptable answers were indicated in two main ways. First, they were often explicitly acknowledged, with expressions such as “yep”, or by the inclusion of a positive indication of quality, such as “excellent” (e.g., line 34). Second, Sam regularly repeated a student's response (e.g. line 55), and the analysis indicated there was a taken-as-shared understanding that this also indicated an acceptable response. Negative evaluations occurred when students' responses contained mathematical errors (e.g., line 56), and when there was no error *per se* but the response was deficient in some way (e.g., line 31). For example, in line 33, the student recognises where his response does not meet Sam's requirements and self-corrects. In line 56, a student offers a mathematically incorrect response; Sam paused before offering some indication as to location of the error and then nominated another student who had their hand up to answer.

One notable shift away from IRE sequences was when there were sequential student turns. Whilst Sam sometimes nominated students to answer questions, it was also common practice for students self-nominate by calling out. In both classes, there were instances where different solutions were given before Sam responded. There did, however, appear to be differences in how the interactions were controlled by Sam when both errors and a correct solution were present. In particular, in the higher attaining class there were eight occasions where there were extended peer-to-peer exchanges. For example, when Sam asked for the value of  $a$  in  $k^7 \div k^7 = a$  the following occurred:

- 244 Students:  $k$
- 245 Student 1: Yes its  $k$  isn't it
- 246 Student 2: One
- 247 Student 3: 'Cause seven divided by seven is one
- 248 Student 4: Seven minus seven is zero
- 249 Student 3: No isn't it zero
- 250 Student 5:  $k$  divided by  $k$  is  $k$
- 251 Student 2: One
- 252 Student 6: I think it's zero
- 253 Student 2: No it isn't its one guys ok its one
- 254 Sam: Er vote then (.) vote for zero

### Extract 2: Class A multiple student contributions

There were no discernable responses from Sam after a number of students had offered “ $k$ ” (lines 244 & 245) or the correct reply of “one” (line 246). The students continued to self-nominate by calling out, although the students were not necessarily responding to the immediately preceding turn (e.g., line 249). After Sam called for a vote for zero or one, started in line 254, he reverted to IRE sequences, where he focused the interactions on the mathematically correct answer by asking about situations related to  $a/a$ , where  $a$  was a range of natural numbers; some of these questions would have been simple for students to answer, such as “four divided by four”.

In the lower attaining class, there were twelve occasions when two or three students self-nominated and called out answers that included an error before Sam replied. For example:

- 308 Sam: What is eight to the power one  
 309 Student 1: One  
 310 Student 2: Eight  
 311 Sam: Eight (.) well done folks

### **Extract 3: Class B multiple student contributions**

In these cases, all the students appeared to be responding to Sam’s original question. In the nine occasions where responses include both an error and a correct response (e.g., lines 309 & 310), Sam positively evaluated the correct response and offered no discernable reaction to the error. The remaining three occurrences only contained errors and were followed up by further IRE exchanges.

The other notable variation was the explicit negative evaluation of errors. In whole-class discussions, there were twelve occurrences of Sam using a bald “no” in class B, the lower attaining class, with one in the higher attaining class. In all but one case an element of correction was included in the turn containing negative evaluation and the student did not take the subsequent turn. Three quarters of occurrences arose outside of IRE interactions, including the one case from class A when students were offering prepared explanations. Towards the end of the discussion about  $2^2 \times 3^4$  the following exchange occurred in class B:

- 168 Sam: If I tried to do (..) two squared plus three to the power of four that’ll (.) sorry times three to the power four (.) is two times two times (.) three times three times three times three (..) I can physically work it out (.) I can work out what the number is but I can’t simplify it like we do in these ones (..) because they’re different numbers  
 [writing:  $2^2 + 3^4 = 2 \times 2 \times 3 \times 3 \times 3 \times 3$ , pointing at common bases in earlier examples]  
 169 Student: Sir can’t you do five to the something like three add two equals five and you do five to the power whatever  
 170 Sam: No because look we can’t do to the power five or the power six because we’ve got these threes and these twos and they’re different numbers and you can’t combine them (..)

### **Extract 4: Bald negative evaluation**

In line 168, Sam concluded his turn with a statement rather than a clearly defined question, so the comment made in line 169 was coded as student-initiated. Sam took the following turn (line 170);

he immediately gave a bald “no” and proceeded to offer an explanation that appeared to be directed at correcting the student’s comment. The student did not take the subsequent turn.

## Discussion

In common with many other studies (e.g., Resnick et al., 2010), the IRE sequence was the dominant form of whole-class interaction for both classes. Moreover, within these IRE exchanges, Sam’s treatment of errors typically conformed to the well-reported approach of indirect negative evaluation in the third turn (e.g., Ingram et al., 2013). These structures allowed Sam to shape the focus of the interactions and provided opportunities for students to undertake further mathematical work to correct errors. The focus on the correct solution and the use of simpler questions after errors could be seen as reducing or removing the mathematical learning opportunities; alternatively, considered as a whole, they could be seen as serving to highlight the underlying mathematical structure. In these situations, the responsibility to correct errors lies at least partially with the students, but the arbiter of mathematical correctness resides with Sam.

When other types of whole-class talk were considered, different interactional patterns emerged, including differences between classes. In both classes there were instances where contradictory solutions were called out by students in response to a question from Sam. In class A, a regular occurrence was for peer-to-peer exchanges to continue beyond multiple replies to Sam’s original question and extended sequences of peer-to-peer turns were formed. The established norm was that if Sam did not respond verbally when the evaluative third turn would have otherwise occurred, then peer-to-peer turns were allowed. Whilst some later students turns appeared to be responding to Sam’s original question, and many were simply making statements of their own position, students also offered justifications or engaged with other students’ comments. For example, in Extract 2, line 247, the third student added a justification for “one”, even though in this case the reasoning was faulty. Sam eventually took a turn and control of the interactions (e.g. extract 2, line 254); these peer-to-peer exchanges were all followed by IRE sequences, which focused the interactions on the correct solution; errors made in the peer-to-peer exchanges were rarely mentioned or interrogated. For instance, after the vote that followed extract 2, Sam constructed an IRE sequence around  $a/a$ , where  $a$  was a range of natural numbers, but the potential origins of zero were not discussed, such as attending to the exponents of  $k^7 \div k^7 = k^a$  or thinking  $k^a = 0$ . In these student-led exchanges, students had the opportunity to consider alternative solutions and some took the opportunity to articulate their reasoning, argue for their position or to challenge others; a shift in accountability, albeit briefly. However, the resolution of the debate was conducted through the more typical IRE exchanges with the final arbitration residing with Sam.

When class B is considered, there did appear to be similar potential starting points that had led to the peer-to-peer turns in class A. For example, extract 3 was one of nine occasions where both incorrect and correct responses were offered in response to Sam’s question, but none of these extended to further peer-to-peer turn taking. Instead, Sam took control of the exchanges at an earlier stage and drew immediate attention to the correct answer through positive evaluation.

The explicit negative evaluations of students’ contributions were predominantly associated with class B and student-initiated comments. As in extract 4, they occurred during whole-class talk when

the students self-nominated to take the next turn and without a direct question being asked by Sam. In a previous study, Ingram et al. (2015) found explicit negative evaluations by the teacher, and the associated corrections, occurred when there was an issue with communication of ideas rather than with the substance of the answer, although these appeared to relate to IRE sequences. In contrast, in this study explicit negative evaluation were associated with key conceptual issues, and occurred outside of IRE exchanges. For instance, in extract 4, the bald “no” followed on from a student misapplying a rule of indices by attempting to combine powers with different bases. The corrections associated with the “no” allowed Sam to redirect the focus of the interactions back to his chosen approach within one turn, but removed the opportunity for students to correct their own or their peer’s error. One possible explanation for the correlation between bald negative evaluations and student-initiated comments is that these, by their nature, have not been planned for in the same manner as responses to questions within IRE sequences. As such, they were not an integral part of Sam’s pedagogical goals; the bald evaluations and corrections allowed a swifter realignment with those goals. From a conversation analysis perspective, a bald evaluation would carry the message that making an error is not embarrassing. However, the benefit of this potential acceptance of errors would have to be considered alongside the management of the pedagogical trajectory away from student-initiated comments, which could be read by students as devaluing their contributions.

## Conclusion

This paper seeks to complement existing research on the treatment of errors, in particular in relation to errors that occur outside of IRE sequences associated with more student-led talk. Here, within the extended peer-to-peer exchanges, students had the opportunity to consider and challenge alternative solutions. However, for this teacher at least, the resolution of those questions relied on the more common IRE exchanges, thereby revalidating the teacher as the arbiter of correctness. The potential tensions between the interactional message that errors are to be avoided and the positive role they can take in learning have been discussed in previous studies. Here, Sam’s use of bald negative evaluations has raised an alternative question; the possibility of a positive interactional message that errors are a natural part of talk, set against the potential loss of learning opportunities and diminishment of the value of student contributions. It is hoped that by raising awareness of these interactional structures, teachers could make informed choices about the different routes available to their treatment of errors and the potential impact on student learning.

*This paper uses analysis of shared video data to discuss teacher responses to public student apparent error. Drawing upon conceptions of student thinking and theories of agency, authority, and mathematical identities, we argue that certain ways of responding to public student apparent error have the potential to elevate student thinking and empower students with mathematical agency, authority, and standing. We also suggest that such teaching practices may be a high-leverage site to develop equitable mathematics teaching.*

**Keywords:** Mathematical knowledge for teaching, teaching practices, positioning, agency, authority.

## Introduction

Maria's 7<sup>th</sup> grade class is beginning to learn arithmetic with integers. She is called to the board to show her solution to the subtraction problem,  $38 - 52$ . Maria writes and says the following:

3 8    "8 take away 2 is 6"  
 $\underline{-52}$     "3 take away 5 is -2"  
 -2 6

Is Maria right? What is there to understand here about place value, with negative numbers? How might the teacher respond to Maria? And what effect will this have on her?

These questions, about this and about countless other similar scenarios, are the object of our study. We are concerned here with the interactions of the mathematics, the student's thinking and standing, and the impact of the teacher response on all three. We are not proposing that there is a "right" teacher response, but we do argue that the response is consequential for the individual student's learning and standing, as well as for that of the collective. Moreover, much knowledge and insight goes into understanding the range of possible responses and their consequences. In particular, what mathematical knowledge for teaching, what knowledge of student thinking, and what cultural and psychological sensitivities might be involved? So, our research question is:

What kinds of teacher responses to public student apparent error can help cultivate students' mathematical agency, authority, and standing?

Student mathematical productions are rarely flawless. Overt error may distract teacher attention from otherwise robust reasoning. A student's lack of technical vocabulary may cloud insightful conceptual expression. Such apparent flaws happen with all students, but they are understandably common among students who are educationally disadvantaged, because of race, ethnicity, poverty, language, etc. For this reason, we feel that our research question matters for equitable instruction.

The title refers to a core task of teaching. Three terms there – “public,” “apparent error,” and “equitable” – deserve comment. “Public” indicates that this is about collective learning and norm setting, more than bilateral teacher-student transactions. The student work and teacher response communicate to the whole class, not just to Maria. “Apparent error” draws attention to the teacher’s perception without evaluating the student’s thinking. Rougée (2017) has studied teacher responses to “apparent student error,” but her study explored the teacher stress and anxiety this can precipitate. As indicated above, we believe that our focus is a high leverage site for “equitable teaching practices.” The latter are often described in terms of inclusive classroom culture and participation structures. Our interest focuses further on how equitable practices intersect with content.

Our method is to first examine records of practice (video and other artifacts), to generate hypotheses about teacher responses to public student apparent error that can either cultivate or degrade students’ mathematical agency, authority, and standing. Robust conclusions of this kind will ultimately require more longitudinal data.

We will here explore the above task of teaching in two cases, one involving 4<sup>th</sup> graders identifying fractions on the number line, the other showing another group of 4<sup>th</sup> graders figuring out a difficult subtraction problem before having learned a general subtraction algorithm. These examples will help to open the analytical space behind our question.

## Conceptual frameworks

Teacher responses to public student apparent error, the focal phenomenon of our study, is a site of confluence of three research traditions – 1) mathematical knowledge for teaching, 2) student mathematical thinking, and 3) agency, authority, and identity – each with its own theoretical frame and perspective. It is our task to coordinate, if not integrate, these traditions for our work. To understand the “work of teaching” we use the “Instructional Triangle” (IA) of Cohen, Raudenbush, and Ball (2003), as later elaborated by Ball (2018).

**Figure 1. Revised instructional triangle (Ball, 2018)**

The “stuff” in our case is “mathematics.” The inner circle represents instruction, where mathematical knowledge for teaching primarily resides. Student mathematical thinking spills into the environment. Agency, authority, and standing constitute an arena in which the instruction may attempt to disrupt inequitable environmental influences. Much mathematics education research is situated at a vertex, or along an edge of the IA. Our question spreads across the entire diagram.

## Mathematical knowledge for teaching

For decades, a core problem in research on mathematics teaching has been what knowledge is needed to teach well. Researchers have approached this problem in different ways. Some have produced lists of what teachers should know. Others have investigated what knowledge teachers have, and yet others have studied knowledge teachers use. Ball (2017) suggested flipping the question by focusing instead on what mathematics the work of teaching entails (see also Ball et al., 2008). This shift was not new. Already two decades ago, it was elaborated in several publications (e.g., Ball, 1999; Ball & Bass, 2000; Ball, Lubienski, & Mewborn, 2001). The present paper follows this line of research and targets the challenges that are embedded in a particular mathematical task of teaching. Eliciting, interpreting, and responding productively to student thinking, all entail deep and flexible mathematical knowledge.

### (Interpreting and responding to) student thinking

As we indicated above, mathematical thinking, by experts as well as students, is rarely flawless. It is typically a mix of ideas, some intuitive or sketchy, some more formalized, some of it sound, some of it not yet fully formed, some of it incorrect. Simply calling this complex package “error” is to ignore the substantial mathematical value there to be discerned. The phrase “apparent error” is our way of keeping open this broader range of possibilities.

When a child publicly presents a problem solution, or a mathematical explanation or comment, what tasks of teaching does this present? One is to *understand* the child’s thinking. This may draw on several knowledge resources: Of the mathematical terrain and the diverse ways it can be represented; of typical student (mis)conceptions and representations of the ideas; and of the child’s identity and background, and the culturally diverse forms of children’s communication (language, gesture, etc.). Once the child’s thinking is understood, what can the teacher do to help make this understanding shared by the other children? And if the teacher does not at first understand, what can she do to probe the child’s thinking to gain such understanding? The above are all challenging tasks of teaching.

Once the teacher possesses an adequate understanding of the child’s thinking, what is the next move? In some common practice, the teacher will first notice (perhaps even before fully understanding the child’s thinking) the mathematical flaws, and either announce them, or simply pass on, without comment, to another student in search of a more “acceptable” response. This can be characterized as a *deficit teacher response*. The opposite kind of response, sometimes called assigning competence (e.g., Cohen & Lotan, 1995), or *asset oriented response*, is to offer some detailed public appreciation of the positive mathematical qualities of the child’s thinking, without prematurely announcing that the mathematical work is done. Sometimes the teacher might even invite other students to comment on “what was good” about the child’s contribution. Again, enactment of this kind of move calls upon a fine-tuned understanding of the mathematics as well as of the student thinking.

### Agency, authority, identity

Teaching is relational work, challenging in its complexity. We highlight three aspects of this complexity: agency, authority and identity.

Agency is the capacity, freedom and autonomy of an actor to act in a given environment. The environment of concern here is the mathematics classroom. Agency may either be encouraged and

supported, or constrained and suppressed, for example through the influence of such factors as race, social class, religion, gender, ethnicity, perceived ability, customs, etc.

Authority is characterized by Benne (1970, p. 393) as a social relationship between the bearer (of the authority, a person or group), the subject(s) (of the authority), and the field (context). The bearer receives willing obedience from the subjects while helping provide for their need of advice, leadership, guidance, or direction in the field. This is an example of “reasoned power,” but distinct from more general forms of power, which may be based on domination and coercion. Benne distinguishes three kinds of authority: Expert (as in the doctor-patient relation); Rule-based (as in say the playing of baseball); and “Anthropogological” authority (partly exemplified by the doctor-medical student relationship, an apprenticeship into practice). In rule-based authority, the rules that govern behavior represent an implicit consensual authority of the community of players, who are thus individually subjects, and collectively bearers.

Authority in a mathematics classroom has at least two aspects. One, common to all classrooms, is about behavioral norms, based on socio-cultural norms. Another, more pertinent here, is about *disciplinary authority*, about how to certify the authenticity of a piece of mathematical knowledge. Education reforms over the past half-century have moved in the direction of giving students more disciplinary agency and authority. How can that be interpreted in the above framework? For Benne, the ‘bearer’ of authority is a human agent, a person or group of persons; so how can we speak of “the authority of the discipline?” Amit and Fried (2005) suggest that mathematics, with its “fixed set of rules,” supports a kind of rule-based authority. We think instead of the discipline as a growing (inanimate) body of knowledge and methods, but that it is the cumulative product of (centuries of) human effort. How do new concepts or methods gain entry into (the current form of) this corpus? There are disciplinary norms for such membership, but human judgment (peer review) is needed to decide if these norms have been adequately met. Thus, in our view, disciplinary authority is mediated through those (human) agents empowered to certify proposed disciplinary claims.

So conceived, it now makes sense to speak of the distribution of disciplinary agency and authority in a mathematics classroom. In the traditional transmission model of instruction, the teacher alone bears expert authority to which the student subjects are expected to conform. In contrast, distributing agency among students means that they can participate in the construction of new knowledge and methods, finding new solution strategies, noticing patterns, speculating, conjecturing, proposing evidence. Distributing authority means that students themselves will judge the adequacy of claims of their peers, and find ways of resolving disagreement. This is somewhat captured in the third mathematical practice standard of the Common Core (2010): Construct viable arguments (agency) and critique the reasoning of others (authority).

This broad distribution of mathematical agency and authority among students, as co-producers (with the teacher) of knowledge, resembles what Benne (1970) calls anthropogological authority.

(Mathematical) identity refers to how students consider themselves as mathematical doers, thinkers, and learners. Aguirre, Mayfield-Ingram, and Martin (2013) define mathematical identity as “the dispositions and deeply held beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics in powerful ways across the contexts of

their lives” (p. 14). Positive mathematical identity involves willingness to take risks to engage in discourse and to see one’s self as capable and worthy of being heard (Berry, 2018). This is related to *productive disposition*, the habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one’s own efficacy (NRC, 2001). A premise of our work is that positive mathematical identity can be cultivated and supported by equitable teaching.

### Case 1: Fractions on the number line

This diverse class of 9 to 10-year old children has learned how to name what fraction of (the area of) a rectangle is shaded. The method is to first assure that the (*whole*) rectangle is divided into a number (*d*) of *equal* size parts, to then count the number (*n*) of those equal parts that are shaded, and finally to name the fraction as  $n/d$ . The lesson segment in the video shows the start of their learning how fractions correspond to points on the number line. This is based on linear measure, in contrast with the area measure of shaded rectangles; on the number line one is counting lengths of intervals, and the unit of measure (the *whole*) is taken to be the interval from 0 to 1. We see the students presented with the following task (Figure 2).

Figure 2. Naming fractions on the number line.

The correct answer is  $1/3$ , but the student notebooks show a variety of answers. The teacher asks who would like to come up and show their work; she calls on Aniyah. The teacher reminds the class that they should “listen closely and see what you think about her reasoning and her answer.” Aniyah puts “ $1/7$ ” next to the orange arrow (an “evident error”), at which point Toni asks, in surprise, “Did she say one-seventh?!” Aniyah responds, “Yeah, because there are seven equal parts, . . .” as she counts, with her spread thumb and index finger, the seven *intervals* (not hash marks) visible on the displayed (portion of the) number line. Here we see the “public student apparent error” to which the teacher responds, not to Aniyah, but to the class: “Before you agree or disagree, I want you to ask questions if there’s something you don’t understand about what she did.” Toni asks, “Why did you pick one-seventh?!” The teacher, affirming “That’s a very good question,” also says, “Let’s listen to her answer.” Aniyah says, “. . . because there’s seven equal parts.” Lakeya asks, “If you start at the zero, how did you get one-seventh?” She may have been thinking about counting hashmarks instead of intervals. Dante then struggles to formulate a more speculative, but difficult to understand question, perhaps to the effect that, “If you moved the orange arrow to where the one is, would you still know it was one-seventh to put it where the orange line is now?”

Several things are noteworthy about the teacher response to Aniyah’s “apparent error.” Though Aniyah’s “one-seventh” is wrong, it is so far not challenged or corrected either by the teacher or the students, though, at the teacher’s invitation, the children pose questions to understand *Aniyah’s thinking*, which is made central to the instruction. The mathematical issue is resolved by the end of

the lesson (beyond the video segment), but we here see the teacher publicly sheltering *Aniyah's standing*, as author of well articulated mathematical reasoning, which is flawed only in not using the standard unit (interval) as the whole. Further the teacher confers on Aniyah's peers the authority to question, and eventually evaluate, Aniyah's solution, free of teacher judgment. In these ways, the students are given/assigned remarkable collective agency and authority to develop the mathematics.

## Case 2: Subtracting before you know how

In this case, the teacher presents a group of five 4<sup>th</sup> graders with the following problem: “The king celebrates his 80<sup>th</sup> birthday today” (this was in 2017). “In what year was he born?” This amounts to calculating  $2017 - 80$ . The teacher has not yet taught these students how to subtract large numbers by using a standard algorithm, though some may know this already. The students show four different approaches. One starts by taking away 17 from 80 to get 63, and then subtracts 63 from 2000 by using a standard algorithm. Another student uses the standard algorithm directly to subtract 80 from 2017. In both these cases, the teacher explains their thinking to the other students, and provides a lot of praise. Two other students come up with more unexpected approaches to solving the problem. Below, we take a closer look at one of these student's method.

When Brian (pseudonym) is called to the board to present his solution, the teacher comments that he noticed how Brian finished the problem quickly. He continues, “So I'm very excited to hear what you were thinking!” Brian explains that he just got rid of the 17, so that you only have 2000. He writes down  $2000 - 80$ . Brian then states, “So, then we have 1920, which is pretty easy!” When Brian has written down this partial answer, the teacher interrupts, “So, now I would just like to repeat what you did. I just want to repeat what you did, so that I understand your thinking.” The teacher asks Brian to move a little bit to the side, before he continues, “I understood from what you were saying, Brian, what you did that I understood, was that, to begin with, you didn't want to deal with the 17. You just jumped back to (points to 2000), and thought: What if we are in 2000 now? And then, when we go 80 years back, we get to 1920. And, now I'm eager to know, what did you do next?” Brian jumps up to continue his explanation, “And then I just added 17, which is pretty easy, simply 20 plus 17.” The teacher proclaims that this is “simply fantastic,” before Brian moves on to write down the answer on the board. When Brian has finished explaining, the teacher asks, “Did anyone understand this clever way?” Anna responds that she understood it, and that she thought it looked like a good way of thinking about the problem. The teacher then continues to rephrase what Brian did when he decided to “jump back 17” and start on 2000, and how “he already then knew that he had jumped back 17 years too long (...) So, when he got to 1920, he had to jump 17 years forward again, to correct it.”

One of the students early displayed an incorrect answer and seemed otherwise distracted at times. He was the only student not called to present his work. His was the only appearance of apparent error. For each of the others, at issue was the uncertainty of their solution strategies, for which they were each praised in varying degrees.

## Concluding discussion

The choices made by the teachers in these two cases differ in several respects. We will here highlight and discuss two particular differences in the teachers' responses. The first relates to how the teachers assign competence to students. In case 1, we notice only one instance of explicit teacher affirmation

or praise, whereas the teacher in the second case offers a lot of praise to the students. We argue that both teacher responses can be described as asset oriented, and we posit that assigning competence does not have to include direct praise or public teacher statements. The teacher in case 1 assigned competence to Aniyah by inviting her to be the teacher. She positioned Aniyah as a recognized contributor, with standing, in the mathematical discussion, and she conferred on Aniyah's peers the authority to analyze and critique Aniyah's work. In the case 2, the teacher assigned competence to Brian by re-voicing his thinking and praising his contribution. This leads to the second highlighted difference, relating to the distribution of mathematical agency and authority, which we next discuss.

The work of mathematics teaching demands a mathematical knowledge that exceeds ability to solve a problem by using the standard algorithm. The teacher in case 2 chose not to confine attention to the two solutions using variants of the standard algorithm, thus disrupting the rule-based authority that is common in many mathematics classrooms. Instead the teacher highlights an unexpected student solution strategy, which he has to interpret and evaluate on the fly and assure that all of the students understand. By bringing Brian to the board, and expressing excitement and eagerness to understand Brian's thinking, the teacher publicly affirms Brian's agency and standing. It is interesting to notice how the teacher, in the middle of Brian's explanation, decides to interrupt to repeat what Brian did and make sure he understands Brian's thinking. It is likely that the teacher in fact understood well what Brian had done, but, by saying "so that I understand your thinking," the teacher was nominally putting himself on the same level as the other students, thus modeling the kind of inquiry needed to understand another student's thinking. In case 1 above, the teacher assigns this work to the students, whereas the teacher in case 2 does not do so. He himself is modeling, by example, how such inquiry is done. This effort is further reinforced when, after Brian has finished his explanation, the teacher again decides to re-voice Brian's explanation, to emphasize the crux of his thinking. Throughout this episode, the teacher demonstrates, and so models, attentive listening, and a pressing need to understand Brian's mathematical thinking. Brian is positioned as a mathematical authority, but one whose thinking needs to be publicly analyzed and sanctioned by the teacher, so that Brian's knowledge is not only validated and praised, but becomes collective, thus hoping to support all of the students' understanding. In case 1, Aniyah also gains mathematical authority, but only after public resolution of the integrity of her thinking by her peers, who are assigned this responsibility.

We have presented two examples of teacher responses to "public student apparent errors." We described, in each case, teacher moves that might have potential to cultivate the mathematical agency and authority of the students. In both cases, student agency is well supported, but in case 2, more of the mathematical authority appears to still reside with the teacher

## Acknowledgment

Our thinking about these ideas owes much to discussions with Deborah Ball and Mark Hoover.

# Conceptual learning opportunities in teachers' differentiated task designs for inclusive mathematics education

Christian Büscher

TU Dortmund University, Germany; christian.buescher@math.tu-dortmund.de

*Inclusive mathematics education creates new challenges to teachers, requiring additional knowledge and possibly changed classroom practices. One teaching job gaining importance is differentiating through task design, as teachers need to provide conceptually rich learning opportunities even to students with mathematical learning disabilities. However, more insight is needed into how teachers engage in this job. This study analyses teachers' designed tasks during a professional development course to reconstruct their categories of differentiation for percentage problems. The observed teachers tend to differentiate in a way that excludes low-achieving students from conceptually rich learning opportunities on percentages. This can be explained by the differentiation strategy of splitting and partitioning teachers' envisioned ideal-typical solution paths to percentage problems.*

*Keywords: Teacher practices, inclusive education, percentages, differentiation, professional development.*

## Introduction

In recent years, a shift can be observed in research on teacher expertise from a focus on general dispositions or concrete performance towards a focus on situation-specific skills (Blömeke, Gustafsson, & Shavelson, 2015). This places an emphasis on the wide array of necessary tasks or jobs demanded of teachers in their classroom work, from small jobs such as choosing and illustrating examples (e.g. Fauskanger & Mosvold, 2017) to large jobs such as adapting textbooks for their own course (e.g. Priolet & Mounier, 2017).

Such a focus calls for careful attention given to the concrete situations of teachers' classroom work, as every situation imposes different situational demands. Recently, a new class of situations is gaining increased attention in mathematics education research: the situations of inclusive mathematics education. In Germany and probably many other countries, large parts of mathematics teachers feel unprepared for dealing with these new situational demands. Research is needed into how teachers can face these situational demands of their teaching jobs in order to develop professional development (PD) courses to support teachers of inclusive mathematics classrooms.

This paper investigates the ways teachers engage with one central job of inclusive mathematics classrooms, namely the job of differentiating through task design in the context of percentage problems. First, this paper introduces a theoretical framing of the construct of teaching jobs, as well as a short overview on situational demands in inclusive mathematics education. The empirical part then illustrates how teachers use ideal-typical solution paths for differentiating through task design, involuntarily limiting conceptual learning opportunities for already low-achieving students.

## Teaching jobs as a focus for research

For conceptualizing teachers' competences and practices, there exist a variety of conceptualizations and specification for these skills, such as 'core tasks and problems of teaching' (Bass & Ball, 2004)

or ‘core practices’ (Forzani, 2014). Empirical research shows how each of these skills, such as choosing and illustrating examples, poses a complex interplay of situational demands to teachers (Fauskanger & Mosvold, 2017). What teachers need to know in order to master these tasks, however, so far remains underspecified.

Already over 25 years ago, Bromme (1992) identified this as a task for empirical research. Instead of providing a list of knowledge or dispositions, Bromme (1992) places specific situational demands (tasks of teaching) into the heart of teacher expertise. Each situational demand requires specific knowledge attained by teachers. This knowledge takes the form of *categories* – personal units of meaning that can structure cognition – that “enable experts to discern a specific order within problematic situations or to construct it (e.g. by arranging instruction)” (ibid., p. 151, translated). Examples for categories for the situational demand of inclusive mathematics education might include ‘learning for all’ or knowledge of specific learning disabilities. It follows that PD programs need to support teachers in coping with their situational demands in teaching by supporting their development of categories.

This study follows the approach outlined by Prediger (in press) to conceptualize teachers’ situational demands as teaching *jobs* (in line with Bass & Ball, 2004) that are organized through teachers’ personal *categories* in order to draw attention to teacher practices instead of knowledge. The empirical task remains to identify the jobs required of teachers by inclusive education and to empirically reconstruct their categories activated for mastering these jobs.

### **Conceptual learning in inclusive mathematics education**

Since the ratification of the UN Convention on the Rights of Persons with Disabilities in 2008 (UN, 2006), inclusive education has seen an increased interest in educational systems across many countries and in mathematics education research. In Germany, ratification of the convention has resulted in a shift from an educational system in which students diagnosed with various disabilities were segregated from ‘regular’ students towards an inclusive system in which (most) students visit the same schools, with or without disabilities. This posed increased challenges to the majority of teachers who had little to none previous experiences with students with disabilities, creating a great demand for professional development (PD) of teachers for inclusive education.

Concerning mathematics education, the largest new group of students for teachers is the risk group of under-achieving students in mathematics, here referred to as students with MLD (mathematical learning disabilities/difficulties, for an overview on terminology see Scherer et al., 2016). MLD is a construct without a clear consensual definition, hindering making distinctions between biological, cognitive, and non-cognitive contributing factors (Lewis & Fisher, 2016). However, research in mathematics education indicates that students with MLD do not fundamentally differ in their learning from students without MLD: under constructivist perspectives on learning, both groups require conceptually rich learning situations in which they can draw on their own experiences in order to develop mathematical concepts (Scherer et al., 2016).

## The teaching job of differentiating through task design

The increased heterogeneity of inclusive classrooms faces teachers with increased demands of differentiated instruction (Tomlinson & Moon, 2013). This heterogeneity can refer to a variety of aspects, including their learning resources (working memory, interest, language proficiency) and mathematical knowledge (informal experiences, conceptions, formal knowledge). Every learner needs instruction that recognizes his or her individual needs. Thus, one teaching job that is of increased importance for inclusive education is the job of *differentiating through task design*.

Differentiated task design can take several forms (see Tomlinson & Moon, 2013). This paper focuses on two forms in particular (for the third form of open-ended differentiation see Buró & Prediger, 2019): students with MLD might need conceptually rich tasks for content different from other students (i.e. differentiated in content). They also need tasks that pose demands that they are able to fulfill (i.e. differentiated in access). In turn, such differentiating tasks might also pose dangers, as they might alienate students with MLD by providing learning content different from that of the ‘regular’ students.

