

# Proceedings of the Eleventh Congress of the European Society for Research in Mathematics Education

**Editors:** Uffe Thomas Jankvist, Marja van den Heuvel-Panhuizen, Michiel Veldhuis

**Organised by:** Freudenthal Group & Freudenthal Institute, Utrecht University

**Year:** 2019

## Editors

Uffe Thomas Jankvist, Danish School of Education, Aarhus University, Denmark.

Marja van den Heuvel-Panhuizen, Freudenthal Group & Freudenthal Institute, Utrecht University, Netherlands; Nord University, Norway.

Michiel Veldhuis, Freudenthal Group, Utrecht University, Netherlands; iPabo University of Applied Sciences, Amsterdam, Netherlands.

## Editorial Board

Mario Sánchez Aguilar; Paul Andrews; Pedro Arteaga; Fatma Aslan-Tutak; Michal Ayalon; Jonas Bergman Årlebäck; Anna Baccaglioni-Frank; Anette Bagger; Arthur Bakker; Berta Barquero; Johannes Beck; Aline Bernardes; Angelika Bikner-Ahsbahi; Irene Biza; Laura Black; Laurinda Brown; Orly Buchbinder; Àngela Bufo; Susana Carreira; Renata Carvalho; Patrick Capraro; Esther Chan; Maria Chimoni; Renaud Chorlay; Anna Chronaki; Alison Clark-Wilson; Jason Cooper; Jenny Cramer; Seán Delaney; Javier Díez-Palomar; Ana Donevska-Todorova; Beatriz Vargas Dorneles; Ove Gunnar Drageset; Viviane Durand-Guerrier; Andreas Eckert; Kirstin Erath; Ingvald Erfjord; Nataly Essonnier; Eleonora Faggiano; Marie Therese Farrugia; Fiona Faulkner; Janne Fauskanger; Carla Finesilver; Marita Friesen; Daniel Frischmeier; Eirini Geraniou; Imène Ghedamsi; Inés M. Gómez-Chacón; Orlando Rafael González; Alejandro S. González-Martín; Koen Gravemeijer; Ghislaine Gueudet; Tanja Hamann; Çiğdem Haser; Dave Hewitt; Jeremy Hodgen; Kees Hoogland; Jenni Ingram; Paola Iannone; Eva Jablonka; Britta Jessen; Heather Johnson; Keith Jones; Sibel Kazak; Beth Kelly; Jeta Kingji; Iveta Kohanová; David Kollosche; Evelyn H. Kroesbergen; Sebastian Kuntze; Ana Kuzle; Aisling Leavy; Esther Levenson; Peter Liljedahl; Božena Maj-Tatsis; Francesca Martignone; Michela Maschietto; Maria Mellone; Christian Mercat; Vilma Mesa; Siún Nic Mhuirí; Morten Misfeldt; Joris Mithalal; Miguel Montes; Hana Moraová; Francesca Morselli; Reidar Mosvold; Andreas Moutsios-Rentzos; Reinhard Oldenburg; Samet Okumus; Antonio M. Oller-Marcén; Chrysi Papadaki; Birgit Pepin; Alon Pinto; Núria Planas; Joao Pedro da Ponte; Caterina Primi; Elisabeth Rathgeb-Schnierer; Miguel Ribeiro; Ornella Robutti; Helena Roos; Kirsti Rø; Charalampos Sakonidis; Libuse Samkova; Judy Sayers; Petra Scherer; Stanislaw Schukajlow; Priska Schöner; Marcus Schütte; Nathalie Sinclair; Karen Skilling; Michelle Stephan; Hauke Straehler-Pohl; Heidi Strømskag; Andreas Stylianides; Gabriel J. Stylianides; Osama Swidan; Michal Tabach; Rukiye Didem Taylan; Melih Turgut; Marianna Tzekaki; Behiye Ubuz; Anita Valenta; Olov Viirman; Hanna Viitala; Katrin Vorhölter; Geoff Wake; Hans-Georg Weigand; Kjersti Wæge; Constantinos Xenofontos; Stefan Zehetmeier.

## TABLE OF CONTENTS

Preface: CERME 11 in lovely Utrecht historic sites <i>Susanne Prediger, Ivy Kidron</i>	1
<b>Introduction</b>	
Introduction to the Proceedings of the Eleventh Congress of the European Society for Research in Mathematics Education (CERME11) <i>Uffe Thomas Jankvist, Marja van den Heuvel-Panhuizen, Michiel Veldhuis</i>	3
<b>Plenary lectures</b>	
Embodied instrumentation: combining different views on using digital technology in mathematics education <i>Paul Drijvers</i>	8
History and pedagogy of mathematics in mathematics education: History of the field, the potential of current examples, and directions for the future <i>Kathleen M. Clark</i>	29
Extensions of number systems: continuities and discontinuities revisited <i>Sebastian Rezat</i>	56
<b>Plenary panel</b>	
ERME anniversary panel on the occasion of the 20th birthday of the European Society for Research in Mathematics Education <i>Konrad Krainer, Hanna Palmér, Barbara Jaworski, Susanne Prediger, Paolo Boero, Simon Modeste, Tommy Dreyfus, and Jana Žalská</i>	81

<b>TWG01: Argumentation and proof</b>	<b>99</b>
Introduction to the papers of TWG01: Argumentation and Proof <i>Gabriel J. Stylianides, Orly Buchbinder, Jenny Cramer, Viviane Durand-Guerrier, Andreas Moutsios-Rentzos, and Anita Valenta</i>	100
Understanding geometric proofs: scaffolding pre-service mathematics teacher students through dynamic geometry system (dgs) and flowchart proof <i>Lathiful Anwar and Martin Goedhart</i>	104
Initial participation in a reasoning-and-proving discourse in elementary school teacher education <i>Kristin Krogh Arnesen, Ole Enge, Kirsti Rø and Anita Valenta</i>	112
Epistemological obstacles in the evolution of the concept of proof in the path of ancient Greek tradition <i>Miglena Asenova</i>	120
Teachers' perspectives on mathematical argumentation, reasoning and justifying in calculus classrooms <i>Sabrina Bersch</i>	128
Integrating Euclidean rationality of proving with a dynamic approach to validation of statements: The role of continuity of transformations <i>Paolo Boero and Fiorenza Turiano</i>	136
The role of the teacher in the development of structure-based argumentations <i>Fiene Bredow</i>	145
Prospective teachers enacting proof tasks in secondary mathematics classrooms <i>Orly Buchbinder and Sharon McCrone</i>	147
Developing Pre-service Mathematics Teachers' Pedagogical Content Knowledge of Proof Schemes: An Intervention Study <i>Fikret Cihan and Hatice Akkoç</i>	155
Games as a means of motivating more students to participate in argumentation <i>Jenny Cramer</i>	163
Towards an interactional perspective on argumentation in school mathematics <i>Markos Dallas</i>	171
A pilot study on elementary pupils conditional reasoning skills and alternatives generation skills in mathematics <i>Anastasia Datsogianni, Stefan Ufer and Beate Sodian</i>	179
What do prospective mathematics teachers mean by definitions can be proved? <i>Merve Dilberoğlu, Çiğdem Haser and Erdinç Çakıroğlu</i>	181
The justification of conjectures in the study of the congruence of triangles by 5th grade students <i>Marisa Gregório and Hélia Oliveira</i>	189
Fundamental task to generate the idea of proving by contradiction <i>Hiroaki Hamanaka and Koji Otaki</i>	191

Student teachers' argumentation in primary school mathematics classrooms <i>Helene Hauge</i>	199
The interplay of logical relations and their linguistic forms in proofs written in natural language <i>Kerstin Hein</i>	201
Mathematical Arguments in the Context of Mathematical Giftedness Analysis of Oral Argumentations with Toulmin <i>Simone Jablonski and Matthias Ludwig</i>	209
"Using geometry, justify (...)". Readiness of 14-year-old students to show formal operational thinking <i>Edyta Juskowiak</i>	217
On the effect of using different phrasings in proving tasks <i>Leander Kempen, Petra Carina Tebaartz and Miriam Krieger</i>	225
Task design for developing students' recognition of the roles of assumptions in mathematical activity <i>Kotaro Komatsu, Gabriel J. Stylianides and Andreas J. Stylianides</i>	233
Primary students reasoning and argumentation based on statistical data <i>Jens Krummenauer and Sebastian Kuntze</i>	241
Questions and answers & but no reasoning! <i>Dorte Moeskær Larsen and Camilla Hellsten Østergaard</i>	249
Factors influencing teachers' decision making on reasoning-and proving in Hong Kong <i>Chun Yeung Lee</i>	257
On teachers' experiences with argumentation and proving activities in lower secondary mathematics classrooms <i>Silke Lekauss</i>	265
An epistemological study of recursion and mathematical induction in mathematics and computer science <i>Nicolás León</i>	274
Explanatoriness as a value in mathematics and mathematics teaching <i>Eva Müller-Hill</i>	276
Proof, reasoning and logic at the interface between Mathematics and Computer Science: toward a framework for analyzing problem solving <i>Simon Modeste, Sylvain Beauvoir, Jonathan Chappelon, Viviane Durand-Guerrier, Nicolás León and Antoine Meyer</i>	284
A systemic investigation of students' views about proof in high school geometry: the official and shadow education systems in a school unit <i>Andreas Moutsios-Rentzos and Eleni Plyta</i>	292
Meta-knowledge about definition: The case of special quadrilaterals <i>Shogo Murata</i>	300
Proof comprehension of undergraduate students and the relation to individual characteristics <i>Silke Neuhaus and Stefanie Rach</i>	302

Abduction in argumentation: Two representations that reveal its different functions <i>Chrysi Papadaki, David Reid and Christine Knipping</i>	310
Some linguistic issues on the teaching of mathematical proof <i>Yusuke Shinno, Takeshi Miyakawa, Tatsuya Mizoguchi, Hiroaki Hamanaka and Susumu Kunitune</i>	318
Planning for mathematical reasoning Surprising challenges in a design process <i>Helén Sterner</i>	326
Metacognitive activities of pre-service teachers in proving processes <i>Nele Stubbemann and Christine Knipping</i>	328
Features of mathematics teacher argumentation in classroom <i>Jorge A. Toro and Walter F. Castro</i>	336
Beyond direct proof in the approach to the culture of theorems: a case study on 10th grade students' difficulties and potential <i>Fiorenza Turiano and Paolo Boero</i>	338
Identifying key ideas in proof: the case of the irrationality of $\sqrt{k}$ <i>Xiaoheng (Kitty) Yan and Gila Hanna</i>	346
<b>TWG02: Arithmetic and number systems</b>	<b>354</b>
Introduction to the work of TWG 2: Arithmetic and number systems <i>Elisabeth Rathgeb-Schnierer, Renata Carvalho, Beatriz Vargas Dorneles and Judy Sayers</i>	355
Use of conceptual metaphors in the development of number sense in the first years of mathematical learning <i>Natividad Adamuz-Povedano, Elvira Fernández-Ahumada, Teresa García-Pérez and Rafael Bracho-López</i>	359
Development of an intervention program in counting principles for first-grade students - Pilot study <i>Évelin Assis and Luciana Vellinho Corso</i>	367
Intervention in counting principles with first-grade students <i>Évelin Assis and Luciana Vellinho Corso</i>	369
Design of a board game around the notion of fractions <i>Alix Boissière</i>	377
Exploring students adaptive use of domain specific knowledge <i>Joana Brocardo, Catarina Delgado, Fátima Mendes, Jean Marie Kraemer</i>	379
Mental computation: An opportunity to develop students' strategies in rational number division <i>Renata Carvalho and João Pedro da Ponte</i>	387
Intervention in counting principles: teachers' perceptions on students learning profile <i>Luciana Vellinho Corso and Évelin Assis</i>	395
Teaching and learning decimal numbers: the role of numeration units <i>Lalina Coulange and Grégory Train</i>	403

The offer of tasks to work on multiplication in grades 2 and 3 <i>Sandra Gleißberg and Klaus-Peter Eichler</i>	411
Considerations on developmental stage models, learning trajectories and maybe better ways to guide early arithmetic instruction <i>Michael Gaidoschik</i>	419
Rational number operations: What understandings do children demonstrate? <i>Sofia Graça, João Pedro da Ponte and António Guerreiro</i>	427
Pairing numbers: An unconventional way of evaluating arithmetic expressions <i>Robert Gunnarsson and Ioannis Papadopoulos</i>	435
Interactions between pupils' actions and manipulative characteristics when solving an arithmetical task <i>Doris Jeannotte and Claudia Corriveau</i>	443
An analysis of understanding the algebraic structure in school mathematics: focusing on the extension of number sets <i>Kazuhiro Kurihara</i>	451
Strategy choices and formal algorithms: A mixed methods study <i>Ems Lord and Andreas J. Stylianides</i>	453
Number line estimation and quantitative reasoning: two important skills for mathematical achievement <i>Camila Peres Nogueira and Beatriz Vargas Dorneles</i>	461
Mental calculations with rational numbers across educational levels <i>Ioannis Papadopoulos, Styliani Panagiotopoulou and Michail Karakostas</i>	469
Students' ability to compare fractions related to proficiency in the four operations <i>Pernille Ladegaard Pedersen and Peter Sunde</i>	477
Flexible mental calculation skills of freshmen and graduates <i>Charlotte Rechtsteiner</i>	485
A tool to evaluate students' performance in solving fraction word problems <i>Maria T. Sanz García, Olimpia Figueras, and Bernardo Gómez</i>	487
Development and variance components in single-digit addition strategies in year one <i>Pernille B. Sunde, and Peter Sunde</i>	495
Learning fractions using a teaching model designed with applets and the number line: The cases of Alvaro and Fernanda <i>Carlos Valenzuela García, and Olimpia Figueras</i>	503
Reflecting on a series of studies on conceptual and procedural knowledge of fractions: Theoretical, methodological and educational considerations <i>Xenia Vamvakoussi, Maria Bempeni, Stavroula Pouloupoulou and Ioanna Tsiplaki</i>	511
Metacognition in non-routine problem solving process of year 6 children <i>Aikaterini Vissariou and Despina Desli</i>	519
<b>TWG03: Algebraic Thinking</b>	<b>527</b>
Algebraic Thinking <i>Maria Chimoni, Dave Hewitt, Reinhard Oldenburg, and Heidi Strømskag</i>	528

Teachers Conceptions of Algebra and Knowledge of Task Purposes <i>Burcu Alapala and Isil Isler-Baykal</i>	532
Strategies exhibited by good and average solvers of geometric pattern problems as source of traits of mathematical giftedness in grades 4-6 <i>Eva Arbona, María José Beltrán-Meneu and Ángel Gutiérrez</i>	534
Investigating early algebraic thinking abilities: a path model <i>Maria Chimoni, Demetra Pitta-Pantazi and Constantinos Christou</i>	542
Students expected engagement with algebra based on an analysis of exams in Norway from 1995 till 2018 <i>James Gray, Bodil Kleve and Helga Kufaas Tellefsen</i>	550
Never carry out any arithmetic: the importance of structure in developing algebraic thinking <i>Dave Hewitt</i>	558
Algebraic thinking in the shadow of programming <i>Cecilia Kilhamn and Kajsa Bråting</i>	566
Linear figural patterns as a teaching tool for preservice elementary teachers the role of symbolic expressions <i>Iveta Kohanová and Trygve Solstad</i>	574
Graphing formulas to give meaning to algebraic formulas <i>Peter Kop, Fred Janssen, Paul Drijvers and Jan van Driel</i>	582
Relational thinking and operating on unknown quantities. A study with 5 to 10 years old children <i>Denise Lenz</i>	590
Enhancing students' generalizations: a case of abductive reasoning <i>Joana Mata-Pereira<sup>1</sup> and João Pedro da Ponte<sup>2</sup></i>	598
Body Motion and Early Algebra <i>Ricardo Nemirovsky, Natividad Adamuz-Povedano, Francesca Ferrara, and Giulia Ferrari</i>	606
Color-coding as a means to support flexibility in pattern generalization tasks <i>Per Nilsson and Andreas Eckert</i>	614
A classification scheme for variables <i>Reinhard Oldenburg</i>	622
Transforming equations equivalently? theoretical considerations of equivalent transformations of equations <i>Norbert Oleksik</i>	630
How students in 5th and 8th grade in Norway understand the equal sign <i>Hilde Opsal</i>	638
Fifth-grade students solving linear equations supported by physical experiences <i>Mara Otten, Marja van den Heuvel-Panhuizen, Michiel Veldhuis and Aiso Heinze</i>	646