These categories for task design thus provide a first list of possible categories for teachers to draw upon in their job of differentiating through task design. However, reconstructing such categories remains an empirical task (Bromme, 1992), as teachers’ personal categories might be richer than the mentioned ones. More insights are needed into how teachers enact this job of differentiating through task design, and how they ensure the conceptually rich learning opportunities required especially by students with MLD. This job here is treated as requiring topic-specific investigation, as differentiating in content requires topic-specific content knowledge. Because a majority of studies about MLD focus on elementary arithmetic (see Lewis & Fisher, 2016), this study instead opts to focus on a topic from secondary school, namely percentages. Thus, two research questions emerge for this paper:

(RQ1) What categories do teachers draw on when engaging in the job of differentiating through task design for percentage tasks?

(RQ2) How do these categories influence the learning opportunities for students with MLD in differentiated percentage tasks?

## Methodology

Research was carried out during a PD course on inclusive education for the content of percentages, situated in the methodological approach of Design Research for teachers with a focus on content-specific professionalization processes (Prediger et al., 2016). Data were collected in this PD course, which is briefly introduced in this section.

### Design of a PD course for inclusive mathematics education for percentages

The PD course aimed at in-service mathematics and special education teachers consisted of three distinct phases. In the first phase, the 25 participants received information on didactic concepts and models as well as on concepts and models of special education. Each of the participants had some own experiences with teaching inclusive classrooms and students with MLD, but most mathematics teachers lacked formal education about special needs, and most special education teachers lacked formal education about mathematics education. This phase consisted of three sessions (15 hours total)

with the research team and participants. Topics included use of representations, fostering understanding for all, language-responsive teaching, working memory and learning, and automatization of routines. During this phase, the teachers were encouraged to discuss these concepts and to relate them to their own experiences. The second and third phases consisted of practice and reflection phases and are not part of this study.

### Course-integrated instruments for eliciting teachers' categories

Investigation into teachers' categories was carried out through *course-integrated instruments*. These were instruments designed to collect written products by the teachers. However, they were not collected in a classical pre-post design, but rather were employed at various points throughout the PD sessions. These instruments served a dual role: on the one hand, they provided the data needed for research, so that they were used as *instruments* for professional development. On the other hand, they activated the participants' prior experiences and, after having been filled out, provided the basis for discussions, so that they could be used as *means* for professional development.

These instruments were designed to actualize the situational demands teachers face in inclusive classrooms in small situations, i.e. to elicit teaching jobs. Figure 1 shows the course-integrated instrument used to elicit the job of differentiating through task design for percentages.

**Figure 1: The course-integrated instrument (translated from German)**

This instrument was given in the third session of the first phase of the PD course. It uses parts of a task on percentages already known to the teachers from the PD course. They also already were familiar with the basic ideas of the percentage bar, which was new to most of the teachers prior to the PD course (see Buró & Prediger, 2019).

### Data collection and data analysis

The instrument was given to the teachers who had 15 minutes to create the differentiated tasks. This short time-frame was chosen to cut down the time for possible group work, so that results would reflect the personal categories more closely. Afterwards, a discussion took place and the written products were collected and digitized. Of the 17 products filled out by teachers, 1 was dropped for being too short for analysis. Data analysis then consisted in reconstructing three types of categories of differentiation: the types of differentiating tasks created by teachers, the perceived groups of students for which teachers create differentiation, and the mathematical learning opportunities provided to these groups through differentiation. The types of tasks were deductively reconstructed as belonging either to tasks differentiated in content or in access. For the perceived groups and mathematical learning opportunities, categories were generated inductively by comparing and contrasting all teacher products. Categories were then refined and condensed, and then used in a

deductive analysis in order to enable a comparison of the different written teacher products. As the categories thus also are an empirical result, they will be illustrated below.

### Teachers' categories for differentiating through task design

Two teachers' products are printed in Figure 2. They can illustrate some common elements of the teachers' differentiations through task design which were reconstructed in the analysis. The first teacher, 'Anna' (left side), differentiates between four different levels (L-M-S-gS, interpreted as the initials of the German words for easy-medium-hard-very hard). This structuring is reconstructed as a differentiation into levels of 'low-middle-high' by combining the levels of 'S' and 'gS'. Her tasks, however, do not differ in complexity, but in content. Students who are assigned to the low level ('L') are tasked with simply reading the given values and with calculating a difference without any reference to percentages. Such instances are coded as *description* (reading, simple description of the involved numbers without explanation) and *subtraction*. Students in the middle level ('M') are assigned with a task that superficially does relate to percentages, but ultimately results again in a simple calculation of a difference. This again is a task of *subtraction*. Students in the high level ('S', 'gS') are tasked with filling out the missing steps in the percentage bar. This is a type of task that was discussed during the PD course as a task that can elicit *proportional* reasoning, often signified by 'simultaneously counting up' percentages and percent values until reaching the desired values. Finally, they are also tasked with a different *percentage* problem.

<p>L - Read off, what is the old price? Answer: _____ the new price? Answer: _____</p> <p>L - How many € did Maurice pay less? Answer: _____</p> <p>M - By how many percent did the old price drop? Answer: _____</p> <p>S - Write fitting numbers on the indentations on the percentage bar!!</p> <p>gS - How many € does Maurice have to pay, if the sneakers are priced at only 50% of the old price?</p>	<p>a) Read off the old price and the new price from the percentage bar</p> <p>b) Calculate how many € Maurice did save. Specify how many percent of the old price Maurice did save.</p> <p>*c) Maurice has 70 € saved up. He sees sneakers with an old price of 90 €. Can he afford the shoes?</p> <p>**d) How high would the old price have to be, so that he could he afford the shoes?</p> <p><u>For all:</u> Mark the upper and lower parts of the percentage bar with labelled arrows.</p> <p>2. For which students would you use which problem?</p> <p>a), b) for all students</p> <p>*c) for the fast, high-performance students</p> <p>**d) for the really clever ones!</p>
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 2: Two teacher differentiations through task design (translated from German)**

The second teacher, 'Beatrice', chooses other categories for her differentiation. Whereas Anna does not make explicit if students are open to change levels as they see fit, Beatrice creates tasks in a progression in which students are expected to follow as far as they are able to, reconstructed as 'for all-middle-high'. She begins with a 'for all' category, which includes the task of *proportional* reasoning (counting up through labelled arrows) that Anna assigned to a much higher level. Her other two tasks a) and b) consist of *description* and *subtraction*. Students in the middle level are then given a different *percentages* problem, as are students in the high level (although a different, probably harder problem).

Comparing these two teachers reveals some interesting differences. In the differentiation of Anna, students with MLD would probably be assigned to the low level, and thus would receive learning opportunities for describing and subtraction, but not for percentages. Even if they would reach the next level, they still would be given learning opportunities for subtraction only. Such learning opportunities are also provided through the differentiation employed by Beatrice. However, through the category ‘for all’ she also includes a learning opportunity for proportional reasoning that students with MLD have access to – an important conceptual foundation for the learning content of percentages, which they could then utilize should they be able to reach the next level. This trend of lacking learning opportunity for percentages can also be observed throughout the differentiations of all teachers. Table 1 gives an overview on the learning content that teachers assign to their levels of differentiation.

	For all	Low	Middle	High
<b>Description</b>	6	10	3	1
<b>Subtraction</b>	1	3	3	1
<b>Proportional</b>	1	2	4	1
<b>Explaining</b>	0	1	4	6
<b>Percentages</b>	0	0	4	5

**Table 1: Number of occurring learning contents for levels of differentiation (n=16)**

The learning opportunities for students with MLD are reflected through the combination of the levels *for all* and *low* (the two grey columns). The learning contents that are conceptually relevant for percentages are represented through the categories *proportional*, *explaining*, i.e. the task of explaining the algorithm or procedure to find a percentage value, and *percentages* (the three grey rows). This shows a lack of conceptual learning opportunities for students with MLD (the dark grey intersection). Students with MLD are most commonly given tasks involving the rather passive description of the given situation or reading of values (16 occurrences). Of the remaining 8 occurrences, half consist of tasks involving simple subtraction. Only in 4 occurrences, these students have access to learning opportunities that involve conceptual understanding of percentages (proportional reasoning as foundation for percentages and explaining strategies for calculating percentage values).

### **The categories of Ideal-typical solution paths, partitioning, and conceptual foundations**

For the aim of teacher PD, this result of missing conceptual learning opportunities requires further explanation, i.e. an identification of the categories underlying the job of differentiating through task design. Anna’s tasks can serve as an example representative of most of the teachers’ products. Her differentiation follows an observable structure: in order to fully understand the situation, students first need to read the relevant information (low level), then acknowledge and quantify the changing values (middle level), and finally use concepts of proportion and percentage to interpret the situation (high level). Breaking down this *ideal-typical solution path* results to her in five small subtasks. Her strategy now is to *partition* this ideal-typical solution path and to assign different tasks to different students. Unfortunately, this results in conceptually poor learning opportunities for students on the

lower levels, as the conceptual heart of the percentage problem is placed at the end of the ideal-typical solution path, and thus only accessible for students assigned to the high level.

Beatrice follows a similar overall structure, but with different emphasis. Her ideal-typical solution path places proportional reasoning as the first part of the solution. This is an important *conceptual foundation* of percentage problems. Because her solution path is not neatly partitioned, but includes a level for all students, students with MLD also gain access to conceptual learning opportunities in this way.

## Conclusions

Like all students, students with MLD require conceptually rich learning opportunities to develop understanding of key mathematical concepts such as percentages. For teachers new to this group of students, this increases the complexity of the teaching job of differentiating through task design. This study shows the ways teachers can enact this job, and how this can influence the learning opportunities students have access to. The empirical analysis shows how partitioning ideal-typical solution paths can result in students with MLD being denied access to conceptual learning opportunities on percentages, instead providing access to subtraction. A more useful approach is to provide access to conceptual foundations by including tasks that focus on proportional reasoning, to be approached by all students. Teachers that used this approach drew on their context knowledge of percentages to present students with MLD with valuable conceptual learning opportunities. However, such an approach was chosen by only a very small fraction of teachers.

This study has followed the approach outlined by Bass & Ball (2004) to focus on teachers' tasks, namely the job of differentiating through task design. However, this study also illustrates that insights are needed into *how* teachers fulfill these tasks. The approach of identifying teachers' categories outlined by Bromme (1992) proved useful as a framework for describing how teachers fulfill their jobs. The approach allowed this study to focus on the situational demands of one very specific job. In classroom practice, however, teachers have to face several such jobs simultaneously. More insights are needed into how this added complexity can be mastered.

So far, the categories of ideal-typical solution paths, partitioning, and conceptual foundations have been reconstructed from one course-integrated instrument during one PD course session. More insights are still needed to empirically ground and to refine these categories. Also, the missing conceptual learning opportunities need to be interpreted carefully: it might justifiably be the case that giving students with MLD access to learning subtraction is a necessary and reasonable decision, e.g. for students that still struggle with subtraction.

*We investigated whether teachers' use of the Small-Group Scaffolding model (SGS model), when supporting heterogeneous student-groups in a collaborative setting in math lessons, raised students' mathematical level more than teacher support without use of the model. Participants were eight teachers and 266 students of two schools working collaboratively in 73 small heterogeneous student-groups on the topic of Early Algebra. The five teachers in the experimental condition were taught to scaffold the groups in their classes according to the SGS model (give support adapted to student-groups' needs). The three teachers in the control condition were not given prior instruction of how to support the students. Analysis of a pre- and post-test on mathematical level raising showed that more mathematical level raising occurred in the Scaffolding condition than in the control condition. We concluded that using the SGS model can lead to more mathematical level raising.*

*Keywords: scaffolding, mathematics, collaborative learning, mathematical level raising, teacher-student interaction.*

### Background

According to Freudenthal (1991) and Van Hiele (1986), the learning of mathematics occurs in discrete steps, implying the existence of levels of mathematical thinking. Van Hiele (1986) described four levels: 1) Visual level: the forms of mathematical objects are the object of study, 2) Descriptive level: the properties of mathematical objects are the object of study, 3) Theoretical level: relations between the properties of mathematical objects are the object of study, and 4) Formal logical level: relations between theorems are the object of study. Freudenthal (1991) built upon this theory and stated that the levels are more relative than discrete, meaning that level raising occurs every time a mathematical activity (performed at a lower level) consciously becomes the object of reflection (at a higher level). Freudenthal (1971) defines a mathematical activity as an activity of organizing subject matter, which can be matter from reality or mathematical matter, according to mathematical patterns or new ideas. For example, at a lower level, patterns of the number of tables and chairs in a table setting can be studied. At a higher level, these patterns themselves become the object of reflection when one tries to create a formula with which the number of chairs in a particular table setting can be calculated when the number of corresponding tables is given.

According to Freudenthal (1978), when students collaborate in a heterogeneous small group (a small group of students of mixed ability) on one task, there will often be at least one student who experiences an "Aha moment" (jumping to a higher level) when understanding the subject matter. A typical higher-level activity will follow for that student, such as reflecting on how he/she mastered the subject matter and explaining to other students in the group what he/she just learned. In other words, discussions between students in a heterogeneous group while performing mathematical activities (mathematical discussions) enhance mathematical level raising.

A reoccurring problem with attaining mathematical level raising when learning Early Algebra in secondary education is that students find it difficult to make a shift from studying patterns at a lower level to understanding formulae at a higher level (Kieran, 1992; Sfard & Linchevski, 1994; Van Stiphout, Drijvers, & Gravemeijer, 2011). Janvier (1987) addressed this problem by defining Algebra representations, situation, graph, table and formulae as four ways to describe the relation between two variables in a formula. He calls the ability to switch between the representations a translation skill. According to Janvier (1987), translation skills are best learned when they are taught in a pair-wise manner. For example, the translation skill modeling is learned best when students first learn how to construct a situation from a formula, followed by learning how to construct a formula given a situation, or vice versa. In this study, all translation skills involving the representation formulae are considered to contribute to mathematical level raising. These translation skills are: Parameter recognition (formulae to situation), Computing (formulae to table), Sketching (formulae to graph), Modeling (situation to formulae), Fitting (table to formulae) and Curve fitting (graph to formulae).

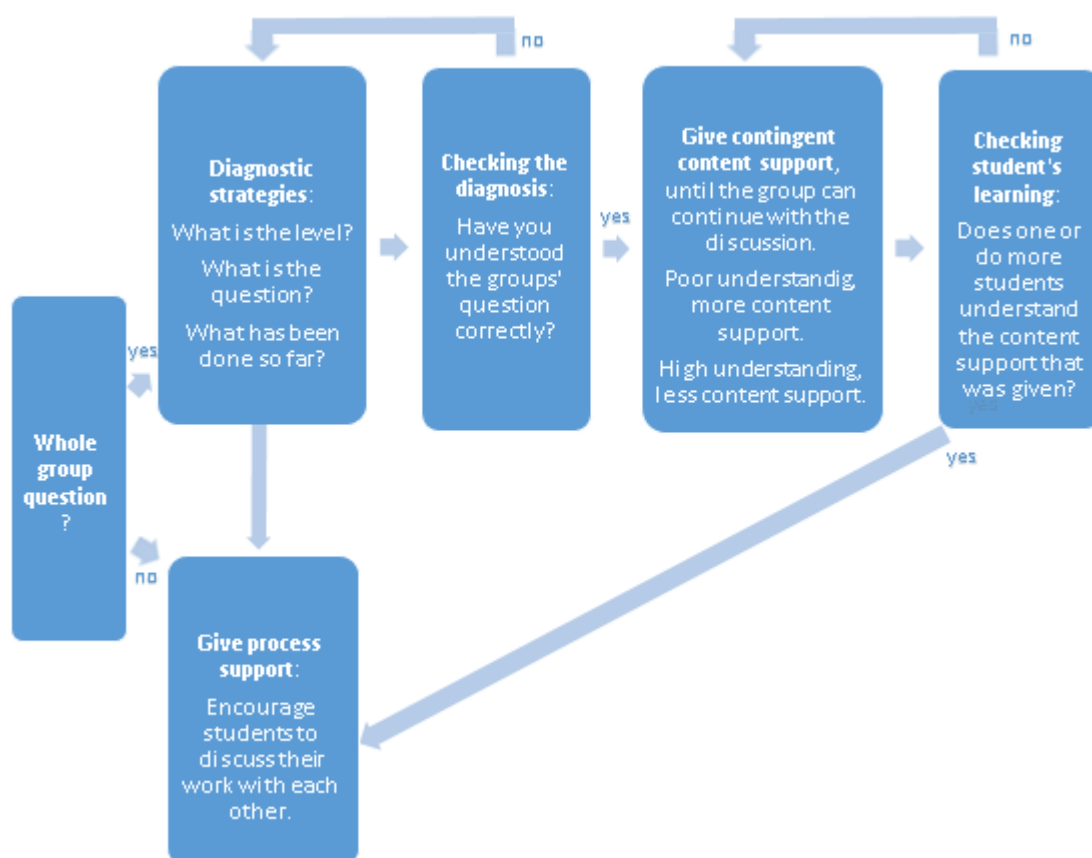

Collaborative learning is considered an important means to improve students' learning of mathematics (Webb, 1982). Several studies have shown that mathematical discussions in small heterogeneous student-groups contribute significantly to mathematical reasoning and level raising (Freudenthal, 1991; Dekker & Elshout Mohr, 1998, 2004). Dekker and Elshout Mohr, (1998) developed a 'Process model' (PM), which promotes and operationalizes mathematical discussions. This model distinguishes three types of learning activities: key activities, which help mathematical level raising; regulating activities, which regulate key activities and mental activities that occur in students' minds. They found that stimulating mathematical discussions by the teacher resulted in more mathematical level raising compared to providing content support (Dekker & Elshout Mohr, 2004). However, teachers find it difficult to support mathematical discussions in small-group learning (Webb, 2009).

Content support adapted to the level of the student's understanding (contingency) is considered one of the key features of scaffolding (Van de Pol, Volman, & Beishuizen, 2010). The other two key features of scaffolding are diminishing content support over time (phasing out) and returning responsibility for learning processes to the learner. Scaffolding in the context of group work seems to enhance learning outcomes in general (Van de Pol, Volman & Beishuizen, 2010; Webb, 2009). Van de Pol, Volman and Beishuizen (2012) developed a model to describe scaffolding interactions, the Contingent Teaching Model (CTM), in which teacher support is adapted to the level of individual students. It consists of four steps: applying diagnostic strategies, checking the diagnosis, applying intervention strategies, and checking students' learning. In the CTM individual students are scaffolded in a small-group setting.

In the context of collaborative learning teachers often scaffold individual students within small groups. How teachers can scaffold small groups at group level and what the effect is on students' mathematical learning, has not yet been investigated. A combination of stimulating discussions and providing contingent content support adapted to the level of the group might result in more mathematical level raising. To help teachers support small heterogeneous student-groups we integrated the CTM (Van de Pol, et al., 2012) and the PM (Dekker & Elshout Mohr, 2004) into a

scaffolding model for small student groups (Calor, Dekker, Van Drie, & Volman, 2019). We call this model the Small-Group Scaffolding model (SGS model).

In Figure 1 a flowchart representation of the SGS model is shown. The model consists of six teaching steps: evaluating if the question is a question of the whole group, applying diagnostic strategies, checking the diagnosis, giving contingent content support, checking students' learning, and giving process support (stimulating mathematical discussions).

**Figure 1: A Flowchart of the Small-Group Scaffolding model (Calor et al., 2019)**

Following the Small-Group Scaffolding model, teachers should first determine if the question is a question of an individual in the group or if it is a question of the whole group. In case the question is a question of the whole group, the teachers should diagnose the group's current level of understanding in the second step, by for example asking students what they have done so far and asking the students to show or tell their work to the teacher. It is possible that one or more students come up with an answer to the question during this step. In that case, the teacher should encourage the students to explain the answer to each other. If none of the students come up with an answer during step two, teachers can check if their diagnosis is correct in the third step. In the fourth step, the teachers should give contingent support to the group (increase support when the students show poor understanding and decrease support when students show high understanding) until one or more students understands the question. In step 5, the teacher should check if at least one of the students understood the content support. If this is the case, teachers should stop giving content support (phasing out, the second key feature of scaffolding) and return responsibility for learning back to the group (third key feature of

scaffolding) (Van de Pol et al., 2010). Returning responsibility for learning to the group can be done by encouraging students to explain and show their work to each other and to criticize each other's work, i.e. give process support, in the last step. In case the outcome of the determination of the question in the first step was that the question was not a question from the whole group, but rather a question of one or more individuals in the group, teachers should return responsibility for learning back to the group by giving process support.

In this study, we combined Fruedenthal's, Janvier's, and sociocultural perspectives as theoretical lenses to study mathematical lessons.

### **Research question**

Does the use of the Small-Group Scaffolding model raise seventh grade students' mathematical level in Early Algebra?

### **Hypothesis**

We hypothesize that the mathematical level of students will be raised more in the Scaffolding condition than in the control condition.

### **Method**

In a quasi-experimental design, we compared the mathematical level raising of students who were taught by teachers who were trained to give help to students according to the SGS model with those of students who were taught by teachers who gave help without prior instruction. In both conditions students worked on an Early Algebra unit that was especially designed to invoke mathematical discussions and raise the level of mathematical knowledge (Calor, Dekker, Van Drie, Zijlstra, & Volman, 2018).

Participants were eight teachers (7 males, 1 female) and their 266 seventh grade students of two schools in Amsterdam, the Netherlands (5 teachers and 169 students of two schools in the Scaffolding condition and 3 teachers and 97 students of one school in the control condition). Two of the eight teachers (one in the Scaffolding condition and one in the control condition) worked with an Early Algebra unit in a collaborative setting in a previous study (Calor et al., 2018). Other than that, the teachers had no experience with collaborative learning. Teachers were matched into pairs according to age and teaching experience. Of every pair one teacher was randomly assigned to a condition. Every teacher taught their own seventh grade class. Teachers in the Scaffolding-condition were trained on the job so that they could be engaged in inquiry into the SGS model and reflection on its use and to provide an opportunity for them to make connections between their learning and classroom practice (Borko, Jacobs, & Koellner, 2010). Prior to the lesson series, teachers in the Scaffolding condition were trained in a two-hour training to give help to students according to the SGS model. In addition, before and after every lesson the use of the model was discussed individually with the teachers and questions were answered. The aim of the research was only known to the teachers in the Scaffolding condition. The teachers in the control condition were instructed to let the students work together on the assignments and give their usual support. All students worked in small heterogeneous groups (46 Scaffolding and 27 control condition). Small student-groups consisted of students of mixed ability according to track advice related to the students by their primary school administration.

Ideally groups consisted of four students, but due to class size restrictions 24 groups of three students (13 Scaffolding and 11 control condition) and one group of two students were formed (Scaffolding condition). Students' age varied between 12 and 15 years. Groups in the Scaffolding condition were instructed by the teacher to explain and show/tell their work to each other, ask each other for explanations, and to criticize each other's work. Teachers in both conditions implemented the lessons as intended (teachers in the Scaffolding condition used the SGS model to support students, whereas teachers in the control condition gave support as they normally would). Implementation check was performed by the first author during and after lessons (check with teacher and watch videotape of lessons).

In both conditions, students worked on a lesson series of 12 lessons of 60 minutes on the topic of Early Algebra for five weeks. We replaced five of these lessons, with lessons that explicitly aim to invoke mathematical discussions and raise the level of mathematical knowledge (Calor et al., 2018). During these five lessons, students worked collaboratively on the same assignment. Every lesson started with 10 minutes introduction by the teacher, followed by students working collaboratively for 50 minutes. During the remaining lessons students sat together in the same small heterogeneous groups and worked on regular assignments from the textbook.

Students' mathematical levels in Early Algebra were measured by means of a test. A pre-test was administered in the lesson prior to the intervention, and the same test was administered as a post-test in the lesson after the intervention. The test aims to measure the mathematical levels of students based on the translation skills from Janvier (1987). The highest level implies being able to translate from representation formulae to representations situation, tables and graphs and vice versa. The lowest level implies not being able to translate from and to the representation formulae at all.

The test consists of six questions and 17 sub-questions, of which 10 were used to measure mathematical levels. They consist of questions involving all translation skills of the representation formulae (Janvier, 1987). The other seven questions were discarded (not included in the scores) during determination of level raising. They consist of basic primary school arithmetic questions so that students would be able to answer at least some of the questions when the test was administered as a pre-test. Scores of 0, 1 and 2 were assigned; 0 meaning low mathematical level, 1 meaning medium mathematical level, and 2 meaning high mathematical level. The sub-questions of the test corresponded to the switches between the Janvier representations involving formulae (Janvier, 1987). The first sub-question only involved a less abstract representation of a formula; therefore, the score for this question was limited to 1 (medium mathematical level). The sum of the scores amounts to a maximal number of 19 points in total that students could score for the test. The levels that were assigned to the sub-questions were discussed with a second coder (the second author of this article). Students worked individually on the test for 60 minutes. An example of a basic primary school arithmetic question is: "Out of one package pancake mix you can bake six pancakes. How many pancakes can you bake with 12 packages of pancake mix?" An example of a question that measures mathematical level is: "Shane wants to get in shape, therefore he goes swimming. With the following (word) formula you can calculate Shane's costs. Number of times swimming  $\times 3 + 30 =$  costs. (Here, 3 stands for €, the cost for swimming once at a swimming pool for a member and 30 stands for €30, the cost of a yearly membership to a swimming pool.) Draw a graph for this formula." A score of 2

(high mathematical level) was assigned when the graph was drawn correctly (linear relationship in the graph was depicted correctly); a score of 1 (medium mathematical level) was assigned when small errors occurred in the graph (e.g. graph starts at (0,0) rather than (0,30)); a score of 0 (low mathematical level) was assigned when the graph made no sense (e.g. when only names of axes were written down). Another example of a question that measures mathematical level raising is: “Eric saves money to buy a smartphone. Every month he saves €27,-. He has currently no money in his savings account. Give the formula with which the amount of money on Eric’s savings account can be calculated”. A score of 2 (high mathematical level) was assigned when the formula was correct; a score of 1 (medium mathematical level) was assigned when the formula contained small errors or when the linear relationship was explained in words; a score of 0 (low mathematical level) was assigned when the formula made no sense (e.g. when only 27 was written down).

Interrater reliability for the pre- and post-test between two coders, determined in a prior study, was excellent (ICC 0.95) (Calor et al., 2018).

A multilevel model for repeated observations on fixed occasions with an unrestricted covariance matrix (Snijders & Bosker, 2012) was used to test for differential growth between the Scaffolding condition and the control condition. The fixed occasions are the measurements (pre- and post-test) nested in individual students. The measurements (pre- and post-test) are the first level, the individual students are the second level, the small groups are the third level, and the classes are the fourth level. This multilevel model (Snijder & Bosker, 2012) enables us to test the growth in the Scaffolding condition against the growth in the control condition.

## Results

We present the means of the pre- and post-test on mathematical level for the Scaffolding condition and control condition in Table 1.

	Scaffolding condition	Control condition
	M (SD)	M (SD)
Pre-test	2.04 (3.32)	1.43 (2.66)
Post-test	11.93 (5.88)	9.22 (6.44)

**Table 1: Means and Standard Deviations Pre- and Post-test on Mathematical Level, Scaffolding condition (N=169) and Control condition (N=97), Maximum Score of 19**

Table 1 shows that the students’ mathematical level improved a fair amount in both conditions. For the Scaffolding condition (SC), the mean score increased from 2.04 to 11.93, and for the Control condition (CC), it increased from 1.43 to 9.22.

A multilevel model for repeated observations on fixed occasions with an unrestricted covariance matrix (Snijders & Bosker, 2012) was used to test for differential growth between the SC and the CC.

We report on the model for three levels (with measurements (pre-test post-test) nested in individual students and classes) since there was no significant improvement in model fit for four levels (measurements, individuals, groups, classes).

The expected outcome for the CC was pre-test = 1.40 and post-test =  $1.40 + 9.20$ . For the SC the expected outcome was pre-test =  $1.40 + 0.692$  and post-test =  $1.40 + 0.692 + 9.20 + 2.116$ . Thus, compared to CC the growth in the SPC is 2.116 larger. This differential growth is significant ( $p = 0.003$ ).

## Discussion/conclusion

In this study, we investigated whether the mathematical level of students who were taught by teachers who were trained to give help according to the Small-Group Scaffolding model was raised more than the mathematical level of students in a control condition.

With respect to our hypothesis, multilevel analyses showed that the mathematical level of students in the Scaffolding condition was raised significantly more than the mathematical level of students in the control condition.

This study was conducted at two schools, which limits the generalizability of our findings. In addition, the conditions were observed at different schools. Consequently, results might be affected by qualitative differences between the schools. For example, the average pre-test score for the Scaffolding condition was higher than that of the control condition. This could be indicative of a higher aptitude, which in turn might be favorable for the growth in the Scaffolding condition. However, this is not very likely since there are no large descriptive differences between secondary schools in the Dutch education system (e.g. track advice given in primary schools determines the track students follow in seventh grade).

In a follow-up study, we will report elaborately on the scaffolding behavior of the teachers in both conditions. We will also focus on the quality of mathematical discussions in the groups, since reflection during mathematical discussions may have a positive effect on mathematical level raising (Freudenthal, 1978).

We conclude that the Small-Group Scaffolding model is a useful extension of the Contingent Teaching Model (Van de Pol et al., 2012). In addition, we conclude that using the SGS model for Early Algebra can raise the mathematical level of students (ability to switch back and forth between representation formulae and other algebra representations (Janvier, 1987)). The SGS model can therefore be useful to help teachers support small heterogeneous student-groups.

Future research should focus on the investigation of what kind of help the teachers in the conditions gave to the students and whether or not the quality of the mathematical discussions mediates mathematical level raising. In addition, this study should be replicated on a larger scale to find more robust findings.

## Introduction

In this poster we will present a learning study conducted by three Swedish teacher educators. The aim of the learning study was to identify critical features concerning the teaching and learning of Mathematical knowledge for teaching (MKT). Two classes of teacher students and 30 lesson plans were analysed using the theory of variation.

Teacher student's theoretical knowledge of learning and teaching mathematics is crucial for their teaching practice. In previous courses we have discerned how teacher students on one hand can describe different strategies for solving a problem and on the other hand describe common misconceptions pupils have in elementary mathematics. Nevertheless, they do not comprehend the relationship between them. To address the problem, we have conducted a learning study focusing on the theoretical framework Mathematical Knowledge for Education (MKT), prepared by Ball, Thames and Phelps (2008), to describe the knowledge required to teach mathematics (Figure 1). The work was also guided by prior research (Bommel, 2012).

**Figure 1: Domains of Mathematical Knowledge for Teaching**

## Method

Learning study offers a potential platform for teachers to collaboratively explore their own practice in order to generate and share knowledge about teaching and students learning. The first learning study was carried out in Hong Kong in 1999. By now over 300 learning studies have been developed in Hong Kong and it has been developed in other parts of the world, including Sweden. Lo and Marton (2012) stress that,

learning study has been found to improve students learning, reduce the gap between the high and low achievers and contributed to teachers' professional development and the learning of researchers (p. 9).

A learning study is an iterative process where a small group of teachers handle a particular pedagogical content. The students' way of making sense of the pedagogical content, initially and after a lesson is systematically scrutinized and revised once or twice and carried out in a different class. The whole process is well documented. The variation theory (Marton & Lo, 2012) is used as a theoretical tool for planning the lessons as well as analysing the lesson and the teacher students' lesson plans.

## Data collection

The data collected consists of lesson plans (written text) and two video recordings of iterative seminars given in the teacher education course. The mathematical topic covered was probability. Prior to, and after each seminar, the teacher students handed in a lesson plan.

## Preliminary results

The analysis of the lesson plans revealed how and what the student teachers understood or not and thus what critical features the seminar should focus on. We could see in the lesson plan that the students wrote an aim with the lesson, a didactic plan for the lesson and also how they would evaluate the pupils learning. What was missing was the connection between the three (critical aspect). In the seminar we let student teachers look at a lesson plan conducted by someone else than the students as well as questions about the alignment between aim, lesson and evaluation in order for them to discern the critical aspects. The result showed that the students had not discerned the critical aspects and one reason could be the lack of contrast between different lesson plans since we only addressed one lesson plan in the seminar. For the second seminar we discussed one lesson plan in whole class and addressed questions about what was missing in the lesson plan between the linking in the alignment. In order for the teacher students to discern the critical aspects they got a lesson plan to compare and contrast with the first one discussed. One critical aspect we overlooked was the student's ability to make the lesson plan concrete enough to work in a classroom. A second learning study will be conducted taking into account the need to vary concrete lesson plans.