Representational variation among elementary school students. A study within a functional approach to early algebra	654
<i>Eder Pinto, Bárbara M. Brizuela, and María C. Cañadas</i>	
Unpacking 9th grade students algebraic thinking	662
<i>Marios Pittalis and Ioannis Zacharias</i>	
Portuguese and Spanish prospective teachers functional thinking on geometric patterns	670
<i>Irene Polo-Blanco, Hélia Oliveira and Ana Henriques</i>	
When a number moves across, it changes its sign Investigating Teachers' Conceptual Understanding of Algebra	672
<i>Mark Prendergast, Aoibhinn Ní Shúilleabháin, Paul Grimes and Niamh O'Meara</i>	
Dealing with quantitative difference: A study with second graders	674
<i>Margarida Rodrigues and Lurdes Serrazina</i>	
Short note on algebraic notations: First encounter with letter variables in primary school	682
<i>Anna Susanne Steinweg</i>	
Structures identified by second graders in a teaching experiment in a functional approach to early algebra	690
<i>María D. Torres, María C. Cañadas and Antonio Moreno</i>	
Comparing the structure of algorithms: The case of long division and log division	698
<i>Christof Weber</i>	
Relationships between procedural fluency and conceptual understanding in algebra for postsecondary students	706
<i>Claire Wladis, Jay Verkuilen, Sydne McCluskey, Kathleen Offenholley, Dale Dawes, Susan Licwinko and Jae Ki Lee</i>	
Forming basic conceptions in dealing with quadratic equations	714
<i>Alexander Wolff</i>	
Provoking students to solve equations in a content-oriented fashion and not using routines by solving slightly modified standard tasks	716
<i>Simon Zell</i>	
<b>TWG04: Geometry Teaching and Learning</b>	<b>724</b>
Introduction to the papers of TWG04: Geometry Teaching and Learning	725
<i>Keith Jones, Michela Maschietto, Joris Mithalal-Le Doze and Chrysi Papadaki</i>	
A computer-based environment for argumenting and proving in geometry	729
<i>Giovannina Albano, Umberto Dello Iacono and Maria Alessandra Mariotti</i>	
The evolution of 9-year-old students' understanding of the relationships among geometrical shapes	737
<i>Melania Bernabeu, Salvador Llinares and Mar Moreno</i>	
Measuring area on the geoboard focusing on using flexible strategies	745
<i>Øyvind Jacobsen Bjørkås and Marja van den Heuvel-Panhuizen</i>	
Justifying geometrical generalizations in elementary school preservice teacher education	753
<i>Lina Brunheira and João Pedro da Ponte</i>	

Professional actions of novice teachers in the context of teaching and learning geometry <i>Caroline Bulf</i>	761
A model of the instrumentation process in dynamic geometry <i>Madona Chartouny, Iman Osta and Nawal Abou Raad</i>	769
Spatial structuring in early years <i>Joana Conceição and Margarida Rodrigues</i>	777
The development of geometrical knowledge starting from arts education <i>Catarina Delgado, Fátima Mendes and Filipe Fialho</i>	779
“Going straight”: discussions and experience at primary school <i>Maria Elena Favilla, Maria Luppi and Michela Maschietto</i>	781
Mathematical creativity and geometry: The influence of geometrical figure apprehension on the production of multiple solutions <i>Panagiotis Gridos, Athanasios Gagatsis, Iliada Elia and Eleni Deliyianni</i>	789
In-service teachers' conceptions of parallelogram definitions <i>Aehsan Haj Yahya, Wajeeh Daher and Osama Swidan</i>	797
Children s use of spatial skills in solving two map-reading tasks in real space <i>Cathleen Heil</i>	805
A step in the development of an evidence based learning progression for geometric reasoning: focus on shape and angle <i>Marj Horne and Rebecca Seah</i>	813
Task design with DGEs: The case of students’ counterexamples <i>Keith Jones and Kotaro Komatsu</i>	821
The connection between angle measure and the understanding of sine <i>Valentin Katter</i>	823
To figure out more than a solution to a geometric problem: What do prospective teachers? <i>Fátima Mendes, Ana Maria Boavida, Joana Brocardo and Catarina Delgado</i>	831
Personal geometrical work of pre-service teachers: a case study based on the theory of Mathematical Working Spaces <i>Alain Kuzniak and Assia Nechache</i>	833
Students’ reasons for introducing auxiliary lines in proving situations <i>Alik Palatnik and Tommy Dreyfus</i>	841
Construction of triangles: some misconceptions and difficulties <i>Paula Vieira da Silva and Leonor Santos</i>	849
Grade 3/4 students’ understanding of geometrical objects: Australian case studies on (mis)conceptions of cubes <i>Ann Downton, Sharyn Livy and Simone Reinhold</i>	857

<b>TWG05: Probability and Statistics Education</b>	<b>865</b>
Introduction to the work of TWG5: Probability and Statistics Education	866
Formalizing students informal statistical reasoning on real data: Using Gapminder to follow the cycle of inquiry and visual analyses	870
<i>Martin Andre, Zolt Lavicza and Theodosia Prodromou</i>	
Design of statistics learning environments	878
<i>Dani Ben-Zvi, Koeno Gravemeijer and Janet Ainley</i>	
Informal statistical inference and permutation tests	886
<i>Øyvind Jacobsen Bjørkås, Kjetil B. Halvorsen and Dag Oskar Madsen</i>	
Unravelling teachers' strategies when interpreting histograms: an eyetracking study	888
<i>Lonneke Boels, Arthur Bakker and Paul Drijvers</i>	
The importance of high-level tasks in the access of statistical errors: A study with future teachers of the first years	896
<i>Ana Caseiro, Ricardo Machado and Tiago Tempera</i>	
Design principles for short informal statistical inferences activities for primary education	904
<i>Arjen de Vetten, Aisling Leavy and Ronald Keijzer</i>	
Chilean primary school difficulties in building bar graphs	912
<i>Danilo Díaz-Levicoy and Pedro Arteaga</i>	
How Realistic Mathematics Education approach influences 6th grade students' statistical thinking	914
<i>Bedriye Doluzengin and Sibel Kazak</i>	
Repurpose and extend: making a model statistical	922
<i>Michal Dvir and Dani Ben-Zvi</i>	
The role of decision-making in the legitimization of probability and statistics in Chilean upper secondary school curriculum	930
<i>Raimundo Elicer</i>	
The challenge of constructing statistically worthwhile questions	938
<i>Daniel Frischemeier and Aisling M. Leavy</i>	
Investigating teachers' pedagogical content knowledge for statistical reasoning via the real life problem scenario	946
<i>Rukiye Gökce and Sibel Kazak</i>	
<i>It's a good score! Just looks low:</i> Using data-driven argumentation to engage students in reasoning about and modelling variability	954
<i>Orlando González and Somchai Chitmun</i>	
Prospective teachers' interdisciplinary learning scenario to promote students' statistical reasoning	962
<i>Ana Henriques, Hélia Oliveira and Mónica Baptista</i>	
The development of a domain map in probability for teacher education	964
<i>Judith Huget</i>	

Testing the negative recency effect among teacher students trying to generate random sequences <i>Olav Gravir Imenes</i>	972
Statistical Graphs Semiotic Complexity, Purpose and Contexts in Costa Rica Primary Education Textbooks <i>Maynor Jiménez-Castro, Pedro Arteaga and Carmen Batanero</i>	980
Building up students' data analytics skills to solve real world problems <i>Sibel Kazak, Taro Fujita and Manoli Pifarre Turmo</i>	988
Interweaving probability games and other mathematical areas in Tamás Varga's spirit in Hungary <i>Anna Kiss</i>	990
Pitfalls and surprises in probability: The battle against counterintuition <i>Signe Holm Knudtzon</i>	992
Why does statistical inference remain difficult? A textbook analysis for the phases of inference <i>Rüya Gökhan Koçer and Fulya Kula</i>	1000
Young children s informal statistical inference experiences through constructing a pictograph <i>Gamze Kurt Birel</i>	1002
What is taught and learnt on confidence interval? A case study <i>Kyeong-Hwa, Lee, Chang-Geun, Song and Yeong Ok, Chong</i>	1010
Prospective high school teachers' interpretation of hypothesis tests and confidence intervals <i>M<sup>a</sup> del Mar López-Martín, Carmen Batanero and María M. Gea</i>	1018
Covariational reasoning patterns exhibited by high school students during the implementation of a hypothetical learning trajectory <i>Miguel Medina, Ernesto Sánchez and Eleazar Silvestre</i>	1026
A Case Study of Teacher Professional Development on Game- Enhanced Statistics Learning in the Early Years of Schooling <i>Maria Meletiou-Mavrotheris, Efi Paparistodemou, Loucas Tsouccas</i>	1034
The influence of the context of conditional probability problems on probabilistic thinking: A case study with teacher candidates <i>Beyza Olgun and Mine Isiksal-Bostan</i>	1042
In-service teachers' design, teaching and reflection on probability <i>Efi Paparistodemou and Maria Meletiou-Mavrotheris</i>	1050
Connecting context, statistics and software for understanding a randomization test: a case study <i>Susanne Podworny</i>	1057
Measuring probabilistic reasoning: the development of a brief version of the Probabilistic Reasoning Scale (PRS-B) <i>Caterina Primi, Maria Anna Donati, Sara Massino</i>	1065

An alternative method to compute confidence intervals for proportion <i>Antonio Francisco Roldán López de Hierro, María del Mar López-Martín and Carmen Batanero</i>	1073
Primary school students reasoning about and with the median when comparing distributions <i>Susanne Schnell and Daniel Frischemeier</i>	1075
A case study on design and application of creative tasks for teaching percentage bars and pie charts <i>Balgeum Song, Kyeong-Hwa Lee and Yeong Ok,Chong</i>	1083
Algorithms as a discovery process in frequentist approach to prediction interval <i>Jannick Trunkenwald and Dominique Laval</i>	1085
The investigative cycle: Developing a model to interpret written statistical reports of pre-service primary school teachers <i>Francisca Ubilla, Núria Gorgorió and Montserrat Prat</i>	1093
Introduction of inferential statistics in high school in Hungary <i>Ödön Vancsó, Peter Fejes-Tóth, and Zsuzsanna Jánvári</i>	1101
<b>TWG06: Applications and modelling</b>	<b>1103</b>
Introduction to the papers of TWG6: Applications and modelling <i>Berta Barquero, Susana Carreira, Jonas Bergman Ärlebäck, Britta Jessen, Katrin Vorhölter, Geoff Wake</i>	1104
The configuration of mathematical modelling activities: a reflection on perspective alignment <i>Lourdes Almeida and Susana Carreira</i>	1112
Enhancing future teachers' situation-specific modelling competencies by using staged videos <i>Alina Alwast and Katrin Vorhölter</i>	1120
An extension of the MAD framework and its possible implication for research <i>Jonas Bergman Ärlebäck and Lluís Albarracín</i>	1128
Simulations and prototypes in mathematical modelling tasks <i>Ana Margarida Baioa and Susana Carreira</i>	1136
Modelling praxeologies in teacher education: the cake box <i>Berta Barquero, Marianna Bosch, Floriane Wozniak</i>	1144
Analysis of textbook modelling tasks, in light of a modelling cycle <i>Ingeborg Katrin Lid Berget</i>	1152
Assessing Teaching Competencies for Mathematical Modelling <i>Rita Borromeo Ferri</i>	1154
On the positive influence of product-orientation in mathematical modeling: A research proposal <i>Wolfgang Bock, Martin Bracke, Patrick Capraro and Jean-Marie Lantau</i>	1162

Comprehending mathematical problem texts Fostering subjectspecific reading strategies for creating mental text representations <i>Jennifer Dröse</i>	1164
Mathematical modeling and the role of language proficiency <i>Sevinç Göksen-Zayim, Derk Pik, Rijkje Dekker and Carla van Boxtel</i>	1172
Pre-service mathematics teachers' learning through designing modelling tasks <i>Carolina Guerrero-Ortiz</i>	1174
Teachers learning to design and implement mathematical modelling activities through collaboration <i>Britta Eyrich Jessen</i>	1182
Development of group creativity in mathematical modeling <i>Hye-Yun Jung and Kyeong-Hwa Lee</i>	1190
Creating contact points between empirical modelling and theoretical modelling in teacher education: The case of pendulum problem <i>Masafumi Kaneko, Akihiko Saeki and Takashi Kawakami</i>	1192
Measuring an aspect of adaptive intervention competence in mathematical modelling processes <i>Heiner Klock and Hans-Stefan Siller</i>	1200
Research into students' evaluations of given modelling solutions and their suggestions for improved modelling - Results from two empirical studies <i>Sebastian Kuntze and Julian Eppler</i>	1208
Effective factors of a teacher training concerning the implementation of interdisciplinary STEM-modelling projects <i>Jean-Marie Lantau and Martin Bracke</i>	1216
Instrumental genesis and heuristic strategies as frameworks to geometric modeling in connecting physical and digital environments <i>Diego Lieban and Zsolt Lavicza</i>	1224
On the notion of mathematical model in educational research: Insights from a new proposal <i>Jesús Montejo-Gámez and Elvira Fernández-Ahumada</i>	1232
The extended theoretical framework of Mathematical Working Space (extended MWS): Potentialities in physics <i>Laurent Moutet</i>	1240
Downscaling and upscaling Fermi problems <i>Marta Pla-Castells and Irene Ferrando</i>	1248
Students of Development Studies learning about modelling and simulations as a research approach in their discipline <i>Amrit B. Poudel, Pauline Vos and F. LeRon Shults</i>	1256
On the role of multicriteria decision support in mathematical modelling <i>Stefan Ruzika and Lisa Schneider</i>	1264
Exploring pre-service teachers' flexibility in solving Fermi problems <i>Carlos Segura and Irene Ferrando</i>	1272

Features of modelling processes of group with visual and analytic mathematical thinking styles	1274
<i>Juhaina Awawdeh Shahbari and Rania Salameh</i>	
Professional competencies for teaching mathematical modelling supporting the modelling-specific task competency of prospective teachers in the teaching laboratory	1276
<i>Raphael Wess and Gilbert Greefrath</i>	
Horizontal mathematization: a potential lever to overcome obstacles to the teaching of modelling	1284
<i>Sonia Yvain-Prébiski and Aurélie Chesnais</i>	
<b>TWG07: Adult Mathematics Education</b>	<b>1292</b>
Introduction to TWG07 Adult Mathematics Education	1293
<i>Kees Hoogland, Beth Kelly and Javier Díez-Palomar</i>	
Doing the time in the mathematics class	1301
<i>Catherine Byrne, Brian Bowe and Michael Carr</i>	
Numeracy in adult education: discussing related concepts to enrich the Numeracy Assessment Framework	1309
<i>Javier Díez-Palomar, Kees Hoogland and Vincent Geiger</i>	
Mathematics and Physics Dialogic Gatherings: Fostering Critical Thinking Among Adult Learners	1317
<i>Javier Díez-Palomar and Evgenia Anagnostopoulou</i>	
Using dialogue scenes with adult mathematics learners: Research questions and methods	1325
<i>Graham Griffiths</i>	
Reproducing social difference in the concept of numeracy skills	1333
<i>Lisanne Heilmann</i>	
Numeracy and mathematics education in vocational education: a literature review, preliminary results	1341
<i>Kees Hoogland, Karen Heinsman and Paul Drijvers</i>	
Initiating a Common European Numeracy Framework	1349
<i>Kees Hoogland, Marlies Auer, Javier Díez-Palomar, Niamh O'Meara and Mieke van Groenestijn</i>	
What motivates adults to learn mathematics through trade unions in the workplace: social factors and personal feelings	1356
<i>Beth Kelly</i>	
Adult learners know more about maths than they think: helping learners to embrace their knowing	1364
<i>John J. Keogh, Theresa Maguire and John O'Donoghue</i>	
Numeracy practices in older age	1372
<i>Alina Redmer and Anke Grotlüschen</i>	

How theories of language-responsive mathematics can inform teaching designs for vocational mathematics <i>Lena Wessel</i>	1380
<b>TWG08: Affect and the teaching and learning of mathematics</b>	<b>1388</b>
Introduction to the work of TWG 8: Affect and the teaching and learning of mathematics <i>Stanislaw Schukajlow, Inés Ma Gómez-Chacón, Çiğdem Haser, Peter Liljedahl, Karen Skilling and Hanna Viitala</i>	1389
Verbal expression of emotions as entry points to examine failure experiences in secondary mathematics: A preliminary study <i>Lucy Alcântara, Nélia Amado and Susana Carreira</i>	1393
Learning geometry in self-made tutorials: the impact of producing mathematical videos on emotions, motivation and achievement in mathematical learning <i>Daniel Barton</i>	1401
Adolescents' Endorsement of Narratives Regarding the Importance of Mathematics: A Dialogic Perspective <i>Naama Ben-Dor and Einat Heyd-Metzuyanim</i>	1403
Learning styles in mathematics - the strength of the motivational factors at 10th grade Portuguese students <i>Miguel Figueiredo and Henrique Manuel Guimarães</i>	1411
Undergraduate students' mindsets in a computer programming mathematical learning environment <i>Wendy Ann Forbes, Joyce Mgombelo, Sarah Gannon and Chantal Buteau</i>	1419
Situation Specific-Skills Working Backward Reasoning: The Student's Perceptions and Affect Dimension <i>Inés M. Gómez-Chacón, Marta Barbero</i>	1427
Teacher-student eye contacts during whole-class instructions and small-group scaffolding: A case study with multiple mobile gaze trackers <i>Eeva Haataja, Visajaani Salonen, Anu Laine, Miika Toivanen and Markku S. Hannula</i>	1435
Collaborative processes when reasoning creatively about functions <i>Ellen Kristine Solbrekke Hansen</i>	1443
What can metaphor tasks offer for exploring preservice mathematics teachers beliefs? <i>Çiğdem Haser</i>	1445
"I don't like Maths as a subject but I like doing it": A methodology for understanding mathematical identity <i>Fionnán Howard, Siún Nic Mhuirí and Maurice O'Reilly</i>	1453
Students' Engagement in Inquiry-based Learning: Cognition, Behavior and Affect <i>Styliani K. Kourti</i>	1461
Investigating emotional intensity in mathematics classrooms: an enhanced methodology or affective gimmickry? <i>Elizabeth Lake</i>	1469