# How teachers use interactions to craft different types of student participation during whole-class mathematical work

Ove Gunnar Drageset

UiT – The Arctic University of Norway, Norway; [ove.drageset@uit.no](mailto:ove.drageset@uit.no)

*This article investigates how different types of teacher interactions craft different types of student participation. The article is based on shared data within Thematic working group 19: Mathematics Teaching and Teacher Practice(s) for CERME 11. Using conversation analysis, each turn was characterized. The findings illustrate the main teacher and student interactions for each classroom, and how some types of teacher interactions typically lead to specific types of student interactions in the following turn. This is a contribution to increase our understanding of how teacher interactions can be used deliberately to activate students' participation in different ways.*

**Keywords:** *Interaction, discourse, student participation, moderating, whole-class mathematical work.*

## Theory

When describing classroom discourse, the IRE pattern (Cazden, 1988; Mehan, 1979) might be the most widely referenced concept. It describes a pattern where the teacher initiates a task or discussion, the student(s) responds, and the teacher evaluates, and is often seen as the default pattern of classroom discourse. According to Franke, Kazemi, and Battey (2007), the IRE pattern describes a procedure-bound pattern with little emphasis on students' thinking and explanations. Often IRE is described as a rather teacher-dominated pattern, where the students only answer when given permission and where the teacher maintains a position of authority given by role rather than by mathematical arguments. However, it is not only who asks the question or who evaluates that decides the quality, but also the quality of the questions and evaluations. Mercer and Littleton (2007) argue that instead of looking at the number of questions (initiatives) a teacher asks, one should look at the function of these questions. It is also necessary to study the function as part of the dialogue, studying how different initiatives nurture specific responses and how these are typically evaluated. This must be done within both IRE patterns and other patterns, leaving the focus on characterizing a discourse as inside or outside IRE behind us and instead look for details that inform about different qualities.

Several authors have described discourse frameworks and concepts that go into more detail. One such example is Fraivillig, Murphy, and Fuson (1999) who, based on a study of one skillful teacher, describe the ACT (Advancing Children's Mathematics) framework, consisting of three components: eliciting children's solution methods, supporting children's conceptual understanding, and extending children's mathematical thinking. These components describe three main ways the teacher acts to advance students' mathematical thinking in detail. Another example is the eight communicative features suggested by Alrø and Skovsmose (2002): getting in contact, locating, identifying, advocating, thinking aloud, reformulating, challenging, and evaluating. These do not separate between teacher and student interactions, but instead describe fundamental types of communication in mathematics independent of who says what. A third example is the redirecting, progressing, and focusing framework (Drageset, 2014) describing thirteen actions teachers use to orchestrate the

classroom discourse. Redirecting actions typically occur when the teacher wants the student(s) to change their approach. This is done either by putting aside the student's suggestion, by advising a new strategy, or by asking a question in such a way that it includes a correction. Progressing actions are about moving the progress forward. This is done by demonstrating the entire solution process, by simplifying through hints and suggestions, by asking closed and often basic questions to move along one step at a time while the teacher controls the process, or by asking open questions and leaving it to the student(s) to choose how to progress. Focusing actions are about stopping the progress to look deeper into some important detail and consist of two main types. One type is to ask students either to elaborate in detail how they solved a problem or thought to arrive at the answer, to justify why their answer or method was mathematically correct, to apply the method to a similar problem, or to assess. The other type is the teacher pointing out important ideas or rules either during the solution process (notice) or after the solution has been found or agreed upon (recap). In a further development of the framework, a third type of focusing actions called moderating is added (Drageset & Allern, 2018). This describes how teachers moderate the discourse in three different ways: choosing whom to speak, requesting student questions, and requesting alternative methods. In general, moderating interactions describe how a teacher can develop and control the discourse while the content of the discourse is the students thinking, questions, and explanations.

In addition to the framework describing different teacher interactions, Drageset (2015) developed five categories of student comment: explanations, initiatives, teacher-led responses, unexplained answers, and partial answers. These add to the categories describing teacher actions, together providing a set of concepts able to describe all mathematically-related comments in these five practices. Together, Alrø and Skovsmose (2002), Drageset (2014), and Fraivillig et al. (1999) illustrate three different approaches to investigate classroom discourse in detail. While Fraivillig et al. (1999) concentrated their effort on describing the main actions performed by the teacher to help students advance their mathematical understanding, Alrø and Skovsmose (2002) described all turns without separating teacher and students, and Drageset (2014, 2015) chose to describe teachers' and students' participation separately before looking at connections. Common to the latter two is the characterization of single comments in order to develop categories.

However, looking at single comments, or turns, yields a very limited scope. According to Sacks, Schegloff, and Jefferson (1974), turns are the most fundamental feature of conversation. Even though people take turns in speaking, sequentially and one at a time, it is not possible to characterize a conversation as a series of individual actions. Instead, conversations are social practices where each turn is thoroughly dependent on previous turns, and individual turns cannot be understood in isolation from each other (Linell, 1998). This means that characterizing different types of single turns are insufficient if one wants to study the discourse. Instead, one needs to study how different types of turns affect one another. It is also important to know that some responses are more relevant or preferred than others (Linell, 1998). Often, a student knows what type of answer is relevant. Such relevance can be related to social norms and socio-mathematical norms (Yackel & Cobb, 1996). Arguably, when a student knows how what is a relevant or preferred answer, then norms are established. And these norms, or relevant answers, do not emerge out of definition or information from a teacher, but gradually through an appropriation process as described by Newman (1990).

## Method

This article reports from a study of shared data within Thematic Working Group 19 for the CERME 11 conference. Three short videos from different classrooms and a transcript from a fourth were shared by different participants of the TWG 19. The idea is that participants in TWG 19 can get a greater insight into the analyses and frameworks of each other when they also have access to the data.

Based on the knowledge that each turn in a conversation is thoroughly dependent on previous turns (Linell, 1998), this article aims to investigate this question: How do teachers use of different types of interactions craft different types of student participation during whole-class mathematical work? To achieve this, the transcripts were analyzed turn by turn, categorizing each turn using the redirecting, progressing and focusing framework developed by Drageset (2014, 2015) and Drageset and Allern (2018). Then the most frequent types of teacher interactions were identified to search for patterns on how students responded to these types. And the student interactions describe the ways the students participate during the whole-class mathematical work.

While the data from each classroom is too limited to say much about the classrooms, this type of data is valuable for its variety. This variety illustrates very different ways of crafting student participation, which is also useful for further development of the frameworks and concepts.

## Findings

In the following, findings related to each classroom will be described. All concepts in *italic* are concepts from the redirecting, progressing and focusing framework by Drageset (2014, 2015) and Drageset and Allern (2018).

### Kleve's classroom

This lesson is studied based on the transcript alone. It comes from a fourth-grade class with 24 students in Norway. The teacher is educated as a pre-school teacher and thus not formally qualified for teaching in school. In this lesson, five students have solved one task each on the blackboard. Then the discourse started, and the teacher talked with each student and the entire class about each task.

For each task, the discourse starts with a task that is solved, but the process and thinking behind the task is not visible. The first question the teacher asked for each task are these:

- Let's see. What is the place value system about, Herman?
- When we are going to find the product of something. What do we have to think about then? Hamid?
- And half of something, Marte, what do we have to think about then?
- Finding x, then we are going to find the missing number. What do we have to do then Oskar?
- Greater than and less than, Tobias. That became [i.e. You got...?]

The first four are similar as they all ask students for an explanation. Herman is asked to explain a concept (place value). Hamid, Marte, and Oskar are all asked to explain a process, either what one needs to think about or what one needs to do. All these questions are about *enlightening details*, to make the thinking behind an answer visible. All these resulted in *student explanations*.

The last question to Tobias is about getting an answer, not requesting an explanation. Instead, this is an *open progress initiative* which resulted in an answer with no explanation (*unexplained answer*).

Further on, the task discourses vary, but also tend to look like this towards the end:

Teacher: And seventy-three and thirty-seven?

Students: Greater than.

Teacher: And twenty-six minus two is?

Students: 12

Teacher: And twelve plus twelve is?

Students: Equal.

All the teacher interactions are questions that have only one correct answer and demands no process to answer (as the answers are already on the blackboard). This means that the teacher interactions are *closed progress details* while the student interactions are *teacher-led responses*. This pattern is found towards the end of four out of five task discourses.

Overall, the discourse pattern seemed to be that the teacher requested details of students thinking first (*enlighten detail*), the student explained, and towards the end the teacher went through all remaining answers using *closed progress details*, receiving *teacher-led responses*.

### **Sakonidis's classroom**

This classroom consists of 22 students at grade five in Greece. The teacher is a mathematician with an interest in advancing children's mathematical thinking. The video shows the teacher at the blackboard with fraction circles, talking with the entire class. This is an excerpt from the discourse:

Student: Eight

Teacher: Eight. How many pieces do I need for a whole pizza here? (Pointing out a circle that is divided into two six pieces, one in light green and the rest in dark green)

Student: Six

Teacher: Six. And here, how many do I need for a whole pizza? (Pointing out a circle that is divided into two four pieces, one in light green and the rest in dark green)

Student: Four

In the above excerpt, both teacher interactions start with a confirmation, then moves on to the next question (next figure). The questions have only one correct answer, and as the figures are drawn on the blackboard it is not difficult to answer (count) correctly. Such questions are *closed progress details* because there is only one correct answer. The student's answers are *teacher-led responses* as the answer are given by the figure.

In this lesson, the dominating type of teacher interactions is *closed progress details*, each followed by a *teacher-led response*. This leads to a typical IRE pattern where the teacher asks all the questions, evaluates all answers, and talk much more than the students.

### Hoover's classroom

This video is from a summer mathematics program with approximately 30 fifth graders in the USA. The teacher has more than 30 years of experience and is also a researcher. The video shows a student suggesting a solution on the blackboard and the subsequent dialogue. Quite often the teacher interacted in a particular way, as illustrated by these examples:

- Okay, would some- You'd like to ask another question, Dante?
- Okay, Toni, what's your question for her?
- Okay, any more questions for Aniyah?

These teacher interactions are similar as they are all about getting students to ask Aniyah about her thinking. It was typical for this lesson that the teacher *requested student questions*.

Another type of interaction observed repeatedly looked like this:

- Before you agree or disagree, I want you to ask questions if there's something you don't understand about what she did. No agreeing and disagreeing. Just- All you can do right now is ask Aniyah questions.

Here the teacher tells the student how to participate in the discourse. The teacher is *moderating* the discourse by *guiding participation and norms*.

The pattern of this classroom seems clear. The teacher sets up the situation by letting a student answer and controls the interaction through the use of *guiding participation and norms* and *requesting student questions*. Then the students' participation follows as requested, with one student *asking questions* and the one by the blackboard subsequently *explaining*. It is also interesting to notice that the teacher does not talk every second time and that the student interactions are rarely short and sometimes long.

### Drageset's classroom

This classroom shows a lesson with five students in grade four and their teacher in Norway. The lesson is part of a large government project where the effect of more teachers at the first grades will be explored. The teacher has about 20 years of experience. The lesson shows these students solving one task (the King is 80 years in 2017, when was he born?) and sharing their strategies. This teacher uses several types of interactions, such as these:

- But remember, you remember what we've been saying. It's not the answer that's going to impress me. What's going to impress me the most is the way you got the answer.
- A good tip right now is not to trust that one sitting beside you.
- You can only trust yourself here. Think for yourself and trust yourself.

Here the teacher informs the students about how to work, which is *guiding participation and norms*. In addition, the teacher regularly asked such questions as these:

- Are there anyone else that wants to show their way of thinking?
- Now it's your turn to explain if you want.

- But you were also, I noticed, quite quick to finish. (...) It looked like you did it in your head for a bit, then [snaps] wrote your answer down. So, I'm eager to know how you did it.

All these are examples of the teacher *requesting alternative methods*. It was the main feature of this lesson that the students presented a variety of solution methods of finding the King's birth year. Both *guiding participation and norms* and *requesting alternative methods* are examples where the teacher controls the dialogue through *moderating*, while the main content of the discourse is the students' explanations. However, bringing alternative methods forward did not result in a discussion.

Another type of teacher interaction was such as this one:

- I just want to repeat what you did so the others will understand what you meant. If you can move aside for a bit. What I understood is that you didn't bother about the 17 at first. You just went straight back and thought that: "What if we're in the year 2000 now?" If we then move 80 years back, we land in 1920. But now I'm eager to know, what did you do next?

Here the teacher stops the student explanation to tell the other students what is done so far and subsequently asking the student to continue the explanation. Such *pointing out* was frequently used by the teacher, and almost all long teacher interactions were about *pointing out*. While the teacher let the student explain, he used *pointing out* to make the explanation clearer and more complete. In this way, the student explanation was complemented and clarified.

The students participated in three main ways; *offer to answer*, *needing clarification*, and *explaining*. The two first were observed in the first part of the lesson, while the students worked on the task individually. The *student explanations* were observed during the last part of the lesson when they shared strategies on the blackboard. Of these explanations, almost all were *explanations of action*.

This lesson had two clear parts. In the first part, when the students worked individually, the teacher mainly contributed by *guiding participation and norms* while the students *offered to answer* when they were ready and *needed clarification*. In the second part, the teacher *requested (alternative) methods*. As a consequence, the students shared their strategy one at a time (*student explanation*) and the teacher *pointed out* during or after their explanations. The use of *pointing out* did not lead to any student interaction, either the student continued explaining, or the *pointing out* ended the explanation.

## Discussion and conclusion

This article has analyzed transcripts and videos from four classrooms to find out how different types of teacher interactions leads to specific types of student interactions. Based on which type of student interaction that follows each type of teacher interaction, there are some clear patterns.

	Most frequent teacher interactions	Most frequent student interactions
<b>Kleve's classroom</b>	<ul style="list-style-type: none"> <li>· Closed progress details</li> <li>· Enlighten detail</li> </ul>	<ul style="list-style-type: none"> <li>· Teacher-led responses</li> <li>· Student explanation</li> </ul>
<b>Sakonidis' classroom</b>	<ul style="list-style-type: none"> <li>· Closed progress details</li> </ul>	<ul style="list-style-type: none"> <li>· Teacher-led responses</li> </ul>

<b>Hoover's classroom</b>	<ul style="list-style-type: none"> <li>· Moderating <ul style="list-style-type: none"> <li>○ Guiding participation and norms</li> <li>○ Requesting student questions</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>· Student explanation</li> <li>· Student questions</li> </ul>
<b>Drageset's classroom</b>	<ul style="list-style-type: none"> <li>· Pointing out</li> <li>· Moderating <ul style="list-style-type: none"> <li>○ Guiding participation and norms</li> <li>○ Requesting alternative methods</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>· Student explanation</li> <li>· Offer to answer</li> <li>· Needing clarification</li> </ul>

**Table 1: Summary of the most frequently used interactions in each classroom, based on concepts from Drageset (2014), Drageset (2015), and Drageset and Allern (2018)**

Perhaps the clearest pattern found is that when a teacher asks for *closed progress details* the student responds with a *teacher-led response*. In these sequences, the teacher asks very easy questions and the students answers shortly. A focus on answer and repetition seems to be a feature of this pattern.

Another pattern is that when the teachers requested the students to *enlighten details* about their thinking or solution process, the student responded with an explanation of the actions or thoughts. This might seem insignificant, but according to Franke et al. (2007), one of the most powerful moves a teacher can take is to make such details about thinking visible for all. Similarly, *requesting alternative methods* resulted in student explanations. This also creates opportunities for discussing different methods or strategies, but this was not observed here.

The teacher interaction of *requesting student questions* was of particular interest. This naturally leads to the students asking questions, but also lead to student explanations in a dialogue between students.

The interaction *pointing out* did not lead to any particular student interactions. Typically, the student either continued the explanation afterward or did not say more when the *pointing out* came as a conclusion. The use of *pointing out* illustrated how this is a tool for clearing up students' explanations.

While both *requesting student questions* and *pointing out* focused on displaying student thinking, it is worth noticing a clear difference. While the teacher in the third classroom (shared by Hoover) was emphasizing that students should ask to find out what the student was thinking, the teacher in the fourth classroom (shared by Drageset) instead pointed out what seemed to be necessary for the other students to understand, and effectively removed the need for student questions.

The interactions that were *guiding participation and norms* seemed to lead to the requested behavior, but this was not possible to see clearly in the turn-by-turn analysis. In general, these interactions are examples of how a teacher can work deliberately to establish norms of how to respond and of what is expected from an answer. This means that *guiding participation and norms* illustrates how these teachers seem to work to establish what Linell (1998) calls preferred responses. When preferred responses are related to the content of mathematics, such as what counts as an explanation, the preferred responses are the same that Yackel and Cobb (1996) calls socio-mathematical norms.

This article has illustrated how the types of teacher interactions rather consistently decide which type of student response comes in the next turn. And responses that are consistent arguably describe how the students participate. Further research is needed in order to understand how teacher turns can be

used deliberately to activate students' participation in different ways, and the sharing of data from different classrooms and cultures is ideal for such a work. The findings also illustrate that the framework used apply cross-nationally and yield coherent characterizations of instructional interactions during whole-class mathematical work.

# Beyond the immediate – illuminating the complexity of planning in mathematics teaching

Helena Grundén

Linnaeus University, Sweden; [annahelena.grunden@lnu.se](mailto:annahelena.grunden@lnu.se)

*In mathematics education, there is a growing interest in research on social aspects such as how mathematics teaching in classrooms is informed by society. Consequently, new sets of theoretical frameworks and methods have to be taken into account. In a focus group study, Critical Discourse Analysis (CDA) was used as a theoretical framework, which enabled the researcher to see how mathematics teachers resist and construct a discourse of mathematics teaching apart from the official discourse. Also shown in the study is that power relations are circulating and thereby influencing teachers in the process of planning in mathematics. In this paper, results from the study are used to emphasize CDA as useful for mathematics education researchers seeking to grasp the complex, dynamic, and emerging nature of mathematics teaching.*

*Keywords: Critical Discourse Analysis, mathematics teaching, power.*

## Introduction

Prior studies within the TWG19 have in different ways underlined “the dynamics of the research activity aiming at ‘unpacking’ teaching practice”, mainly by focusing “the micro-level of classroom practice, on the resources teachers draw on as they engage in it, and their (intentional or unintentional) professional activity” (Sakonidis, Drageset, Mosvold, Skott, & Taylan, 2017, p. 3039). However, mathematics teaching is framed by “contextual, epistemological, and social issues” (Potari, Figueiras, Mosvold, Sakonidis, & Skott, 2015, p. 2972), which means that ‘unpacking’ teaching practice and exploring the complexity of mathematics teaching requires research moving beyond immediate classroom situations.

Teachers’ planning is one aspect of mathematics teaching practice(s) that often is done outside classrooms. One aspect of understanding development of this specific part of teaching practice(s) is to explore influence of various factors such as “how micro-level interactions (classroom and school) are informed by macro-level structures (society, culture and the politics)” (Sakonidis et al., 2017, p. 3033). Theoretical frameworks and methods traditionally used for classroom studies might not be enough to grasp what Sakonidis et al. (2017) refer to as the macro-level structures, i.e., society, culture, and politics. Hence, a framework acknowledging “the significance of the multiple micro- and macro factors that may influence how learning and lives in classrooms unfold” (Skott, Mosvold, & Sakonidis, 2018, p.171) is needed.

An ongoing focus group study focuses on planning in mathematics teaching. The study aims to explore in what ways power is visible in mathematics teachers’ talk about planning and the research questions guiding the study are: “What practices are visible when teachers talk about planning in mathematics?”, and “In what ways do teachers refer to these practices?”. In this paper, theoretical assumptions underlying the design of the study and preliminary results from the study are presented

through an empirical example, discuss Critical Discourse Analysis (CDA) as an option for studies aiming at going beyond the immediate and observable classroom events.

## **Theoretical framing**

In the following section, CDA and relevant theoretical constructs of practice, power, and discourse are presented in relation to previous mathematics education research. CDA is emphasized as a useful approach when wanting to explore relations between educational practices and social contexts (Mullet, 2018). In CDA the research interest is social practices, which include both communicative interaction (between actors) and the structural conditions framing the communication (Chouliaraki & Fairclough, 1999). Hence, a CDA perspective will embrace both structures and actors acknowledging that discourses shape humans as much as humans shape discourses (Fairclough as cited in Lund & Sundberg, 2004, p. 25). There is a dialectic relation between on the one hand to preserve and reproduce structures, and on the other hand, actors transforming and diversifying discourses (Lund & Sundberg, 2004). Adopting this perspective in relation to planning in mathematics would imply seeing the teacher as an actor within the structure of mathematics, the structure of mathematics education, and the structure of school.

Within CDA there is no disjunction between micro-, macro-, and meso level. Instead of analyzing different levels, different aspects of practice are analyzed through phases of text, discursive practice, and social practice. Texts expressed discursively are produced within a social practice (Chouliaraki & Fairclough, 1999). CDA has been used and discussed in mathematics education, mainly with a focus on texts and linguistics (e.g., Le Roux, 2008; Morgan, 2014). However, staying close to the text is not the only possibility. In CDA, focus on three levels is possible: “the communicative interaction itself; the discursive resources used in the interaction and the orders of discourse from which they are drawn; the social structures and socio-cultural practices within which the interaction is situated” (Chouliaraki & Fairclough, 1999 as cited in Morgan, 2014, p.6). In Le Roux (2008) Fairclough’s three-dimensional model is used “as a framework for studying the relationship between the written text of a mathematics problem, the associated discursive practices (the processes of text production, distribution and consumption of the text) and the wider social practice of which the discursive practices form part” (La Roux, 2008, p. 313). The three-dimensional model can also be used to describe a teacher talking about planning. The teacher produces a text (the talk) within a discursive practice (i.e., the college of mathematics teachers in the school) that is embedded within a social practice.

## **Practices**

Within the CDA perspective, as well as in prior mathematics education research, the term ‘practice’ is common. However, there is not a mutual understanding of the term. In mathematics education research, the term has evolved from a cognitive, individual perspective focusing on actions and behaviors and underlying beliefs, intentions and knowledge, to a sociocultural perspective within which ‘practice’ is a social phenomenon and includes teachers’ and students’ recurrent activities and norms (Skott et al., 2018). The meaning of the term ‘practice’ has in some studies also expanded to include parts of teachers work that happens outside the mathematics classroom (Skott et al., 2018). This latter understanding of the term is in line with meaning of practice in the CDA perspective where

‘practice’ grasps both individuals’ actions and the more habitual, common ways of acting (Chouliaraki & Fairclough, 1999). Hence, thinking of planning for mathematics teaching as a practice would enable to see teachers’ actions both as individual and shared by other mathematics teachers. It would also enable to get hold of the relationship between abstract structures and peoples acting, or how social structures govern people’s possibilities to act.

In the CDA perspective, using the term practice implies that there are internal power relations and a struggle between different actors. In the practice of planning, there are actors such as colleagues, students, and school leaders who may not share the same ideas about mathematics teaching. These different ideas lead to tensions and influence teachers’ planning (Grundén, 2019), which can be seen as a struggle between actors. This struggle reproduces and transforms structural conditions. However, the internal power relations of a practice are also influenced by its relation to other practices (Lund & Sundberg, 2004). Teachers’ planning in mathematics teaching is thus framed by structural conditions produced in past and present educational systems but is also framed by structural conditions produced by mathematics community, and mathematics education community. Hence, there is an on-going struggle where structural conditions are negotiated.

### **Power**

In mathematics education research, different notions of power are used (Gutiérrez, 2013; Valero, 2008). In this paper, power is used from a CDA perspective, i.e., always present in and between practices, and seen as situated, relational, and in constant transformation. Transformation occurs when people participate and act in the construction of discourses (Valero, 2004). Hence, power in relation to planning for mathematics teaching is in constant circulation and transformation. Power is not seen as only operating from ‘above,’ from for example government and school leaders. On the contrary, all actors within a practice, such as teachers, students, and parents as well as government and school leaders might have power.

### **Discourse**

Another construct important within the CDA perspective is discourse. The term is used in a variety of ways in mathematics education research and the conceptual clarity in many discourse studies is weak. In a literature review on mathematics education, articles were found to focus on three topics: discourse as social interaction; minds, selves, and sense-making; and cultural and social relations (Ryve, 2011). In this paper, the focus is on social structures and meaning is seen as situated and co-constructed which would place the research within the topic area of cultural and social relations. In Ryve’s categorization, this implies an interest in “macro processes of social and institutional actions” (p. 172). Many studies within this topic area draw on work of Foucault, with the consequence that discourses are analyzed as language games maintained by power relations and little agency is ascribed to individuals (Ryve, 2011). This perspective is often criticized since there are few possibilities to transcend the binding discourse order (Lund & Sundberg, 2004).

On the other hand, within the CDA perspective there is a dialectic relationship between humans and discourses (Lund & Sundberg, 2004) and discourse is seen as “use of language seen as a form of social practice, and discourse analysis is analysis of how texts work within sociocultural practice” (Fairclough, 1995, p.7). Within a discursive practice such as a college of mathematics teachers

planning for teaching, texts are produced, distributed, and consumed in specific ways and in line with the social context in which it is embedded. What is analytically interesting is not to “discover” and construct “new” discourses but how the individual teachers through acting represent, produce, and legitimate discourses on specific grounds. Discourses are studied based on their effects on different levels; situational, institutional, and societal (Lund & Sundberg, 2004, p. 26)

### **Empirical example – Focus group**

Results from a previous study (Grundén, 2017) in which teachers were interviewed with a focus on meaning in relation to planning in mathematics show that teachers refer to aspects beyond the immediate planning in their talk, they refer to practices other than the practice of planning in mathematics. In an ongoing study, focus group interviews are used to explore how these practices are visible and how power operates within and between them. The researcher met with six different groups at four different schools. The number of participants in the groups was between 2 and 5. The interviews lasted between 65 and 90 minutes. After an introduction consisting of a presentation, a reminder of informed consent, and a short presentation of the previous study the researcher started the discussion by placing pieces of paper in the middle of the table. On some of the pieces, there were words written; some of them were empty. The words that were written were six common influencing aspects identified in the previous interview study: Students, School management, National tests, Templates/forms, Parents, and Textbook. Participants were asked to look at the words and think about if any of them had any relation to their process of planning in mathematics. The words were seen as stimuli for the discussion. Participants were also told that they could add aspects they thought were missing and remove aspects that they did not think were related to planning. During the discussion, the role of the researcher was to ask follow up questions and challenging questions and to make room for all participants and invite them in the conversation, and through small words and gestures confirm that she was listening.

Since the aim of the study was about the practice of planning rather than individual teachers' planning the discussions were transcribed without marking different voices. Instead, all statements were seen as examples from the practice of planning in mathematics teaching. For this paper, preliminary results from one of the focus groups are presented. The reason for presenting results from this group was a telling example of when a social practice influenced planning in mathematics teaching. The group consists of four teachers working in school year 1 at the same school, a small school with pre-school class, first class, and second class. The teachers had scheduled time together every week and were used to working together. At the beginning of the discussion, the group wanted to add an aspect, ‘National support for assessment,’ that for them was related to planning. A transcript of the discussion that followed was analyzed as described in the following section.

Acknowledging meaning as situated and power as an issue in social practices (e.g. Valero, 2004) implies that power is present also in the interview situation. In this study, efforts were made to diminish influence of researcher by letting participants choose and talk freely about issues related to planning introduced with no further explanation. However, there is always a possibility that researchers influence arguments in texts produced by participants which have to be taken into considerations when valuing results.

## Analysis and results

There is no particular method for analysis in CDA studies. However, there are common features in the analysis made within the perspective where the analysis “oscillates between a focus on structure and a focus on action” (Fairclough, 2001 as cited in Mullet, 2018, p. 118). Mullet (2018) describes a general analytical framework for CDA in which several CDA approaches are condensed into seven stages of analysis. The first three stages are preparatory and include selecting the discourse under investigation, select data sources and prepare them, and examine the background of text and producers of text. The fourth stage when analyzing a text is to identify overarching themes for example by using thematic analysis. (Mullet, 2018). After that analysis of external (stage 5) and internal relations (stage 6) in the text takes place. When analyzing external relations, interdiscursivity, social practices’ influence on arguments in the text as well as the text’s influence on social practices are examined. The analysis of internal relations is focused on “patterns, words, and linguistic devices that represent power relations, social context (e.g., events, actors, or locations), or speakers’ positionalities.” (p. 124). In stage 7 meanings of major themes and internal and external relations identified in stage 4, 5, and 6 are interpreted.

In the following section, results of the external and the internal analysis of the focus group study are presented. The theme of the first example is assessment material on number sense from the National Agency of Education that is mandatory to conduct with all year 1 students. One of the groups wanted to add ‘National assessment support’ to the words in the middle of the table. The following discussion took place<sup>1</sup>:

- |   |          |                                                                                                                                                                     |
|---|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Teacher: | It is extremely time-consuming. It takes too much time from teaching                                                                                                |
| 2 | Teacher: | ...teaching has to come first, before Skolverket’s [National Agency of Education] assessment support ...                                                            |
| 3 | Teacher: | We have also said that the assessment support and national tests have never shown us something we didn’t already know.                                              |
| 4 | Teacher: | And the municipality requires documentation from us, and they have chosen another type of documentation than Skolverket wants, which leads to additional workload”. |

In this section, we can see that there are social practices influencing arguments in the text (stage 5). Teachers talk about Skolverket [National Agency for Education] (line 2 and 4) and municipality (line 4) which both can be seen as actors within an official practice. Other elements of the official practice are visible when teachers talk about the assessment support (line 1, 2, and 3) and national tests (line 3).

By focusing on patterns, words, and linguistic devices, i.e., the internal relations (step 6) in the text we can see how teachers have to relate to the assessment support when planning. In the first utterance, a teacher implicitly expresses that they have less time for ‘teaching,’ thereby also implicitly saying that doing the assessment tasks with students is not part of ‘teaching.’ By the choices of words

---

<sup>1</sup> My translation from Swedish

‘extremely’ and ‘too’ the teacher reinforces the impression that the assessment support is something that is not considered valuable. This view is also visible in the second utterance, where the teacher emphasizes that teaching is something else, more valuable than the assessment support. By seeing Skolverket as the owner of the material, the teacher distances herself and gives the impression that the assessment support intrudes teaching.

In the third statement, the participant sees herself as part of a practice by referring to ‘we.’ Within the practice, information obtained by assessment support and national tests is unnecessary because it already has emerged through teaching. In the last statement “the municipality requires” another type of documentation than “Skolverket wants” indicates that the documentation for Skolverket seems more reasonable than the documentation for the municipality. This is strengthened by the claim that the requirements from the municipality lead to “additional workload.”

The counterpart in the above example is Skolverket, which on their webpage describes the assessment support as follows:

In the subject of mathematics there is a national assessment support in number sense for school year 1–3. It is mandatory for head of school<sup>2</sup> to use assessment support in school year 1. It is Skolverket’s assessment support in number sense, published in 2018, that should be used [...]. The assessment support aims to make it easier for you as a teacher to follow up on students’ knowledge in school year 1–3. With help from assessment support students that already have, or are in the risk of having, difficulties in number sense in mathematics can be early identified. You can also see when a student has come further in her knowledge development and need further stimulation (Skolverket, 2018<sup>3</sup>).

Here, the words ‘support’ and ‘mandatory’ are of interest. Making support mandatory assumes that users, in this case, the teachers, are in need of support and that they do not seek the support they need. Since the assessment support is “mandatory for the head of school” an alternative interpretation could be that Skolverket by saying that it is mandatory wants to clarify that the head of school has to create conditions for teachers to make the assessments. However, there are wordings such as ‘for you as a teacher’ indicating that teachers are the actual receivers, and teachers are also the ones who conduct the assessments in the material.

Through the analysis of the four utterances and the quotation from Skolverket, it is possible to see that power is circulating around and within the practice of planning. Through the way the teachers speak, it becomes clear that the assessment material is seen as worthless and something that stands in the way for teaching. On the contrary, Skolverket emphasizes the assessment support as helpful in teachers’ possibilities to individualize teaching. The teachers can either choose to resist given instructions and not let their students do the assessments or choose to follow them and thereby renounce what they count as teaching. In this case, the teachers choose to conduct the assessments, which in line with the analysis have the consequence that students have less mathematics teaching.

---

<sup>2</sup> In Sweden, ‘head of school’ means the authority responsible for a school or several schools. It can be a municipality, the state, or a private actor.

<sup>3</sup> My translation from Swedish

## Discussion and conclusion

By analyzing what the teachers said with regard to external relations (Mullet, 2018) Skolverket's influence on arguments in the text was made visible. It was also visible how decisions made by Skolverket influenced decisions that the teachers made regarding their teaching. By focusing on internal relations (Mullet, 2018), the resistance of the teachers was apparent. In their meta-reflection on planning the teachers emphasize explicit power relations and perceive Skolverket and the municipality as disturbing power factors. When expressing dissatisfaction, they resist the official practice and make room for an alternative discourse of mathematics teaching where the actors of the official discourse are not invited. Hence, teachers enter as actors in a discursive struggle for power where they, on the one hand, perceive instructions and requirements from Skolverket and the municipality as “something else” than their own pedagogical discourse and on the other hand realize that they have to follow instructions and requirements given by them.

Relating the power relations and the struggle between actors visible in the above examples to what is happening in the mathematics classroom is two-folded. On the one hand, it contributes to explanations of what is happening in the teaching situation when the students do the assessment tasks, but also bring clarity to aspects of teaching that never are visible in classrooms. Teachers in the example abandon what they consider to be teaching to comply with the directives of Skolverket. Insights like this might be important for example in discussions about implementing research results. Often it seems to be assumed that teachers do not teach desirable ways because they do not know how to do. Consequently, implementing research seems to be about telling teachers how to do. Findings indicate that an awareness that teachers make decisions in a practice influenced by others and sometimes not teach the way they want is crucial in implementation work.

So, is CDA useful in mathematics education research? Results presented above indicate that theoretical constructs from CDA such as practice (e.g., Chouliaraki & Fairclough, 1999) and power (e.g., Valero, 2004) help to make visible what Sakonidis et al. (2017) describe as how classroom and schools are informed by society, culture and politics. Hence, CDA might be a possible answer to the call for a framework that acknowledges “the significance of the multiple micro- and macro factors that may influence how learning and lives in classrooms unfold” (Skott et al., 2018, p.171), and studies using CDA might contribute to research in mathematics teaching with insights beyond the immediate.

## **The work of equitable mathematics teaching: Leading a discussion of student solutions**

Mark Hoover<sup>1</sup> and Imani Goffney<sup>2</sup>

<sup>1</sup>University of Michigan, USA; [mhoover@umich.edu](mailto:mhoover@umich.edu)

<sup>2</sup>University of Maryland, USA; [igoffney@umd.edu](mailto:igoffney@umd.edu)

*Mathematics teaching produces and reproduces social injustice. It also has the potential to disrupt patterns of inequity and advance just communities of practice. Drawing from literature on equitable mathematics teaching, we analyze the work of leading a discussion of student solutions in ways that nurture healthy identities, relationships and societies. From a conceptual analysis of a Norwegian mathematics lesson, we first identify dynamics of race and gender at play, then identify three key aspects of mathematics teaching that can serve to disrupt these dynamics while creating opportunities for alternative identities, relationships and futures: (i) having regard for property and its use; (ii) taking up student thinking as participatory citizenship; and (iii) orchestrating collective mathematical work. We discuss nuances of this work and implications for research on teaching.*

*Keywords: Research on teaching, equity, work of teaching, mathematics teaching.*

Inequities that play out in classrooms are well documented and a growing body of literature has proposed ways of teaching attentive to social differences (e.g., Ladson-Billings, 2014; NCTM Research Committee, 2018). Nevertheless, conceptualizations of equitable teaching are nascent. We need specifications that can undergird professional practice in a coherent educational system. At the same time, specific dynamics of oppression are intimately contextual. We need to more fully understand the dynamics of marginalization and privilege as they play out in classrooms and the work involved in altering those dynamics. In this study, we analyze a discussion of students' mathematical solutions to conceptualize further the work of equitable mathematics teaching. Video and transcript of this discussion was part of a collection of data shared with TWG19 participants at CERME11. Accordingly, descriptions given in this paper are abbreviated.

### **Conceptual and contextual background**

We view teaching as responsible design and management of instructional interactions. We draw on features visible across developing theories of teaching — the didactical/instructional triangle, emphasis on interaction and joint action, and regard for milieu and broader environments (Brousseau, 1997; Cohen, Raudenbush, & Ball, 2003; Jaworski, 1994; Wickman 2012). We see teaching as professional practice identified through logical analysis in professionally useful domains and decomposable into constituent tasks for the purpose of examining, learning, and reconstituting new knowledge and skill into practice (Ball & Forzani, 2009; Grossman & McDonald, 2008; Hoover, Mosvold, & Fauskanger, 2014).

In this work, we focus on specifying teaching in ways that disrupt patterns of inequity and advance healthy communities of practice. We understand equity to mean being equal, fair, and even-handed, with “reasonableness and moderation in the exercise of one's rights, and the disposition to avoid insisting on them too rigorously” and with “recourse to general principles of justice (the *naturalis*

*æquitas* of Roman jurists) to correct or supplement the provisions of the law” (Equity, 2018). While recognizing no definitive authority for deciding what is equitable, we understand regard for equity as integral to teaching. In order to decide questions of equity, we draw on our sense of humanity and invite readers to do the same. Further, we want to be explicit that we understand education to be both a matter of development of the child and an invitation to children to reimagine the world. Equitable teaching is more than just not being inequitable. We understand teaching to be about engagement in and creation of a healthy learning community — one that both enriches without oppressing and is open and responsive to individuals, their experiences, and their spirit.

## **Design of the study**

To understand the work of leading of a discussion of students’ mathematical solutions, we analyzed a session from a national study in Norway. Intervention schools were provided an additional mathematics teacher, with the goal of evaluating whether increased teacher-student ratios, with increased small-group instruction, will increase student learning. For the session we analyzed, the additional teacher is experienced and locally recognized as skilled. At this school, rotating groups of 4-6 students leave their regular mathematics class to work in a small group with this teacher. The session is 21.5 minutes, with 5 year-four students, two boys (B1 and B2) and three girls (G1, G2, and G3). It occurred in 2017 on the 80<sup>th</sup> birthday of the King of Norway. The teacher asked students to determine the year in which the king was born. Sitting around a large table, students work on their own for about 6 minutes, at which time the teacher has students share solutions.

Our analysis is empirical yet focused on concept formation (Gerring, 2001). It is conceptual-analytic research in line with Sleep (2012). Drawing on our experiences, literature, and records of teaching practice (such as video, transcript, lesson plans, student work, and interviews), we generate and test ideas about recurrent tasks of teaching. We build, revise, and discard ideas based on logical coherence with purpose, enactment, and learning of teaching and on coordination of different perspectives, in particular of the discipline of mathematics and of pedagogy (Thames, 2009). In this study of entailments of equitable teaching, we first examined potential patterns of structural oppression and marginalization. Then we analyzed opportunities for disrupting these patterns.

## **Potential patterns of structural oppression and marginalization**

First we examine interactions in the classroom that might be indicative of the reproduction of societal patterns of marginalization and oppression. The teacher begins by encouraging students to cooperate, yet during the first six minutes of the video, G1 and B2 dominate the verbal bandwidth, primarily talking to themselves, or no one in particular, with occasional, mostly ignored responses. As the task is launched, B2 announces that the problem is “child’s play” and that the answer is 1933, which he then amends to 1923. G1 says, “21<sup>st</sup> of January,” to which G3, the one identified black student, says, “It’s not the 21<sup>st</sup> of January, he has his birthday on the 21<sup>st</sup> of February.” G3’s comment is participatory in the sense that she has listened to G1 and is responding substantively to her, yet G1 dismisses her concern, adjusts her thinking, and covers her statement with, “But, I’m writing when he was born, so the 21<sup>st</sup> of February...January....” Perhaps her response is sincere and responsive, but its forceful expression seems to shut down and end the exchange. Sexism and racism are well-documented societal issues. Might they bear on these classroom interactions?

A similar dynamic plays out again two minutes later when G3 announces, “I know! It’s 1937!” to which G1 puts up a hand to stop her and shouts, “You can’t say it out loud! We’re trying here....” The teacher also counters G3, “But remember, you remember what we’ve been saying. It’s not the answer that’s going to impress me. What’s going to impress me the most is the way you got the answer.” After a brief flurry then of students all wanting to explain and the teacher saying to wait, G3 reflects further, quietly stating, “It has to be 1937. I’m certain.” This time, B2, sitting next to her says, “No, it isn’t.” This sequence is striking in several ways. G1 objects to G3 for announcing her answer, when B2 has announced his several times without objection. Likewise, each of the boys indicated that he has an answer, but the teacher did not counter them. G3, a black girl, is shut down by a white girl, white teacher, and white boy in succession. Given the documented marginalization of people of color internationally, this exchange warrants consideration. Might it be a case of the reproduction of patterns of marginalization and oppression that occur in the larger society? Whether it is or not, noticing it matters for teaching and can inform the development of disruptive practice.

Turning to the teacher’s engagement with student solutions, several other observations can be made. Following the explanation of G1’s approach (reducing 80 by 17, then subtracting 63 from 2000), the teacher praises her ability to figure out the calculation, when “you haven’t really learned this.” He again repeats that he is “extremely impressed” and “should almost write an article” about her solution. Then, following B1’s explanation (removing 17 from 2017, subtracting 80, then adding 17 back in), the teacher characterizes it as a “clever way”. In contrast, following G2’s explanation (conventionally subtracting 80 from 2017), he acknowledges that she did it “elegantly and nice”, but then makes the point that B1’s approach is easier and “really smart”. Given the lavish praise given to G1, the teacher’s qualified praise for G2’s work seems inconsistent, as G2 performed the “difficult calculation” and did so flawlessly. G2 began the session expressively, but with the dominance of the talk of G1 and B2, her voice remains muted for the remainder of the lesson.

The last student to present was G3. She says, “What I did was first: Nineteen... [Writes 1900.] And then I did... Plus... 20 since the King is 80 years old. Then I added 17. [Writes 1937.]” On the board, she now has, “ $1900 + 20 = 1920 + 1937$ ”. The teacher says she started with the year 1900, “But now you’re challenging me, I’m actually not entirely sure how you thought. Why did you start at 1900 and why did you add 20?” The teacher has an exchange with G3 and ends by saying he sees and that it is pretty clever, but a full explanation is not elicited, and the teacher does not offer a recapitulation to the other students as he does with each of the approaches.

These exchanges suggest societal dynamics of power and privilege that might be forming and playing out. Both boys in the class speak with authority and a sense of entitlement, without hesitancy and with an expectation that others care and will listen. One talks extensively, with limited regard for others around him and little apparent understanding of the problem or its solution. The other works independent of the group, quickly generating a correct answer and presenting his solution with conviction and little attention to audience. These ways of being are consistent with what McIntosh (1988) identifies as white male privilege — where privilege is unearned benefits resulting from societal patterns of discrimination and oppression. Dynamics of privilege are central to sexism and racism (Collins, 2018; Keith, 2017; Lipsitz, 1998) and deserve thoughtful consideration in teaching and learning.

Turning to the girls, the first also talks extensively, forcefully inserting herself into exchanges about the problem, in contrast to the second girl, who seems to retreat after a few early comments. These two ways of being in the classroom are suggestive of the overbearing woman and the deferential woman sub-stereotypes respectively (Kite, Deaux, & Haines, 2008). They exist in relation to one another within two core dimensions of gender stereotypes: agentic being more male (active, confident, competent, and independent) and communal being more female (emotional, expressive, understanding, and concerned with the welfare of others) and remain relatively consistent across age and nationality (see Kite, Deaux, and Haines, 2008 for a review). How might these dynamics of privilege and enacted stereotypes be symptomatic of larger societal patterns? How might they be creating such patterns? How do they shape these students' identities and what sort of patterns do they establish for relationships these students have with others in the future?

Also noteworthy are patterns related to racial discrimination. In the wake of the WWII, reference to race became taboo in European politics and academia (Wodak & Reisigl, 1999). Rising immigration, though, has resurfaced its visibility and prompted policies aimed at monitoring racism and advancing integration and cultural diversity. As Maeso and Araújo (2017, p. 29) argue, though, these anxieties and policies “fail to address its [racism's] embeddedness in political culture, and therefore in institutional structures and practices.” Or, as De Genova (2018, p. 1765) contends, the “migrant crisis” is an “unresolved racial crisis that derives fundamentally from the postcolonial condition of ‘Europe’ as a whole.” Norway is implicated in this history. In their analysis of the 2011 attack in Oslo, Mulinari and Neergaard (2012, p. 15) point out that Norway has parliamentary representation for culturally racist parties and that mainstream discourses, policies, and practices make this permissible, again implying that racism is alive and well in Norway and in its institutions.

Might dynamics of sexism and racism be playing out in these classroom interactions? The boys act with entitlement and are treated in kind. The girls navigate in relation to the boys. G3 is negatively critiqued and her approach devalued. It is unclear whether her solution has been understood. It is not sufficiently supported to be useful to others. How is this experience likely to shape her sense of self? What does it suggest about how these children are likely to engage across gender and race in the future? Blacks are often seen as less capable; Black women as invisible. The enactment of privilege, stereotypes, and discrimination is hard to dismiss in this session.

## **Opportunities for equitable teaching**

Next we examine teaching's possibilities for disrupting patterns of inequity and advancing healthy communities of practice. Teaching is a powerful force. It shapes learning and lives. The children's experiences shape their sense of themselves as doers of mathematics, as capable or not. It shapes their sense of their relations to others, with regard to both connection and power. How do they work together? How do they contribute their ideas, take up the ideas of others, and develop new thinking? In many ways, participation in this class is practice for participation in the world. How might teaching shape that practice and the future world? We start by observing that the potential power of teaching in this session is extensive in large part because of the choice of the problem for these students, the orchestration of the session as problem solving, and the focus on explanation. These could be used to create rich opportunities for forming identities, relationships, and ways of working

together in the world. Within teaching, though, are discretionary spaces, often filled with habitual talk and actions, unconsciously accumulated from being in the world as it is (Ball, 2018).

Teaching is a complex space, with much to consider. Our focus on disrupting patterns of inequity and advancing healthy communities led us to identify three key aspects of teaching as it plays out in this session: (i) having regard for property and its use; (ii) taking up student thinking as participatory citizenship; and (iii) orchestrating collective mathematical work. These are related in significant ways, but we distinguish them as offering different lenses on the dynamics of the work of teaching related to this session.

First is an issue of property. Who has say over what? At the start of the session, the teacher tells students to “close the book for now.” G1’s book is open and she is looking between her book and a worksheet. While talking, the teacher nonchalantly reaches down, closes her book, and slides both it and the worksheet away from her and into table space in front of him. Whose property is this? Respect for personal space and personal property are important, as are agency and skills of self-monitoring, transition, and collaboration. What message does this action send? This may seem like a small matter, but it continues throughout the lesson. For instance, to whom does the whiteboard belong? The teacher? Or is it the class’ whiteboard and a resource for collective work? Extending this to intellectual property, who has authority when it comes to student explanations? The teacher maintains extensive control over G1’s explanation. He stands at the whiteboard, creates a representation for her approach, and makes claims about her thinking. It is as if he uses her work as a medium for presenting his own thinking, in a way that might be experienced and seen as co-opting her thinking for his purposes. Who owns ideas and how do we know?

We do not mean to imply that any one of these actions is good or bad. Our point is that issues of property in classrooms are important sites of power and that without thoughtful consideration will likely be places where patterns of marginalization play out. On the flip side, they are sites for disruption. Providing a sense of property in a classroom, where respect for property is accorded, can give students, who may otherwise feel marginalized, a sense of belonging, of being valued, of having a legitimate place at the table of knowledge. While implicit and explicit messages tell girls and children of color they do not belong in mathematics, being a property owner in a mathematics classroom can create a strong counter narrative. Teaching can help this happen. Equitable mathematics teaching reflects on the multiple forms of property that exist in a mathematics classroom, ways property might be distributed, with what effect, and how to ensure respect for it.

This leads us to a second important aspect of teaching: taking up student thinking. Whether student thinking is taken up, and how it is taken up, matter. As already mentioned, the teacher dominates the presentation of G1’s work. It is then striking to watch B1 stride to the whiteboard, take the pen from the teacher’s hand, and explain his approach. With white male privilege, B1 claims the space and his ideas. He begins, “I thought like this. We remove 17 so there’s only 2000 left.” Then, midway in B1’s presentation, the teacher steps in to “repeat” what B1 said for the benefit of others. The teacher says, B1 “didn’t bother about the 17 at first,” but thought, “What if it we’re in the year 2000 now?” This differs from what B1 actually said and is likely confusing for other students. B1 began by “bothering” about the 17. He began by removing 17 to simplify the subtraction, with the

idea of compensating later. This is left implicit in B1's explanation but is consistent with what he said. Greater focus on B1's thinking, perhaps with questions to ask why he removed 17, or at least checking in with him about an interpretation, might push back on the low demand placed on his explanations as a privileged white male. It might also create for other students, more equitable access to his thinking. In contrast, for a marginalized student, focus on their thinking might serve to include them more fully and communicate value for their thinking. Either way, the work of hearing students and interpreting and treating their thinking with integrity is crucial to equitable teaching and opportunities for disrupting patterns of privilege and marginalization. Our point here is that everyone suffers from oppression, in different ways and to different extents. If teaching acquiesces to white male privilege and skips over marginalized students, it may routinely fail to provide learning opportunities — prematurely accepting explanations of white males and dismissing the explanations of others.

For the first three students who explain their approach, the teacher steps in to explain the student's thinking, often couched as necessary for other students' understanding. We suspect that this is a pedagogical impulse that many teachers feel. Teachers often feel responsible for students' understanding and know they are, as the teacher, the one who is supposed to know the content. As they struggle to understand unconventional, emergent thinking, they may feel compelled to explain each student's thinking to the other students. Unfortunately, the demands of knowing intimately what others think are great and such a teaching practice often serves to reenact dynamics of privilege for some and marginalization for others. It runs a risk of causing students to feel unheard, silenced, and invisible. And it can undermine students' opportunities to learn from and with their peers. It is also a missed opportunity in the sense that a focus on student thinking can be used to counter patterns of oppression. Honoring each student's thinking as offered, with support for its expression and its respectful, authentic reception by other students, can nurture the healthy communities of practice that can rebuild our world.

This relates to the third key aspect of teaching implicated: the nature of the collective mathematical work. Collective work is an obvious avenue for addressing identities, relationships, and future worlds. This session again suggests challenges and opportunities. The teacher starts by characterizing the task as challenging and encouraging students to "cooperate". What, though, does it mean to cooperate on this problem? What might students need to be taught about how to cooperate for this work? A minute later, as a way to encourage students to focus on thinking about the problem and not jumping quickly to an answer, the teacher says, "A good tip right now is not to trust that one sitting beside you ... only trust yourself ... think for yourself." At this point, students are working relatively independently, and this comment reinforces independent work.

As the class shifts from problem solving to presenting their approaches, the nature of the collective work changes, as does the work of teaching. To prepare productive citizens, schools need to provide students with skills and experience crucial to public engagement, even in mathematics classes. Students need to learn how to present their mathematical ideas to an audience, be aware of who has and has not had airtime, and respond substantively to other's mathematical ideas. Mathematical work has a specific form and function. Students need to learn what counts as a mathematical explanation and how mathematical claims are decided, but many of its features extend broadly to

public discourse — clear communication, attention to audience, space for others to express themselves, thoughtful listening, respect for differences, and so forth. Equitable mathematics teaching creates opportunities for collective mathematical work and accountable discourse. In addition, it supports students' contributions, making sure students are ready to contribute, instructing them on how to present, teaching others how to listen, and supporting productive response. The teaching in this session creates opportunities for collective work and public discourse, but it provides inadequate student support (e.g., not teaching students how they might cooperate), inserts itself in ways that close off opportunities (e.g., explaining students' thinking for them), and truncates exchanges in ways that undermine authentic public discourse (e.g., providing a teacher summation in lieu of responses from others and collective resolution).

Our analysis of leading a discussion of student solutions in this brief session reveals three key aspects of teaching that can serve to disrupt inequitable dynamics. Each involves nuanced work, operating in big and small ways in classrooms. Together, they provide an image of sensibilities and skills that would serve teachers well. They also suggest the depth that would be required to disrupt patterns of privilege and marginalization and avoid reproducing them.

# Learning from Lessons: A study on structure and construction of mathematics teacher knowledge – First results of case study

Judith Huget and Andrea Peter-Koop

Bielefeld University, Faculty of Mathematics, IDM, Germany; [jhuget@math.uni-bielefeld.de](mailto:jhuget@math.uni-bielefeld.de)

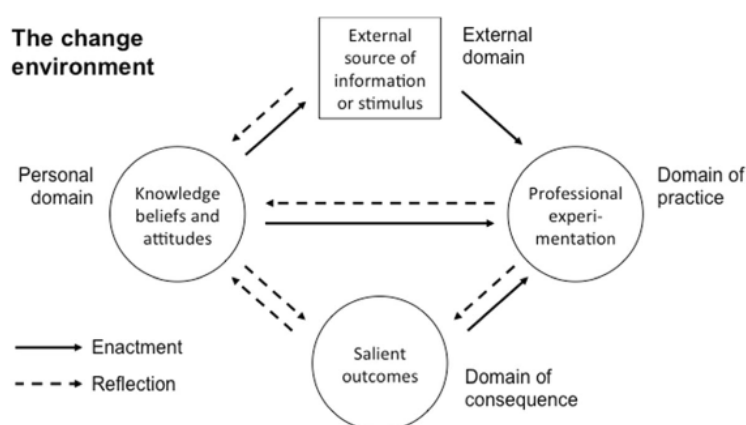

*Keywords: Teacher learning, teacher attention, teacher knowledge, mixed methods, international comparison, mathematics lessons.*

## Introduction

Teachers are not only learning professionally during their university training; their learning continues and shifts to professional development programs and their own classroom practice. Understanding the teacher learning process should therefore help improve teacher knowledge and development at all levels (Chan, Clarke, Clarke, Roche, Cao & Peter-Koop, 2018). “Learning from Lessons”, a project about studying the structure and construction of mathematics teacher knowledge, aims to “understand teacher in situ learning” (ibid, p. 91) by generating and analyzing data on the teacher’s adaptation of a pre-designed lesson, planning a follow-up lesson and comparing the collected data from three different countries. In this poster the theoretical background of the study, the research questions and the extensive international data collection will be presented and first results from the German case studies will be introduced and discussed.

## Theoretical background and following research questions

The theoretical background is based on the non-linear “interconnected model of teacher professional growth” initially developed by Clarke and Peter (1993) and elaborated on by Clarke and Hollingsworth (2002). In this model (see Fig. 1), teacher learning is determined throughout the enactment between several domains and reflection as essential mechanisms for occurrence of teacher learning.

**Figure 1: The interconnected model of teacher growth (Chan et al., 2018, 93)**

The main research questions of the international collaborative project are:

To what classroom objects, actions and events do teachers attend and with what consequence for their learning?

How is teacher selective attention influenced by

- existing teacher knowledge and beliefs?
- the lesson's content and structure?
- contextual characteristics of school and classroom?

Do teachers in different countries/cultures attend to different classroom events and consequently derive different learning benefits from teaching a lesson?

## **Data collection and analysis**

The international data collection involves both qualitative (video and audio material from lessons and interviews) as well as quantitative data (questionnaires). A codebook that allows for the consistent coding of the qualitative data from all three countries is currently being developed by the international research team. Two sub-studies are being carried out in order to address the research questions guiding the project:

*Case studies* with Grade 5, 6 and 7 teachers from Australia, China and Germany observing two teachers per Grade level and focusing on the interaction between the teacher and the lesson in sufficient detail seek to reveal the mechanisms connecting teacher attention to teacher learning. observing two teachers per grade level.

*Online surveys* in all three countries aim at recruiting at least 40 teachers per Grade level in each country seek to collect data about patterns in teacher attention and consequent learning in order to generate and test hypotheses.

Participating teachers in both sub-studies will teach lessons according to their modifications of lessons plans provided for specific topics and develop and teach a follow-up lesson as well as respond to questionnaires about their beliefs, their pedagogical and mathematical content knowledge drawn from the TEDS-M study.

# **‘Balancing’ the ‘live’ use of resources towards the introduction of the Iterative Numerical method**

Lina Kayali<sup>1</sup> and Irene Biza<sup>1</sup>

<sup>1</sup>School of Education and Lifelong Learning, University of East Anglia, United Kingdom;

[l.kayali@uea.ac.uk](mailto:l.kayali@uea.ac.uk), [i.biza@uea.ac.uk](mailto:i.biza@uea.ac.uk)

*This paper draws on the Knowledge Quartet (Rowland, Huckstep, & Thwaites, 2005) to analyse an introductory to the Iterative Numerical Method Year 13 lesson of a secondary mathematics teacher who uses a range of paper based and electronic resources including Autograph, a mathematics-education software. Data were collected during one lesson observation and a follow up interview with the teacher. Analysis identifies the different aspects of the Knowledge Quartet dimensions: foundation, transformation, connection and contingency, in relation to the introduction to the Iterative method and to the teaching of Year 13 students. Findings demonstrate how the teacher used students’ contributions as resource for his teaching; how he balanced his use of resources; and how he created connections between these resources while he remained attentive to exam requirements.*

**Keywords:** *Knowledge Quartet, foundation, transformation, connection, contingency, resource.*

## **Introduction**

For some decades, it was thought that access to more teaching resources (e.g. textbooks, mathematics-education software) meant better teaching practice (Cohen, Raudenbush, & Ball, 2003). However, “more resources do not necessarily lead to better practice” (Adler, 2000, p. 206), and priority should be given to how such resources are used (Adler, 2000; Cohen et al., 2003). This is especially important when digital resources are used as these are thought to add to the complexity of teaching (Clark-Wilson & Noss, 2015), also due to the overwhelming number of resources available online nowadays. Teachers interact with these resources, choose from them and manage them; and “these interactions play a central role in the teacher’s professional activity” (Gueudet, Buteau, Mesa, & Misfeldt, 2014, p. 141) and have great impact on students’ learning (Carrillo, 2011). Resources influence and are influenced by teachers’ professional knowledge, and a close look at the interactions between the two help identify opportunities to develop both (Rowland, 2013). The study presented here explores secondary mathematics teachers’ ways of managing and balancing the different resources that influence their work, especially when they use a range of resources including mathematics-education software (Kayali & Biza, 2017). We are interested in how teachers use the available resources in relation to their teaching aims and how they materialise and manage their lessons in the light of the available resources. To reflect on such complex teaching situations, we draw on the *Knowledge Quartet* (Rowland et al., 2005) to analyse lesson observations and post observation interviews. Here, we present analysis of an introductory to the Iterative Numerical Method Year 13 lesson observation and a follow-up interview from one participant. With this analysis, we aim to investigate the resources used by this participant and the characteristics of his work with these resources by using the Knowledge Quartet. In the following two sections we offer an overview of what we consider as resource in this paper, and of the Knowledge Quartet. Then, we present a detailed analysis of selected parts of the lesson and teacher’s reflections. We conclude the paper with a discussion on our findings.

## Resources

Resources include artefacts, teaching materials, as well as social and cultural interactions that can be used or affect a teacher's teaching and teaching preparation work (Gueudet & Trouche, 2009). An artefact is an object that is designed and used for a specific purpose (Gueudet & Trouche, 2009). It could be a mathematical technique for solving a specific problem, a mathematics-education software or a tool like a pen. Teaching materials are textbooks, calculators, and any other materials designed for teaching mathematics (Adler, 2000). Social and cultural interactions are the interactions with the environment, students and colleagues, for example a student's feedback on an activity (Gueudet & Trouche, 2009). The term "resource" can also be "the verb re-source, to source again or differently" (Adler, 2000, p. 207). This implies that teachers interact with resources, manage them and reuse them to achieve their teaching aims (Gueudet, 2017). And "the effectiveness of resources for mathematical learning lies in their use, that is, in the classroom teaching and learning context" (Adler, 2000, p. 205). In this paper, we closely examine one teacher's use and interaction with resources, in the wider range defined above, using the Knowledge Quartet lens.

## Knowledge Quartet

The Knowledge Quartet (Rowland, Huckstep, & Thwaites, 2005) was developed as a tool for analysing teachers' knowledge and beliefs. It can be used to trigger teachers', teacher educators' and researchers' reflections towards the development of mathematics teaching (Rowland, 2013). It is defined by four dimensions: *foundation*, *transformation*, *connection* and *contingency* (Rowland et al., 2005). The first dimension, foundation, represents teachers' knowledge and beliefs. This includes their knowledge about mathematics as well as about the teaching and learning of mathematics, and their beliefs about mathematics and its teaching and learning (Rowland, 2005). The codes listed under this dimension look at teachers': *adherence to textbook*; *awareness of purpose*; *concentration on procedures*; *identification of errors*; *overt subject knowledge*; *use of theoretical underpinning*; and *use of terminology*. The transformation dimension "concerns the ways that teachers make what they know accessible to learners and focuses in particular on their choice and use of representations and examples" (Thwaites, Jared, & Rowland, 2011, p. 227). Its codes cover aspects such as *choice of examples*; *choice of representation*; *demonstration*; and *use of instructional materials*. The connection dimension looks at teacher's choices in terms of their lesson plans, sequence of activities, and their connections between procedures and concepts where possible. Its codes concern teachers' *anticipation of complexity*; *decisions about sequencing*; *making connections between procedures*; *making connections between concepts*; and *recognition of conceptual appropriateness*. Finally, the contingency dimension examines how teachers respond to "unanticipated and unplanned events" (ibid, p. 227). This involves their *responses to unexpected student contributions*; *deviation from agenda*; *use of opportunities*; and *responses to the (un)availability of tools and resources* (ibid). The four dimensions of the quartet afford a focused look at the details of teachers' work in class which has great impact on students learning and achieving learning outcomes (Carrillo, 2011). In this paper we use these dimensions to investigate the characteristics of one teacher's use of resources.

## Methodology

The study is conducted in East Anglia region of the UK and looks at upper secondary mathematics teachers' work when they employ mathematics-education software along with other resources. It provides qualitative findings established on an interpretative research methodology that values the participant's views and reflections and looks for meanings within the participant's environment (Merriam & Tisdell, 2016; Stake, 2010). Here, we discuss one video-recorded lesson observation (50-minute long) and the audio-recorded follow-up interview of one participant, George, with 15 years of teaching experience mostly in upper secondary education. George was teaching a mixed gender group of Year 13 students (17-18 years old), who were preparing for their school leaving examination. The lesson was on *Numerical Methods*. George started the lesson by introducing the chapter "Numerical Methods" from Wiseman and Searle (2005, pp. 118-135) including four methods: Change of Sign method, Iterative method, Mid-ordinate rule, and Simpson's rule by justifying why teaching this chapter is important. Then, he briefly introduced the four methods, and started explaining the Iterative method in detail using Autograph (a dynamic environment with visualising graphs affordances, see <http://www.autograph-maths.com>). George then showed his students some past exam questions about the Iterative method and went over their mark schemes. Finally, he asked his students to solve some textbook questions of his choice in the remaining time of the lesson. Later, George was interviewed (by the first author), and he reflected on his teaching of Iterative method and especially on points the first analysis had identified, such as his choices of resources and actions in the lesson (e.g. his aims, justification of his choices). An analysis of George's actions during the lesson and his responses in the interview was performed using the Knowledge Quartet. In the next section, we offer a detailed account of selected parts of the lesson observation, where his work with resources in the class was more visible through his communication with students, and relevant parts from the interview. These parts regard the introduction to Numerical methods and the demonstration of the Iterative method to the students also with the use of Autograph.

## Introducing the Iterative method- A look through the Knowledge Quartet lens

### Introducing "Numerical methods"

In his introduction to the chapter of "Numerical Methods" and its four methods: Change of Sign method, Iterative method, Mid-ordinate rule, and Simpson's rule; George justified its importance:

The whole chapter is about things that you can't solve by doing the algebra to them, or just by integrating them, okay. And, it turns out that there are way more functions and things that you can't solve algebraically than there are ones that you can, ok. There are loads of horrible things to integrate that are too difficult to integrate, that it's just easier to do a numerical thing and kind of approximately, a bit like a trapezium rule

George reminded the students that they saw trapezium rule and Simpson's rule in a previous lesson. He explained that Simpson's rule and the mid-ordinate rule were about finding the area and extension of the trapezium rule, while the change of sign method and the Iterative method were about solving equations. Then, he briefly introduced the four methods, and mentioned that he was going to focus on the "Iterative method" and when this lesson's methods are good to use. This introduction reflected George's *awareness of purpose* and how he was addressing *connections* (e.g. numerical methods and

trapezium rule). He tried to *connect concepts/procedures*, for example, to connect Simpson's rule and integration used in previous lessons to the methods he was planning to teach in this lesson.