Pupils' perception of their understanding in mathematics and its connection to private supplementary tutoring <i>Gabriela Novotná</i>	1477
Reflections on the development and application of an instrument to access mathematical identity <i>Patricia Eaton, Christine Horn, Elizabeth Oldham and Maurice O'Reilly</i>	1485
Upper Secondary Mathematics Teachers' epistemological beliefs concerning the nature of mathematics <i>Marilena Pantziara, Alexandra Petridou and Marianna Karamanou</i>	1493
Engagement in mathematics through digital interactive storytelling <i>Giovannina Albano, Anna Pierri and Maria Polo</i>	1501
Self-concept in university mathematics courses <i>Stefanie Rach, Stefan Ufer and Timo Kosiol</i>	1509
First-person vicarious experiences as a mechanism for belief change <i>Annette Rouleau, Natalia Ruiz, Cristián Reyes and Peter Liljedahl</i>	1517
I am scared to make a drawing. Students' anxiety and its relation to the use of drawings, modelling, and gender <i>Stanislaw Schukajlow, Judith Blomberg, Johanna Rellensmann</i>	1525
Distinguishing engagement from achievement: understanding influential factors for engaged and disengaged low achieving mathematics students <i>Karen Skilling</i>	1533
Do students perceive mathematics and the mathematical subdomain of functions differently with regard to their self-concept and interest? <i>Ute Sproesser, Markus Vogel, Tobias Doerfler and Andreas Eichler</i>	1541
How can teachers influence their students' (mathematical) mindset? <i>Marloes van Hoeve, Michiel Doorman and Michiel Veldhuis</i>	1549
Low achiever's mathematical thinking: The case study of Maya <i>Hanna Viitala</i>	1557
The impact of a mathematics game programming project on student motivation in grade 8 <i>Eline Westerhout, Paul Drijvers and Arthur Bakker</i>	1565
"I want a high-educated job that pays well and is fun": Secondary students' relevance beliefs for taking advanced mathematics <i>Anders Wiik and Pauline Vos</i>	1573
<b>TWG09: Mathematics and Language</b>	<b>1581</b>
Introduction to TWG09: Transforming language-sensitive mathematics education research into papers and posters <i>Núria Planas, Marie Therese Farrugia, Jenni Ingram and Marcus Schütte</i>	1582
Taking advantage of the different types of mathematical languages to promote students' meaningful learning <i>Helen Alfaro Viquez</i>	1590

Learning mathematics in French at the undergraduate level in Algeria <i>Nadia Azrou</i>	1598
Textual configurations as an approach to evaluate textual difficulties of mathematical tasks <i>David Bednorz and Michael Kleine</i>	1606
Relations between school achievement and language abilities in mathematics classrooms <i>Aur�lie Chesnais</i>	1614
Construction of mathematical discourses on generalization during group interaction <i>Judit Chico</i>	1622
Metacognitive and discursive activities - an intellectual kernel of classroom discussions in learning mathematics <i>Elmar Cohors-Fresenborg</i>	1630
Explorative study on language means for talking about enlarging figures in group work <i>Kirstin Erath</i>	1632
Young children's mathematizing during free play with 'loose parts' <i>Marie Therese Farrugia</i>	1640
High school teachers' evaluation of argumentative texts in mathematics <i>Giovannina Albano, Cristina Coppola and Pier Luigi Ferrari</i>	1648
The role of writing in the process of learning to speak mathematically <i>Marei Fetzner</i>	1656
Solving problems collaboratively in multi-age classes - a possibility for learning? <i>Rachel-Ann Friesen, Marcus Sch�tte, Judith Jung</i>	1664
Exploration of patterns in different contexts <i>Anne Birgitte Fyhn and Lisbet Hansen</i>	1672
Centripetal and centrifugal forces in teacher-class dialogues in inquiry-based mathematics <i>Ing�lfur G�slason</i>	1680
The importance of a meaning-related language for understanding multiplication <i>Daniela G�tze</i>	1688
Claims and demonstrations of understanding in whole class interactions <i>Jenni Ingram and Nick Andrews</i>	1696
Talking about standardized units in preschool supporting language and mathematical learning <i>Sarah Keuch and Birgit Brandt</i>	1704
Mathematical reasoning as a classroom discourse <i>Farran Mackay, Marieke Thurlings, Alexander Schueler-Meyer, and Birgit Pepin</i>	1712
Researching translanguaging: Functions of first and second languages in Maltese mathematics classrooms <i>Angel Mizzi</i>	1714

Adopting a discursive lens to examine functions learning and language use by bilingual undergraduate students <i>Máire Ní Riordáin and Éilis Flanagan</i>	1722
Specialized language support in mathematics education through the use of radio resources <i>Franziska Peters</i>	1730
Classroom communication: Defining and characterizing perpendicular lines in high school algebra <i>Valentina Postelnicu</i>	1738
Disentangling students' personal repertoires for meaning-making: The case of newly arrived emergent multilingual students <i>Susanne Prediger, Ángela Uribe, and Taha Kuzu</i>	1746
Preservice teachers' reflections on language diversity <i>Toril Eskeland Rangnes and Andrea Synnøve Blomsø Eikset</i>	1754
Sense and reference of signifiers for elements of polygons <i>Frode Rønning and Heidi Strømskag</i>	1762
Abstract thinking and bilingualism: Impact on learning mathematics <i>Leila Salekhova and Nail Tuktamishov</i>	1770
Teaching mathematics in an international class: Designing a path towards productive disposition <i>Marc Sauerwein</i>	1778
Which factors coincide with mathematical learning gains in bilingual classrooms? German language proficiency and mixed language use <i>Alexander Schüler-Meyer, Susanne Prediger, and Henrike Weinert</i>	1786
Publishing as an English non dominant language author. First results from a survey of support offered by mathematics education journals <i>Rudolf Sträßer</i>	1794
Variations in students' reading process when working on mathematics tasks with high demand of reading ability <i>Frithjof Theens</i>	1802
Generalizing distributive structures in primary school <i>Annika Umierski and Kerstin Tiedemann</i>	1810
<b>TWG10: Diversity and Mathematics Education: Social, Cultural and Political Challenges</b>	<b>1818</b>
Introduction to the work of TWG10: Diversity and Mathematics Education: Social, Cultural and Political Challenges <i>Hauke Straehler-Pohl, Anette Bagger, Laura Black, Anna Chronaki and David Kollosche</i>	1819
Construction of Critical Thinking Skills by the infusion approach in Probability and Statistics in Daily Life <i>Einav Aizikovitsh-Udi</i>	

The politics of early assessment in mathematics education <i>Anette, Helena Vennberg and Lisa Björklund Boistrup</i>	1831
Critical uses of knowledge and identity: Embedded mathematics as a site for/of class struggle in educational praxis <i>Laura Black, Julian Williams, David Swanson, Sophina Choudry and Emilia Howker</i>	1839
Mathematics education s solidarity assimilation methodology <i>Tânia Cabral, Alexandre Pais and Roberto Baldino</i>	1846
Assessing students' perceptions of democratic practices in the mathematics classroom <i>Wajeeh Daher</i>	1854
Diversity, inclusion and the question of mathematics teacher education - How do student teachers reflect a potential-related view? <i>Timo Dexel, Ralf Benölken and Marcel Veber</i>	1862
A farewell to mathematics: A personal choice or social exclusion? <i>Oğuzhan Doğan</i>	1870
A call for nuancing the debate on gender, education and mathematics in Norway <i>Trine Foyen</i>	1878
The relevance of mathematics and students' identities <i>Andualem Tamiru Gebremichael</i>	1886
Social inequalities in mathematics from a socialization theoretical point of view - Analysis of problem-solving processes of students <i>Belgüzar Kara, Bärbel Barzel</i>	1894
Towards guidelines for the analysis of teaching materials in linguistically and culturally diverse mathematics classrooms <i>David Kollosche</i>	1896
How do we teach mathematics to refugee students? A qualitative study of the teaching and learning of mathematics in International Preparatory Classes <i>Maike Lüssenhop and Gabriele Kaiser</i>	1904
Using photo-elicitation in early years mathematics research <i>Dorota Lembrér</i>	1912
Referring and proffering: An unusual take on what school mathematics is about <i>Jean-François Maheux, Jérôme Proulx, Rox-Anne L'Italien-Bruneau and Marie-Line Lavallée-Lamarche</i>	1920
The contextual power dynamics in defining and utilising problem solving tasks: A case study at an Egyptian private school <i>Mariam Makramalla and Andreas J. Stylianides</i>	1928
Discourse of otherness in a Universally Designed undergraduate mathematics course <i>Juuso Henrik Nieminen</i>	1936
Lávvu and mathematics <i>Siv Ingrid Nordkild and Ole Einar Hætta</i>	1944

Interdisciplinarity, culturally sustaining pedagogies, and the problem of pandisability as culture: Co-creating diverse mathematics learning contexts <i>Alexis Padilla and Paulo Tan</i>	1946
The teaching of higher education mathematics by pre-service mathematics teacher educators: How might this contribute to social justice? A consideration of a possible approach <i>Hilary Povey</i>	1954
The student's perspective on school mathematics - a case study <i>Ann-Sofi Røj-Lindberg and Kirsti Hemmi</i>	1962
Agency and identity of female Arab students entering a technological university <i>Soryna Sabbah and Einat Heyd-Metzuyanin</i>	1970
Students' experiences of learner autonomy in mathematics classes <i>Shipra Sachdeva</i>	1978
Locally disrupting institutional racism by enacting mathematics in a U. S. laboratory classroom <i>Sabrina Bobsin Salazar</i>	1986
Visible pedagogy and challenging inequity in school mathematics <i>Pete Wright</i>	1994
Real-life mathematics: Politicization of natural life and rethinking the sovereign <i>Ayşe Yolcu</i>	2002
<b>TWG11: Comparative studies in mathematics education</b>	<b>2010</b>
Thematic working group 11: Comparative studies in mathematics education <i>Paul Andrews, Eva Jablonka, and Constantinos Xenofontos</i>	2011
Order of factors in multiplying decimal numbers and gender differences: a comparison of tasks <i>Cascella Clelia and Giberti Chiara</i>	2014
The centrality of the unit of analysis in comparative research in mathematics education: comparing analytical accounts of student collaborative activity in different social groups <i>David Clarke and Man Ching Esther Chan</i>	2022
Impact of access requirements on the mathematical knowledge of students admitted to Primary Teaching programs: a microcomparative study <i>Núria Gorgorió, Lluís Albarracín, and Anu</i>	2031
Introduction to early algebra in Estonia, Finland and Sweden - some distinctive features identified in textbooks for Grades 1-3 <i>Kirsti Hemmi, Madis Lepik, Lars Madej, Kajsa Bråting and Joakim Smedlund</i>	2039
A preliminary comparison of Chinese and German state mandated curricula for mathematics education (years 1 to 6) <i>Eva Jablonka</i>	2047
Reform on a shaky ground? A comparison of algebra tasks from TIMSS and Swedish textbooks <i>Kristina Palm Kaplan</i>	2055

Time series analysis: Moving averages as an approach to analysing textbooks <i>Jöran Petersson, Judy Sayers and Paul Andrews</i>	2057
A cross-cultural study of curriculum systems: mathematics curriculum reform in the U.S., Finland, Sweden, and Flanders <i>Hendrik Van Steenbrugge, Heidi Krzywacki, Janine Remillard, Tuula Koljonen, Rowan Machalow and Kirsti Hemmi</i>	2062
The use of problem in upper-primary and lower-secondary textbooks of the Republic of Cyprus <i>Constantinos Xenofontos</i>	2073
A cross-cultural comparative study into teachers questioning patterns in lower secondary mathematics lessons in the UK and China <i>Wenping Zhang and David Wray</i>	2081
<b>TWG12: History in Mathematics Education</b>	<b>2089</b>
Introduction to the papers of TWG12: History in Mathematics Education <i>Renaud Chorlay, Aline Bernardes, Tanja Hamann and Antonio Oler-Marcén</i>	2090
Generalizing a 16th century arithmetic problem with prospective Secondary education teachers <i>Álvaro Barreras and Antonio M. Oller-Marcén</i>	2093
On the didactical function of some items from the history of calculus <i>Stephan Berendonk</i>	2101
Justifying a calculation technique in years 3 and 6 <i>Renaud Chorlay</i>	2109
New Math at primary schools in West Germany a theoretical framework for the description of educational reforms <i>Tanja Hamann</i>	2117
Relevance of mathematics journals for Dutch teachers in the 18th and 19th century <i>Jenneke Krüger</i>	2125
Semiotic potential of a tractional machine: a first analysis <i>Michela Maschietto, Pietro Milici and Dominique Tournès</i>	2133
On the historical development of algorithms - hidden in technical devices? <i>Regina Möller and Peter Collignon</i>	2141
Historical tasks to foster problematization <i>Bruna Moustapha-Corrêa Aline Bernardes and Victor Giraldo</i>	2149
The development of Thales theorem throughout history <i>Slim MRABET</i>	2158
Original sources, ICT and mathemacy <i>Marianne Thomsen and Inge Marie Olsen</i>	2160
Rizanesander's Recknekonsten or "The art of arithmetic" - the oldest known textbook of mathematics in Swedish <i>Reza Russell Hatami and Johanna Pejläre</i>	2162

I Spy with my Little Eye – Teachers’ linkages about historical snippets in textbooks <i>Sebastian Schorcht</i>	2170
Exams in calculations/mathematics in Norway 1946 2017 content and form <i>Bjørn Smestad and Aina Fossum</i>	2170
History of mathematics in Dutch teacher training <i>Desiree van den Bogaart-Agterberg</i>	2180
History of mathematics and current developments in education <i>Ysette Weiss and Rainer Kaenders</i>	2188
Lucas Bunt and the rise of statistics education in the Netherlands <i>Bert Zwaneveld and Dirk De Bock</i>	2196
<b>TWG13: Early Years Mathematics</b>	<b>2204</b>
Early Years Mathematics: Introduction to TWG 13 <i>Ingvald Erfjord, Bozena Maj-Tatsis, Esther Levenson, Priska Sprenger and Marianna Tzekaki</i>	2205
Pips (times) Pods: Dancing towards multiplicative thinking <i>Sandy Bakos and Nathalie Sinclair</i>	2209
Framework for analysing children s ways of experiencing numbers <i>Camilla Björklund and Ulla Runesson Kempe</i>	2217
Pre-schoolers ability to synchronise multiple representations of numerosity in embodiment of a counting-on-strategy <i>Morten Bjørnebye</i>	2225
Development of strategies for a combinatorial task by a 5 year old child <i>Kerstin Bräuning</i>	2233
Kindergarten teachers’ orchestration of mathematical learning activities: the balance between freedom and structure <i>Svanhild Breive</i>	2241
Creative processes of one primary school child working on an open-ended task <i>Svenja Bruhn</i>	2249
Characterising the mathematical discourse in a kindergarten <i>Ingvald Erfjord, Martin Carlsen, and Per Sigurd Hundeland</i>	2257
Paper plate patterns: teachers developing patterning in pre-school <i>Sue Gifford and Helen Thouless</i>	2265
Investigating mediation strategies used by early years mathematics teachers in Malawi <i>Fraser Gobede</i>	2267
Developing mathematical literacy in an inquiry-based setting working with play-coins in a second-grade classroom <i>Benedikte Grimeland and Svein Arne Sikko</i>	2269
Student teachers' definitions of the concept teaching mathematics in preschool <i>Maria Johansson, Timo Tossavainen, Ewa-Charlotte Faarinen, and Anne Tossavainen</i>	2277

Using finger patterns - the case of communicating age <i>Miriam M. Lüken</i>	2285
Evidence of relational thinking at kindergarten level <i>Andrea Maffia and Simona Mancarella</i>	2293
Task characteristics that promote mathematical reasoning among young students: An exploratory case study <i>Bozena Maj-Tatsis and Konstantinos Tatsis</i>	2301
Exploring how primary teacher education prepares pre-service teachers to teach early years Mathematics <i>Justina Longwe Mandala</i>	2309
Preschool children's understanding of length and area measurement in Japan <i>Nanae Matsuo and Nagisa Nakawa</i>	2311
The use of structure as a matter of language <i>Lara Müller and Kerstin Tiedemann</i>	2319
Children's use of mathematical language <i>Beate Nergård</i>	2321
Fostering children's repeating pattern competencies by physical activity <i>Kathrin Nordemann and Thomas Rottmann</i>	2329
Toddlers exploring structural elements in play <i>Hanna Palmér and Camilla Björklund</i>	2331
What can five-, six- and seven-year-olds tell us about the transition from mathematics in kindergarten to that in school in Norway? <i>Geir Olaf Pettersen and Monica Volden</i>	2339
Inquiry-based implementation of a mathematical activity in a kindergarten classroom <i>Chrysanthi Skoumpourdi</i>	2347
Perceiving and using structures in sets the contribution of eye-tracking in a three- level evaluation process <i>Priska Sprenger and Christiane Benz</i>	2355
Construction of scientific basis for pre-school teacher education <i>Christina Svensson</i>	2363
Shedding light on preschool teachers' self-efficacy for teaching patterning <i>Pessia Tsamir, Dina Tirosh, Esther Levenson, Ruthi Barkai</i>	2365
Generalization in early arithmetic <i>Marianna Tzekaki and Evaggelia Papadopoulou</i>	2373
Characterisation of the learning trajectory of children aged six to eight years old when acquiring the notion of length measurement <i>Yuly Vanegas, Montserrat Prat and Alba Rubio</i>	2381
Chances and obstacles of 'indirect' learning processes in situations with preschool teachers <i>Anna-Marietha Vogler</i>	2389