### Rearranging an equation – Why $x^2 + 4x + 1 = 0$ ?

After the introduction to the chapter, George started explaining the method, he mentioned that he needed to use an equation that cannot be factorised but can be solved using the quadratic formula. He spontaneously chose the quadratic equation  $x^2 + 4x + 1 = 0$ , and asked his students to suggest rearrangements of the equation to the form  $x = \dots$  (e.g.  $x = \frac{-x^2}{4} - \frac{1}{4}$ ). After that, he asked them to find the equation roots using what they previously learned on how to solve quadratic equations or using calculators. Students used calculators and gave the approximate answers “-0.267” & “-3.732”. George was spontaneous in his *choice of example*. He chose a quadratic equation with the aim that students would be able to solve it with the formula but not with factorisation; which would show them that the Iterative method worked. His choice was based on *awareness of purpose* which is to show the students that the Iterative method gives them a good approximation of the solutions. George also tried to *connect procedures* when he asked his students to create different rearrangements of the equation. Later, after finding the different rearrangements, George again tried to create a *connection* between the equation's solutions students found on their calculators and the Iterative method would “zoom in on the answers”. He was always *responding to students' ideas*, commenting on when two rearrangements were the same and just written differently and on when a student completed the square instead of rearranging the equation. George was *demonstrating* about iteration to students while at the same time inviting them to contribute. These contributions were essential parts in the flow of his lesson, for example, when students suggested the rearrangements and calculated the quadratic solutions. We consider these *students' contributions* as a *resource* (Adler, 2000; Gueudet, 2017) that George triggered and used during the lesson, along with other resources.

### The use of Autograph

After working with the students on finding the equation's different rearrangements and solutions, George's next step was to use Autograph (*instructional material*) in order to further explain about the Iterative method and show how the different rearrangements would work. He used Autograph to graph the functions  $y = x$  and  $y =$  the other side of the rearrangement (e.g. for  $x = \frac{-x^2}{4} - \frac{1}{4}$  he graphed  $y = x$  and  $y = \frac{-x^2}{4} - \frac{1}{4}$ ). The first rearrangement he graphed on Autograph (Figure 1) was  $x = \sqrt{-4x - 1}$  and it did not “work” as George said while pointing at the graphs on Autograph:

Now, I can see that the blue one [ $x = \sqrt{-4x - 1}$ ] does not quite, I think it almost touches, but not quite touches the red one [ $y = x$ ], okay. So, they in fact don't cross. So, for that particular rearrangement sadly it's not going to work out. So, let's not do that one, let's pick a different one. Which one do you want?

We noticed here one *contingency* incident (*use of opportunity*: (un)anticipated outcome on the software) that happened when George entered the equations from one rearrangement on Autograph and noticed that the graphs of these equations did not cross, in this case he commented that some rearrangements did not work and asked the students to pick a different one. Again, a student's contribution here is a *resource* that George used to demonstrate ideas. In this case, one student picked

$x = \frac{-1}{x+4}$ . George graphed  $y = x$  and  $y = \frac{-1}{x+4}$  on Autograph (Figure 2 left) and commented that the two graphs crossed this time at two points. Having noted that the two points are close to  $x = -0.2$  and  $x = -3$ , George explained that the Iterative method is based on replacing the  $x$  in the denominator of this rearrangement by  $x_n$  and replacing the isolated  $x$  by  $x_{n+1}$ . Thus, he suggested the formula  $x_{n+1} = \frac{-1}{x_n+4}$  to be used to complete a table with a starting value  $x_0 = 1$ . This shows how George *used different representations* such as tables and graphs; and tried to create *connections between procedures* and also *between different resources* (student's contribution + Autograph).

**Figure 1:  $y = x$  and  $y = \sqrt{-4x - 1}$  on Autograph**

**Figure 2: George's work on the rearrangement  $y = x$  and  $y = \frac{-1}{x+4}$  on Autograph**

After showing the Iterative method procedure on the board, George decided to show how the Iterative method works on the graph by using Autograph (Figure 2 right):

Look at this you started with number 1, okay. The number 1 went, which way did it go? It's gone down to the curve, across to the line and that was our 0.2 [sic]. And then, here look at that down to the curve across the line, down to the curve if I zoom in further oh missed it. Down to the curve and across to the line. Zooming in further, look at that! And we could keep on going down to the curve, across to the line zoom in zoom in zoom in there. It is, look at that, and the thing if I zoom out again looks like a staircase kind of. So, this is staircase diagram.

This use of Autograph showed teacher's *knowledge about the software* affordances and its use. It also showed an attempt to *connect different representations* (staircase diagram + formula). George then used  $x_{n+1} = \frac{-1}{x_n+4}$  with different starting points for  $x_n$  on Autograph. When he used  $x_0 = 10$  as a starting point, the software returned "overflow", namely no convergence, and he changed the point to  $x_0 = -10$  without commenting on the outcome. He did not *use this opportunity* to explain what that meant during the lesson. One student asked what would happen if  $x_n + 4 = 0$  in  $x_{n+1} = \frac{-1}{x_n+4}$ . At that point George used the graph on Autograph to show that this would not work, as he commented:

You know like when you know your tan graph at 90 degrees, that 90 degrees on a tan graph is effectively saying we've got an infinitely tall triangle which wouldn't be a triangle at all, because it would be at 90 degrees. You're talking two parallel lines that's why tan of 90 doesn't work.

This is a *contingency* moment (*responding to students' ideas*) where George used Autograph as *instructional material* and *connected concepts* students had met previously (dividing by zero, tan of 90 degrees, parallel lines, asymptotes of the graph of the tangent line) to respond to student questions.

### How to zoom on to a specific root?

Afterwards, George worked on different formula rearrangements and different starting points to show how some rearrangements “work” (when the two functions cross at two points) and some do not (when the two functions do not cross). He also wanted to show how a rearrangement that “works” can lead to one root or to different roots of the equation, when different starting values ( $x_0$ ) are used. But, until this point, his work on different rearrangements with different starting points was leading to the same root. This made the students question how they could zoom to a specific root and how they could tell if they were going to zoom in on a certain root in the exam. George said “I don’t know the answer to this” but he promised to comment on this question later during the lesson (not deviating from the *lesson's agenda*). He returned to this point later when he invited students to practice on past-exam questions by saying that exam questions would provide both rearrangement and initial point. His response reflected his attention to *exam requirements* and their importance to his teaching. After that conversation about how to zoom to specific roots, a student suggested the use of calculators to do the Iterative method. The teacher approved the student’s use and method of use of calculators by commenting that it was a “really quick way”. This is an example of him *responding to the availability of resources* (student’s contribution + calculator). The use of calculators facilitated the zooming in on the other root, as this way was quicker students tried different starting points and found out that  $x=3$  would lead to the second root (-3.732). George used  $x=3$  on Autograph and showed the students how this number worked for the purpose of zooming in on to the other root. This is an example of *connections between resources* (student contribution +calculator +Autograph+ staircase diagram).

### George’s reflections

In the interview, George was invited to reflect on three aspects. First, about his spontaneous choice of equation, he said he preferred working “live” in the class over showing the students “a specific and special example”. He added that he was happy to work slowly with different examples to show that not all examples work. George’s spontaneous choice of equation reflected his confidence to *deviate from his agenda* which could create more contingent moments during the lesson. His purpose was to “show” the students that not all rearrangements “work out”. Second, about what the “overflow” means on Autograph, he said it indicated that the Iterative method “instead of converging, it will diverge” at that point. During the lesson, George did not *use the opportunity* to explain the meaning of this outcome to the students. His focus was on getting a number and comparing this number to one of the equation roots students had found. Third, he was asked about the use of calculators. He said:

That’s what they need to do in the exam. So, the Autograph is just to explain, show, demonstrate it in a lesson. When they then move onto the calculators, that’s them saying yeah they are happy with it, they understand it, and this is what they then need to do. This is how they do it in the exam.

George’s comment on the use of calculators reflected again his considerations of *exam requirements* while at the same time his attention to *connections between resources*.

## Discussion and conclusion

In this study we are interested in how teachers, in our case George, use the available resources in relation to their teaching aims and how they materialise and manage their lessons in the light of the available resources and we used the Knowledge Quartet lens to analyse teacher actions and justification of these actions. In our analysis, we noticed aspects of George's foundation knowledge including his awareness of purpose, use of terminology, identifying errors, concentration on procedures, his subject knowledge as well as his knowledge about the mathematics-education software (Autograph here) and exam requirements. When a student asked him a question he could not answer, he responded that students were not required to know the answer for the exam, so he could not answer the question because it was "beyond exam requirement". This indicates how important the exam requirements are in his teaching priorities. In his transformation of ideas, he was spontaneous in his choice of "live" examples and representations, and he seemed confident in these spontaneous choices. His use of instructional materials included the use of Autograph, textbook, past-exam papers and calculators. He used the textbook as source of exercises for classroom practice. He also asked for students' contributions and used these contributions as an essential resource in the flow of his teaching also in connection to other resources and instructional materials including Autograph. For him, students' contributions were predictable, as they were within a range of possible answers (like choosing one rearrangement of equation). He made decisions about sequencing the different parts of the lesson and frequently connected concepts and procedures. He was responding to students' ideas and sometimes using these as opportunities to create connections between concepts. In terms of contingency, George was responding to students' ideas and to the availability of tools and resources, and sometimes deviated slightly from his lesson's agenda without losing his overall aim. We distinguish the students' ideas under the contingency dimension from the students' contributions under the transformation dimension, as these are unpredictable students' ideas that George did not directly invite. While students' contributions are a deliberate result of George questioning students and engaging them in his demonstration of mathematical ideas, thus, we see them as a characteristic part of his teaching. As we consider students' contributions as resources used frequently by George, we suggest an extension of the code "*use of instructional materials*" that includes the use of resources. We recommend the code to be rephrased to "*use of resources*" to involve both instructional materials and students' contributions under the transformation dimension. We also saw George connecting between different resources he used (e.g. Autograph, textbook and student contributions). We recommend the code "*connection between resources*" to be added to the connections dimension. These suggestions are established on the episode included in this paper as well as other episodes with George. Overall, our standpoint is that the use of resources is intertwined with teachers' aims and actions (Gueudet & Trouche, 2009). The analysis of George's lessons, as well as of other lessons in this study, indicate that this use is a 'balancing' act on resources that become 'live' in their lessons. These resources go beyond textbooks or other digital (or not) materials and include students' contributions as well, which teachers use, balance and connect in their work.

# The King's birthday, potentials for developing mathematics teaching

Bodil Kleve<sup>1</sup>, Ida Heiberg Solem<sup>1</sup> and Gerd Ånestad<sup>1</sup>

<sup>1</sup>OsloMet – Oslo Metropolitan University, Norway; [bodil.kleve@oslomet.no](mailto:bodil.kleve@oslomet.no)

*In this paper, we have analysed a video in which a small group of students were asked to find out when the Norwegian King was born given his 80 years of age today on his birthday Feb 21<sup>st</sup> 2017. We have identified potentials for initiating shifts in discourse in which children's ways of solving a problem could become an explicit object of reflection. We suggest that revoicing as a talk move to encourage collective reflection, did not work as suggested in the research literature. Additionally, working on a number line could have been a joint activity of making what was previously done in action, to an object of reflection.*

*Keywords: Reflective discourse, collective reflection, empty number line, revoicing.*

## Background and context

The lesson, from which this episode is taken, is part of a Norwegian national project, which investigates if decreased student/teacher ratio is beneficial for students' learning. In the project, one dedicated teacher takes a group of students, typically 4–6 into a separate classroom to teach specific subjects and methods. The teacher is by the researchers in this project, acknowledged as a “skilled teacher” with more than twenty years teaching experience. According to the research team, the episode investigated here, is a typical example of this teacher's teaching practice.

Five year-four children (two boys and three girls) were seated around a table, and the teacher was standing up front by the flip over. The episode lasted for about twenty minutes. The teacher presented a task (problem) that the children were asked to solve:

I am going to give you a task now, [ ]. You will get a sheet on which you may draw. Just close your books for now. The task is to find out when the [Norwegian] King was born. He is 80 years today, so you shall try to find out in what year he was born. [ ] The year is 2017, and 80 years backwards.

After having presented the problem, the teacher said they were allowed to collaborate. He emphasized that the task “is quite challenging” and that he would give them some time to solve the problem. One of the children, a girl, here called Tove, addressed the teacher and the other children several times throughout the whole episode. As a response to her, the teacher said: “I will give you a tip, not to trust anybody else, but only to think for yourself and trust yourself”.

When having started working on the task, the children both aloud and inaudible, suggested solutions. However, the teacher interfered after about 2 minutes saying: “*remember what we have been saying, it is not the answer that is going to impress me. It is the way you have got the answer, that will impress me the most*”. He thus emphasized the process rather than the product. The children continuously volunteered to come up with an answer. However, the teacher told them to wait yet another minute.

We watched the video clip several times. Focusing on the rehearsal of students' proposed solutions of the problem, we noticed that the teacher frequently revoiced students' explanations and made

claims about their thinking: “So you have been thinking like this,...”, was a repetitive comment from the teacher on students’ proposed solutions.

Against this backdrop, we address the role of classroom discourse in examining potentials for supporting mathematical sense making within a group of children. We draw on the concepts of *reflective discourse* and *collective reflection* (Cobb, Boufi, McClain, & Whitenack, 1997) in searching for potentials for development of possibilities for mathematical learning in this episode (Cobb, Stephan, McClain, & Gravemeijer, 2011).

## **Theoretical and methodological perspectives**

### **Reflective discourse and collective reflection**

Cobb et al. (1997) focused on classroom discourse, which appeared to support the development of students’ conceptual activity. In this work, they considered students’ conceptual activity as a source of mathematical ways of knowing, and meaningful mathematical activity as creation and manipulation of mathematical objects. They introduced the term “reflective discourse which is characterized by repeated shifts such that what the students and teacher do in action subsequently becomes an explicit object of discussion” (Cobb et al., 1997, p.1). They emphasized the teacher’s role, because the teacher is in the position to judge the significance of the children’s mathematical activity, and thus initiate shifts in discourse. One such shift may occur in further probing children for more ways of solving a task. Another shift occurs when the children’s different solutions of a mathematical problem may emerge as an explicit object of discourse. This activity involves comparing different solutions and a discussion of how they may relate to each other together with a corresponding reflection. This reflection does not occur simultaneously for all children since all participate in a common discourse, but it occurs as a collective reflection. Pragmatically, analysis of “reflective discourse” can clarify how teachers may support students’ mathematical development and potentials for such, and the term “collective reflection” refers to the joint activity of establishing what was previously done in action, as an object of reflection. Students’ participation in the discourse “collective reflection” may constitute conditions for possibilities of learning (Cobb et al., 1997; Cobb et al., 2011). The role of students is crucial in these activities. If no child is able to respond to the teacher’s initiation of shift in discourse, no shift will occur. The individual child’s reflective activity may contribute to developing a discourse with potential for mathematical sense making.

Cobb et al. (1997) argue that the teacher must initiate shifts in discourse so what the children have done in action, becomes an explicit object of reflection. In our data, the activity was solving a problem and proposing solutions. Our research problem was to investigate how students’ access to mathematics was supported, and to identify potentials for initiating shifts in discourse where children’s ways of solving the problem could become an explicit object of reflection and a collective reflection could take place.

### **The issue of revoicing**

Chapin, O’Connor, & Anderson (2013) presented four suggestions for using whole-class discussions in problem solving: to understand the problem; to explain one solution method, to extend students’ knowledge and to compare solution methods. We consider the latter crucial with regard to collective reflection in our study. In order to encourage whole-class discussions, Chapin et al. (2013) suggested

talk moves which may help individual students clarify and share their thoughts: wait time; turn and talk; stop and jot; will you share that with the class and revoicing (so you are saying....). They suggested revoicing as a talk move if it seemed as if what the student was trying to say made things more confusing if the student carried on. As a goal for the teacher is to improve all students' mathematical thinking, the teacher cannot give up on an unclear explanation from one student. Revoicing was also suggested if a student says something insightful, which might move the class or group forward. Revoicing what a student is saying, will give that student a chance to clarify and the other students a chance to hear it again, may be in a clearer version. We wanted to further investigate revoicing as a talk move, and we discuss how a group discussion on comparing solution methods could become a discourse of collective reflection.

Kazemi and Hintz (2014) build on the talk moves of Chapin et al. (2013) and emphasise revoicing as “repeat some or all of what the student has said, then ask the student to respond and verify whether or not the revoicing is correct. Revoicing can be used to clarify, amplify, or highlight an idea” (p. 21).

Since the mathematical activity involved multidigit subtraction, using both standard algorithm and mental strategies, we have also drawn on Plunkett (1979) as well as on theories about the use of empty number line (Beishuizen, 2003; Gravemeijer, Bruin-Muurling, Kraemer, & Van Stiphout, 2016).

In addressing our research problem, we posed the following research questions: (i) What potentials for facilitating productive mathematical discussions did we see? (ii) How did revoicing as a talk move influence the group's discourse in supporting students' access to mathematics?

### **Presentation of the episode and analysis**

The purpose of our analysis was to identify potentials for development of reflective discourse and collective reflection. We discuss four students' presentations in light of the frameworks presented above. The teacher frequently revoiced students' explanations and thoughts. In the literature (Chapin et al., 2013; Kazemi & Hintz, 2014), revoicing is suggested as a talk move to encourage whole-class discussions in order to extend students' knowledge and to compare solution methods. We have analysed the part of the episode in which the students presented their solutions.

Tove was the first student (after eagerly volunteering) who was asked by the teacher: “Can you tell us about the way to figure out the answer?”

- Tove: I started with seventeen minus eighty. I removed seventeen from eighty so I could figure out what to remove from 2000
- Teacher: What answer did you get when you removed 17 from 80?
- Tove: I got 63
- Teacher: What do you want with 63? What are you going to do with these 63?
- Tove: I will remove 63 from 2000 to find the answer.

At this point, the teacher intervened Tove's explanation, while he was drawing on the board:

**Figure 1: Teacher's drawing to illustrate Tove's thinking**

Teacher: Right. Look at this. Tove, look at this. We are here in 2017, and now we are traveling 80 years back in time. She started by thinking... First, she wanted to go to the year 2000, and then go from 2000 to the year the King was born. Right? Therefore, you started with 80 minus 17, and got 63. She removed 17 from 80. Then you got 63. Then she wanted to find what 2000, from here, and jumping 63 years backwards from year 2000. That is how she thought. You tried to do 2000 minus 63, but this is a really difficult equation. Because... You have not really learned this, with such large numbers. Did you manage to finish it, too?

Alternating between addressing Tove directly and as a third person, the teacher made claims about her thinking in saying “She started by thinking...,” and “That’s how she thought”. He revoiced her explanation, probably in order to clarify for the group. He underpinned and highlighted with an illustration (figure 1). The empty number line which he drew, indicated a linear or sequential way of thinking (Beishuizen, 2003). However, studying the continuation of Tove’s explanation, there was a move away from a linear thinking towards the use of the standard algorithm, as the teacher also did:

Teacher: So you tried to do 2000 minus 63, but this is a really difficult equation

Tove: Yeah. I removed a thousand and exchanged it for 10 hundreds, and then I exchanged a hundred for tens, and a ten for ones. (Removed 3 from 7. 3 from 10. Yeah, 3 from 10. Then I had 7 left, so I removed... Umm... 9... Umm, 6... [ ] 9 minus 6. Then I had 3. But I still didn’t have any to be removed here, and I didn’t have 10 here, since I removed one. So I have 9 here. Then I removed one thousand, so I have one left.

While sitting, Tove explained orally how she had subtracted 63 from 2000 through the use of standard algorithm for subtraction. She was not only referring to digits, but to “ones”, “tens”, “hundreds” and “thousands”. Again, the teacher intervened:

Teacher: I must say that I am extremely impressed. You managed to figure out by yourself without having learned it before. I still want to show her way first, then you can explain afterwards. I just want to show her way of thought.

At this point, the teacher had left his earlier sequential thinking and use of empty number line. He revoiced what Tove had explained (orally), claimed her thoughts (I just want to show her way of thought) and used the flip over to explain and show the standard algorithm in detail.

The teacher monitored the conversation, and there was no communication between the students. The other four students in the group were not invited to participate. Instead of asking if there were questions or comments to Tove’s explanation, he “wanted to show her way of thought”, without

knowing if there was a need for that. As an alternative initiation of the whole-class discussion, (Kleve & Solem, 2014), the other students could have been invited to ask clarifying questions (Chapin, et al., 2013). Although having emphasized that it was not the answer as such, that was going to impress him, he neither challenged Tove's thinking, nor encouraged students to ask clarifying questions.

After having spent some time on Tove's way of solving the problem, three more students were invited to present their strategies. Lars, Vera and Kari. The teacher had obviously noticed that Lars had written down the right answer without any written calculations very quickly. Inviting Lars to explain he said: "I am eager to know how you have been thinking to get the answer, how did you think?" This initiated a shift discussed by Cobb et al. (1997). Lars responded to the invitation and walked up front.

Lars: I thought like this. We remove 17 so there's only 2000 left (writing 2000 on the flip over).

T: Yeah.

Lars: Then do minus 80 (writing 80 underneath).

T: Ah, you thought like that!

Lars: Afterwards we get 1920. That is simple...

Teacher: Can you write 1920, so we have it written down? I just want to repeat what you did so the others will understand what you meant. If you can move aside for a bit. What I understood is that you did not bother about the 17 at first. You just went straight back, and thought that: "What if we are in the year 2000 now?" If we then move 80 years backwards, we will land on 1920. Now I am eager to know, what did you do next?

Lars: I added 17, which is simple. Just 20 plus 17.

Teacher: Fantastic!

Lars: And that is... Nineteen...

Teacher: 1920 plus 17. Then you got? Nineteen?

Lars: Thirty...Thirty-seven.

Teacher: Did anyone understand this clever way?

As an answer to the teacher's question, a fifth student, said:

Per: Yeah. When he wrote 1920, I thought it looked like... I thought it looked good, in a way. Seemed like a good way to think.

Per's comment indicated an individual reflective activity, which was not followed up.

**Figure 2: Lars' presentation and our illustration of it with an empty number line**

Again, the teacher's use of revoicing and making claims about a student's thinking became evident. In this case, the teacher intervened, saying, "I just want to repeat what you did so the others will understand what you meant". A reason for revoicing might have been that the teacher found Lars' presentation being "clever". According to Chapin et al. (2013), revoicing is recommended when a student says something insightful, because there may be a potential then to move the class forward.

At this point we see another possibility for moving the class forward through a potential shift in discourse. Comparing Tove's and Lars' solutions and making that into an object of reflection could have created conditions for possibilities of learning (Cobb et al., 1997). What were the similarities between the two ways of solving the problem? How did Tove's solution differ from that of Lars'?

Following and contrasting this, Vera now volunteered to present saying: "I actually did not really do it that complicated". Hence, a comparison of methods was initiated by a student, and a potential shift in discourse was identified. Vera went to the board and subtracted 80 from 2017, using the standard algorithm. The teacher praised Vera's method and compared it to that of Lars:

You actually chose to use the algorithm in subtracting from 2017. It demands good knowledge to set that up. You worked it out elegantly and nicely and got the correct answer. However, his [Lars'] way of doing it was a method that is easy to use in mental calculation. [To Lars]: Really smart, that is why you spent so little time.

Here the teacher emphasized why a mental strategy may be smart compared to the use of the standard algorithm (Plunkett, 1979). The teacher elaborated the shift in discourse, initiated by Vera, further. He referred to mental calculation and speed, and a potential occurred to move the class forward. However, a discussion, which could have involved a collective reflection on the differences, did not take place. In figure 2, we have illustrated Lars' mental strategy, his sequential way of thinking, on a number line. Such an illustration could have been useful in comparing the two methods (Beishuizen, 2003; Gravemeijer et al., 2016).

The last student to present was Kari. She was invited to present her solution on the flip over:

Kari: First I did: Nineteen... [Writes 1900]. And then I did... Plus... 20 since the King is 80 years old. Then I added 17. [Writes 1937]

**Figure 3: Kari's presentation and our illustration of it with an empty number line**

- Teacher: Right. You started with the year 1900. Now you are challenging me, I am actually not entirely sure how you have been thinking. Why did you start at 1900 and why did you add 20?
- Kari: It is since the King became 80 years old,...
- Student: [Whispers] 8 and 2 are “ten-buddies”
- Kari: and 8 and 2 are “ten-buddies” so then I added 20.
- Teacher: Ah, I see, because you knew that there are 80 years between 1920 and 2000?
- Kari: Yeah
- Teacher: I see! So you started here and tried to come up to the year where you had 80 years from there, up to the year in which we are now? I have to say, that is pretty smart.

The teacher seemed to have a different approach to Kari’s presentation than to the others. Kari had used a mental strategy, which for the teacher seemed “difficult to catch” (Plunkett, 1979, p. 3). In response, he asked clarifying questions rather than revoicing Kari’s presentation. Although a student “rescued” Kari in answering why she added 20 (“ten-buddies”), the teacher neither utilized it as a potential to involve the other students in further discussion nor to ask clarifying questions.

## Discussion

### Potentials for facilitating productive mathematical discussions

In the episode there were shifts in discourse, for example when the teacher was further probing for more ways of solving the task. However, these shifts were not followed up by a collective reflection. Potentials for other shifts in the discourse, which could lead to collective reflection, have been identified. We pointed out a possible shift in discourse in suggesting to compare Tove’s and Lars’ solutions and make that an object of reflection. Per’s comment on Lars’ way of solving the problem indicated an individual reflective activity, which was a potential for collective reflection. In her presentation, Vera initiated a shift in discourse. The teacher followed this up in comparing Vera’s use of the standard algorithm with Lars’ informal strategy, which he valued. Here the students could have been invited to participate in a collective reflection on the methods, which would have created possibilities for learning. With regard to Kari’s use of informal strategies, the teacher was challenged, and did not utilize the other students’ help (“ten-buddies”) for a further discussion.

Tove and Vera used standard algorithm for subtraction while Lars and Kari displayed a sequential way of thinking. Although the teacher started by representing Tove’s explanation with an empty number line, sequential thinking, he left it, preferring Tove’s use of the standard algorithm. He never went back to the number line when Lars and Kari both demonstrated a sequential way of thinking. We have illustrated Lars’ and Kari’s ways of thinking on empty number lines, figure 2 and figure 3.

Mental strategies, as Lars and Kari used, are difficult to explain (Plunkett, 1979). Representations are useful in making mathematics accessible for students, for sharing different strategies and ideas, hence facilitating productive mathematical discussions (Duval, 2006). Working on a number line (see figure 2 and figure 3) could have been a joint activity of making what was previously done in action to an

object of reflection and thus create conditions for possibilities of learning (Cobb et al., 1997). This could serve as a tool for Vera, who found Lars' method complicated, to see connections (similarities and differences) between the different strategies.

### **“Revoicing” or revoicing: A pitfall or potential for developing productive mathematical discussions?**

In the analysis above, we have pointed out instances where the teacher revoiced students' contributions, but in a way that students were not encouraged to respond or contribute and take part in a discussion. Rather, the revoicing discussed in our analysis served as an interruption. When Per commented on Lars' method, he was not encouraged to explain further. Contrary to what is recommended in the research literature, revoicing as a talk move was neither used to clarify or amplify ideas, nor to extend students' knowledge and compare strategies. Our findings suggest that, instead of being a mean for shift into a reflective discourse, “revoicing” became a pitfall for developing a productive mathematical discussion.

*A learning trajectory constitutes a hypothesis and a description of students' thinking related to learning a mathematical notion. The study reported here, employing a multiple case study approach, investigates the use of learning trajectories in the teaching of fractions by three 5<sup>th</sup> grade Greek primary school teachers. Particularly, the research problem pursued concerns the teachers' meaning making and use of the concept of learning trajectories introduced by a recent Mathematics Curriculum reform. The results of analyzing the teachers' answers to two semi-structured interviews and the transcripts of a non-participant observation of their lessons show that learning trajectories were understood as means of planning teaching and used as 'maps' of navigating classroom instruction, predominately successful when students' previous knowledge and thinking, and not just their difficulties, are taken into consideration.*

*Keywords: Learning trajectories, fractions, mathematics education, teaching mathematics.*

### Learning trajectories in mathematics education

Learning trajectories consist of three parts: the goal, the developmental path and a sequence of appropriate tasks that correspond to each level of thought and help the child proceed to the next level. There is also a relationship between developmental progress and the activities selected (Clements & Sarama, 2009). The “big ideas” of mathematics, i.e., sets of ideas and skills that are coherent and are central to mathematics, are the objectives (Kuntze et al., 2011). Developmental paths refer to the levels of thinking, each of which is more sophisticated than the previous one and leads to the achievement of the mathematical objective (Clements & Sarama, 2009). Notwithstanding the distinct levels, it is not to be assumed that the track is linear or specified. Various factors, such as differences between formal and informal learning, affect the development of a learning trajectory (IEP, 2014). Finally, the sequence of the tasks is a set of work corresponding to each level of thinking, supporting the learning of mathematical ideas and skills belonging to each stage and including solving, investigating, experimenting and communicating in the context of the student's activity.

Learning trajectories are promising tools that can help in curriculum development, mathematics teaching and assessment. A substantial use of learning trajectories can bring about several reversals in the expected developmental paths of students and in the expected research findings as it opens new routes in learning. Moreover, it seems to give new possibilities both for the design and the implementation of the curriculum as well as for teaching due to the detailed theoretical basis it can offer (Clements & Sarama, 2009). There are two studies worth mentioning that make use of the notion of learning trajectory. The first is part of a wider research program emphasizing the development of formative assessment tools for the trajectory of fractions (Confrey & Maloney, 2010). The results of the study reveal that a coherent trajectory leads to its redesigning,

distinguishing between the levels of thought on the one hand and the parameters of the tasks on the other, clarifying the non-linearity of the procedure. The second study concerns the work of Steffe (2004), who has been extensively involved with students' learning and knowledge of fractional numbers. According to the findings of this study, a trajectory allows teachers to understand how students construct mathematical concepts in order to influence the evolution of notions and processes so that, through productive teaching, productive learning is supported.

The study aims to explore the understanding and the use of the notion of learning trajectories by three primary teachers teaching fractions in the 5th grade, where this mathematical notion holds a central position in the respective curriculum, concluding their 'fractional' thinking at the threshold to secondary education and to being introduced to the set of rational numbers in a mainly formal way.

### **Fractions in school mathematics: Students' difficulties**

Understanding fractions is crucial for pupils' mathematical thinking because of its significance in becoming numerate citizens; also for its relation to learning related fundamental mathematical notions like proportion and percentage or developing powerful mathematical modes of thinking like algebra. In the current discussion in mathematics education the focus is on educating pupils as numerate future citizens, i.e., citizens who can operate successfully in the modern society by understanding and handling quantitative data that they encounter in everyday life. Being competent in dealing with the notion of rational numbers constitutes a basic prerequisite. During schooling, many hours are devoted to teaching fractions, but the difficulties and misconceptions of students identified as early as in the 1970's persist, fueling substantial research activity on children's understanding of fractions and on developing new teaching tools and approaches to the subject matter. The numerous studies on fractions tended to initially focus their interest on the way students learn but also on the difficulties they meet. Subsequently, research interest shifted to teaching fractions with emphasis on the conceptual or the procedural mode of the relevant knowledge pursued and on how students responded to these two modes of knowing and thinking. Finally, attention was drawn to the teachers' role and teaching practices (Van Dooren, Lehtinen & Verschaffel, 2015).