Developing a social training of spatial perception and spatial cognition <i>Martina Wernicke, Jasmin Kizilirmak, Barbara Schmidt-Thieme and Kristian Folta-Schoofs</i>	2397
<b>TWG14: University Mathematics Education</b>	<b>2399</b>
Introduction to the papers of TWG14: University Mathematics Education <i>Alejandro S. González-Martín, Irene Biza, Jason Cooper, Imène Ghedamsi, Ghislaine Gueudet, Vilma Mesa, Alon Pinto and Olov Viirman</i>	2400
How Lisa's mathematical reasoning evolved at undergraduate level on the role of metacognition and mathematical foundation <i>Aaltje Berendina Aaten, Gerrit Roorda, Johan Deprez and Martin Goedhart</i>	2408
Students' conceptions of the definite integral in the first year of studying science at university <i>Inen Akrouti</i>	2416
The transition from high school to university mathematics: the effect of institutional issues on students' initiation into a new practice of studying mathematics <i>Amalia-Christina Bampili, Theodossios Zachariades and Charalampos Sakonidis</i>	2418
Students' understanding of the interplay between geometry and algebra in multidimensional analysis: representations of curves and surfaces <i>Matija Bašić and Željka Milin Šipuš</i>	2426
Understanding the secondary-tertiary transition in mathematics education: contribution of theories to interpreting empirical data <i>Christer Bergsten and Eva Jablonka</i>	2434
External Didactic Transposition in Undergraduate Mathematics <i>Marianna Bosch, Thomas Hausberger, Reinhard Hochmuth and Carl Winsløw</i>	2442
Students' difficulties to learn derivatives in the Tunisian context <i>Rahma Bouguerra</i>	2450
The integration of digital resources into teaching and learning practices of the derivative concept <i>Danilo Christo and Sonia Iglioni</i>	2452
Restored narratives on the agency and disputes of mathematicians and mathematics educators in the education of mathematics teachers <i>Cleber Dias da Costa Neto, Victor Giraldo and Elena Nardi</i>	2454
Evaluation of a connecting teaching format in teacher education <i>Andreas Datzmann and Matthias Brandl</i>	2462
Students difficulties at the secondary-tertiary transition: the case of random variables <i>Camille Doukhan and Ghislaine Gueudet</i>	2464
Participation of female students in undergraduate Mathematics at the University of Malawi <i>Levis Eneya, Lisnet Mwadzaangati and Mercy Kazima</i>	2472
Supporting the use of study skills in large mathematics service courses to enhance students' success - one example <i>Frank Feudel and Hans M. Dietz</i>	2474

Digital learning materials in traditional lectures and their evaluation at the example of a voluntary pre-university bridging course <i>Yael Fleischmann, Tobias Mai, Rolf Biehler and Alexander Gold</i>	2482
Study and research paths at university level: managing, analysing and institutionalizing knowledge <i>Ignasi Florensa, Berta Barquero, Marianna Bosch and Josep Gascón</i>	2484
Two situations for working key properties of R <i>Macarena Flores González, Alain Kuzniak, Elizabeth Montoya Delgadillo and Laurent Vivier</i>	2492
To whom do we speak when we teach proofs? <i>Mika Gabel and Tommy Dreyfus</i>	2494
Towards an interplay between TDS and ATD in a Design-Based Research project at the entrance to the university <i>Imène Ghedamsi and Thomas Lecorre</i>	2502
The graph of a function and its antiderivative: a praxeological analysis in the context of Mechanics of Solids for engineering <i>Alejandro S. González-Martín and Gisela Hernandez-Gomes</i>	2510
Calculus students' difficulties with logical reasoning <i>Gabriel Herrera Alva, Antonio Rivera Figueroa and Kinrha Aguirre-De la Luz</i>	2518
The VEMINT-Test: Underlying Design Principles and Empirical Validation <i>Reinhard Hochmuth, Marcel Schaub, Andreas Seifert, Regina Bruder and Rolf Biehler</i>	2526
An exploration of the relationship between continuous assessment and resource use in a service mathematics module <i>Emma Howard, Maria Meehan and Andrew Parnell</i>	2534
How to assess students learning in mathematics literacy education: An attempt to use students' comments for assessment <i>Mitsuru Kawazoe</i>	2542
On tasks that lead to praxeologies formation: a case in vector calculus <i>Margo Kondratieva</i>	2544
What can be 'annoying' about mathematical conventions? Analysing post-exchanges of mathematically competent discursants <i>Igor' Kontorovich</i>	2552
Beliefs about learning attributed to recognized college mathematics instructors <i>Valentin A. B. Kühle and Shiv S. Karunakaran</i>	2560
Features of innovative lectures that distinguish them from traditional lectures and their evaluation by attending students <i>Christiane Kuklinski, Michael Liebendörfer, Reinhard Hochmuth, Rolf Biehler, Niclas Schaper, Elisa Lankeit, Elena Leis and Mirko Schürmann</i>	2562
Students' work with a task about logical relations between various concepts of multidimensional differentiability <i>Elisa Lankeit and Rolf Biehler</i>	2570

Teaching of discontinuous functions of one or two variables: A didactic experience using problem posing and levels of cognitive demand <i>Uldarico Malaspina and Carlos Torres</i>	2578
Identifying sense-making in algebra instruction at U.S. post-secondary colleges <i>Angeliki Mali, Anne Cawley, Irene Duranczyk, Vilma Mesa, April Ström and Laura Watkins</i>	2586
From university mathematics students to postsecondary teachers <i>Sarah Mathieu-Soucy, Claudia Corriveau and Nadia Hardy</i>	2594
The structure of EQIPM, a video coding protocol to assess the quality of community college algebra instruction <i>Vilma Mesa, Irene Duranczyk, Laura Watkins and the AI@CC Research group</i>	2596
University Student Use of Dynamic Textbooks: An Exploratory Analysis <i>Vilma Mesa, Angeliki Mali and Elena Castro-Rodríguez</i>	2604
An exploratory study of calculus students' understanding of multivariable optimization problems <i>Thembinkosi P. Mkhathshwa</i>	2606
Towards a better understanding of engineering students use and orchestration of resources: Actual Student Study Paths <i>Birgit Pepin and Zeger-Jan Kock</i>	2614
Conceptualising knowledge of mathematical concepts or procedures for diagnostic and supporting measures at university entry level <i>Guido Pinkernell</i>	2622
Formative assessment of proof comprehension in undergraduate mathematics: Affordances of iterative lecturer feedback <i>Alon Pinto and Jason Cooper</i>	2630
Relations between academic knowledge and knowledge taught in secondary education: Klein's second discontinuity in the case of the integral <i>Gaëtan Planchon</i>	2638
Theorizing coordination and the role of course coordinators <i>Chris Rasmussen, Jessica E. Hagman and Naneh Apkarian</i>	2640
OPTES+ A Mathematical Bridging Course for Engineers <i>Anna-Katharina Roos, Gerhard Götz, Hans-Georg Weigand and Jan Franz Wörler</i>	2642
The connectivity in resources for student-engineers: the case of resources for teaching sequences <i>Hussein Sabra</i>	2644
<b>TWG15: Teaching Mathematics with Technology and Other Resources</b>	<b>2652</b>
Introduction to the papers of TWG15: Teaching Mathematics with Technology and Other Resources <i>Alison Clark-Wilson, Ornella Robutti, Melih Turgut and Iveta Kohanová</i>	2653
Teachers' strategic choices when implementing technology <i>Henrik P. Bang, Niels Grønbaek and Claus R. Larsen</i>	2661

Turning dilate from point tool into part of an instrument: an example of a preservice mathematics teacher working on a dynamic geometry system <i>Gulay Bozkurt, Candas Uygan and Melih Turgut</i>	2663
Towards linking teaching, technology and textbooks <i>Maike Braukmüller, Angelika Bikner-Ahsbahr and Dirk F. Wenderoth</i>	2671
Project in preparation - Connected classroom technology (CCT) to enhance formative assessment in mathematics education <i>Mats Brunström and Maria Fahlgren</i>	2679
Key Factors for Successfully Embedding a Programming Approach to the Primary Maths Curriculum at Scale <i>Alison Clark-Wilson, Richard Noss, Celia Hoyle, Piers Saunders and Laura Benton</i>	2681
The co-design of a c-book by students and teachers as a process of meaning generation: The case of co-variation <i>Dimitris Diamantidis, Chronis Kynigos, Ioannis Papadopoulos</i>	2689
Addressing the problem of digital tools with digital methods <i>Jonas Dreyøe</i>	2697
The forgotten technology. Teachers' use of mini white-boards to engage students <i>Thomas F. Eidissen, Karen Bjerkeli, and Ove Gunnar Drageset</i>	2699
Investigating similar triangles using student-produced videos <i>Anders Støle Fidje and Ingvald Erfjord</i>	2701
Silent video tasks: Towards a definition <i>Bjarnheiður (Bea) Kristinsdóttir, Freyja Hreinsdóttir and Zsolt Lavicza</i>	2709
A new era of manipulatives: making your own resources with 3D printing and other technologies <i>Diego Lieban, Eva Ulbrich, Marina Menna Barreto and Zsolt Lavicza</i>	2711
Surveying teachers' conception of programming as a mathematics topic following the implementation of a new mathematics curriculum <i>Morten Misfeldt, Attila Szabo and Ola Helenius</i>	2713
Designing an problem for learning mathematics with programming <i>Morten Munthe</i>	2721
Developing MAP for integrating mathematical applets in teaching sequence <i>Gal Nakash-Stern and Anat Cohen</i>	2723
The impact of technology on the teachers' use of different representations <i>Helena Rocha</i>	2731
An overview of gamification and gamified educational platforms for mathematics teaching <i>Cecilia Russo and Zsolt Lavicza</i>	2739
Professional development through a web-based portal: The progress of mathematics teachers teaching algebra based on hypothetical learning trajectories <i>Dilek Tanışlı, Nilüfer Köse and Melih Turgut</i>	2741

Self-efficacy the final obstacle on our way to teaching mathematics with technology? <i>Daniel Thurm and Bärbel Barzel</i>	2749
How to distinguish simulations? Development of a classification scheme for digital simulations for teaching and learning mathematics <i>Jan Franz Wörler</i>	2757
Mathematical practices of teachers in technology-enhanced classrooms: A case of teaching slope concept <i>Seçil Yemen Karpuzcu and Mine Işıksal Bostan</i>	2765
<b>TWG16: Learning Mathematics with Technology and Other Resources</b>	<b>2773</b>
Introduction to the papers of TWG16: Learning Mathematics <i>Hans-Georg Weigand, Nathalie Sinclair, Ana Donevska-Todorova, Eleonora Faggiano, Eirini Geraniou, Osama Swidan</i>	2774
Desirable difficulties while learning mathematics: Interleaved practice based on e-learning <i>Maria Afrooz and Rita Borromeo Ferri</i>	2778
Types of graphic interface design and their role in learning via mathematical applets at the elementary school <i>Eitan Ben-Haim, Anat Cohen and Michal Tabach</i>	2780
Meanings in Mathematics: using Internet Memes and Augmented Reality to promote mathematical discourse <i>Giulia Bini, Ornella Robutti</i>	2788
Students Process and Strategies as They Program for Mathematical Investigations and Applications <i>Chantal Buteau, Eric Muller, Kirstin Dreise, Joyce Mgombelo, and Ana Isabel Sacristán</i>	2796
Big events in Mathematics using math trails <i>Amélia Caldeira, Ana Moura and Christian Mercat</i>	2804
Multiplicative reasoning through two-handed gestures <i>Sean Chorney, Canan Gunes and Nathalie Sinclair</i>	2806
Physical and virtual classroom in the learning of mathematics: analysis of two episodes <i>Agnese Del Zozzo and George Santi</i>	2814
Design of a multi-dimensional instrument for reviewing the quality of apps for elementary geometry <i>Ana Donevska-Todorova and Katja Eilerts</i>	2816
Student engagement in mobile learning activities: breakdowns and breakthroughs <i>Khristin Fabian</i>	2818
A picture is worth a thousand words: visualizing collaboration through gaze synchrony graphs <i>Enrique Garcia Moreno-Esteva, Jessica F. A. Salminen-Saari, Miika Toivanen &amp; Markku S. Hannula</i>	2826

University students' engagement with an asynchronous online course on digital technologies for mathematical learning <i>Eirini Geraniou and Cosette Crisan</i>	2828
Dynamic vs. static! Different visualisations to conceptualize parameters of quadratic functions <i>Lisa Göbel and Bärbel Barzel</i>	2836
The effect of digital tools on visual attention during problem solving: Variance of gaze fixations when working with GeoGebra or on paper <i>Markku S. Hannula and Miika Toivanen</i>	2838
An Exploration of the effect of Bray's Activity Design Heuristics on Students' Learning of Transformation Geometry <i>Aoife Harrison, Aibhín Bray and Brendan Tangney</i>	2846
Didactical resource purposes as an aspect of students' decision making regarding resources used to learn mathematics <i>Eivind Hillesund</i>	2848
Guidelines for design of didactic sequences utilizing dynamic geometry affordances related to mathematical reasoning competency <i>Ingi Heinesen Højsted</i>	2850
Issues in modelling terms involving subtraction in a manipulative environment for linear equations and a possible solution <i>Thomas Janßen, David Reid &amp; Angelika Bikner-Ahsbals</i>	2852
Exploring with digital media to understand trigonometric functions through periodicity <i>Myrto Karavakou, Chronis Kynigos</i>	2860
Moving fingers and the density of rational numbers: An inclusive materialist approach to digital technology in the classroom <i>Doyen Kim and Oh Nam Kwon</i>	2868
Investigating students use of dynamic materials addressing conceptions related to functional thinking <i>Edith Lindenbauer</i>	2876
A virtual environment dedicated to spatial geometry to help students to see better in space <i>Xavier Nicolas and Jana Trgalova</i>	2884
Students' perceptions in a situation regarding eigenvalues and eigenvectors <i>José Orozco-Santiago, Carlos-Armando Cuevas and Luc Trouche</i>	2892
Why digital tools may (not) help by learning about graphs in dynamics events? <i>Sonia Palha</i>	2900
Learning environments applying digital learning tools to support argumentation skills in primary school: first insights into the project <i>Melanie Platz</i>	2908
Digital media support functional thinking: How a digital selfassessment tool can help learners to grasp the concept of function <i>Hana Ruchniewicz and Bärbel Barzel</i>	2916

Exploring pre-calculus with augmented reality. A design-based-research approach <i>Florian Schacht and Osama Swidan</i>	2925
Exploring critical aspects of students' mathematics learning in technology-enhanced and student-led flipped learning environments <i>Stefanie Schallert and Robert Weinhandl</i>	2933
Practicing place value: How children interpret and use virtual representations and features <i>Axel Schulz and Daniel Walter</i>	2941
Exploring non-prototypical configurations of equivalent areas through inquiring-game activities within DGE <i>Carlotta Soldano and Cristina Sabena</i>	2949
The graphing calculator as an instrument of semiotic mediation in the construction of the function concept <i>Manuela Subtil and António Domingos</i>	2957
Drawing topology using Ariadne <i>Moritz L. Sümmermann</i>	2959
Semiotic analysis of modelling activities in a rich-digital environment <i>Osama Swidan and Eleonora Faggiano</i>	2961
Automated feedback on the structure of hypothesis tests <i>Sietske Tacoma, Bastiaan Heeren, Johan Jeuring and Paul Drijvers</i>	2969
Problem-solving techniques in the context of an educational video game: the Mudwall puzzle in Zoombinis <i>Georgios Thoma and Irene Biza</i>	2977
Repeated sampling in a digital environment: A remix of data and chance <i>Marianne van Dijke-Droogers, Paul Drijvers and Arthur Bakker</i>	2985
Reflections on item characteristics of non-routine items in diagnostic digital assessment <i>Irene van Stiphout and Madelon Groenheiden</i>	2993
Role of tablets in teaching and learning mathematics <i>Fabrice Vandebrouck and Barbara Jaworski</i>	3001
The long-term effects of MathCityMap on the performance of German 15 year old students concerning cylindric tasks <i>Joerg Zender and Matthias Ludwig</i>	3003
Exploring the role of context in students meaning making for algebraic generalization <i>Angela Zoupa and Giorgos Psycharis</i>	3011

## TWG17: Theoretical Perspectives and Approaches in Mathematics

### Education Research 3019

Introduction to the Thematic Working Group 17 on Theoretical Perspectives and Approaches in Mathematics Education Research of CERME11 <i>Angelika Bikner-Ahsbabs, Arthur Bakker, Heather Lynn Johnson, Man Ching Esther Chan</i>	3020
--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------

Table of Contents: Thematic Working Group 17	3028
Comparing a priori analyses	3029
<i>Ivy Kidron</i>	
Rethinking the connection between theory and methodology: a question of mutual affordances	3038
<i>Man Ching Esther Chan, David Clarke</i>	
Boundary crossing by design(ing): a design principle for linking mathematics and mathematics education in preservice teacher training	3046
<i>Erik Hanke, Angelika Bikner-Ahsbals</i>	
How concepts turn into objects: an investigation of the process of objectification in early numerical discourse	3054
<i>Felix Lensing</i>	
On the epistemology of the Theory of Objectification	3062
<i>Luis Radford</i>	
An epistemological and philosophical perspective on the question of mathematical work in the Mathematical Working Space theory	3070
<i>Alain Kuzniak, Laurent Vivier</i>	
A phenomenological methodology based on Husserl's work in the service of mathematics education research	3078
<i>Andonis Zagorianakos</i>	
Creating art laboratory settings and experiencing mathematical thinking: towards a philosophical dimension in mathematics education research	3086
<i>Cláudia Regina Flores</i>	
Networking theories in design research: an embodied instrumentation case study in trigonometry	3088
<i>Rosa Alberto, Arthur Bakker, Oia Walker-van Aalst, Peter Boon, Paul Drijvers</i>	
Generativity in design research: the case of developing a genre of action-based mathematics learning activities	3096
<i>Arthur Bakker, Anna Shvarts, Dor Abrahamson</i>	
Theory, methodology and design as an insightful bundle: a case of dual eye-tracking student-tutor collaboration on an embodied mathematical task	3104
<i>Anna Shvarts</i>	
Assembling mathematical concepts through trans-individual coordinated movements: the role of affect and sympathy	3106
<i>Elizabeth de Freitas, Francesca Ferrara, Giulia Ferrari</i>	
Locally integrating theories to investigate students' transfer of mathematical reasoning	3114
<i>Heather Lynn Johnson, Evan McClintock, Amber Gardner</i>	
Epistemological and methodological foundations of creating a learning trajectory of children's mathematics	3122
<i>Nicole L. Fonger, Amy Ellis, Muhammed F. Dogan</i>	

Conceiving teaching trajectories in the form of series of problems: a step for the theoretical reconstruction of the Hungarian Guided Discovery approach <i>Katalin Gosztonyi</i>	3130
Students' learning paths about ratio and proportion in geometry: an analysis using Peirce's theory of signs <i>Georgia Bampatsikou, Triandafillos A. Triandafillidis, Stefanos Asimopoulos, Kostas Hatzikiriakou</i>	3138
Connected Working Spaces: the case of computer programming in mathematics education <i>Jean-baptiste Lagrange, Dominique Laval</i>	3146
Multi-theoretical approach when researching mathematics teachers' professional development in selforganized online groups <i>Yvonne Liljekvist, Jorryt van Bommel, Ann-Christin Randahl, Christina Olin-Scheller</i>	3154
Extending Yackel and Cobb's socio-mathematical norms to ill-structured problems in an inquiry-based classroom <i>Katie Makar, Jill Fielding-Wells</i>	3162
Understanding powers – individual concepts and common misconceptions <i>Christos Itsios, Bärbel Barzel</i>	3170
Questioning the paradidactic ecology: internationally shared constraints on lesson study? <i>Koji Otaki, Yukiko Asami-Johansson, Jacob Bahn</i>	3178
<b>TWG18: Mathematics teacher education and professional development</b>	<b>3186</b>
International perspectives on mathematics teacher professional development <i>Stefan Zehetmeier, João Pedro da Ponte, Laurinda Brown, Àngela Buforn, Janne Fauskanger, Marita Friesen, Maria Mellone, Libuse Samkova</i>	3187
Working with example sets: A productive focus in Lesson Study <i>Jill Adler and Jehad Alshwaikh</i>	3191
Reflections upon a research project seen as a means for teachers' professional development <i>Mette Andresen</i>	3199
Portfolios as a way of documenting and reflecting learning processes in a mathematics teachers professional development program <i>Jennifer Bertram</i>	3201
The story of Maia: I will try to survive! <i>Annette Hessen Bjerke</i>	3203
Connecting mathematical knowledge with engagement in mathematics teaching practices <i>Timothy Boerst and Meghan Shaughnessy</i>	3211
High school teacher training challenges in the Italian interdisciplinary project Liceo Matematico <i>Laura Branchetti, Roberto Capone, Francesco Saverio Tortoriello</i>	3219

Researching as a mathematics teacher educator: analysing mathematics teachers' detailed descriptions of first lessons <i>Laurinda Brown</i>	3221
Using mixed-assessments to evaluate opportunities to learn in mathematics teacher education <i>Nils Buchholtz, Katrin Vorhölter, Anna Orschulik and Nadine Krosanke</i>	3229
Mathematical knowledge for teaching of a prospective teacher having a progressive incorporation perspective (PIP) <i>Esra Bukova Güzel, Gülseren Karagöz Akar, Aytuğ Özaltun Çelik, Semiha Kula Ünver, Nurdan Turan</i>	3231
Teachers' Collaboration in a Mathematics Lesson Study <i>João Pedro da Ponte and Marisa Quaresma</i>	3239
How to visualize classroom norms through social interaction - A pilot study of two frameworks <i>Jonas Dahl, Christina Svensson and Richard Wester</i>	3247
Understanding student teachers' professional development by looking beyond mathematics teacher education <i>Andreas Ebbelind</i>	3249
Retrospective reflections on 'Missions' as pedagogies of practice <i>Elisabeta Eriksen, Annette Hessen Bjerke, Camilla Rodal and Ida Heiberg Solem</i>	3257
Learning to represent students' mathematical ideas through teacher time-outs in rehearsals <i>Janne Fauskanger and Kjersti Wæge</i>	3265
How does the professional vocabulary change when pre-service teachers learn to analyse classroom situations? <i>Marita Friesen, Carmel Mesiti and Sebastian Kuntze</i>	3273
Prospective mathematics teachers' interpretative knowledge: focus on the provided feedback <i>Jeannette Galleguillos and Miguel Ribeiro</i>	3281
Using participant generated influence maps to gain insights into the influences on early career primary teachers' teaching of mathematics <i>Alison Godfrey</i>	3289
A zone theory analysis of identity formation in mathematics teacher educators <i>Merrilyn Goos and Anne Bennison</i>	3297
Analyzing attitude towards learning and teaching mathematics in members of professional learning communities: A case study <i>Birgit Griesse</i>	3305
Math MOOC UniTo & MathCityMap - Exploring the potentials of a review system in a MOOC environment <i>Iwan Gurjanow, Eugenia Taranto, Matthias Ludwig, Virginia Alberti, Roberta Ferro</i>	3313
Cross-linking maths: Using keynotes to structure a curriculum for future teachers <i>Tanja Hamann and Barbara Schmidt-Thieme</i>	3321

Teacher education: Developing the individual within the collaborative <i>Fiona Haniak-Cockerham</i>	3323
Teacher Professional Development and Collegial Learning: A literature review through the lens of Activity System <i>Frida Harvey and Anna Teledahl</i>	3331
Between natural language and mathematical symbols (<, >, =): the comprehension of pre-service and preschool teachers' perspective of Numbers and Quantity <i>Dina Hassidov and Bat-Sheva Ilany</i>	3339
Similarities and differences in problem solving: case of "exhibition grounds" <i>Radka Havlíčková, David Janda, Derek Pilous and Veronika Tůmová</i>	3347
Formulating our formulations: the emergence of conviction as becoming mathematics teacher educators <i>Tracy Helliwell and Julian Brown</i>	3349
Tasks Designed for Training Secondary Mathematics Teachers Using Technology <i>Alexánder Hernández, Josefa Perdomo-Díaz and Matías Camacho-Machín</i>	3357
Opportunities for Adopting a Discourse of Explorations in a Professional Development Setting <i>Einat Heyd-Metzuyanin and Talli Nachlieli</i>	3362
On the efficiency of a professional development program for mathematics teachers in upper-secondary schools in Iceland <i>Freyja Hreinsdóttir</i>	3373
Algebraic solutions of German out-of-field elementary school teachers <i>Lara Huethorst</i>	3375
Mathematics teacher educators' critical colleagueship <i>Suela Kacerja and Rune Herheim</i>	3384
Prospective Secondary Mathematics Teachers Development of Core-Practices During Methods Courses: Affordances of Quantitative Reasoning <i>Gulseren Karagöz Akar, Esra Bukova Güzel, Serkan Özel</i>	3392
From judgmental evaluations to productive conversations: Mathematics teachers' shifts in communication within a video club <i>Ronnie Karsenty, Yochai Peretz and Einat Heyd-Metzuyanin</i>	3400
Construction of teachers' roles in collegial discussions <i>Odd Tore Kaufmann and Andreas Ryve</i>	3408
From instrumental to relational Malawi mathematics teacher educators' research lessons <i>Mercy Kazima, Janne Fauskanger and Arne Jakobsen</i>	3416
How can we help teachers using guided discovery method, who have not used it before <i>Eszter Kovács-Kószó, Katalin Gosztonyi and József Kosztolányi</i>	3424
Diagnostic competence of future primary school teachers hypothesizing about causes of students' errors <i>Macarena Larrain</i>	3426

Thinking about Mathematics classroom culture through spontaneous videos <i>Cristina Loureiro, Cristina Moraes and Helena Gil Guerreiro</i>	3435
Preservice teachers learning about critical mathematics education <i>Camilla Meidell, Diana Paola Piedra Moreno and Georgia Kasari</i>	3443
Retrospective competence assessment in a PD course on teaching statistics with digital tools in upper secondary schools <i>Ralf Nieszporek and Rolf Biehler</i>	3445
Learning through/about Culturally Relevant Pedagogy in Mathematics Teacher Education <i>Kathleen Nolan and Lindsay Keazer</i>	3453
Using teachers' research to elicit professional development among pre- and in-service mathematics teachers: a qualitative meta-analysis of mathematics education in graduate programs <i>Tikva Ovadiya</i>	3455
A quasi-experimental impact study of a professional development course for secondary mathematics teachers in South Africa <i>Craig Pournara and Patrick Barmby</i>	3463
Orchestrating collective mathematical discussions: practices and challenges <i>Ana Maria Roque Boavida, Ana Paula Silvestre and Cátia Prata</i>	3471
Pre-service mathematics teachers interpret observed teachers' responses to students' statements <i>Sigal Rotem, Michal Ayalon and Shula Weissman</i>	3473
Using Concept Cartoons in future primary school teacher training: the case of problem posing and open approach <i>Libuše Samková</i>	3481
Generation and generation tasks in mathematics didactics <i>Marianne Schäfer and Rita Borromeo Ferri</i>	3489
Interweaving Mathematical-News-Snapshots as a facilitator for the development of Mathematical Knowledge for Teaching <i>Ruti Segal, Atara Shriki, Nitsa Movshovitz-Hadar and Boaz Silverman</i>	3497
Examining pedagogical and classroom discourse through the lens of figured worlds: The case of an elementary school teacher <i>Galit Shabtay and Esther Levenson</i>	3505
Impacts of a mathematical mistake on preservice teachers' eliciting of student thinking <i>Meghan Shaughnessy, Rosalie DeFino, Erin Pfaff, Merrie Blunk and Timothy Boerst</i>	3513
Beliefs and expectations at the beginning of the bachelor teacher training program in mathematics <i>Evelyn Süss-Stepancik and Stefan Götz</i>	3521
Pre-service teachers' geometrical discourses when leading classroom discussions about defining and classifying quadrilaterals <i>Gry Anette Tuset</i>	3523

Developing professional development programmes with gamification for mathematics teachers in Uruguay <i>Fabián Vitabar, Zsolt Lavicza and Markus Hohenwarter</i>	3531
Action research as a potent methodology for improving teaching and learning in mathematics <i>Eda Vula</i>	3539
<b>TWG19: Mathematics Teaching and Teacher Practice(s)</b>	<b>3547</b>
Introduction to the papers of TWG19: Mathematics Teaching and Teacher Practice(s) <i>Charalampos Sakonidis, Reidar Mosvold, Ove Gunnar Drageset, Siún Nic Mhuirí, Rukiye Didem Taylan</i>	3548
Comparison of students and researchers' choice of significant events of math lessons <i>Christoph Ableitinger, Astrid Anger and Christian Dorner</i>	3556
Between-desk-teaching as a deliberate act of making content available: The case of Bernie teaching ratio <i>Nick Andrews</i>	3564
Teachers' learning goals for a mathematics lesson <i>Kristin Krogh Arnesen and Yvonne Grimeland</i>	3572
A math teacher's participation in a classroom design research: teaching of ratio and proportion <i>Rukiye Ayan, Mine Isiksal-Bostan and Michelle Stephan</i>	3580
A comparison of the treatment of mathematical errors arising from teacher-initiated and student-initiated interactions <i>Fay Baldry</i>	3588
Teacher responses to public apparent student error: A critical confluence of mathematics and equitable teaching practice <i>Hyman Bass and Reidar Mosvold</i>	3596
Conceptual learning opportunities in teachers' differentiated task designs for inclusive mathematics education <i>Christian Büscher</i>	3604
Effects of a Scaffolding Model for small groups in mathematics <i>Sharon Calor, Rijkje Dekker, Jannet van Drie, Bonne Zijlstra and Monique Volman</i>	3612
How to improve teacher students' awareness of critical aspects in a lesson plan <i>Jonas Dahl, Anna Wernberg and Cecilia Winström</i>	3620
How teachers use interactions to craft different types of student participation during whole-class mathematical work <i>Ove Gunnar Drageset</i>	3622
Beyond the immediate - illuminating the complexity of planning in mathematics teaching <i>Helena Grundén</i>	3630
The work of equitable mathematics teaching: Leading a discussion of student solutions <i>Mark Hoover and Imani Goffney</i>	3638

Learning from Lessons: A study on structure and construction of mathematics teacher knowledge - First results of case study <i>Judith Huget and Andrea Peter-Koop</i>	3646
Balancing the live use of resources towards the introduction of the Iterative Numerical method <i>Lina Kayali and Irene Biza</i>	3648
The King's birthday, potentials for developing mathematics teaching <i>Bodil Kleve, Ida Heiberg Solem and Gerd Ånestad</i>	3656
Learning trajectories and fractions: primary teachers meaning attributions <i>Anna Klothou, Charalampos Sakonidis and Vagia Arsenidou</i>	3664
Good mathematics teaching at lower primary school level <i>Marianne Maugesten</i>	3672
Analysis of differences between teachers' activity during their regular and constructivist lessons <i>Janka Medová, Kristína Bulková and Soňa Čeretková</i>	3680
Noticing mathematical potential - A proposal for guiding teachers <i>Elisabet Mellroth and Jesper Boesen</i>	3688
The work of positioning students and content in mathematics teaching <i>Reidar Mosvold and Raymond Bjuland</i>	3696
Evolving discourse of practices for quality teaching in secondary school mathematics <i>Talli Nachlieli, Yishay Mor, Einat Gil and Yael Kashtan</i>	3704
A lens on two classrooms: Implications for research on teaching <i>Siún Nic Mhuirí</i>	3712
Assessing how teachers promote students' metacognition when teaching mathematical concepts and methods <i>Edyta Nowińska</i>	3720
Teachers probing questions in mathematical classrooms connected to their practice of encouraging students to explain their thinking <i>Anna Östman</i>	3728
Linking the micro and macro context: A sociocultural perspective <i>Maria Pericleous</i>	3730
Teachers attempts to address both mathematical challenge and differentiation in whole class discussion <i>Giorgos Psycharis, Despina Potari, Chrissavgi Triantafyllou and Theodossios Zachariades</i>	3738
Investigating the relation between teachers' actions and students' meaning making of mathematics <i>Karin Rudsberg, Marcus Sundhäll and Per Nilsson</i>	3746
Mathematics teaching and teachers' practice: tracing shifts in meaning and identifying potential theoretical lenses <i>Charalampos Sakonidis</i>	3754