The main students' difficulties identified in the relevant studies arise from the different nature of fractions compared to natural numbers. Rational numbers indicate the relation between two quantities, whereas natural numbers refer to one quantity. Also, rational numbers are dense because of continuity and infiniteness, while natural numbers are distinct. Unlike natural numbers, where each number is represented in a unique way, rational numbers can be denoted by fractions, decimals and percentages or even by a set of equivalent fractions. Furthermore, operations may differ in the two sets of numbers. For example, the result of division and multiplication of fractions is not less or bigger than the original number respectively, when the divisor or the multiplier is less than 1, as happens with natural numbers.

Apart from students' difficulties arising from the close connection of rational numbers and thus of fractions with natural numbers, difficulties with fractions have been found to also be related to the abstract nature of the processes involved in operating with fractions as well as to the erroneous

application of the related rules. Finally, teachers' inadequate knowledge of fractions and poor teaching practices as well as cultural issues have been identified to contribute to students' learning of this important mathematical notion.

## **The study**

The reported study focuses on: (a) teachers' meaning making of the learning trajectories in general; (b) teachers' understanding and use of the notion of learning trajectories in teaching highly demanding mathematical learning contexts: fractions in the 5th grade. The method adopted is a 'multiple case study' of three female teachers working in an experimental primary school in an urban area of northern Greece.

The three teachers have had almost the same years of teaching experience but different scientific and professional profiles. Teacher A is a graduate of both a primary education and a mathematics department, with 17 years of teaching experience; teacher B, a graduate of a primary education department, holds a postgraduate diploma and a PhD and has 14 years of teaching experience. Finally, teacher C is a graduate of a two-year course with 16 years of teaching experience. Teachers A and C participated actively in the piloting of a new mathematics curriculum which promoted active learning and approaches like 'learning trajectories' that support this type of learning, while teacher B did not. The research tools employed were a semi-structured interview (one initial and one at the end of the study) and a series of non-participant observations of their mathematics instruction. The non-participant observation was used to provide information for the final interview and to offer a further source of data thus enhancing the credibility of the study.

The first semi-structured interview, consisting of two parts, served the first research question. The questions in the first part explored teachers' understandings of conceptual aspects of the construction of learning trajectory in mathematics and how its use influences the choice of the mathematical content. The questions in the second part were related to the teaching and learning benefits of exploiting learning trajectories in the mathematics classroom (in the context of the new mathematics curriculum).

For the second research question, a second semi-structured interview was conducted, which also consisted of two parts. The questions in the first part were common to all three teachers: on planning, implementing and reflecting on teaching fractions based on the notion of learning trajectory. In the second part of the interview, based on extracts from each teacher's instruction identified in the observations, the teachers were asked to comment on how they used the learning trajectory approach. For each participating teacher, two double teaching sessions on fractions were observed (non-participant observation). Field notes were kept, with the emphasis being on teachers' communication with students, on tasks used and generally on teachers' actions and discourse. The aim was to identify ways in which the trajectory of fractions was used and adapted to the students' needs. Where necessary, a brief discussion with the teachers was carried out to clarify and explain choices.

A combination of Grounded Theory and Content Analysis techniques was used for analyzing the data. More specifically, a three-stage analysis was followed for the interview data: (a) careful reading of the data and detection of relevant extracts (b) coding of the extracts and grouping them in

sub-groups of similar meaning and (c) repetition of stage (b) within each of the emerging sub-groups for the formation of third level categories. For reliability reasons, the whole process was realized simultaneously by the three researchers. The non-participant observation data collected for the second research question were used for completing and refining categories emerging from the interview data analysis, but also for providing critical teaching incidents used in the final interview for the teachers to comment on.

## Results

Due to the limited space, only the results of the 1st and 2nd semi-structured interviews will be presented. As far as the first research question is concerned, the meanings attached to the notion of a Learning Trajectory (LT) developed by the three teachers converge only to some respect to the relevant literature.

In particular, teacher A considers that the trajectories are organized into thematic areas (algebra, geometry, etc.). She recognizes a similarity between LT and mathematics as a discipline. This similarity concerns both the way mathematical knowledge is organized and the historical progress of human thinking in mathematics.

The trajectory matches with mathematics in my view, how they are structured...in this way the approach of knowledge suits with the construction of knowledge and of human's thought because it seems that the notion of number has progressed developmentally in a similar way. And this helps a lot... (teacher A)

Teachers B and C seem to be more influenced by learning theories and interpret the organization of knowledge through LTs in a similar way.

In the trajectory you are interested in student's understanding, you want to activate his thought rather than to help him practice his memory and to simply remember the terms... (teacher B)

Teacher B, recognizing constructivist elements in the idea of LTs, considers them as providing a specifically arranged infrastructure for the construction of the mathematical knowledge, where the pre-existing knowledge serves to shape the new.

In the trajectory, I think that somehow a gradual construction of knowledge must be carried out...that is, starting with the natural numbers, we will go to the fractions... (teacher B)

Teacher C, on the other hand, indicates various and somewhat contradictory views on how knowledge is organized in learning paths through LT notion (e.g., constructivism as well as behaviorism).

We start to break the notion into parts and after each one is completed, we say that we have completed the particular part... (teacher C)

It appears that the three teachers' understandings of LTs are not identical but are overall compatible to the relevant literature with respect to the way in which a LT organizes and represents the progress of knowledge. But what they certainly do not distinguish is that a LT is not a simple organization of cognitive objectives but an empirically formulated proposal on how a student learns a mathematical concept. In addition, organizing knowledge along a LT suggests a learning approach

with specific characteristics derived from the constructivist perspective. These basic characteristics are conceptual understanding (teacher B) and engagement in active learning (teacher C).

Now, I do not know what exactly they learn. But I see that they start to investigate, they ask questions, I like that. In traditional contexts they wouldn't do that because they do not work this way.... But now they pose questions, they ask, "Why do we do that in this way?" (teacher B)

We felt that our experience was positive, and we saw that children responded very well, they liked this approach. Through an informally provided feedback, we see that their high school mathematics teachers are very pleased with these students... (teacher C)

This line of thinking is compatible with the concept of LT, since the first use of the term was made by Simon (1995), who proposed it as a teaching tool for the "constructivist" teacher.

On the other hand, teacher A considers LT to be independent from learning and teaching issues, limiting its use to the level of organizing mathematical content, which can be then framed by a variety of teaching approaches chosen by the teacher. This is a position also adopted by teacher C. However, teacher B argues that LT use in teaching improved her own knowledge of mathematical concepts resulting in her understanding better students' thinking. Finally, all three teachers report that LTs, combined with various teaching practices, contributed both to the learning process (teacher B) and to the learning outcomes (all teachers) in a variety of ways, such as, by facilitating logical connections and strengthening exploratory learning.

But if you can use the model or remember the wall of fractions, you can reach the equivalence much more easily... Or let's say the addition  $\frac{1}{4} + \frac{1}{2}$ , if the student depicts it and puts  $\frac{1}{4}$  and  $\frac{1}{2}$  close, he ends up much more easily to rules of addition than if you dictate the rule to him. (teacher B)

Teacher A also reports that she has too identified improvement in students' attitudes towards the lesson, but this is not the case for teacher C, who believes that the improvement noticed can be attributed to various factors. This finding is in line with that of Clements and Sarama's (2009) about LTs and the reinforcement of mathematical knowledge.

As far as the second research question is concerned, that is, how teachers claim to use LTs, the analysis of the relevant data reveals that LTs provided a general framework for organizing teaching, within which each teacher worked in her own way. Thus, the intermediate stages of the trajectory of fractions appeared to have provided successive intermediate learning targets for the instruction. Thus, teacher A attempted to incorporate LTs from different areas of the curriculum to simultaneously meet different objectives. This choice is of interest since the relevant research refers to the contribution of interacting LTs to pupils' learning. For achieving these objectives, tasks were organized, which not only corresponded to the objectives but also incorporated socio-cultural features, such as the history of mathematics and issues of everyday life, according to teacher A. Thus, in terms of lesson planning, LTs were used by teachers as a 'curriculum' that organizes the learning objectives. However, it is noteworthy that during the implementation of the lesson plan, LTs tended to be adapted by the teachers accordingly to the students' emerging needs.

All three teachers attempted to obtain relevant information about students through informal assessment processes during the instruction. This was mainly done through students' answers to the tasks, with the emphasis being on the explanations and the justification provided. At the same time, feedback was provided through students' work (teacher A) and by the way the students used the manipulatives and the models of fractions while dealing with the tasks (teachers B and C).

Also, the difference is that with LT I also use manipulatives. I do not just use the textbook or representations only, I use materials that students use, test them, change, see them differently... (teacher C)

Teacher A provided additional comments for each student individually about the progress and the difficulties in relation to the basic learning objectives included in the trajectory of fractions. Thus, she could have a "picture" of the whole class with regard to the points of the trajectory that students found more difficult. In one way or another, therefore, the teachers collected information about their students' learning. Likewise, the three participating teachers interpreted the information collected in their own way and proceeded to make decisions about their instruction. Their interpretations influenced their teaching choices. It seems, however, that LT supported a more focused interpretation taking into account students' past knowledge and thinking in order to guide the learner to the desired objective through a developmental path.

Maybe the knowledge they are building using the trajectories is more solid...When you tell them about the multiplication or the division, if they have learnt only the procedures without understanding them, they cannot go on...but with the trajectories it is so easy for them to perceive  $\frac{3}{6}$ ,  $\frac{4}{8}$ ,  $\frac{5}{10}$  and they say "this is a half" without any stress. (teacher C)

The LT of fractions seems to have played an active role in teaching, whereas the developmental path that it offered made it easier for the teachers to link the pupils' previous knowledge to the new one. Thus, there were several occasions where, in order to understand some issues and to deal with the difficulties of fractions, teachers used students' knowledge coming from other trajectories (i.e., natural numbers). This approach is consistent with the literature claiming that teachers should adjust LTs on the basis of children's pre-existing knowledge and preferences. It also presents similarities with the use of learning trajectories by the Dutch TAL project, where the aims of a trajectory were linked to each other in ways that could be achieved through this association (Simon & Tzur, 2004).

When dealing with students' difficulties, however, the choices for the development of the instruction did not always include the active use of the trajectory of fractions. For example, an occasion in which the trajectory did not seem to have played an important role was the extended stay on a target, backing it up with extra tasks and supporting material (often digital).

We had difficulties in finding  $\frac{1}{2}$  of  $\frac{3}{4}$ . We had difficulties in these things, but again, the models and various digital applications in the internet showed the way...How one can use  $\frac{1}{2}$  of  $\frac{3}{4}$  ... and we also used manipulatives where the students, in groups, were experimenting...how I can find  $\frac{1}{3}$  of  $\frac{3}{6}$ , let's say. (teacher A)

Another option was to use LT to simplify activities to suit the potential of students. This may indicate a case in which, as the relevant literature suggests, the teacher adapted the trajectory to

students and chose activities appropriate to their level (Clements & Sarama, 2009). Thus, on the one hand, the objectives were not always at the ideal level, but on the other, students were given the opportunity to follow a course compatible with their level and needs.

In addition, teachers tended to allow each student to go at their own pace and go along with their own progress on a “micro-scale”. This personal progress often began from the intuitive and ended up to the formal level or started from a simple and reached to a more complex stage (teacher A). This appears to be very close to the proposal of the new Mathematics Curriculum (2014) according to which the sense of number is cultivated progressively and at successive levels of abstraction and generalization. Furthermore, there were many occasions where different solutions to problems corresponding to different levels of understanding would appear (teacher B) indicating that a LT allows students to expose individual differences in learning (IEP, 2014). It therefore follows that, in general, the notion of LT has been used in the class by teachers in various ways as a general framework and as a useful tool, not just as a list of cognitive objectives and corresponding tasks.

You can go ahead and see that something has not been understood...don't you come back to negotiate it again? You have to. So, you can come back and deal with the notion again (teacher B)

In general, however, LT's incorporation into teaching was proven to be more substantial when using the knowledge held by the students. In other words, a learning trajectory may be more useful and effective in teaching when the teacher takes into account the basic principles of constructivism, such as the developmental progress of learning and the importance of pre-existing knowledge. This goes back to its original purpose, when the term was first mentioned by Simon (1995), considering it as a tool for designing teaching according to constructivist principles.

## **Discussion and concluding remarks**

The participating teachers interpret the concept of LT in ways that present similarities and deviations from the official literature. They tend to recognize that there is a certain sequence in teaching and to identify constructivist elements such as building on pre-existing knowledge and active engagement of the learner in the learning process. However, they view LT as a way of organizing mathematical content rather than as assumptions about the development of students' thinking when learning a mathematical notion, and so it seems that they perceive it yet as another local curriculum. As to the meaning attributions related to the application of LTs, overall, the contribution of LT to teaching is found either in organizing the content or in improving teachers' knowledge of mathematical notions and consequently in improving teaching. Thus, the participating teachers treated LTs just as means of organizing the mathematical content. At the same time, the use of the notion of LT did have a positive effect both on the learning process and the learning outcomes, as it encouraged exploratory learning procedures, exploited learning through connections between the notions and led to a solid and structured formulation of knowledge.

Learning trajectories appear to have provided the teachers with a general framework for organizing their teaching in ways that shared common features but also varied. These ways were not limited just to organizing the content. At the first phase, the use of LTs was related to lesson planning, including the development of individual objectives for a mathematical notion and the corresponding

tasks. However, during the instruction and on several occasions, the teachers modified the originally planned instruction under the light of emerging issues and students' thought. Thus, in order to teach the new mathematical content, the pre-existing knowledge that was part of the trajectory of fractions or of a different trajectory was used. Also, LT was adapted to the capabilities and the level of students' thinking through simplification of objectives and varied problem solving processes. Furthermore, a personal route of the students from the intuitive to the formal and from the simple to the complex was realized, for example, in the comparison of fractions. In contrast to the above, the LT of fractions was not particularly effective in cases where difficulties were simply identified without further interpretation of students' thinking. Teachers tended to stay for a long time in a learning objective without actually taking into account students' background so as to combine it with the trajectory at hand.

# Good mathematics teaching at lower primary school level

Marianne Maugesten

Østfold University College, Norway; marianne.maugesten@hiof.no

*This paper explores Norwegian lower primary teachers' views about good mathematics teaching as revealed in a focus group interview at the end of a two-year school-based professional development program. Analyses of the empirical data indicate three main categories of findings: the teachers' facilitation of learning, the students' thinking in and about mathematics and the use of teaching aids in teaching. The results are discussed in relation to other Nordic studies and possible implications are also provided.*

*Keywords: Mathematics teachers' discussion, lower primary school, good mathematics teaching.*

## Introduction and theoretical background

This study investigates teacher views about good mathematics teaching. Several studies attempt to identify the components of good mathematics teaching without finding a clear answer (Cai, Kaiser, Perry, & Wong, 2009; Franke, Kazemi, & Battey, 2007; Hiebert & Grouws, 2007; Kilpatrick, Swafford & Findell, 2001). A challenge is that cultural as well as political differences influence mathematics teaching. Views about the role of the teacher, about the subject in school and society, and about learning differ across cultures (Cai et al., 2009). In the Chinese context, for instance, mathematics teaching is teacher-oriented and exam-oriented, and teachers are more focused on the students and their learning than on themselves and their teaching (Li, 2011). In the Nordic context, Fauskanger, Mosvold, Valenta and Bjuland (2018) conducted a study in which upper primary school teachers' views on good mathematics teaching were revealed through group interviews at the start of a major professional development project. The teachers referred to their role as teaching facilitators by having good structure, classroom management, and the possibility to differentiate using different types of assignments, which both motivates the students and invites more and diverse solutions. According to Fauskanger et al. (2018), good teaching was also about motivated, engaged, creative and curious students. In another study, Fauskanger (2016) investigated views on the ingredients of good mathematics teaching among lower and upper primary school mathematics teachers who participated in a professional development program. These teachers felt that student response was the most decisive factor for high quality teaching. They emphasized teacher qualities such as enthusiasm and attitude towards the subject rather than the teachers' own knowledge. Hemmi and Ryve (2015) studied Swedish and Finnish teacher educators' views of good mathematics teaching through focus group interviews and individual interviews. There were many apparent similarities between Sweden and Finland, but the Finnish teacher educators emphasized clear presentation of mathematics for the whole class, routines for mental arithmetic and homework, and clear learning goals for each class, while the Swedish teacher educators referred to the relationship with each individual child, building on the students' capabilities and finding mathematics in everyday situations. In three studies carried out among Finnish student teachers (at lower primary school level), Kaasila and Pehkonen (2009) looked

at students teachers' views of good mathematics teaching. They believed that teachers needed to be goal-oriented, listen to the students' thinking and show flexibility when unexpected episodes arise. The student teachers pointed out that teachers should have knowledge of varied work methods, base their teaching on the students' day-to-day experiences and have a particular focus on problem solving. Continuous assessment and development of socio-mathematical norms were considered important elements of good mathematics teaching.

Teaching mathematics is complex and researchers have attempted to distinguish the different aspects to identify main practices. These are referred to as core practices (McDonald et al., 2013) or high-leverage practices (Forzani, 2014). This study focusses on the Nordic context, therefore core practices are not discussed further.

The study in this paper is based on a group of Norwegian teachers at lower primary school level who, together with a teacher educator in a focus group interview, reflected on their own mathematics teaching at the end of a two-year school-based mathematics professional development program. The content in this development program were decided by the headmaster in cooperation with representatives of the mathematics teachers at the school. Among the themes were numeracy, different approaches to the four arithmetical operations and how to lead productive mathematical discussions. This study does not measure the effect of the program, but it can be assumed that the teachers' descriptions of good mathematics teaching has been influenced by them trying out exercises and activities in their own classes and by improved research-based knowledge of mathematics didactics throughout the two-year period. To my knowledge of research in the field, few studies have examined Norwegian lower primary school teachers' descriptions of good mathematics teaching. On this basis, the study seeks to answer the following research question: What might Norwegian lower primary school teachers' views about good mathematics teaching look like? Teaching refers to the interaction between teachers and students relating to subject matter. Cohen, Raudenbush and Ball (2003) describe this interaction as the instructional triangle.

## **Methodological approach**

The empirical data used in this study is from a focus group interview with seven lower primary school teachers at a school that has completed a two-year professional development program for mathematics teachers. The interview included two teachers from each of the years one to year three and one from year four. Two were men and five were women. Two of these were experienced preschool teachers who have worked at lower primary level for about 15 years. The others were primary and lower secondary teachers with between 15 to 30 ECTS credits in mathematics and between four and 20 years of experience from primary and lower secondary school. The school has three teachers on each of the four years of lower primary school.

The participants were informed of the topic of the focus group interview in advance. They were asked to discuss and reflect on their own mathematics teaching on the basis of their experiences from competence raising and what they had tried out, and their definition of good mathematics teaching. The interview lasted one hour and was recorded and transcribed in full.

Transcripts from the focus group interviews were analyzed using conventional content analysis (Fauskanger & Mosvold, 2015; Hsieh & Shannon, 2005) used in studies that attempt to describe a phenomenon in order to better understand it. The phenomenon described in this study is mathematics teaching. In conventional content analysis, inductive codes are linked to suitable categories, as shown in a table in Figure 1. The interview subjects are referred to as R1 to R7. The transcribed interviews were placed in a table with rows containing individual statements, such as R3 in Figure 1, key words from these, inductive codes and categories. The material was analyzed twice with a two-month interval to prevent categories being overlooked. One of the challenges of conventional content analysis is not obtaining a complete understanding of the context because of categories being left out (Hsieh & Shannon, 2005).

Category	Inductive code	Examples of individual comments
The teachers' facilitation of learning	Communication in the classroom	R3: 'Some years ago, if I spent much too much time on a conservation, it felt like "when are we going to do the maths?"'
	Representation – particularly transitions between representations	R4: 'because we've used manipulatives before too... And the transition from using manipulatives to actually drawing up maths problems [...]'
The students' thinking in and about the subject of mathematics	The students' thinking in the subject of mathematics	R5: 'show them that there is more than one way of working it out, several strategies.'
	The students' thinking about the subject of mathematics	R3: 'The challenge is that there are a few students in the class that you don't manage to engage in the conversation, that only really become involved when they are given the maths problem in the book'.
Subject resources in the facilitation	Textbook	R6: 'And then I suppose it's very safe. You probably very much trust that those who have written the textbooks know what we need to get through and...it's also related to time pressure sometimes, that it's easy.'
	Type of task: open, explorative, tasks related to daily activities	R2: '...to see the maths in everything around us. Grasp the everyday situations.'

**Table 1: Codes and categories**

## Results

The analysis of the empirical data led to three main categories of findings: teachers' facilitation of learning, students' thinking in and about mathematics and use of teaching aids in teaching. These three main categories are sometimes related. For example, the students' thinking in and

about a mathematics exercise might be connected with the teacher's facilitation of learning through communication in the classroom. This is in line with the description of teaching in the instruction triangle as an interaction between subject matter, the students and the teacher (Cohen et al., 2003). Through the focus group interview, the teachers emphasized increased awareness of several areas at the same time as they still had challenges in a number of these areas. When the results are presented, both challenges and increased awareness are shown in each category.

### **Teachers' facilitation of learning**

The teachers seemed to use more whole class conversations and dialogue in mathematics teaching after participating in the professional development. They also said that it was challenging to engage the students in subject-related talks. The teachers viewed the dialogues with the students and between students as an aid to developing the students' thinking: 'Kind of building a bridge between the terminology they have and... sort of new knowledge' (R3). This remark may indicate a view of learning in which the students develop new knowledge from already established terms. The same teacher had started using learning pairs and felt that the students gave each other ideas that were useful to the subsequent conversation with the whole class. The teachers did not feel that the class failed if they spent time on discussion and deviated from the class plan (R1). R6 reported that they often used to think 'Oh no, now I have to get the other part done,' where the other part referred to solving exercises in the textbook. This can mean that the teacher thought more about quality and what led to learning than quantity, as in solving lots of math problems in the mathematics teaching. R3 described the use of dialogues in teaching as a *quantum leap* in relation to before the professional development program. In communication with the students, the teachers expressed that they had become more precise in their use of terms, as described by R1: 'addition and subtraction, and not plus and minus.'

R4 specified what was meant by more dialogue in the following example. Previously, the date and day were written on the board in the morning assembly, while the content was now more mathematical: 'Who's birthday is next? How many days are there until...? How long ago was Christmas?' The teachers developed math problems from the information that emerged, and the students were encouraged to develop their own problems.

Several teachers found dialogues to be challenging for both students and teachers in mathematics classes. Students needed to practice talking and explaining their thoughts. Some students asked (R2): 'Can't we just do a task?' The teachers stated that they needed to learn what questions to ask in order to elicit student thinking. To address some of the challenges described by the teachers in my study, it will be necessary to develop classroom norms and relations that are in line with several of the high-leverage practices (Forzani, 2014).

The teachers in the study taught at lower primary level and found it important to use various representations, such as concrete manipulatives and semi-concrete manipulatives, drawings, verbal representations and written representations in the form of math problems and numbers intended to help more students to understand more. They expressed great awareness of the use of new representations such as sketches of blank number lines: "Blank number line. Open number line. I think it's almost been revolutionary. I use it in nearly every possible context, very positive to use," (R6). The transition from concrete representation to abstract ideas was

challenging for the students, according to several of the teachers. R4 gave an example where she lined the students up at the front of the class to show doubles and halves. For the students to understand what numbers represented half and double, the teachers felt that they had improved their knowledge as to what questions to ask in order for the students to see the connection between the practical and the written parts. The teachers believed that this transition was important (R3). This indicated that they found it important to facilitate students' learning and how their current abilities could be related to what they were going to learn.

### **The students' thinking in and about the subject of mathematics**

This category was also concerned with communication in mathematics teaching. When students explain their thoughts, it takes place in a communication situation. The teachers felt that the students must be given time to think and ask questions and that they, as teachers, should not feel that the students should rather be solving written math problems. By letting the students show their thoughts when solving problems, the teachers could emphasize that mistakes can be positive in that they can help the teachers and students to understand. "And understanding kind of how they think, and going into it and understanding a bit more why things are wrong and why it is hard, I think is very important" (R4). This showed that knowing about common student mistakes and ways of thinking was important for the teacher. According to the teachers, the students also became aware of there being more than one way of reaching the solution. They believed that the students acquired a better understanding by explaining their thoughts since this formed a 'bridge' between the terminology the students already had and new knowledge.

The teachers gave examples of their students' remarks when thinking *about* the subject of mathematics: "Oh yes, now I understand it." This expressed a sense of mastery. However, the teachers also described the challenges relating to students' different understandings of the mathematics subject. As mentioned earlier, it can be a challenge to get the students to talk in mathematics classes precisely because they are of the impression that mathematics means solving lots of math problems. R3 explained it in the following way: "The challenge is that there are a few students in the class that you don't manage to engage in the dialogue, that only really become involved when they are given the math problem in the book." She also believed that this particularly applied to students who were quick at calculations and those who were not particularly motivated in the subject of mathematics. This may indicate a view that mathematics is about quickly solving lots of math problems.

### **Subject matter/resources**

When the teachers described the content of their own teaching, the main topics of discussion were the textbook and different types of tasks (often aside from the book). They expressed an increased awareness in relation to both.

In relation to the types of tasks, R4 explained that she no longer made booklets containing extra tasks, but used open-ended and problem-solving tasks that the students could work on over time. She also stated that, "I hope they have become better at thinking at least, to sort of, solve problems." This may imply that the teachers felt that investigation and problem solving were key elements of students' understanding, and thereby of good mathematics teaching. The

teachers also told that they discussed mathematics teaching with colleagues more than earlier, because the tasks were challenging. At lower primary level, the teachers gave the students notebooks where they could draw and write problems and solutions themselves. An open exercise for year one students was the hundred-day party where the mathematical topics the teachers covered were even numbers, odd numbers, ten friends, bridging through ten, counting, subtraction and addition. The teachers in my study explained that they had become more alert to the mathematics in everything around them, which could be linked to the types of exercises. R2 commented: “Grasp the everyday situations. And get them into what’s related to mathematics in the class.” When the teachers in my study seem to have increased awareness of using mathematics in all subjects, this might relate to the fact that the basic skill of calculation in all subjects had been a theme in the professional development program. R7 summed up what she thought good mathematics teaching was in the following way: “When the students understand when and how they can use their knowledge of mathematics in everyday life.”

When the textbook was raised as a topic, there was some disagreement among the teachers. R7 told that she has become “critical to the textbooks, and I don’t completely trust that the textbooks necessarily meet all the learning goals.” R2 has become more aware of being freer in relation to the textbook, while R6 finds the textbook safe. This shows that teachers can disagree about the textbook’s role in mathematics teaching.

According to the research question, the teachers’ views about good mathematics teaching was described in the three main categories of findings in this section. Some of them were related to results in other Nordic studies, as discussed in the next session, but also to the content of the two-year professional program. This paper does not assess the effect of the program, but the teachers’ views about good mathematics teaching can be influenced by this content and improved research-based knowledge. The teachers emphasized the use of open-ended and problem solving tasks and acceptance of communication and dialogues to facilitate learning.

## Discussion

There were both similarities and differences between how good mathematics teaching was described by the teachers in this study as compared with other Nordic studies (Fauskanger, 2016; Fauskanger et al., 2018; Hemmi & Ryve, 2015; Kaasila & Pehkonen, 2009) that have examined good mathematics teaching.

The Norwegian teachers’ descriptions of dialogs in lower primary school teaching were similar to those of other studies. Fauskanger et al. (2018) pointed out that facilitating conversation and discussion in mathematics teaching was a key aspect of students’ learning at the same time as such conversation could inform the teacher about the students’ thinking. International research highlights classroom discussion in mathematics teaching (e.g., Franke et al., 2007).

Based on the empirical data, students’ thinking appeared to influence the planning of mathematics teaching for the participating teachers. Similar to the Finnish study the findings of this study documented that the teacher needs to listen to the students in order to understand their way of thinking (Kaasila & Pehkonen, 2009). The student teachers in Hemmi and Ryve’s (2015)

study believed that Swedish teachers build on an extreme expression of constructivism and were therefore more student-focused, while the Finnish referred to whole class discussion.

Selecting open tasks and investigative activities that are motivating and give the students opportunities to show several solutions was emphasized by both Fauskanger et al. (2018) and Hemmi and Ryve (2015). Connecting mathematics with everyday life seemed to be important both in the Swedish and Finnish education studies (Hemmi & Ryve, 2015; Kaasila & Pehkonen, 2009) which are in line with the findings of my study.

In this concluding discussion, I will highlight one characteristic of good teaching that the teachers focused on and one characteristic that previous research has highlighted, but that was not mentioned in my focus group interview.

During the focus group interview, the teachers believed that using several different representations and working on the transition between these both contributed to good teaching and entailed a challenge. Using different representations has not been included in the characteristics of good mathematics teaching in other Nordic studies. This could of course mean that the use of representations and the transition between representations were included in some of the other categories in these studies. However, it may also be explained by the fact that the teachers in my study were teachers at lower primary school level and here, the need to use different representations was greater, and the transition from concrete to abstract thinking was more difficult than for older students. Work on expressing math problems or amounts in numbers after using manipulatives were considered particularly difficult for this age group.

A characteristic of good mathematics teaching mentioned in both Fauskanger et al. (2018) and Kaasila and Pehkonen's (2009) studies, is the structure of classes, with clear learning goals and classroom management. This was not mentioned, nor asked about, in the lower primary school teachers' focus group interview. This does not mean that it is not important to the lower primary school teachers in this study; it is perhaps more important here than in other years. However, the teachers might see classroom management and clear learning goals as such obvious factors that they did not mention them explicitly when they described mathematics teaching.

At the end of the professional development program the teachers felt that they had not only become more aware of dialogues with the students, but they also had more conversations and reflections among themselves. They feel that such discussion and reflection provide support and inspiration for their teaching. Knowledge sharing among the teachers may therefore contribute to long-term competence raising and deserve further research. Effect studies of professional development also need to be researched further.

## **Analysis of differences between teachers' activity during their regular and constructivist lessons**

Janka Medová, Kristína Bulková and Soňa Čeretková

Constantine the Philosopher University in Nitra, Faculty of Natural Sciences, Department of Mathematics, Nitra, Slovakia; [jmedova@ukf.sk](mailto:jmedova@ukf.sk), [kristina.bulkova@ukf.sk](mailto:kristina.bulkova@ukf.sk), [sceretkova@ukf.sk](mailto:sceretkova@ukf.sk)

*Different aspects involved in the constructivist teaching mode were assessed in the eight observed mathematics lessons conducted by four upper-secondary in-service teachers. Four among these lessons were identified as 'regular' by the teachers themselves, the other four lessons followed the same constructivist lesson plan designed by the respected educational expert. The main differences were found in the way how the students were working and achieved their independent learning capabilities. The lessons following the constructivist lesson plan were clustered together by the means of hierarchical cluster analysis. The regular lessons were more influenced by the teachers' personalities than the constructivist lessons.*

### **Introduction**

The traditional transmissive “chalk-and-talk” methods have already been criticized continually, while concurrently the student-centred pedagogies have frequently and gradually been approved for several decades (Steffe & Kieren, 1994). Teachers face a lot of issues and challenges when implementing awaited constructivist approaches (Appleton & Asoko, 1996). Teachers lacking any experience in the constructivist classroom often struggle with the setting up such a learning environment that is demanded for the constructivist perspective (Windschitl, 2002).

According to Schoenfeld (2010) the teachers' decisions during the lesson are influenced by their resources (i.e., knowledge, material just being available), goals (e.g., such aims which they are trying to achieve) and orientations (e.g., their beliefs, values, biases). Teachers' professional knowledge can be seen as an outcome of their overall different experiences they have been involved in, including both formal and initial training, as well as professional development and informal forms of learning through their own practice or media. The overall teachers' knowledge has been constructed and developed gradually. Such process has been always influenced by their prior beliefs, pre-knowledge or originating knowledge and experiences of the knowers (Smith, 1993). As such, different people experiencing the same intervention will achieve and develop their own and usually quite different constructions of that experience (Lachance & Confrey, 2003).

### **Theoretical framework**

Beerenwinkel and von Arx (2017) describe the constructivist-oriented teacher as a person who activates the overall students' pre-knowledge and provides them with some suitable issues and problems, often related to their everyday context. During the problem-solving activity of students, the teacher creates a space for independent learning, encourages rethinking and seeks to demonstrate certain scientific approach to generating such knowledge.