Pre-service teachers' experiences in selecting and proposing challenging tasks in secondary classrooms	3762
<i>Leonor Santos, Hélia Oliveira, João Pedro da Ponte, Ana Henriques</i>	
Teachers actions in classroom and the development of quantitative reasoning	3770
<i>Lurdes Serrazina, Margarida Rodrigues and Ana Caseiro</i>	
Contradictions in prospective mathematics teachers' initial classroom teaching as sources for professional learning	3778
<i>Konstantinos Stouraitis and Despina Potari</i>	
Analyzing a novice teacher's instructional actions in response to unexpected moments in teaching	3786
<i>Rukiye Didem Taylan and Merve Esmer</i>	
Feedback for creative reasoning	3794
<i>Anna Teledahl and Jan Olsson</i>	
Revisiting teacher decision making in the mathematics classroom: a multidisciplinary approach	3802
<i>Steven Watson</i>	
<b>TWG20: Mathematics teacher knowledge, beliefs, and identity</b>	<b>3810</b>
Introduction to the papers of TWG20: mathematics teacher knowledge, beliefs, and identity	3811
<i>Miguel Ribeiro, Francesca Martignone, Fatma Aslan-Tutak, Kirsti Rø, Miguel Montes, Sebastian Kuntze</i>	
Mathematical and didactical knowledge about patterns and regularities mobilized by teachers in a professional learning task	3815
<i>Marcia Aguiar, Alessandro Jacques Ribeiro and João Pedro da Ponte</i>	
Mathematics Teachers Specialized Knowledge Model as a Metacognitive Tool for Initial Teacher Education	3823
<i>Álvaro Aguilar-González and Luis J. Rodríguez-Muñiz</i>	
Knowledge of a mathematician to teach divisibility to prospective secondary school teachers	3831
<i>Marieli Vanessa Rediske de Almeida, Miguel Ribeiro, Dario Fiorentini</i>	
Emergent model for teachers' conceptions of argumentation for mathematics teaching	3839
<i>Michal Ayalon &amp; Samaher Naama</i>	
A student teacher's responses to contingent moment and task development process	3847
<i>Emine Aytekin and Mine Işıksal Bostan</i>	
Using the Knowledge Quartet to analyse interviews with teachers manipulating dynamic geometry software	3855
<i>Nicola Bretscher</i>	
An analysis of the nature of the knowledge disseminated by a mathematics teacher training policy: The PROFMAT case	3863
<i>Marlova Estela Caldatto and Miguel Ribeiro</i>	

Prospective primary teachers' knowledge about the mathematical practice of defining <i>Myriam Codes, Nuria Climent and Isabel Oliveros</i>	3871
Empowering teachers conceptually and pedagogically through supporting them in seeing connections between school mathematics and relevant advanced mathematics knowledge <i>Cosette Crisan</i>	3879
Teacher educators understanding of mathematical knowledge for teaching <i>Matthew Dahlgren, Reidar Mosvold and Mark Hoover</i>	3887
Exemplifying mathematics teacher's specialised knowledge in university teaching practices <i>Rosa Delgado-Rebolledo and Diana Zakaryan</i>	3895
The probability subjective view: developing teachers' knowledge to give sense to students' productions <i>Rosa Di Bernardo, Maria Mellone, Ciro Minichini and Miguel Ribeiro</i>	3903
"Sometimes it goes wrong!" Teachers' beliefs concerning experiments in mathematics <i>Sebastian Geisler and Sarah Beumann</i>	3905
Chinese and Dutch mathematics teachers' beliefs about inquiry-based learning <i>Luhuan Huang, Michiel Doorman and Wouter van Joolingen</i>	3913
Preservice teachers' mathematical knowledge for teaching combinatorial thinking <i>Veronika Hubeňáková and Ingrid Semanišinová</i>	3921
Malawian preservice teachers' perceptions of knowledge at the mathematical horizon <i>Everton Lacerda Jacinto and Arne Jakobsen</i>	3929
Applying the Knowledge Quartet to student teachers lesson plans: An intervention <i>Lena Karlsson</i>	3937
Preservice teachers noticing of mathematical opportunities <i>Hulya Kilic, Oguzhan Dogan, Nil Arabaci and Sena Simay Tun</i>	3939
Design of repertory grids for research on mathematics teacher conceptions of process-related mathematical thinking <i>Peter M. Klöpping and Ana Kuzle</i>	3947
Constructing tasks for primary teacher education from the perspective of Mathematics Teachers Specialised Knowledge <i>Montes, Miguel, Climent, Nuria, Carrillo, José, Contreras, Luis Carlos</i>	3955
A Look into Turkish Preservice Teachers Translation Skills: Case for Model Representations <i>Zeynep Pehlivan and Fatma Aslan-Tutak</i>	3963
Prospective primary teachers' knowledge of problem solving process <i>Juan Luis Piñeiro, Elena Castro-Rodríguez and Enrique Castro</i>	3970
Conceptualising tasks for teacher education: from a research methodology to teachers' knowledge development <i>Milena Policastro, Maria Mellone, Miguel Ribeiro and Dario Fiorentini</i>	3978

Kindergarten teachers' knowledge in and for interpreting students' productions on measurement	3986
<i>Milena Policastro, Miguel Ribeiro and Alessandra Rodrigues de Almeida</i>	
Developing an identity as a secondary school mathematics teacher: Identification and negotiability in communities of practice	3988
<i>Kirsti Rø</i>	
Students abilities on the relationship between beliefs and practices	3996
<i>Safrudiannur, and Benjamin Rott</i>	
Secondary school preservice teachers' references to the promotion of creativity in their master's degree final projects	4004
<i>Alicia Sánchez, Vicenç Font and Adriana Breda</i>	
The problem of 0.999 &: Teachers school-related content knowledge and their reactions to misconceptions	4012
<i>Verena Spratte, Laura Euhus and Judith Kalinowski</i>	
"In school you notice the performance gap and how different it is between the students" - Student teachers' collective orientations about the learners' heterogeneity in mathematics	4020
<i>Ann-Kristin Tewes, Elisa Bitterlich, Judith Jung</i>	
Teachers noticing of language in mathematics classrooms	4028
<i>Carina Zindel</i>	
<b>TWG21: Assessment in mathematics education</b>	<b>4036</b>
Introduction to the papers of TWG21: Assessment in mathematics education	4037
<i>Paola Iannone, Michal Ayalon, Johannes Beck, Jeremy Hodgen and Francesca Morselli</i>	
Strategies of formative assessment enacted through automatic assessment in blended modality	4041
<i>Alice Barana and Marina Marchisio</i>	
National standardized tests database implemented as a research methodology in mathematics education. The case of algebraic powers.	4049
<i>Giorgio Bolondi, Federica Ferretti, George Santi</i>	
Students' attitudes and responses to pair-work testing in mathematics	4057
<i>Eszter Bóra and Péter Juhász</i>	
Classroom assessment tasks and learning trajectories	4059
<i>Eleni Demosthenous, Constantinos Christou and Demetra Pitta-Pantazi</i>	
Diagnosis of basic mathematical competencies in years 8 and 9	4067
<i>Christina Drüke-Noe and Hans-Stefan Siller</i>	
Assessment and argumentation: an analysis of mathematics standardized items	4075
<i>Rossella Garuti and Francesca Martignone</i>	
Evaluating students' self-assessment in large classes	4083
<i>Jokke Häsä, Johanna Rämö and Viivi Virtanen</i>	

Large scale analysis of teachers' assessment practices in mathematics <i>Julie Horoks, Julia Pilet, Sylvie Coppé, Marina De Simone and Brigitte Grugeon-Allys</i>	4091
Preservice Middle School Mathematics Teachers Development in Formative Assessment <i>Gözde Kaplan Can and Çiğdem Haser</i>	4099
An assessment of non-standardized tests of mathematical competence for Norwegian secondary school using Rasch analysis <i>Morten Riise Klegseth, Eivind Kaspersen and Trygve Solstad</i>	4107
Mathematics described proficiency levels: connecting psychometric and teaching analyses <i>Cristina Lasorsa, Rossella Garuti, Marta Desimoni, Donatella Papa, Antonella Costanzo and Rosalba Ceravolo</i>	4115
Teachers' Perceptions of Using Incentives in State Examinations to Increase the uptake of Higher Level Mathematics <i>Mark Prendergast, Páraic Treacy and Niamh O'Meara</i>	4117
Teachers use of Descriptive Assessment methods in primary school mathematics education in Iran <i>Ali Akbar Sangari, Marja van den Heuvel-Panhuizen, Michiel Veldhuis and Zahra Gooya</i>	4119
Developing and evaluating an online linear algebra examination for university mathematics <i>Christopher Sangwin</i>	4121
The role of formative assessment in fostering individualized teaching at university level <i>Annalisa Cusi and Agnese Ilaria Telloni</i>	4129
Teaching, learning and assessing in grade 10: an experimental pathway to the culture of theorems <i>Fiorenza Turiano, Paolo Boero and Francesca Morselli</i>	4137
Using student and instructor characteristics to predict student success in Algebra courses <i>Laura Watkins, Rik Lamm, Nidhi Kohli, Patrick Kimani, and the AI@CC Research group</i>	4145
<b>TWG22: Curriculum resources and task design in mathematics education</b>	<b>4153</b>
Introduction to the papers of TWG22: Curriculum resources and task design in mathematics education <i>Birgit Pepin, Sean Delaney, Andreas Eckert, Nataly Essonnier, and Andreas J. Stylianides</i>	4154
Exploring teachers' assignment of mathematical competencies to planned lessons using Epistemic Network Analysis <i>Benjamin Brink Allsopp, Jonas Dreyøe, Andreas Lindenskov Tamborg, Brendan Eagan, Sara Tabatabai, David Williamson Shaffer and Morten Misfeldt</i>	4162

Supporting the reinvention of the slope of a curve in a point: A smooth slope to slide is a smooth slide to slope <i>Rogier Bos, Michiel Doorman, Kristijan Cafuta, Selena Praprotnik, Sanja Antoliš, Matija Bašić</i>	4170
Conjecturing tasks for undergraduate calculus students <i>Sinéad Breen, Caitríona Ní Shé, and Ann O'Shea</i>	4178
Developing the task progressions framework <i>Scott A. Courtney and Dubravka Glasnović Gracin</i>	4186
Combining Differentiation and Challenge in Mathematics Instruction: A Case from Practice <i>Seán Delaney and Ann Marie Gurhy</i>	4194
Designing tasks with self-explanation prompts <i>Anneli Dyrvold &amp; Ida Bergvall</i>	4202
Designing for digitally enriched Math Talks The case of pattern generalization <i>Andreas Eckert and Per Nilsson</i>	4210
Social creativity in the collaborative design of a digital resource embedding mathematics into a story <i>Nataly Essonnier, Chronis Kynigos and Jana Trgalova</i>	4218
Building bridges between school mathematics and workplace mathematics <i>Rune Herheim and Suela Kacerja</i>	4226
Task design with a focus on conceptual and creative challenges <i>Jonas Jäder</i>	4234
The Influence of Teacher Guides on Teachers Practice: A Longitudinal Case Study <i>Ljerka Jukić Matić and Dubravka Glasnović Gracin</i>	4242
Community documentation targeting the integration of inquiry-based learning and workplace into mathematics teaching <i>Elissavet Kalogeria and Giorgos Psycharis</i>	4244
The use of variation theory in a problem-based task design study <i>Berie Getie Kassa and Liping Ding</i>	4252
Web of problem threads (WPT) a theoretical frame and task design tool for inquiry-based learning mathematics <i>Dániel Katona</i>	4260
Secondary school mathematics teachers' selection and use of resources <i>Zeger-Jan Kock and Birgit Pepin</i>	4262
Multiplicative reasoning task design with student teachers in Scottish schools: valuing diversity, developing flexibility and making connections <i>Helen Martin</i>	4264
Comparison of Japanese and Turkish textbooks: Giving opportunities for creative reasoning in terms of proportion <i>Yasin Memiş</i>	4266

Making Mathematics fun: The Fear Room game <i>Christina Misailidou and Ronald Keijzer</i>	4274
Examination of mathematical opportunities afforded to learners in grade 1 Malawian primary mathematics textbooks <i>Lisnet Mwadzaangati</i>	4276
Two primary school teachers pedagogical design capacity of using mathematics textbooks in Delhi, India <i>Meghna Nag Chowdhuri</i>	4284
Ability maps in the context of curriculum research <i>Lisbeth Liv Nøhr, Mia Onsvig Gregersen</i>	4292
Task design fostering construction of limit confirming examples as means of argumentation <i>Annalisa Cusi and Shai Olsher</i>	4294
Towards improving teaching and learning of algorithmics by means of resources design: a case of primary school education in France <i>Rafalska Maryna</i>	4302
Length measurement in the textbooks of German and Taiwanese primary students <i>Silke Ruwisch and Hsin-Mei E. Huang</i>	4310
A Hypothetical Learning Trajectory for the learning of the rules for manipulating integers <i>Jan Schumacher and Sebastian Rezat</i>	4318
"First you have to know it exists." Cultivating teachers' thinking about resource options <i>Helen Siedel</i>	4326
Alignment of mathematics curriculum to standards at high schools in Colombia <i>Silvia Solano, Pedro Gómez and María José González</i>	4334
The concept of function in secondary school textbooks over time: An analysis made with the Theory of Conceptual Fields <i>Patricia Sureda and Laura Rossi</i>	4336
The potential of Problem Graphs as a representational tool with focus on the Hungarian Mathematics Education tradition <i>Eszter Varga</i>	4344
From teacher s naming system of resources to teacher's resource system: Contrasting a Chinese and a Mexican case <i>Chongyang Wang, Ulises Salinas-Hernández and Luc Trouche</i>	4346
<b>TWG 23: Implementation of research findings in mathematics education</b>	<b>4354</b>
Introduction to the papers of TWG23: Implementation of research findings in mathematics education <i>Mario Sánchez Aguilar, Ana Kuzle, Kjersti Wæge and Morten Misfeldt</i>	4355
Identification and diagnosis of students' mathematical misconceptions in a dynamic online environment <i>Morten Elkjær</i>	4363

Implementation research in primary education: Design and evaluation of a problem-solving innovation <i>Inga Gebel and Ana Kuzle</i>	4365
Operationalizing implementation theory in mathematics education research - identifying enablers and barriers in the Swedish “Boost for Mathematics” <i>Rikke Maagaard Gregersen, Sine Duedahl Lauridsen and Uffe Thomas Jankvist</i>	4373
A learning path for rational numbers through different representations <i>Helena Gil Guerreiro, Cristina Morais, Lurdes Serrazina and João Pedro da Ponte</i>	4381
Coherence through inquiry based mathematics education <i>Per Øystein Haavold and Morten Blomhøj</i>	4389
Competencies and curricula: Danish experiences with a two-dimensional approach <i>Tomas Højgaard and Jan Sølberg</i>	4397
Adapting implementation research frameworks for mathematics education <i>Uffe Thomas Jankvist, Mario Sánchez Aguilar, Jonas Dreyøe and Morten Misfeldt</i>	4405
Implementation through participation: Theoretical considerations and an illustrative case <i>Boris Koichu and Alon Pinto</i>	4413
Designing inquiry-based teaching at scale: Central factors for implementation <i>Dorte Moeskær Larsen, Mette Hjelmberg, Bent Lindhart, Jonas Dreyøe, Claus Michelsen and Morten Misfeldt</i>	4421
Towards a common understanding of implementation research in mathematics education research <i>Andreas Lindenskov Tamborg</i>	4429
Capturing Problem Posing landscape in a grade-4 classroom: A pilot study <i>Ioannis Papadopoulos and Nafsika Patsiala</i>	4431
Models of school governance and research implementation. A comparative study of two Swedish cases, 1960-2018 <i>Johan Prytz</i>	4439
Implementing alternative models for introducing multiplication <i>Anna Ida Säfström, Ola Helenius and Linda Marie Ahl</i>	4447
Implementing theories for preschool teaching with play-based pedagogies <i>Nina Ullsten Granlund</i>	4455
<b>TWG24: Representations in mathematics teaching and learning</b>	<b>4462</b>
Introduction to the work of TWG24: Representations in mathematics teaching and learning <i>Anna Baccaglini-Frank, Carla Finesilver, Samet Okumus and Michal Tabach</i>	4463
From concrete to abstract and back: Metaphor and Representation <i>Pierre Arnoux and Jorge Soto-Andrade</i>	4467
“He’s so fast at drawing” – Children’s use of drawings as a tool to solve word problems in multiplication and division <i>Heidi Dahl</i>	4475

Functional representations produced and used by students during their introduction to the concept of derivative: a window on their understanding processes <i>Sarah Dufour</i>	4483
Moving towards understanding graphical representations of motion <i>Carolien Duijzer, Marja Van den Heuvel-Panhuizen, Michiel Veldhuis, and Michiel Doorman</i>	4491
A training in visualizing statistical data with a unit square <i>Andreas Eichler, Carolin Gehrke, Katharina Böcherer-Linder and Markus Vogel</i>	4499
Learning to 'deal': A microgenetic case study of a struggling student's representational strategies for partitive division <i>Carla Finesilver</i>	4507
Utilizing dynamic representations to foster functional thinking <i>Stephan Michael Günster</i>	4515
Connecting the everyday with the formal: the role of bar models in developing low attainers' mathematical understanding <i>Sue Hough, Steve Gough and Yvette Solomon</i>	4523
Visualization of fractions - a challenge for pre-service teachers? <i>Ellen Konstanse Hovik and Camilla Markhus Rodal</i>	4531
Leveraging difference to promote students' conceptions of graphs as representing relationships between quantities <i>Heather Lynn Johnson, Evan McClintock, and Amber Gardner</i>	4539
Diagrammatic representations for mathematical problem solving <i>Vinay Kathotia and Elizabeth Kimber</i>	4547
Capturing 'time': characteristics of students' written discourse on dynagraphs <i>Giulia Lisarelli, Samuele Antonini and Anna Baccaglini-Frank</i>	4549
Effective choices of representations in problem solving <i>Jasmina Milinkovic, Aleksandra Mihajlovic and Mirko Dejjic</i>	4557
Geometric prediction: proposing a theoretical construct to analyze students' thinking in geometrical problem-solving <i>Elisa Miragliotta</i>	4565
Fibre mathematics: exploring topological forms through material practices <i>Kate O'Brien and Elizabeth de Freitas</i>	4573
Prospective mathematics teachers extrapolative reasoning about misleading bar graphs <i>Samet Okumus and Ercan Dede</i>	4581
The role of students' drawings in understanding the situation when solving an area word problem <i>Manuel Ponce de León Palacios and Jose Antonio Juárez López</i>	4589
Exploring Strategies Used to Solve a Non-Routine Problem by Chilean Students; an Example of "Sharing Chocolates" <i>Farzaneh Saadati and Mayra Cerda</i>	4591

Who is right? Theoretical analysis of representational activities <i>Michal Tabach and Boris Koichu</i>	4593
Teaching practice regarding grade 3 pupils use of representations <i>Isabel Velez, João Pedro da Ponte and Lurdes Serrazina</i>	4601
Explaining geometrical concepts in sign language and in spoken language a comparison <i>Annika M. Wille and Christof Schreiber</i>	4609
Characterizing fraction addition competence of preservice teachers using Rasch analysis <i>Marius Lie Winger, Julie Gausen, Eivind Kaspersen and Trygve Solstad</i>	4617
<b>TWG25: Inclusive Mathematics Education – challenges for students with special needs</b>	<b>4619</b>
Introduction to the work of TWG25: Inclusive Mathematics Education challenges for students with special needs <i>Petra Scherer, Evelyn Kroesbergen, Hana Moraová, Helena Roos</i>	4620
Strategies that promote the mathematical activity of students with language disorders: an analysis of language interactions <i>Raquel Isabel Barrera-Curin, Laurie Bergeron and Audrey Perreault</i>	4628
Low entrance or reaching the goals? Mathematics teachers' categories for differentiating with open-ended tasks in inclusive classrooms <i>Sarah Buró and Susanne Prediger</i>	4636
Teaching mathematics to students with intellectual disability: What support do teachers need? <i>Chun-ip Fung and Dichen Wang</i>	4644
K-12 Namibian teachers' beliefs on learning difficulties in mathematics: Reflections on teachers' practice <i>Shemunyenge Taleiko Hamukwaya</i>	4652
An in-service training to support teachers of different professions in the implementation of inclusive education in the mathematics classroom <i>Laura Korten, Marcus Nührenbörger, Christoph Selter, Franz Wember and Tobias Wollenweber</i>	4660
Designing mathematical computer games for migrant students <i>Janka Medová, Kristína Bulková and Soňa Čeretková</i>	4662
Diagnosis tools of dyscalculia contribution of didactics of mathematics to numerical cognition <i>Florence Peteers and Cécile Ouvrier-Bufferet</i>	4664
I just don't like math, or I think it is interesting, but difficult... Mathematics classroom setting influencing inclusion <i>Helena Roos</i>	4672
The potential of substantial learning environments for inclusive mathematics student teachers' explorations with special needs students <i>Petra Scherer</i>	4680

Mathematical discourses of a teacher and a visually impaired pupil on number sequences: Divergence, convergence or both? <i>Angeliki Stylianidou and Elena Nardi</i>	4688
Do hearing-impaired students learn mathematics in a different way than their hearing peers? A review <i>Kinga Szűcs</i>	4696
Supporting braille readers in reading and comprehending mathematical expressions and equations <i>Annemiek van Leendert, Michiel Doorman, Paul Drijvers, Johan Pel and Johannes van der Steen</i>	4704
<b>TWG26: Mathematics in the context of STEM education</b>	<b>4712</b>
Introduction to TWG26: Mathematics in the context of STEM education <i>Behiye Ubuz, Koeno Gravemeijer, Michelle Stephan and Patrick Capraro</i>	4713
Enhancing mathematics and science learning through the use of a Human Orrery <i>Maha Abboud, Philippe Hoppenot and Emmanuel Rollinde</i>	4721
Integrating the methods of mathematical modelling and engineering design in projects <i>Imad Abou-Hayt, Bettina Dahl, and Camilla Østerberg Rump</i>	4729
Mathematics and art in primary education textbooks <i>Teresa F. Blanco, Valeria González-Roel and Jose Manuel Diego-Mantecón</i>	4737
Mathematical modeling of musical fountains and light organs - Where is the M in interdisciplinary STEM projects? <i>Wolfgang Bock, Martin Bracke and Patrick Capraro</i>	4739
STEM analysis of a module on Artificial Intelligence for high school students designed within the I SEE Erasmus+ Project <i>Laura Branchetti, Olivia Levrini, Eleonora Barelli, Michael Lodi, Giovanni Ravaioli, Laura Rigotti, Sara Satanassi and Giulia Tasquier</i>	4747
Promoting mathematics teaching in the framework of STEM integration Maria Cristina Costa and António Domingos	4749
Reflecting on the value of mathematics in an interdisciplinary STEM course <i>Nelleke den Braber, Jenneke Krüger, Marco Mazereeuw and Wilmad Kuiper</i>	4757
Complex modeling: Does climate change really exist? Perspectives of a project day with high school students <i>Maren Hattebuehr and Martin Frank</i>	4765
Inter TeTra Interdisciplinary teacher training with mathematics and physics <i>Eduard Krause, Nguyen Van Bien, Tran Ngoc Chat, Nguyen Phuong Chi, Frederik Dilling, Jochen Geppert, Kathrin Holten, Tuan Anh Le, Simon Kraus and Chu Cam Tho</i>	4767
Student mathematical preparedness for learning science and engineering at university <i>Ciara Lane and Gráinne Walshe</i>	4775
Pre-service teachers' perspectives on the role of statistics in a learning scenario for promoting STEM integration <i>Hélia Oliveira, Ana Henriques and Mónica Baptista</i>	4783

Student conception of angles and parallel lines in engineering context <i>Premkumar Pugalenth, Michelle Stephan and David Pugalee</i>	4791
Opportunities to engage in STEM practices: Technology and design course <i>Behiye Ubuz</i>	4799
Gamification with Moodle in higher education <i>Ana Júlia Viamonte and Isabel Perdigão Figueiredo</i>	4807
Complex Modeling: Insights into our body through computer tomography perspectives of a project day on inverse problems <i>Kirsten Wohak and Martin Frank</i>	4815

## ADDENDUM

<b>TWG11: Comparative studies in mathematics education</b>	<b>4823</b>
Cultural effects on mathematics lessons: through the international collaborative development of a lesson in two countries <i>Stéphane Clivaz and Takeshi Miyakawa</i>	4824
<b>TWG14: University Mathematics Education</b>	<b>4832</b>
Relevant aspects of proficiency in secondary school arithmetic for a successful start in STEM subjects <i>David Schönwälder, Guido Pinkernell and Gerhard Götz</i>	4833
A mathematician's deliberation in reaching the formal world and students' world views of the eigentheory <i>Sepideh Stewart, Jonathan Epstein, Jonathan Troup and David McKnight</i>	4835
A case study on mathematical routines in undergraduate biology students' group-work <i>Floridona Tetaj and Olov Viirman</i>	4843
Recall and substantiation routines in exam scripts: injective and surjective functions <i>Athina Thoma and Elena Nardi</i>	4851
Students as Partners in Complex Number Task Design <i>Stephanie Treffert-Thomas, Barbara Jaworski, Dave Hewitt, Nikolaos Vlaseros and Marinos Anastasakis</i>	4859
Post-secondary students' enactment of identity in a programming and mathematics learning environment <i>Amanjot Toor, Joyce Mgombelo and Chantal Buteau</i>	4867
Using history of mathematics to inform the transition from school to university: Affective and mathematical dimensions <i>Seyda Uysal and Kathleen M. Clark</i>	4875
Epistemological characteristics influencing didactic choices in course planning – the cases of Basic Topology and Differential Geometry <i>Olov Viirman and Magnus Jacobsson</i>	4883
Calculus variations as figured worlds for math identity development <i>Matthew Voigt, Chris Rasmussen and Antonio Martinez</i>	4891

## **Preface: CERME 11 in lovely Utrecht historic sites**

Susanne Prediger	&	Ivy Kidron
ERME President		ERME Vice-President
Dortmund (Germany)		Jerusalem (Israel)

Each second year, the European Society for Research in Mathematics Education (ERME) organises a conference. The 11th Congress of ERME (CERME 11) took place in Utrecht (The Netherlands), in February, 6 to 10, 2019. The conference was hosted by the Freudenthal Group, in collaboration with the Freudenthal Institute, of Utrecht University. The participants of the conference were offered an excellent academic environment in a place in which important blocks in the foundation of mathematics education research were laid fifty years ago by Freudenthal and his collaborators.

CERME is getting larger from congress to congress: from 774 participants at CERME 10 to 900 participants at CERME 11 - the highest number of participants in comparison with the previous CERMEs. In order to avoid overflow (more than 300 more people were interested in participating), the ERME board had to decide to stop the growth tendencies with stopping at 900 participants. Most participants at CERME 11 are European researchers, but CERME is getting increasingly international with 152 researchers from outside Europe: Asia (30), North–America (54), South-America (40), Australia/New Zealand (9), Africa (19). The European researchers are essentially from Germany (169), Norway (82), United Kingdom (57), Sweden (54), Italy (40), The Netherlands (39), Israel (36), Spain (36), France (33), Portugal (31), Denmark (27), Turkey (26), Greece (23), Ireland (19), Austria (14), Finland (13), Cyprus (11), Hungary (8), Czech Republic (6), Croatia (5), Switzerland (4), Iceland (3), Slovakia (3), and Poland (2), and many other countries with one participant each.

A conference with such a huge number of participants requires a perfect organization in order to be successful, and indeed it was a real success. All the members of the Local Organizing Committee contributed to the excellent organization, especially the chair of the LOC, Marja van den Heuvel-Panhuizen, and her co-chair, Michiel Veldhuis. They did a wonderful work. They paid attention to all the small details before and during the conference. Both paid attention to all the specific needs of each participant. They dealt successfully with all the issues, challenges (small and big), and always with a smile. We thank both of them so deeply! Inclusion and quality is an integral part of the CERME spirit. The success of the conference is tightly connected with the quality of the scientific program, which was excellent. We address our sincere thanks to the International Program Committee, especially to the chair of the IPC, Uffe Thomas Jankvist, and his co-chair, Miguel Ribeiro, for their excellent work before, during and after the conference, taking into account ERME principles: selecting deep and interesting plenaries, organizing a panel discussion, organizing the distribution of Thematic Working Groups and the publication process of the proceedings.

In his plenary lecture, Paul Drijvers offered a deep reflection on a promising integrative approach to tool use, called embodied instrumentation, which is based on three lenses: a Realistic Mathematics Education view; instrumental approaches, and embodied views on

cognition. In the second plenary lecture, Kathleen M. Clark offered a thoughtful analysis of examples in which research on the use of history of mathematics contributed to the broader landscape of research in mathematics education. The examples address the role of history of mathematics in the learning of different mathematical concepts, ranging from the function concept to determinants of matrices, as well as topics in analysis and abstract algebra. The third plenary talk was given by Sebastian Rezat. Using the transition from natural numbers to integers as an exemplary case, Rezat delineated an insightful analysis on transitions from one number system to the other with a particular interest in continuities and discontinuities in the teaching of these number systems. Rezat integrated the results in an approach to achieve learner-centered coherence in the learning of number. Three papers corresponding to these three plenary addresses are included in the proceedings.

On the occasion of the 20<sup>th</sup> anniversary of ERME, the IPC organized an anniversary panel chaired by Konrad Krainer and Hanna Palmer. The panel offered a deep reflection on ERME contribution to research in mathematics education. Barbara Jaworski and Susanne Prediger (past and current ERME president), Paolo Boero and Simon Modeste (representatives of YESS and YERME - Young Researchers in ERME), and Tommy Dreyfus and Jana Žalská (editor and reader of the ERME book) made up the panel.

The work done in the plenaries and the panel contributed substantially to the success of the conference.

The core and the heart of each CERME are the Thematic Working Groups and the serious work which is done in all of them. In the TWGs, the collaboration between experienced and young researchers supports the scientific development of the young researchers. At CERME 11, 575 papers and 152 posters were accepted. 26 TWGs were organized with 8 TWGs which were divided in two subgroups due to the large number of participants. Our sincere thanks are addressed to the 34 working group leaders and 99 co-leaders for their huge and wonderful work. Before the conference, the leaders and co-leaders organized the review process and devoted much time in planning the program of the TWG. As a result, they were able to lead excellent discussions during the work of the TWG at the conference. A wonderful atmosphere and a lot of motivation characterized the work in the working groups. Every participant was involved in the work. After the conference, the authors had the possibility to further revise their papers, integrating significant changes which emerged in the discussions in the TWGs. The leaders and co-leaders organized this final review process.

The work done by all the organizers and deep involvement of the TWG leaders, IPC members, LOC members and ERME board members contributed to the success of the conference. We thank everybody who has contributed to this success. Specific thanks go to Uffe Thomas Jankvist, Miguel Ribeiro, Marja van den Heuvel-Panhuizen and Michiel Veldhuis for all their work with a wonderful result.

We encourage interested researchers to meet us at the next CERME that will take place in February 2021 in Bolzano (Italy).

Susanne Prediger  
ERME President

& Ivy Kidron  
ERME Vice-President

# Introduction to the Proceedings of the Eleventh Congress of the European Society for Research in Mathematics Education (CERME11)

## About CERME11

The Eleventh Congress of European Research in Mathematics Education (CERME 11) took place in Utrecht, the Netherlands from 5th to 10th of February 2019. Uffe Thomas Jankvist (Denmark) was the chair of the International Programme Committee (IPC), which comprised Miguel Ribeiro (Portugal/Brazil, IPC Co-chair), Marianna Bosch (Spain), Therese Dooley (Ireland), Eirini Geraniou (UK/Greece), Ghislaine Guedet (France), Jeremy Hodgen (UK), Bożena Maj-Tatsis (Poland), Angel Mizzi (Germany/Malta), Aoibhinn Ni Shuilleabhain (Ireland), Marja van den Heuvel-Panhuizen (The Netherlands, LOC chair), and Stefan Zehetmeier (Austria). Marja van den Heuvel-Panhuizen and Michiel Veldhuis were chair and co-chair, respectively, of the Local Organizing Committee (LOC).

CERME11 hosted 26 Thematic Working Groups, listed in the table below. The TWGs 07, 25, and 26 were new TWGs, created following a call launched just after CERME10, and a selection process involving the CERME11 IPC and the ERME board. They have all been very successful, and all but one (TWG11) will be part of CERME12 in February 2021. Eight of the TWGs recieved so many submissions they had to be split in two – more precisely the TWGs 01, 05, 09, 14, 16, 18, 19 and 20 – and more TWG leaders and co-leaders had to be invited. In the end, CERME11 had 34 TWG leaders and 99 TWG co-leaders.