According to Widodo & Duit (2004), there are four categories comprising the significant indicators for the constructivist teaching: (a) construction of knowledge (CK); (b) personal relevance (PR); (c) social interaction (SI), and (d) independent learning (IL). Beerenwinkel and von Arx (2017) defined evident facets for each of the listed indicators that are suitable for quantification. Construction of knowledge can be assessed according to status in the learning process, activation of pre-knowledge, providing problems, evolutionary development of knowledge, revolutionary development of knowledge, thinking aloud and demonstration of the scientific approach to knowledge generation. Personal relevance is based on exploring the interest, accounting for needs, everyday-life context and transfer to other subjects. Social interaction can be quantified according to extent of student-student interaction, student-teacher interaction with the whole classroom and student-teacher interaction while individual work or group work. Independent learning is manifested in space for independent learning, encouraging the rethinking, fostering the metacognition, benefit from independent learning and metacognitive abilities.

In our study we focused on the differences between the regular lessons of Slovak mathematics teachers and the lessons conducted by the same teachers based on the lesson-plan prepared by the relevant expert in constructivist teaching and learning. We stated the following research questions: (i) In what facets of constructivist teaching does the regular lesson differ from the lesson based on the lesson-plan prepared by the relevant expert? (ii) What are the relations between the episodes from regular and constructivist lessons of investigated teachers? (iii) What are the (implicative) relations between the facets of constructivist teaching observable in the lessons of investigated teachers?

## **Materials and methods**

Within the project PRIMAS supported by the European Union FP7 the course aimed at the professional development (CPD) of mathematics teachers was implemented at the authors' university. The CPD focused on the implementation of inquiry-based learning and thus also constructivist teaching in upper-secondary schools. Several authors (e.g. Jaworski, 2006) see inquiry as fitting with the constructivist view of knowledge and learning.

The structure of the course followed the spiral model of teachers' professional development, consisting of the following three repeating steps: Reflection - Analysis - Implementation. The course was aimed at the transformative learning of the participating teachers as mentioned by Thompson and Zeuli (1999). Firstly, the teachers reflect on the lesson they labelled as 'regular'. Later in the course, the teachers went through this cycle for three more times. They did specific changes in their practice, videotaped their lesson, reflected on it and came with specific conclusions that might influence their further practice. The first change was in the way of questioning. The second lesson should follow expert-prepared lesson plan. Detailed lesson plans including typical student questions and suggested answers were chosen with the aim to offer teachers tools that they were not familiar with prior to the study. Any and every positive experience in implementing constructivist approach is very good motivation for their further practice. The third lesson was planned by teachers themselves according their experience from previous cycles.

In order to answer the research questions we analysed eight videotaped lessons taught by the four participants of CPD that implemented the same lesson plan named *Counting trees* (Mathematics Assessment Resource Service, 2015). Two lessons for each participating teacher were analysed. The first of the lessons were recorded after the first 90-minute session of the CPD. The teachers were required to record their regular mathematics lesson following the national curricula. The second analysed lesson was the one following the *Counting trees* lesson plan. The teachers did not get any special support to this particular resource. On the other hand, the constructivist lesson was carried out after completing the 52 out of the 60 group contact lessons of the CPD. The subsequent sessions reflecting on the lessons were conducted in researcher-teacher pairs.

The lessons were divided into smaller episodes according to the activity during the lesson (i.e., teacher lecturing, group-work, etc.). The time for each episode was recorded. Each episode was labelled by pseudonym of the given teacher, number of lesson (1 - regular, 2 - constructivist) and phase of lesson. The defined facets were assessed for each episode. The levels were defined from 0 (the facet was not manifested in the observed lesson) to 3 (the facet regularly occurs in the observed lesson). The facets describing the personal relevance got almost for each observation the zero value, so we decided to omit this indicator from the further analysis.

The weighted arithmetic mean for each facet was calculated and the mean value of the lessons was compared by the means of paired *t*-test (De Winter, 2013) performed in R environment (RCoreTeam, 2018). The hierarchical cluster analysis was performed using the Euclidean distances and UPGMA clustering method. The cophenetic correlation coefficient was used to determine the most accurate clustering method. The statistical implicative analysis (SIA) (Gras et al., 1996) using package *rchic* (Coutrier, Pazmiño Maji, Conde González, & García-Peñalvo, 2015) was applied to explore the implicative relations between the facets of constructivist teaching.

## Results

Four of the observed facets significantly differed between the regular and constructivist lesson. The means, *t* statistics and *p* values are summarized in Table 1. The evolutionary development of knowledge (CK4) and teachers' thinking aloud (CK6) were more prevalent in the course of the regular lessons. Surprisingly, the revolutionary development of knowledge (CK5), typical for the constructivist classroom was not significantly higher in the lesson based on the constructivist lesson plan.

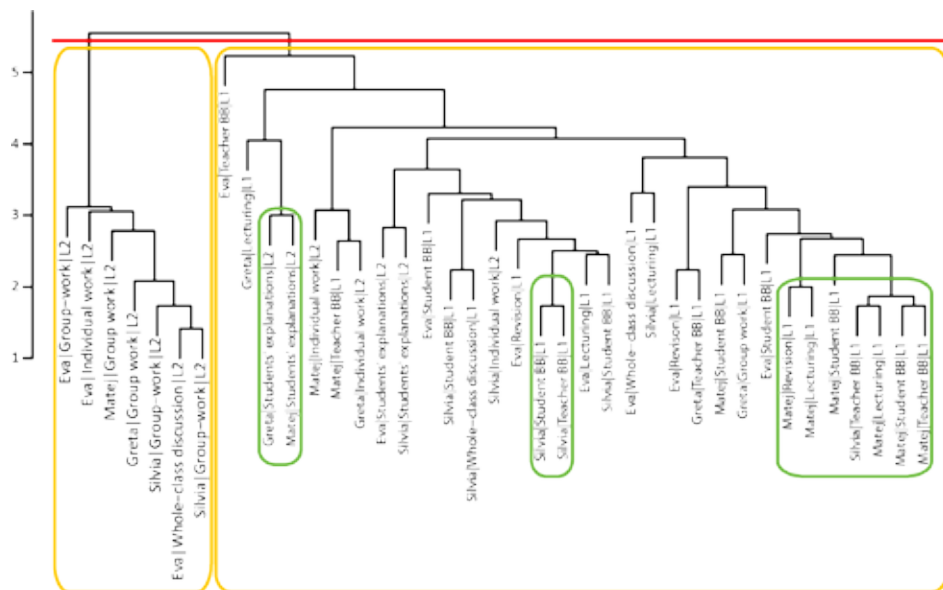

The student-student interactions occurred more often in the constructivist lessons as there was actually a large space devoted to the group-work during the lesson. The level of student-teacher interactions did not differ significantly, neither for the individual, nor for the group communication. Fostering metacognition features (IL3) and benefits from the independent learning (IL4) were the two characteristics of individual learning that did differ significantly between the two lesson types.

Facet	Description of facet	Lesson 1	Lesson 2	<i>t</i>	<i>p</i>
-------	----------------------	----------	----------	----------	----------

		<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>		
CK1	Status in the learning process	0.82	0.47	0.03	0.01	2.00	0.092

*M* = mean, *SD* = standard deviation, Lesson 1 = the regular lesson, Lesson 2 = the *Counting trees* lesson

**Table 1: Mean values of the levels for the facets describing indicators of constructivist teaching**

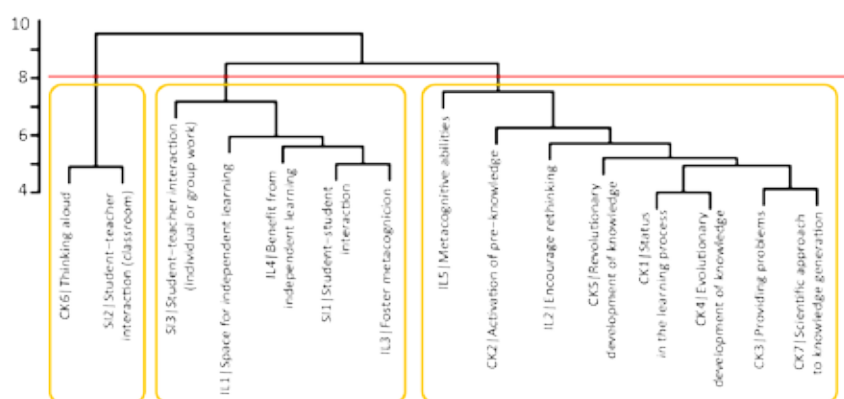

Name of the teacher|Episode of the lesson|Number of lesson; BB means solving a task on the blackboard; L1 regular lesson, L2 *Counting tree* lesson.

**Figure 1: Dendrogram grouping the episodes from the observed lessons**

The observed variables from our analysis of the observed lessons were grouped into two clusters (Figure 1). The first one contained the variables representing episodes of constructivist lessons: the students work in groups (Eva, Greta, Matej, Silvia|Group-work|L2) with students' individual work (Eva|Individual work|L2) and whole-class discussion (Eva|Whole-class discussion|L2). The second cluster comprised of several smaller subclusters grouped by the same type of an episode of lesson and by the style of teaching conducted by the observed

teacher. For example, one subcluster contained almost all episodes of the observed lesson Matej1 (see Fig. 2 in green square). Some of teachers connected discussion in groups with the work on the project. In the first cluster, also one variable for individual work (Eva|Individual work|L2) is grouped. We assume that the teacher encouraged students also during their individual work.

The fifteen facets of constructivist teaching were grouped into the three clusters (Figure 2). In the first cluster, only two didactical variables were grouped: CK6 (thinking aloud), and SI2 (student-teacher interaction in the classroom). The second cluster contained the following five grouped variables: SI1 (student-student interaction), IL3 (fostering metacognition), IL4 (benefit from the independent learning), IL1 (space for the independent learning), and SI3 (student-teacher interaction during the individual or group work). The third cluster comprised of the following three didactical variables: CK1 (status in the learning process), CK4 (evolutionary development of knowledge), CK3 (providing problems), CK7 (demonstration of the scientific approach to knowledge generation).

**Figure 2: Dendrogram of different facets of constructivist teaching**

The statistical implicative analysis produced the three R-rules (Figure 3). The first connected subgraph  $IL2 \rightarrow CK6 \leftarrow SI2 \leftarrow CK2$  represents the aspects influencing the teachers' thinking aloud.

**Figure 3: R-rules of the different facets concerning to constructivist teaching**

Based on the results of the *t*-test we can conclude that since the lessons varied in their structure, the actual and real difference was mainly in the way how the students had been working. The teachers did not engage in “think aloud” too much and more time was devoted to the individual work of students. Student-student communications were observed more frequently which implied greater benefits for students as a result of independent thinking during constructivist lessons.

The variables grouped in the first cluster imply that the discussion in classroom about the given problem or topic is encouraged by teacher's thoughts aimed at revising or expanding a knowledge structure or framework. Students had real opportunities to reflect on their observations (or perceptions) related to the discussed issue (e.g., creating a definition, possible strategies, or solutions). Teachers' thinking aloud about the topic influenced the intensity of the interaction in the classroom between the teacher and students.

The variables in the cluster 2 represent the aspects of group-work in the classroom. The teacher supporting interactions between the students in groups, helps students share their opinions about the given topic and strategies in the solving process. The independent work gives some space to the students for managing time, tools, and strategies to achieve their assignment. Especially as far as the group work, the mutual discussion can bring several diverse ideas as far as the methods, form of collaboration, or managing of timing, and developing their soft or mathematical skills. The teacher enters into a conversation or group work only as a facilitator.

Based on the cluster 3, any knowledge, that is new for the students, can be easier integrated by linking it or by the reinterpretation and reinforcing of an existing previous knowledge. The scientific approach in the learning process may keep and support the quality of any new information for its integration into the knowledge structure. The grouped variable CK5 (revolutionary development of knowledge) confirms the teacher's role as a facilitator in the learning process, where the teacher gives comments, stimulating cognitive conflicts. In this sense, the variables IL2 (encourage rethinking), CK2 (activation of pre-knowledge) and IL5 (metacognitive abilities) represent such a new knowledge, that is activated through the discussion process, where the students can explain their arguments and thinking and the teacher encourages them to do so.

Results of the SIA indicate that the pre-knowledge covering a topic is activated in the discussion process headed by the teacher. Such discussion factually does represent an interaction between the teacher and the students in the classroom. Encouragement of rethinking is clearly an influential aspect to thinking aloud. The second rule ( $SI1 \rightarrow IL3$ )  $\rightarrow IL1$  contains the strongest implication:  $SI1 \rightarrow IL1$ , meaning, the mutual interaction between the students is conditionally a factor for their independent learning. Especially, while they are involved in group work in the classroom, students have a space to discuss their opinions independently from the teachers' leading. The teacher is only a guide who can help with some ideas in small groups ( $SI1 \rightarrow SI3$ ). We concluded that for the independent work it is necessary to create a space for discussions between the students focused on developing the relevant questions, ideas or solutions. Discussion is interrupted by the teacher only with some comments enhancing the discourse. Finally, the rule  $CK5 \rightarrow IL5$  represents how cognitive conflicts offered by the teacher can help the students to explicate their thinking, learning or problem solving.

## Discussion

The study builds on the characteristics of constructivist teaching described by Widodo and Duit (2004) and further elaborated by Beerenwinkel and von Arx (2017) for science education. The framework was implemented and used as a base for our quantitative analysis of eight mathematics lessons. Four lessons were usual for the teachers, and four were based on

constructivist lesson plan designed by an expert. Students' activity was changed and the teacher had to adopt the new role of a mentor and facilitator of students' discussion.

Teachers in Slovakia frequently engage in lecturing practices. On the other hand, this style of teaching-lecturing is not seen too frequently in countries such as Israel or Japan where independent work of students connected with between-desk-teaching is usual. It also differs from the situation in Finland where the whole-class discussion is the usual teaching approach (Gunnarsdóttir & Pálsdóttir, 2015). The second lesson provided students with more opportunities for independent learning. Taylan (2015) recognised independent learning in both, individual and group work if the mathematical discussion was carefully prepared. It was the case also in *Counting trees* lesson plan that suggested teachers' questions to start and support students to discuss. The teachers' thinking aloud apparently decreased in the constructivist lessons. Despite Ayalon and Hershkowitz's (2015) claim that different teachers can see the same task differently, the proposed lesson plan seemed to have similar effects in participating teachers' classes. It may indicate similar experience with setting up the constructivist learning environment. The participating teachers were involved in the CPD aiming at the constructivist teaching style. We can assume teachers' willingness to teach in the constructivist mode as they had chosen this kind of course.

## Conclusions

The outcomes and results of the study confirmed actual differences between the usual lesson and a lesson based on constructivist lesson plan. The episodes of the constructivist lessons when students worked independently were clustered together. Clustering the episodes of the regular lessons depended more on teachers' personality than on the phases of the lessons. Teachers during their regular lessons appeared to hold the main authority in the classroom. Based on our observations, teachers' thinking aloud or interaction between the student(s) and the teacher were more prevalent in the regular lessons. On the other hand, when the teacher was following the constructivist lesson plan, a higher level of independent learning was observed. The carefully prepared lesson plan enables the teacher to implement lesson in a constructivist approach. Further research is needed to evaluate impacts of the actual experience with constructivist lessons on teachers' regular practice.

*It has been shown to be problematic for teachers to use Krutetskii's definition of mathematical abilities to recognize mathematically highly able pupils (MHAPs). Aiming to concretize what teachers can notice in pupils' problem-solving processes, we connect a 10-year-old boy's problem-solving process to some of the abilities defined by Krutetskii. The results give clear descriptions of what teachers can observe in pupils' mathematical activities to notice their mathematical potential. We concretize, for example, how a pupil's abilities to grasp a problem's formal structure and to generalize can be observed. To be able to notice MHAPs, teachers need research-based support on how and what to observe in their pupils. Our proposed guide needs to be tested and validated to explore if it will help teachers to notice MHAPs and subsequently support their learning.*

**Keywords:** Mathematical ability, highly able pupils, teachers.

## Background

Schnell and Prediger (2017) have shown that teachers need the capacity to notice pupils' mathematical potential in order to support all pupils in their development. Mellroth, van Bommel, and Liljekvist (2019) have shown that this is a challenging task for teachers when it concerns highly able pupils. It is therefore important to give teachers research-based guidance on how to discover pupils who need more challenges than others, for example MHAPs. If a teacher does not notice these pupils and provide greater challenges for those who, for example, improve their skills quickly, the pupils "may slip into a stage of boredom" (Liljedahl, 2017, p. 1147).

Krutetskii's (1976) work on the mathematical abilities is, for many, still the seminal work on the nature of mathematical ability. However, using his ideas to notice pupils' mathematical potential poses significant difficulties for many teachers. This is shown by Mellroth, et al. (2019) in a study where teachers working in groups analysed pupils' potential to show, in their problem-solving processes, the abilities defined by Krutetskii. The following transcript of a discussion among three teachers (A, B, and C), shows some of the teachers' frustration:

- 1 B: So, we are supposed to use those and apply them to a problem we choose.
- 2 A: The words are pretty difficult.
- 3 C: This is harder, oh!

Teacher A reads aloud the Swedish translation of one of the abilities from Krutetskii's work.

- 4 B: Oh my God!

Primary teachers are the ones who first meet children in formal learning situations, and they should therefore be given the best support to notice pupils' mathematical potential. It is also these teachers' responsibility and duty to support and challenge all children. Teachers in primary school do not usually have deep knowledge in mathematics. It is, however, reasonable to argue that all teachers of young children want the best for their pupils and want to give them the challenges necessary for learning. To do this for pupils with high ability in mathematics, teachers need to be able to notice them (Shayshon, Gal, Tesler, & Ko, 2014).

The aim of this paper is to propose a structure to help primary teachers notice their pupils' mathematical potential. More precisely, through richer descriptions and commented examples from a pupil's problem-solving process, we concretize what teachers can notice as characteristic of mathematical high ability. In this paper we will present and describe the development of such an emerging structure, based on the seminal work of Krutetskii (1976). How well the structure works to improve teachers' observational skills remains for further studies to explore.

### **Krutetskii's way of describing mathematical ability**

There are newer frameworks than Krutetskii's (1976) describing mathematical ability, such as those used by Schnell and Prediger (2017). It is, however, easy to ascertain that these frameworks are descendants of Krutetskii's (1976), so we have chosen to use the original framework, since it is unquestionably the most used in the research field of education for MHAPs.

Several researchers suggest that pupils should be active in problem-solving activities that are meaningful for them, in order for their teachers to be able to notice their mathematical potential (Krutetskii, 1976; Schnell & Prediger, 2017; Singer, Pelczer, & Voica, 2015). In particular, so-called rich problems fulfil many criteria known to be important for supporting and stimulating MHAPs by, for example, demanding higher order thinking (Sheffield, 2003). Therefore, when MHAPs work with rich problems, it can be assumed that they are participating in an activity that is meaningful for them.

In his work, Krutetskii (1976) describes mathematical abilities and categorises them into four groups. His four groups divide the components of mathematical ability in the following way (pp. 350-351): 1. Obtaining mathematical information; 2. Processing mathematical information; 3. Retaining mathematical information; and 4. General synthetic component. The first three groups proceed from basic stages in problem solving. The fourth, specified as a mathematical cast of mind, is a more general component that Krutetskii identified during his experiments. To fulfil the aim of this article, we here present and explain some of the mathematical abilities described by Krutetskii. Due to space limitations, we have chosen to focus on the abilities for which we can show clear evidence in one empirical case. This paper focuses on primary teachers. As the third component has been shown to be easier to observe in older students (Szabo & Andrews, 2017), we exclude it from this paper. The fourth component requires observation over a longer period of time (Krutetskii, 1976), so we also exclude also it. We describe here how the abilities chosen are interpreted in this paper.

#### **1. Obtaining mathematical information**

"1a. The ability for formalized perception of mathematical material, for grasping the formal structure of a problem" (Krutetskii, 1976, p. 350)

This is the ability to grasp the formal mathematical structure. Children with this ability want to understand the mathematical structure of the problem. They are not only interested in individual variables, but also in the relationships between different variables. Children with this ability have a need or desire to understand the mathematical structure of the problem and to discover relationships available to connect these relationships. Children who lack this ability often work unsystematically. They mainly utilize the mathematical connections they already know, even if the connection to the actual problem may be weak.

## **2. Processing mathematical information**

The second group contains six subdomains, a-f; of these, a, b, d and f are accounted for below.

“2a. The ability for logical thought in the sphere of quantitative and spatial relationships, number and letter symbols; the ability to think in mathematical symbols” (Krutetskii, 1976, p. 350)

This is the ability to think logically and to understand mathematical symbols. Children with this ability think logically—for example, they easily identify a common principle in a series of numbers or pictures (Vilkomir & O’Donoghue, 2009)—and they have no problem understanding and working with mathematical symbols.

“2b. The ability for rapid and broad generalization of mathematical objects, relations, and operations” (Krutetskii, 1976, p 350)

The ability to generalize mathematically materials can be viewed in two ways: 1. The pupil can apply a known general concept to a specific case, that is, based on a known general concept, the pupil can propose a concrete case that applies in the given situation; 2. Based on a concrete case, the pupil can rapidly extrapolate to a general formula. Krutetskii makes a distinction between the pupil using an already-known generalization and deducing a new generalization. When using the term rapid, he is not primarily referring to time, but rather to the number of concrete examples a pupil needs before he or she can deduce or apply a general relationship (Krutetskii, 1976).

“2d. Flexibility of mental process in mathematical activity” (Krutetskii, 1976, p. 350)

This is the ability to have a flexible mind-set. Children with this ability are not limited by only using known methods. They do not necessarily try to apply a known method to the problem. The important thing for these children is the search for solutions, and they easily change strategies.

“2f. The ability for rapid and free reconstruction of the direction of a mental process, switching from a direct to a reverse train of thought (reversibility of the mental process in mathematical reasoning)” (Krutetskii, 1976, p. 350)

This is the ability to recognize and work with reverse problems. Children with this ability easily solve a reverse problem without any special instructions. They quickly identify it as the opposite of what they had just solved, and it is not difficult for them to switch between a direct and a reverse way of thinking. Given the equation  $12/3=4$ , an example of a reverse problem would be  $4 \times 3 = 12$ .

## Method

For this paper, we use empirical data from a previous study (Mellroth, 2009). Data consists of audio recordings, field notes, and the pupil's written solutions from six 50-minute-long problem-solving sessions. During these meetings, the pupil worked with nine tasks, five of which were rich problems (Sheffield, 2003). Field notes and audio recordings were taken by one of the authors over a period of one semester. The pupil was a 10-year-old boy, "Marcus", in his fourth year at a public primary school. The sessions were carried out during school hours, at the school. Each session comprised either one or two tasks. Sessions were led by one of the authors, and only the pupil and the researcher were present during the sessions. The sessions had the following format: The task was introduced both orally and on paper, and the pupil was instructed to think aloud. In general, no specific feedback was given to the pupil during the sessions, but in some instances feedback of the following nature was given: "This isn't completely correct, can you try to explain it in a different way?" Sometimes encouraging statements, such as "you can continue in this way", were made. The pupil was chosen because his teacher had identified him as potentially highly able in mathematics. In addition, Marcus's problem-solving process clearly fulfils the criteria of MHAPs given by Krutetskii (1976), demonstrated below. Therefore, the case of Marcus is a good example that concretizes how teachers can notice mathematical potential. In advance of his participation, Marcus and his parents were informed about the study, the aim, and the methods, and the pseudonym Marcus was chosen by the boy. The study was performed following ethical recommendations for research.

Here we show results of the analysis for one problem, the flowerbed. Analysis was carried out in the following way: A) a holistic overview of the whole solution process was written down, B) each of Krutetskii's components (1, 2a-f, 3, and 4) was analysed separately, meaning that we sought examples of evidence for that specific component in the whole solution. This was repeated and discussed between the authors until we reached agreement. We first present the task, then Marcus's solution process, and finally how we interpret the abilities to be concretized in Marcus's solution process.

### The Flowerbed

Dilan has a flowerbed. He wants to put paving stones around it. The flowerbed has four sides of the same length, each paving stone is the same size as the flowerbed (see left picture in Figure 1).

- 1) How many paving stones does Dilan need to be able to encircle the whole flowerbed?
- 2) Dilan decides that he want to have two flowerbeds next to each other and put paving stones around them in the same way (see right picture on in Figure 1).

How many paving stones are needed if he wants to have the following number of flowerbeds:

- 3) 10?                      4) 30?                      5) 90?
- 6) If Dilan has 50 paving stones, how many flowerbeds can they be used to encircle?
- 7) If he has 79 paving stones, how many flowerbeds can they be used to encircle?

**Figure 1: The flowerbed with surrounding paving stones**

In this problem, hands-on material can be used, but eventually it will become impossible, or very time consuming, to build or draw a solution. To be able to completely solve the problem, the pupil must work in a structured way and find a connection between the number of paving stones and flowerbeds.

### Marcus's problem-solving process

Marcus very quickly grasped the structure of the flowerbed. After introduction of the problem, he immediately started to work on the solution; it was a rare quiet moment. However, he seldom did any writing, but he was thinking aloud and was encouraged to do so. His way of approaching the problems was similar in all the problem-solving sessions. The flowerbed consists of subtasks 1–7, and as soon as Marcus had finished one subtask, he was eager to continue with the next.

### Holistic description of the solution process

When working with the problem, Marcus quickly gave correct answers on the first three subtasks. After answering the third subtask, he was asked to explain his thinking.

5 Marcus: Well, it is 10 flowerbeds, and 2 on each side, that equals 12, times 2, equals 24. Then there are also 2 on the edges, so 26.

The researcher continued to give Marcus subtasks 4 and 5, and he answered correctly and quickly, without making notes. Thereafter, subtask 6 was given. Marcus thought a little bit more, but less than three minutes. His answer, 24 flowerbeds, was incorrect. The researcher asked him to explain his thinking. At this point, there was an illustrating picture on the table (see left image in Figure 2).

**Figure 2: Illustration of the problem, produced during the solution process**

6 Marcus: First I took away those 2 [he points to the 2 dark grey side pieces in the middle image of Figure 2], then it is 48, then divide by 2, equals 24. So, 24 flowerbeds.

The correct answer is 22 flowerbeds. The researcher drew the image on the right in Figure 2 to show her thought process.

7 Researcher: It is possible to count backwards to check if the calculation is correct. Let's try.

The researcher explained her thought process to explore if Marcus was able to change his thinking. Marcus was convinced his solution was correct, but he followed willingly and without difficulty.

8 Researcher: I am thinking: Double the number of paving stones going out from the number of flowerbeds, then add 6, since it will always be 6 on the sides. Then we can check. If we have 24 flowerbeds, how many paving stones are needed? First we will have 2 rows of paving stones...

Marcus interrupts the researcher.

9 Marcus: It must be 22 flowerbeds.

The researcher and Marcus together checked the answer, based on his way of thinking, as shown in the middle image in Figure 2. The length of the rows with paving stones equals 22 plus 2, and two of

these is  $2 \cdot 24 = 48$ . Finally, add the 2 paving stones on the sides to get 50 in total. Correct. The allotted time for the problem-solving session was running out; only 5 minutes remained, and Marcus looked tired, so the researcher suggested ending the session. But Marcus noticed that one more subtask remained, number 7, and he wanted to also do it before he joined his regular class, which was on break. The researcher told him that only 5 minutes remained; Marcus replied,

10 Marcus: I can do it!

11 Marcus: 36 flowerbeds and 1 paving stone is left over.

12 Researcher: How did you get that?

13 Marcus: First I searched for something that was reasonable.

Marcus gave his answer after thinking for 2 minutes. In the discussion, he explained that he tried 31 and 34 flowerbeds and then concluded that it must be 36 flowerbeds and that one paving stone would be left over.

### **Interpretations of how the abilities are concretized**

With the goal of concretizing for teachers how MHAPs may show some of the abilities defined by Krutetskii (1976), we here describe the process and criteria we used to tie Marcus's problem-solving process to specific abilities, as describes in the section about Krutetskii's abilities.

#### *1a. The ability for formalized perception of mathematical ...*

Marcus seemed to quickly grasp the problem statement, as is shown by his rapid and correct responses to the first three subtasks, where he did not explain how he came to the correct answer. However, when he explained his thinking—"Well, it is 10 flowerbeds, and 2 on each side, that equals 12, times 2, equals 24. Then there are also 2 on the edges, so 26"—he showed that he had grasped the mathematical structure of the problem.

What further strengthens the conclusion that he has an ability to see the mathematical structure is that he showed no signs of unsystematically searching for solutions, that is, he did not randomly guess.

#### *2a. The ability for logical thought ...*

In his solution there is no evidence of the use of mathematical symbols other than numbers and the word addition. What evidence for logical thought can be seen? We claim that his rapid answers in subtasks 1–3, together with the explanation in subtask 3, transcript row 5, shows evidence of logical deduction, as he identified a common principle from the two given figures. In addition, when the problem was turned around in subtask 6, where the number of paving stones is given instead of the number of flowerbeds, he had no difficulty understanding the problem. Furthermore, he also deduced, without hesitation, that there is a paving stone left over in subtask 7 (see transcript row 11).

#### *2b. The ability for rapid and broad generalization ...*

Marcus showed proof of this ability when he explained his thinking on subtask 3 (transcript row 5). On his own, he deduced a general way to solve the problem. Thereafter, through his work on subtasks 6 and 7, it can be deduced that he used the general solution proposed by the researcher (transcript row

8), that is, after a single case, he adapted the given generalisation to new cases (transcript rows 9, 11, and 13).

#### *2d. Flexibility of mental process in mathematical activity*

When Marcus rapidly adopted the alternative strategy the researcher suggested for arriving at the solution (transcript rows 8 and 9), he showed that he can easily change strategies.

#### *2f. The ability for rapid and free reconstruction ...*

Subtask 6 reverses the problem. First Marcus gave the wrong answer. However, when he described his thinking (transcript row 6), it became clear that he did understand the question and that he had a strategy to solve it. Therefore, we claim that he quickly identified the reverse problem.

### **Discussion and implications**

We strongly believe that teachers can notice pupils' mathematical potential when they are supported by clear explanations in conjunction with examples of how MHAPs can show their mathematical abilities. We also argue that this is a matter of schools' responsibilities since MHAPs are present in most classes, pupils from homes with high socio-economic statuses will manage well, but MHAPs can origin from all homes, and hence it's important that the school as organization have knowledge on how to support these pupils. Using previous research as a basis, we have proposed rich descriptions and provided and commented on examples of a MHAP's problem-solving process." We have thereby concretized what teachers can pay attention to in their pupils' problem-solving processes in order to identify those who may be highly able in mathematics.

To continue the work begun in this paper, the next step is to conduct a study to explore if our descriptions—or ones similar to them—give teachers support in noticing MHAPs. We have designed and piloted a workshop with this aim. In it, teachers are asked to evaluate pupils' oral and/or written solutions, to note if they find indicators of a certain ability (based on those proposed by Krutetskii), and if they do find them, to rate how strong the indicators are. In addition, they are asked to grade, on a scale of 0 to 2, how easy it is to detect the ability based on the pupils' solutions. However, to show its value the workshop must be validated with a larger number of teachers.

To be able to notice MHAPs, teachers need support based on research. This support can be orchestrated, for example, through professional development programmes (Shayshon et al., 2014). Observing mathematical abilities by using Krutetskii's (1976) framework is likely not the only way teachers can notice MHAPs. For example, as Singer et al. (2015) wrote, allowing pupils to work with problem modification is also a suitable way to notice MHAPs, who generally work in a structured manner, changing one variable at a time to control how changes may affect the problem. The results reported by Singer et al. (2015) also provide important knowledge for teachers to use in their endeavours to notice MHAPs.

Naturally, the support teachers give to pupils after they have noticed their mathematical potential is important, for example to prevent boredom, which can be a result of too little challenge (Liljedahl, 2017). Of special importance is teachers' ability to notice and support mathematical potential in underprivileged pupils, for example those from disadvantaged socioeconomic backgrounds (Schnell & Prediger, 2017). One way for teachers to support the learning of all pupils, including MHAPs, is

to use rich problems (Nolte & Pamperien, 2017; Sheffield, 2003). Pupils have different learning needs; some require more help to understand a concept or problem, while others need complex tasks to develop their learning (Sheffield, 2003). It is therefore important that research is conducted with the aim of giving teachers support on how to differentiate teaching in the regular classroom. To develop pupils' learning according to their potential is, of course, the main goal of teaching. To do this for MHAPs, however, the first step is to help teachers notice them (Shayshon et al., 2014).

*Whereas other studies have applied positioning theory to analyses of teaching and learning mathematics, this paper takes a practice-based approach to unpack what positioning in mathematics teaching might entail. From analysis of a shared video where a teacher leads a mathematical discussion of the naming of a fraction on the number line, we unpack the work of continually balancing attention to the mathematical content with positioning of students in their relation to each other, to the teacher, and to the mathematical content.*

*Keywords: Mathematics teaching, work of teaching, positioning, intentionality.*

## Introduction

There is agreement in the field of mathematics education that a special knowledge of mathematics is required to teach well. Numerous studies have investigated the nature and composition of this knowledge, how it can be developed and improved, and whether and how it influences student learning and the quality of teaching (Hoover, Mosvold, Ball, & Lai, 2016). Studies have investigated how much and what mathematical knowledge teachers need to know, what teachers should know, or what knowledge mathematics teachers use in teaching. Ball (2017) suggests that our field should shift attention from the mathematics teachers need to know towards the entailments of the special mathematical work of teaching. She thereby calls for more attention to the knowing and doing that is embedded in teaching. To illustrate what this might look like, she analyzes a record of practice where the teacher (Ball) calls on an African American girl to name a fraction on the number line and then facilitates a mathematical discussion around this. From her analysis, Ball (2017) identifies, names, and unpacks the special mathematical work of teaching. One aspect of this work is attending to positioning of students and their mathematical identities. In the present paper, we analyze the same data to further unpack what positioning might entail in mathematics teaching.

## Conceptual background

The idea of positioning is not new. To position someone is to place them in a certain location or disposition, or to make a certain location or disposition available. Positioning can refer to placement of objects, but it can also refer to the relation, rank or standing of one person relative to another (Oxford English Dictionary). The latter is in focus here. Positioning theory has developed from social psychology and linguistics; social psychology contributes with theories of roles and subjectivity, whereas the idea of a discursive production of selves comes from linguistics (Davies & Harré, 1990). Positioning theory has been applied in mathematics education for some years, but the importation of the theory from one field to another is not void of challenges (Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015). We will examine some of these challenges in our concluding discussion.

In this paper, we have deliberately decided to start with analysis of practice rather than with theory, because we do not take it for granted that a theory developed to describe interpersonal relations in social psychology is relevant to studies of mathematics teaching. Our practice-based approach targets positioning in teaching, and three important assumptions underlie this approach. First, we consider teaching to be a professional practice. Describing a practice as professional implies some kind of consensus among professionals in terms of specifying the given practice. Currently, no such consensus exists, but we base our work on plausible conceptions of practice that practitioners might realistically agree about (Hoover, Mosvold, & Fauskanger, 2014). To this end, engaging in analysis of shared data of mathematics teaching is particularly promising. Second, we follow Ball (2017) when we describe teaching as “work”. This implies an emphasis on the effortful and dynamic nature of teaching. It also implies a shift in focus from characterizing teaching as actions of teachers to exploring the work that is to be done in teaching, and the entailments of this work. Third, we consider teaching to be instructional interactions between teacher and students around a particular content, within an environment (Cohen, Raudenbush, & Ball, 2003).

### **Data material and analytic approach**

To explore positioning in mathematics teaching, we analyze one of the shared datasets that has been prepared for use in TWG19. This dataset shows a group of students (age 9–11), who have worked individually with a problem of naming fractions on a number line. Ball (2017) explains that the class has just shifted from naming fractions with area models to identifying fractions on the number line. The students have written their answers in their notebooks, and the teacher has been walking around, noticing the students’ range of ideas and explanations.

Based on our conception of teaching, our analysis is grounded in three basic questions: How does the teacher position particular students? How does the teacher position herself? How does the teacher position the mathematical content? When approaching these questions, we carefully consider instances of the teacher’s verbal as well as non-verbal communication that constitute evidence of positioning. We also ask about possible intentions behind making the identified positions available.

### **Analysis**

As a first step in our analysis, we divided the video into thematic sequences. We identified six thematic sequences, and our analysis below is organized around these.

#### **Sequence 1: Positioning Aniyah in the role of teacher**

Teacher: (standing near the back of the room) Who would like to try to explain what you think the answer is? And show us your reasoning by coming up to the board? Who’d like to come up to the board and try to tell– And you know, it might not be right. That’s okay because we’re learning something new. I’d like someone to come up and sort of be the teacher and explain how you are thinking about it. Who’d like to try that this morning? (Several children raise their hands to volunteer.) Okay, Aniyah? (Aniyah, a Black girl, gets up from her seat and walks to the whiteboard at the front of the classroom.)

Before selecting Aniyah to come up, the teacher provides some important signals to the class. First, she signals that she is more interested in their explanations and reasoning than in their answer. To emphasize this characterization of the available position, she states that “it might not be right,” and that this is okay. Furthermore, she explains that the reason why it is okay to present an incorrect answer is that they are now in the process of learning something new, and they are therefore not expected to know this already. She thereby indicates that students can successfully participate in the discussion without having the correct answer. Second, she describes the available role as one in which a student is going to “be the teacher.” When a student is invited to take the role of teacher, this implies that the teacher will temporarily step out of this role herself.

Several students volunteer to present on the board, but the teacher decides to call on Aniyah. We assume that this is an intentional act. The teacher might have decided that Aniyah’s solution is mathematically useful for the learning trajectory of the class. Another possibility is that the teacher keeps an eye out for students who rarely present at the board. Another possibility is that the choice is related to Aniyah’s racial identity. Aniyah is one of 22 African American students in class, and the teacher might attempt to disrupt systemic patterns of racism and inequity by calling on her — as indicated by Ball (2017). The first possible reason for calling on Aniyah refers to the mathematical quality of her reasoning, the second refers to her identity and role in the class, whereas the third relates to pressing issues in the environment outside the class. Balancing consideration for all three aspects is a challenge that is embedded in the mathematical work of teaching.

## **Sequence 2: Positioning students in relation to social norms of presenting mathematical ideas**

- Teacher: When someone’s presenting at the board, what should you be doing?
- Students: Looking at them.
- Teacher: Looking at that person—uh-huh.
- Aniyah: (to the teacher) You want me to write it?
- Teacher: (to Aniyah) You’re trying to mark what you think this number is and explain how you figured it out. (to class) Listen closely and see what you think about her reasoning and her answer. (Teacher moves to back of the classroom; Aniyah is in front at the whiteboard. Aniyah writes  $\frac{1}{7}$  by the orange line).

In this second sequence, the teacher provides two additional signals about the norms of participation when someone is presenting at the board. The teacher first emphasizes that the students should always look at whoever is presenting. Understanding what others say in a discussion is necessary to productively contribute, and the other students have to pay careful attention to Aniyah’s presentation in order to understand her thinking. Paying attention without looking is hard. The students seem to know how to behave when someone presents, but the teacher’s question emphasizes this norm of participation. After telling Aniyah what to do, the teacher asks the class to listen and see what they think about Aniyah’s reasoning and answer. This explicit emphasis on the norms of participation signals a certain position that the students should take while interacting with each other, but it also signals a positioning of the students in relation to the mathematical content. The students in class are directed to take a position of someone who listens carefully to make sure they understand Aniyah’s

reasoning, and they are asked to critically consider what they think about the reasoning as well as the answer. This position is different from a more traditional pattern in recitation, where the students answer the teacher's question and then receive feedback.

### Sequence 3: Positioning Toni by praising her question

- Aniyah: I put one-seventh because there's—
- Toni: Did she say one-seventh? (An African American girl, sitting close to where Aniyah is standing, asks quietly, almost to herself)
- Aniyah: Yeah (Hearing her question, Aniyah turns toward her and nods). Because there's seven equal parts, like one, two, three, four, five, six, and then seven (Demonstrates using her fingers spread to measure the intervals to count the parts on the number line).
- Teacher: (still standing at the back, addresses the class) Before you agree or disagree, I want you to ask questions if there's something you don't understand about what she did. No agreeing and disagreeing. Just—all you can do right now is ask Aniyah questions. Who has a question for her? Okay, Toni, what's your question for her?
- Toni: Why did — (looks across at children opposite her and laughs, twisting her braid on top of her head)
- Teacher: (to Toni) Go ahead, it's your turn.
- Toni: (to Aniyah) Why did you pick one-seventh? (Toni giggles, twisting her braid.)
- Dante: (laughing across the room at Toni) You did not!
- Teacher: Let's listen to her answer now. (to Toni) That was a very good question. (to Aniyah) Can you show us again how you figured that— why you decided one-seventh?
- Aniyah: First, I thought it might be seven because there's seven equal parts.
- Teacher: Did you write one-seventh? I can't see very well from here.
- Aniyah: Uh-huh. Yes.

This is the crux of the episode, and there are at least three decisive moments that require careful balancing of considerations for the interactions between students and with the mathematical content.

First, there is the moment when Toni interrupts with her first question. With a low voice, she asks: "Did she say one-seventh?" The teacher could have decided to tell Toni to be quiet when someone else is presenting. Instead, she decides to wait. By doing that, the teacher gives Aniyah the necessary space to stay in the role of a teacher and respond to Toni's question. We notice how Toni's question triggers Aniyah to continue her reasoning and show how the unit interval must be partitioned in equal parts by using her fingers spread to measure the intervals to count the parts on the number line.

Second, we notice how and when the teacher decides to interact. After Aniyah has given her explanation in response to Toni's first question, the teacher remains in the back of the classroom. This highlights her intention to remain in the role of facilitator, and thereby maintains the positioning

of Aniyah as the teacher. The teacher positions the children to participate in the discussion, establishing an open atmosphere by guiding the children to pose clarifying questions and not agree or disagree in this initial phase of the discussion. She also limits the space of acceptable interactions to maintain the positioning of students in relation to the mathematical content that we described above. After having reminded the children about the social norms and rules, the teacher encourages Toni to pose her question to Aniyah. By allowing Toni to pose her question instead of rebuking her for interrupting Aniyah, the teacher allows Toni to take the role of a productive contributor in the mathematical discussion that is unfolding.

Third, it is interesting to notice how the teacher reacts to Toni's question. She could have commented on Toni's laughter and pointing, and thereby positioned her as disrupting the discussion. Instead, the teacher praises her question. This decision influences the ongoing positioning of Toni. Her question is seen as an important mathematical question, and the teacher's move emphasizes the importance of asking questions in mathematics, which represents an indirect positioning of the mathematics. By repeating and rephrasing it to Aniyah, the teacher also puts Aniyah in a position to further develop her explanation. The teacher's question — "Can you show us again?" — indicates that she wants Aniyah to relate her answer to the figure on the board. Aniyah repeats that there are seven equal parts, illustrating the distance from zero for a given point on the number line.

#### **Sequence 4: Positioning of Lakeya and repositioning of Aniyah**

- Teacher: (The teacher nods affirmatively, and turns to the class) Okay, any more questions for Aniyah? In a moment, we're going to talk about what you think about her answer, but first, are there any more questions where you're not sure what she said, or you'd like to hear it again or something like that? Lakeya?
- Lakeya: (looks back at the teacher at the back of the room) If you start at the—
- Teacher: (gestures toward Aniyah) Talk to her, please.
- Lakeya: Oh! (turns toward Aniyah) If you start at the zero, how did you get one seventh?
- Aniyah: Well, I wasn't sure it was one-seventh, but first, I thought that the seven equal parts.

The teacher then refrains from evaluating Aniyah's explanation and thereby enables Aniyah to stay in the role of teacher. The teacher clarifies that they will soon discuss Aniyah's answer, but encourages more children to participate by posing clarifying questions. This comment indicates that understanding an argument is crucial in mathematics, and it thereby positions the mathematics in the discussion. This gives Lakeya an opportunity to ask a question and contribute to the discussion. We notice how the positioning of Lakeya also constitutes a repositioning of Aniyah. By asking Lakeya to address Aniyah and not herself, the teacher affirms Aniyah's position as teacher in this context. The teacher gives Aniyah the responsibility and agency, and Aniyah gets the opportunity to explain her thinking again.

In this sequence, the teacher could have commented that Toni has just asked a similar question, or that Aniyah has already explained this. Instead, the teacher appears to notice a difference in the questions of Toni and Lakeya. Toni asked why Aniyah picked "one SEVENTH", which indicates an emphasis on the whole. Lakeya asked how she got "ONE seventh", indicating a focus on the parts.

By deciding to let Aniyah respond, the teacher enables Lakeya to remain in the position of a productive contributor to the discussion, and she allows Aniyah to stay in the role as a teacher. Again, we see how the positioning of one student constitutes a repositioning of another, and we see how the teacher is challenged to balance attention to the positioning of students with attention to the content.

### **Sequence 5: Balancing positioning of Dante and Aniyah**

- Teacher: Okay, would some— You'd like to ask another question, Dante?
- Dante: Yeah.
- Teacher: Yes, what?
- Dante: So, if it's at the zero, how did you know that if like if I took it and put it at the— Hold on. Which line is— What if it didn't like— What if the orange line wasn't there, and you had to put it where the one is? What if the orange line wasn't there? And how would you still know it was one-seventh to put it where the orange line is now?
- Aniyah: (pauses) I don't know.
- Teacher: (pauses) Okay. Does everyone understand how Aniyah was thinking?
- Students: Yes.

Following Aniyah's response to Lakeya, Dante is given the opportunity to contribute. We observe that Dante relates Aniyah's answer to the orange line in the figure. His three repeated "What if"-statements indicate that Dante not only asks questions, but he also attempts to make sense of Aniyah's answer and extend their mathematical thinking about the mathematical content. Aniyah does not know how to answer Dante's questions. The teacher could have decided to praise Dante's contribution, but this might have been interpreted as a repositioning of Aniyah. When she decides not to comment, she gives both Dante and Aniyah the opportunity to remain in their positions as contributors to the discussion. When the teacher asks if they now understand Aniyah's thinking, this again represents positioning of the mathematics by emphasizing understanding of an argument, and by indicating that mathematics is the collective thinking of people. The supportive response from the class might be interpreted to indicate that Dante has made his classmates aware of the connection between Aniyah's answer one-seventh and the position on the number line. The response from the class might thus serve as an implicit positioning of Dante. The positioning of Dante could also involve a repositioning of Aniyah, indicating that her idea and explanation could be a starting point for a more focused discussion that follows.

### **Sequence 6: Positioning of Aniyah by allowing her to stay or going out of the role as teacher**

- Teacher: Yes? Okay. (to Aniyah) You can sit down now. We're going to try to get people to comment. Do you want to take comments up there? Would you like to stand there and take the comments, or do you want to sit down and listen to the discussion? What would you prefer?
- Aniyah: Sit down.
- Teacher: Sit— You'd like to sit down? Okay.

In this last sequence, the teacher decides to not simply ask Aniyah to sit down. Instead, she gives Aniyah the choice to stay in her role as a teacher and take comments from the board, or to sit down and listen to the discussion. This choice might be seen as an implicit positioning of Aniyah.

## Concluding discussion

Earlier in our paper, we mentioned how it might be challenging to import positioning theory for use in mathematics education (Herbel-Eisenmann et al., 2015), and how we deliberately decided to avoid using this theory and take a practice-based approach instead. We will now make two points that elaborate on some of these challenges and point to some potential contributions of our analysis. The first point relates to how positioning in mathematics teaching involves a careful balancing of multiple considerations regarding the interaction between students and teacher around a particular content. The second relates to the challenges of identifying positionings in analysis of teaching.

Whereas studies that use positioning theory in mathematics education tend to investigate how positionings might influence the development of students' mathematical identities (Herbel-Eisenmann et al., 2015), our analysis has identified various challenges that might be involved in the work of positioning students and the mathematical content. Our analysis indicates that positioning is tightly integrated with teaching. Teaching can be seen as interactions between teacher and students around a particular content with an ever-present influence with the environment (Cohen et al., 2003), and positioning in teaching is tightly connected with these instructional interactions. The challenges of positioning in mathematics teaching is thus rarely about singular and easily identifiable positionings. Positioning of one student tends to imply repositioning of another. The teacher is often challenged to make quick decisions that influence positioning of students, while simultaneously balancing this with careful attention to the mathematical content. In positioning the students — both in relation to each other, to the teacher, and to the mathematical content — the teacher has to balance multiple considerations. We suggest that the complexity of this balancing is at the heart of the work of teaching; this balancing defines the work that has to be done by the teacher. When the teacher invited Aniyah to present her thinking at the board, she had to navigate concerns for Aniyah and her developing mathematical identity, the development of other students, and to the class as a whole. At the same time, the teacher had to make decisions about her own position and how to lead the mathematical discussion without removing Aniyah from her position, and without placing any of the students in a negative position. The teacher also had to balance the positioning of the students and herself in relation to the students while paying careful attention to the mathematical content being discussed, and she had to make decisions about how to position the students and herself in relation to the mathematical content. We observe how establishing and maintaining norms of participation played an important role here, and we suggest that establishing and maintaining norms is also a deliberate and challenging work that is tightly related to positioning in teaching.

In their discussion of how positioning theory has been used in mathematics education, Herbel-Eisenmann et al. (2015) also notice how positionings tend to be identified in a singular way. Although the focus of our study was not on identifying positionings, but rather to unpack some of the challenges of positioning in mathematics teaching, our analysis indicates that the identification of positionings in mathematics teaching is complex. As observers, we rarely know for sure how a teacher intended

to position students in a particular moment of interaction, and we rarely know how students experienced being positioned. For instance, Aniyah might have experienced being positioned by the teacher in a way that differs from what the teacher's intentions were, and Dante, Lakeya, and Toni might have yet other interpretations of how Aniyah was positioned. In addition, the students are positioned (or experienced being positioned) in relation to the teacher, to each other, and to the mathematical content.

In her discussion of the special mathematical work of teaching, Ball (2017) identified positioning as an integral part of this work. In the present paper, we have further unpacked entailments of positioning in mathematics teaching, with a particular emphasis on the challenges of balancing positioning of students while at the same time retaining careful attention to the mathematical content. Although we have only analyzed one example of a slice of the mathematical work of teaching, we suggest that this balancing of positioning students in relation to the mathematical content is at the core of mathematics teaching. However, further studies are needed to investigate what this balancing might entail in different parts of the work of teaching, with different content, and at different grade levels. Further efforts are also needed to investigate ways of studying the intentionality and interpretation that is involved in this work.

*This paper presents initial findings from the project PRAQTAL: PRActices for Quality Teaching. Our project focuses on conceptualizing and identifying teaching practices for quality teaching of secondary school mathematics and physics. This work is driven by the understanding that to document, conceptualize, analyze and promote quality teaching, we need to constitute a discourse which articulates the diverse practices of teachers, in their multiple resolutions, and link them to educational theories on one hand and specific instruments on the other. For this purpose, we adopted Commognition as a conceptual framework. Here, we present our working definition of a teaching practice and our criteria for quality teaching practices. We discuss the procedures for identifying and documenting practices and their representation and illustrate our arguments with an example from the project's emerging database.*

*Keywords: Teaching practices, quality teaching, routines, secondary school mathematics.*

### Introduction

This paper presents initial findings from project PRAQTAL: PRActices for Quality Teaching. PRAQTAL focuses on conceptualizing and identifying practices for quality teaching of secondary school mathematics and physics. Why focus on teaching practices? Our team arrived at the need to explicate practice from two seemingly distinct paths: the first coming from an attempt to improve a teacher-education program from more “reflective” and “principles” based towards “practice” based. We noticed that the task of shifting the preservice teachers’ traditional-teacher-centered approach towards more reform-student-centered approach (Gregg, 1995) calls for explicit discussion and explication of practices. The second path originated in a series of projects aimed at promoting innovative and effective use of technologies in mathematics education. One of the core observations of these projects was the gap between theories of teaching and learning, and the actions practitioners took in the classroom. Following the traditions of educational design research (Mor & Winters, 2007) and learning design (Mor, Craft & Hernández-Leo, 2013), these projects identified this gap with a need for articulating and sharing design knowledge: the knowledge of solving practical challenges, or affecting change, by translating abstract theory into action, and explaining action by reference to theory. The initial account of practitioner experience was expressed in the form of design narratives. The derived design knowledge was captured in design patterns (Warburton & Mor, 2015): statements of the form “in context X, you are likely to encounter the challenge Y, and can address it using method Z”. The aim of the pedagogical design patterns community is to use this structure to articulate and share valuable elements of educational practice.

## Teaching practices

The need to explicate practice, specifically for promoting teaching programs, resulted in the flourishing of many projects that aim at identifying and teaching teaching-practices (Grossman, 2018). Some projects were content specific, some focus on specific grade levels, others are general, but most grew from the needs of training programs for preparing teachers to practice. A prime example is the University of Michigan *Teaching Works* project (<http://www.teachingworks.org/>) that identified a set of high-leverage instructional practices to prepare beginning teachers “who are skillful at connecting with and helping their students develop.” Several additional projects are discussed in Grossman’s book *Teaching core practices in teacher education* (2018). McDonald et al. (2013) identify a major shift in teacher training: from a focus on the knowledge required for teaching to a greater attention to the core practices of teaching. This move towards core practices, argue McDonald et al, reflects an attempt to connect the development of knowledge of teaching with the capacity to enact this knowledge in the classroom. McDonald et al. review the shifts in pedagogical approaches in teacher training over the last half century, corresponding to the change in dominant perspective on teaching and learning. From an “acquisition” model of learning, to “participationist” model of learning. However, Grossman and McDonald (2008) warn us that the field of research on teaching lacks a structured method and vocabulary for describing, analysing, evaluating and improving practices of teaching.

Various definitions are offered for teaching-practices. One such definition is offered by Windschitl (2016), who defines teaching practices as the recurring professional work devoted to planning, enacting and reflecting on instruction. This definition emphasizes the role of teaching practices prior, during and after instruction in class. According to Windschitl, the purpose of teaching practices is to overcome the divide between teacher instruction and student learning. The CPC group (Core Practices Consortium) whose aim is to develop shared understanding and common language regarding what it takes to prepare teachers for practice, to improve learning opportunities available to all students. They have identified characteristics that most sets of core-practices adhere to: (1) high frequency in teaching; (2) practices that teachers can enact in classroom across different curricula or instructional approach; (3) practices that allow teachers to learn more about students and about teaching; (4) practices that preserve the integrity and complexity of teaching; and (5) practices that are research-based and have the potential to improve student achievement (Grossman, Hammerness and McDonald, 2009).

Lampert (2010) addresses the difference between teaching practices and the practice of teaching. The practice of teaching involves adopting the identity of a teacher, doing what teachers do and believing what teachers believe in. This raises the question whether a practice can be learned in isolation or whether it requires participation in collective activity.

For the purpose of our project we need a working definition of teaching-practice and quality teaching-practice. To this end, we adopt the socio-cultural commognitive conceptual framework that conceptualizes mathematics (and any other discipline) as a special type of communication or discourse, including unique ways of saying and doing (Sfard, 2008), and learning mathematics as changes in the learner’s mathematics discourse. Adopting the commognitive conceptual framework,

we identify teaching-practice with a teaching-routine. Let us explain: according to our initial understanding, teaching practice is *a recognizable pattern of actions used by teachers in a given context to achieve specified aims*. This definition includes three constituents: pattern of action, context and aims. By the term “pattern of actions” we refer to actions that are repeated in situations that the performer would consider as similar. The assignment of a practice to a given context is crucial. Practices are inherently situated in material, social and intentional environments, and only make sense within these environments. Finally, practices are not arbitrary, they serve a goal. Identifying practices with routines will address those three requirements. Following Lavie, Steiner and Sfard (2019), we define a teaching-practice similar to their definition of routines: *the task the teacher saw herself performing together with the procedure she executed to perform the task* (p. 161). Such task could be *having to address a student's idea that she had not thought of earlier, or eliciting students' thinking*.

Thus, our goals in project PRAQTAL are to identify typical, interesting or challenging tasks that the teachers set themselves before, during and after a lesson, and possible related teaching-practices. That is, for each task we identify the various procedures that teachers chose to execute to perform the task. The plurality is used here to denote that our point of departure is that for each task, different teachers may consider different procedures to perform.

The advantage of this definition is that a task and therefore also a routine are recursive structures: a task could be parted to sub-tasks and a routine to sub-routines. This recursive structure is apparent in Table 1. This conceptualization of teaching-practices allows us to view teaching from different “zoom-ins” or different granularities: the highest level (left-most column in Table 1) provides us with the rational for everything that takes place in class. This is apparent with the highest meta-level of “providing students opportunity to become explorative participants in the mathematics discourse”. At the other end, the *procedure* and *empirical example* (two right-most columns of Table 1), provide us detailed steps to follow and perform, with different levels of sub-tasks in between. This relates to one of the issues with which we were concerned early on - the question of the “granularity” of practices: is “pausing for 5 seconds after asking a question” a teaching practice? Is “leading a classroom discussion” one? The first seems too miniscule, the second too expansive. The answer we found is that practices are networked in a fractal manner (as alluded to in the project name): they are spread across a continuous space with granularity on one axis and generality on the other. Complex practices are composed of other smaller-size practices. This granularity is apparent by Table 1. So “pausing for 5 seconds...” could be written in the procedure column of Table 1 as a part of procedure for performing a “larger size” task, such as “eliciting students' thinking”.

### **Quality teaching and quality teaching-practices**

Now we are left with the task of defining what counts as a quality teaching-practice (QTP). Defining mathematics as a specific type of discourse with unique ways of saying and doing, and learning mathematics as becoming more central participants in the mathematics discourse (Sfard, 2008), makes itself evident that QTP will be those that are most likely to prompt and support learners in participating in this discourse. Specifically, in the lessons we observed in our study and in literature, we identified three meta-tasks (or principles) that seem to underlay today's thinking

about mathematics teaching and seem to be shared by all mathematics teachers: (1) Provide students opportunities to become central participants in mathematics discourse; (2) Help students to develop a positive identity as mathematics learners; and (3) Encourage students to participate in equitable, egalitarian mathematical discourse. Therefore, our definition for quality-teaching-practice is *a teaching-practice that a teacher would perform that is aligned with the above three meta-tasks*. By the words “aligned with” we mean that the QTP supports at least two of those tasks, and does not violate any of those tasks.

## **Sourcing, Documenting and Representing Practices**

Having considered the definition of a QTP, we set out to identify and articulate such objects. In this section we explain how we identify teaching-practices. Our identification of a teaching-practice includes identifying typical, challenging or interesting tasks that the teacher saw herself as having to perform, and then identifying various procedures that could be enacted to perform the task. Our two primary sources of data are video recordings of secondary-school mathematics lessons taught by expert-teachers, and literature. Each video-taped lesson is fully transcribed, and subtitles are added to the video. We also have video-taped discussions with the teachers about the lesson before and after the lesson, written documents about the lesson (such as the teacher’s lesson plan) and access to the teacher for any questions that we have during our analysis of the lesson. This is highly required as our analysis, which is based on identifying the tasks that the teacher considered herself facing when choosing to perform certain actions, is interpretative in nature. Having the teachers react to our findings allow us to learn more about teaching practices that often remain implicit.

For each video-taped lesson, we focus on the teaching-actions performed by the teacher and ask: *what is the task that the teacher may achieve by those actions?* We return to the teachers and discuss our suggestions with them. We then ask whether the teaching-practice, that is, the task and the related procedure, supports at least two of the three meta-tasks defined earlier and does not violate any of them. If we find that the teaching-practice is repeated, either in a specific lesson or across different lessons, or if we find similar teaching-actions reported upon in the literature, we designate it as a candidate for quality-teaching-practice. We use Table 1 as our primary working-tool. In Table 1, the leftmost “meta-task” column is fixed, and includes the three meta-tasks described earlier (in Table 1 we only present the first of the three meta-tasks in the sake of brevity). The other columns become more and more fixed as we continue with our analysis. Rubrics in the two right-most columns keep adding as we analyze lessons. We document the performed action(s) found in the analyzed lessons in the “empirical example” column of Table 1 and list the various tasks and sub-tasks that a teacher performing these actions could be facing.

To clarify our methodology, an example from a 90-minute lesson on complex-numbers is demonstrated next. The lesson was taught in an advanced 12<sup>th</sup> grade mathematics classroom in an Israeli high-school. This lesson was the first on this topic. Before focusing on the specific example, we describe the lesson’s thematic structure: In this lesson the teacher faced the challenge of teaching a new mathematical object, a set of numbers that the students are not yet familiar with – the complex numbers. Her choice was to follow the idea that ontogenetic processes often follow phylogenetic ones, and walk her students through the historical development of those numbers, in

four steps: (1) realize that as long as you only have real numbers, there is a no such thing as square root from negative number, (2) conclude that a 3<sup>rd</sup> power polynomial has at least one root. (3) introduce the students to the suggestion of Girolamo Cardano which led to mathematics results including square roots of negative numbers, and then Rafael Bombeli's suggestion of determining such entities as mathematics objects – numbers. (4) Show that the new entity “complex number” is a number by showing that it has similar attributes as the corresponding operations on rational and real numbers. Our example focuses solely on this fourth section, during which the following discussion took place [timestamp 57:50]:

- Teacher        ... so I see that this addition has different characteristics that are... the existence of a neutral element in addition
- Student        but why do we need this?
- Teacher        To know the structure. I want to convince you that this structure of the complex-numbers justifies the name “numbers”. Ok, why do I call these numbers? In what sense are those numbers? I want to convince you that this behaves similarly to real numbers regarding operations.

In this short excerpt, we find a student's interesting question “why do we need this?” This question is interesting as it seemed from the video that the student was not having a difficulty with the mathematics procedures that the students and teacher were performing neither was she trying to say that “she is not interested”, or that “she does not want to study”. It seemed that she was trying to make sense of the reasons for which the teacher was showing that the set of complex numbers have different specific characteristics (thus – proving that it is a field). The teacher's answer addresses the three meta-tasks: (1) *Provide students opportunities to become participants in mathematics discourse*: in mathematical discourse, when an object is introduced by expanding a familiar class (category), it is imperative to check its properties against the definition of the class to which it is supposed to belong, or by considering its characteristics (the object of *number* is not well defined in mathematics). More generally, when a new object is introduced or when an object is identified, this identification should adhere to the conditions of a mathematical definition. As was found in various studies, this is not a simple endeavor, and therefore requires explicit teaching:

The discursive activity of defining seems to be pushed aside by our strong tendency to use words in a direct, unmediated manner, without accounting for this use and without monitoring its appropriateness. This inclination for unmediated, spontaneous use of words is the basic characteristic of human communication. .... In schools, one's spontaneous uses of words are supposed to be translated into scientific. For this modification to happen, the students will have to learn to suspend their spontaneous discursive decisions for the sake of reflective, meta-discursively mediated choices of words. This, as was already observed, is a difficult thing to learn (Nachlieli & Sfard, 2003. pp. 3-355–3-356).

(2) *Enable students to develop a positive identity as mathematics learners*: the teacher's answer explicates her encouragement of students' questions, of seeing the students as capable of participating in a challenging mathematics discussion.

(3) *Encourage students to participate in egalitarian mathematical discourse:* In the classroom, when a teacher introduces an object, students often accept it as belonging to that class/category. It is as if they accept the teacher as the primary authority. In this example the teacher encourages her students to break away from the ritual participation of accepting a “truth” because it was stated by the teacher, and leads them to an empowered, explorative participation, where they identify objects by reference to a definition. This is apparent through the words “I want to convince you” – the teacher stresses that she needs to do the work of convincing the students, that she does not expect them to just accept whatever she tells them. She does not place herself as the primary authority.

The QTP that we elicited from this excerpt, based also on literature (e.g. Sfard & Nachlieli, 2003), includes the following task and practice:

**Task.** When the teacher faces the task of introducing new objects, or of expanding a familiar class (category), the new object needs to be identified by checking its properties against the definition of the class, or by considering its characteristics.

**Procedure.**

1. The teacher raises the question, or invites the students to raise the question, or addresses the question if arises: is this object compliant with the definition of the base class?
2. The teacher guides the students in independent verification of the new object against the conditions of the definition.
3. The teacher ascertains that the students continue to work with the object as compliant with the definition.

Meta-task	Task	Sub-task	Procedure	Empirical example