Thematic Working Group	Leader	Co-Leaders
<b>TWG 01a</b> Argumentation and Proof	Gabriel J. Stylianides (UK)	Anita Valenta (Norway) Viviane Durand-Guerrier (France)
<b>TWG 01b</b> Argumentation and Proof	Andreas Moutsios-Rentzos (Greece)	Orly Buchbinder (USA) Jenny Cramer (Germany)
<b>TWG 02</b> Arithmetic and Number Systems	Elisabeth Rathgeb-Schnierer (Germany)	Beatriz Vargas Dorneles (Brazil) Renata Carvalho (Portugal) Judy Sayers (Sweden)
<b>TWG 03</b> Algebraic Thinking	Reinhard Oldenburg (Germany)	Dave Hewitt (UK) Heidi Strømskag (Norway) Maria Chimoni (Cyprus)

<b>TWG 04</b> Geometry Teaching and Learning	Joris Mithalal (France)	Michela Maschietto (Italy) Keith Jones (UK) Chrysi Papadaki (Germany)
<b>TWG 05a</b> Probability and Statistics Education	Caterina Primi (Italy)	Sibel Kazak (Turkey) Orlando Rafael González (Thailand)
<b>TWG 05b</b> Probability and Statistics Education	Aisling Leavy (Ireland)	Pedro Arteaga (Spain) Daniel Frischemeier (Germany)
<b>TWG 06</b> Applications and Modelling	Berta Barquero (Spain)	Susana Carreira (Portugal) Katrin Vorhölter (Germany) Geoff Wake (UK) Jonas Bergman Ärlebäck (Sweden) Britta Jessen (Denmark)
<b>TWG 07</b> Adult Mathematics Education	Kees Hoogland (The Netherlands)	Beth Kelly (UK) Fiona Faulkner (Ireland) Javier Diez-Palomar (Spain)
<b>TWG 08</b> Affect and the Teaching and Learning of Mathematics	Stanislaw Schukajlow (Germany)	Inés M. Gómez-Chacón (Spain) Çiğdem Haser (Turkey) Peter Liljedahl (Canada) Karen Skilling (UK) Hanna Viitala (Norway)
<b>TWG 09a</b> Mathematics and Language	Núria Planas (Catalonia-Spain)	Marie Therese Farrugia (Malta) Kirstin Erath (Germany)
<b>TWG 09b</b> Mathematics and Language	Jenni Ingram (UK)	Marcus Schütte (Germany)
<b>TWG 10</b> Diversity and Mathematics Education: Social, Cultural and Political Challenges	Hauke Straehler-Pohl (Germany)	Anette Bagger (Sweden) Laura Black (UK) Anna Chronaki (Greece) David Kollosche (Austria)
<b>TWG 11</b> Comparative Studies in Mathematics Education	Paul Andrews (Sweden)	Eva Jablonka (Germany) Jeta Kingji (Slovenia) Constantinos Xenofontos (Cyprus)
<b>TWG 12</b> History in Mathematics Education	Renaud Chorlay (France)	Aline Bernardes (Brazil) Tanja Hamann (Germany) Antonio M. Oller-Marcén (Spain)
<b>TWG 13</b> Early Years Mathematics	Ingvald Erfjord (Norway)	Esther Levenson (Israel) Bożena Maj-Tatsis (Poland) Marianna Tzekaki (Greece) Priska Schöner (Germany)

<b>TWG 14a</b> University Mathematics Education	Alejandro S. González-Martín (Canada/Spain)	Ghislaine Gueudet (France) Imène Ghedamsi (Tunis) Jason Cooper (Israel)
<b>TWG 14b</b> University Mathematics Education	Irene Biza (UK)	Olov Viirman (Sweden) Alon Pinto (Israel) Vilma Mesa (USA)
<b>TWG 15</b> Teaching Mathematics with Technology and Other Resources	Alison Clark-Wilson (UK)	Ornella Robutti (Italy) Iveta Kohanová (Norway/Slovakia) Melih Turgut (Turkey)
<b>TWG 16a</b> Learning Mathematics with Technology and Other Resources	Hans-Georg Weigand (Germany)	Ana Donevska-Todorova (Germany/Macedonia) Eirini Geraniou (UK)
<b>TWG 16b</b> Learning Mathematics with Technology and Other Resources	Nathalie Sinclair (Canada)	Eleonora Faggiano (Italy) Osama Swidan (Israel)
<b>TWG 17</b> Theoretical Perspectives and Approaches in Mathematics Education Research	Angelika Bikner-Ahsbals (Germany)	Arthur Bakker (The Netherlands) Esther Chan (Australia) Heather Johnson (USA)
<b>TWG 18a</b> Mathematics Teacher Education and Professional Development	Stefan Zehetmeier (Austria)	Laurinda Brown (UK) Maria Mellone (Italy)
<b>TWG 18b</b> Mathematics Teacher Education and Professional Development	Joao Pedro da Ponte (Portugal)	Libuse Samkova (Czech Republic) Marita Friesen (Germany) Janne Fauskanger (Norway) Àngela Bufo (Spain)
<b>TWG 19a</b> Mathematics Teaching and Teacher Practice(s)	Charalampos Sakonidis (Greece)	Rukiye Didem Taylan (Turkey) Ove Gunnar Drageset (Norway)
<b>TWG 19b</b> Mathematics Teaching and Teacher Practice(s)	Reidar Mosvold (Norway)	Siún Nic Mhuirí (Ireland)
<b>TWG 20a</b> Mathematics Teacher Knowledge, Beliefs and Identity	Miguel Ribeiro (Brazil/Portugal)	Fatma Aslan-Tutak (Turkey) Miguel Montes (Spain)
<b>TWG 20b</b> Mathematics Teacher Knowledge, Beliefs and Identity	Francesca Martignone (Italy)	Sebastian Kuntze (Germany) Kirsti Rø (Norway)

<b>TWG 21</b> Assessment in Mathematics Education	Paola Iannone (UK)	Michal Ayalon (Israel) Johannes Beck (Germany) Jeremy Hodgen (UK) Francesca Morselli (Italy)
<b>TWG 22</b> Curricular Resources and Task Design in Mathematics Education	Birgit Pepin (The Netherlands)	Seán Delaney (Ireland) Andreas Eckert (Sweden) Nataly Essonnier (France) Andreas Stylianides (UK)
<b>TWG 23</b> Implementation of Research Findings in Mathematics Education	Mario Sánchez Aguilar (Mexico)	Kjersti Wæge (Norway) Ana Kuzle (Germany) Morten Misfeldt (Denmark)
<b>TWG 24</b> Representations in Mathematics Teaching and Learning	Anna Baccaglini-Frank (Italy)	Carla Finesilver (UK) Christian Mercat (France) Samet Okumus (Turkey) Michal Tabach (Israel)
<b>TWG 25</b> Inclusive Mathematics Education – Challenges for Students with Special Needs	Petra Scherer (Germany)	Evelyn H. Kroesbergen (The Netherlands) Hana Moraová (Czech Republic) Helena Roos (Sweden)
<b>TWG 26</b> Mathematics in the Context of STEM Education	Behiye Ubuz (Turkey)	Michelle Stephan (USA) Koeno Gravemeijer (The Netherlands) Patrick Capraro (Germany)

## Editorial information

These proceedings are available as a complete volume online on the ERME website and each individual text is also available on the HAL open archive, where it can be found through keywords, title or author name. This has been the practice since CERME9, to increase the visibility of the huge work done in CERME conferences.

This volume begins with texts corresponding to the four plenary activities of CERME11: the plenary lecture by Paul Drijvers (The Netherlands) on “Embodied instrumentation: combining different views on using digital technology in mathematics education”; the plenary lecture by Kathleen M. Clark (USA) on “History and pedagogy of mathematics in mathematics education: History of the field, the potential of current examples, and directions for the future”; the plenary lecture by Sebastian Rezat (Germany) on “Extensions of number systems: continuities and discontinuities revisited”; and finally the “ERME anniversary panel on the occasion of the 20th birthday of the European Society for Research in Mathematics Education” by Konrad Krainer (Austria), Hanna Palmér (Sweden), Barbara Jaworski (UK), Susanne Prediger (Germany), Paolo Boero (Italy), Simon Modeste (France), Tommy Dreyfus (Israel), and Jana Žalská (Czech Republic).

After the plenaries, the reader will find 26 chapters corresponding to the work done in the TWGs of CERME11 (all the split TWGs chose to do combined introductions). These chapters follow a similar

structure: they start with an introduction; then the long contributions (8-page papers) and the short contributions (2 pages) are presented – in alphabetical order by first author's name. However, TWG17 has chosen a different order, corresponding to subthemes in the group.

There are two kinds of introductions to the TWGs, according to the team's choice: short introductions (4 pages) presenting the contributions; or long introductions (8 pages), which propose, in addition, an analysis of the current research on the theme of the TWG, and perspectives for the future. TWGs 06, 07, 09, 14, 15, 17, 19, 22, 23, 25 and 26 have chosen this form of long introduction.

The publication of these proceedings is the result of a collaborative work, involving CERME11 IPC, the TWG leaders and co-leaders, and the LOC co-chair. We warmly thank all these people for their involvement, and hope that this volume will contribute to the development of mathematics education research in Europe and beyond.

# Embodied instrumentation: combining different views on using digital technology in mathematics education

Paul Drijvers

Utrecht University, the Netherlands;

HU University of Applied Sciences Utrecht, the Netherlands; [p.drijvers@uu.nl](mailto:p.drijvers@uu.nl)

*The potential of digital technology for mathematics education has been widely investigated in recent decades. Still, much remains unknown about how to use tools to foster mathematics learning. To address this issue, I first consider the didactical functionalities of digital technology in mathematics education, and the overall modest effects of using these tools for learning. Next, to find possible explanations of these findings I address three relevant views: (1) a Realistic Mathematics Education (RME) view on tool use, (2) an instrumental approach to tool use, and (3) an embodied view on cognition. As a conclusion, I claim that all three lenses share a focus on mathematical meaning. Whereas the RME view provides important general guidelines, an integrative approach to tool use, which I label embodied instrumentation, and which includes the careful alignment of embodied and instrumental experiences, seems promising to generate powerful learning activities.*

*Keywords: Digital technology, Embodied instrumentation, Embodiment, Instrumental approach, Mathematics education, Realistic mathematics education.*

## An introduction to tool use

Since the origin of mankind, humans have been using tools to extend their scope and to carry out tasks more easily and more efficiently. A wide range of tools has been developed over time. The most basic ones, such as a stone axe for chopping wood, enabled their users to go beyond their physical limitations to achieve specific goals. The tools were not always designed as such. In some cases, people – or animals, as tool use is not limited to the human species – appropriated objects for a specific task, and in this way ‘turned objects into tools’. For example, one could use a tree branch to hit somebody harder than one could do with bare hands, but the branch did not grow from the tree to facilitate beating.

Over time, tools have become more sophisticated and have been designed to address cognitive tasks. Think, for example, of clay tablets to capture calculations (Proust, 2012). Writing down calculations assumes ways to represent numbers and operations, which are quite abstract mathematical notions; these representations themselves can be considered tools already (Monaghan, Trouche, & Borwein, 2016). Since clay tablets, many other tools for mathematics have been designed and used over the centuries. Physical artefacts such as the abacus and compasses respectively facilitated calculations and geometrical constructions.

Gradually, new types of tools emerged, such as mechanical tools – think of Pascal’s Pascaline (Maschietto & Soury-Lavergne, 2013) – and digital tools. Nowadays, digital technology such as calculators, tablets (but no longer made from clay), smartphones and smart watches, gives access to a wide range of mathematical features, including sophisticated computer algebra engines and statistical packages. In many cases, the mathematics embedded in the latter types of software has a

non-transparent black-box character. In addition to this, the role of mathematics under the hood of advanced tools, such as search engines, navigation tools and credit cards, to mention just some examples, is becoming more and more invisible.

As education prepares for future private and professional life, the development and widespread availability of sophisticated mathematical tools affects mathematics education. These tools transform mathematical activity (Hoyles, 2018). However, much is still unknown about how to exploit the potential of these powerful technologies for mathematics learning. In spite of the available body of literature (for overviews see Ball et al., 2018; Hoyles & Lagrange, 2010; Trgalová, Clark-Wilson, & Weigand, 2018), the mathematics education community is still struggling with the integration of digital technology in teaching and learning. The question of how the use of digital technology may foster mathematics learning and which theoretical lenses may guide us, is waiting to be answered.

To address this question, I will first globally address the didactical functionalities of digital technology in mathematics education, and the overall modest effects of using these tools for learning. To consider possible explanations of these findings, I will then address three relevant theoretical views in more detail: (1) a Realistic Mathematics Education view on tool use, (2) an instrumental approach to tool use, and (3) an embodied view on cognition. Finally, I will claim that these three lenses share a focus on mathematical meaning. Whereas the RME view provides important general guidelines, an integrative approach to tool use, which I will label embodied instrumentation, and which includes the careful alignment of embodied and instrumental experiences, seems promising to generate powerful learning activities.

## **Digital tools in mathematics education**

### **A taxonomy of digital tools**

In the last decades, a myriad of digital tools for mathematics education has been developed. These tools show a wide variety with respect to mathematical focus, didactical functionality, user-friendliness, and other features. All, however, come with affordances and limitations, with opportunities and constraints. Let me try to sketch an overview of the fragmented landscape of digital technology in mathematics education. A first dimension, of course, is the tool's mathematical functionality. A categorization of the mathematical functionality of a tool can be close to a categorization of the field of mathematics itself. Digital tools can carry out algebraic work, graphing tasks, statistical analyses, calculus procedures, and geometric jobs. The traditional domains of school mathematics (e.g., number, ratio, algebra, geometry, calculus, statistics) may do for globally classifying the mathematical functionality of digital tools for mathematics education. It goes without saying that a specific digital tool may cover a range of these domains and as such serve more than one mathematical functionality, but this mathematical categorization still seems to work.

Slightly more complicated is a taxonomy of the didactical functionality of a digital tool, all the more as this is not just a matter of the tool itself, but also highly depends on the type of tasks and on the way the use is embedded and orchestrated in the teaching and learning processes. In spite of this evident limitation, I do feel that the very global model presented in Figure 1 (Drijvers, Boon, & Van Reeuwijk, 2011; Drijvers, 2018b) may help teachers and educators to prepare their teaching with technology, and to be explicit about their main goals and corresponding choices with respect to the

tool to use. The first didactical functionality in Figure 1 is to “do mathematics”. This functionality does not target the heart of the mathematical activity itself, but concerns outsourcing part of the work to relieve the student’s mind. In this way, energy can be saved for the core matter; a division of labour between student and machine, so to say. Next, Figure 1 shows two types of didactical functionality that focus on learning. With respect to learning through practicing mathematical skills, digital tools may offer variation and randomization of tasks, and automated and intelligent feedback. As such, the digital tools form a personal environment in which one can safely make mistakes and learn from them. Finally, tool use for concept development involves using a digital tool to explore phenomena that invite conceptual development. This is probably the most challenging and subtle didactical functionality to exploit, as concept development can be considered a higher-order learning goal.

Of course, the categories in this didactical functionality taxonomy are not mutually exclusive; in many cases, the “developing concepts” didactical functionality rests on the outsourcing function for doing mathematics. Also, the didactical function of a digital tool is just a tool feature to a lesser extent than the mathematical functionality is; it also depends on the type of tasks and student activity, and the educational setting. This being said, the model may help to identify some main roles of digital technology in the learning of mathematics.

**Figure 1: Didactical functionality of digital technology in mathematics education (Drijvers, Boon, & Van Reeuwijk, 2011; Drijvers, 2018b)**

### The benefits of tool use

After this global sketch of the mathematical and didactical landscape, one might wonder about the benefits of using digital technology in mathematics education. How much evidence is there for the learning gains? Recently, OECD was not very optimistic about this evidence:

Despite considerable investments in computers, internet connections and software for educational use, there is little solid evidence that greater computer use among students leads to better scores in mathematics and reading. (OECD, 2015, p. 145)

To further investigate this, I revisited some review studies in this domain (Drijvers, 2018a). While doing so, a main source was a second-order meta-analysis carried out by Young (2017), who, interestingly enough, took the didactical functionality typology shown in Figure 1 as a starting point. Including 19 meta studies, Young finds a significant positive effect of the use of technology in mathematics education with a small to moderate average effect size of 0.38 (Cohen, 1988). In his calculation, Cohen’s  $d$  and Hedges  $g$  are considered comparable. This average varies slightly over the

three different didactical functions: 0.47 for the “do mathematics” role, 0.42 for the “practice skills” role, and 0.36 for the “develop concepts” role. This not surprising to me, as the latter functionality usually requires more student reflection than the other two do. For studies in which the different didactical functionalities are combined, however, the average effect size is lower, namely 0.21.

An interesting finding by Young (ibid.) is that the reported average effect size seems to decrease with the increasing quality of the meta-analyses included. Quality here refers to both the meta-analysis itself and to the quality of the studies included in it. For example, the three review studies mentioned in Table 1 are the only ones rated high quality and they show relatively low effect sizes. A more detailed look at these studies also reveals that the effect sizes reported in the different research reports do not significantly increase over time, whereas one might hope that technological tools are improving, along with teachers’ ability to exploit them in teaching. A possible explanation might be that a possible positive development over time is compensated by other factors, such as more rigorous study designs and methods, and bigger sample sizes.

Study	Number of effect sizes	Average effect size	Global conclusion according to the authors
Li & Ma, 2010	85	$d = 0.28$ (weighted)	Moderate significant positive effects
Cheung & Slavin, 2013	74	$d = 0.16$	A positive, though modest effect
Steenbergen-Hu & Cooper, 2013	61	$g$ range 0.01 – 0.09	No negative and perhaps a small positive effect

**Table 1: Effect sizes reported in in three high-quality meta review studies (based on Drijvers, 2018a)**

Of course, this zooming out approach suffers from important limitations. The review studies are based on older research, so the picture might have changed since then. Also, the review studies only include experimental, quantitative studies and neglect qualitative or design-based research. And, finally, overviews such as these do not distinguish educational levels, types of technology used, and other educational factors that may be decisive.

Still, it would be too easy to ignore the above findings because of these limitations. The effect sizes are not overwhelming and the OECD quote at the start of this section seems appropriate. Why is the integration of digital technology in mathematics education not the success that one might have hoped for? In my opinion, the question “does ICT work in mathematics education?” is too broad. If we would replace “ICT” by “textbook”, for example, no one would be surprised to get an answer like “it just depends on the quality of the textbook”. In a similar way, exploiting the full potential of digital tools in mathematics education is a complex issue that requires more detailed insights into the learning processes that play a role, into the targeted mathematical content, and in the ways in which the mathematical activity is affected by the use of the tool. Therefore, I will now zoom in on three theoretical and more nuanced views on the use of digital tools in mathematics education, that may offer principles and frameworks to better tackle the subtlety of the topic.

## A Realistic Mathematics Education view

Even though the theory of Realistic Mathematics Education (RME) applies to mathematics education in general, it might also shed some light on the possible benefits of using digital technology in mathematics education. Let me first explain some general RME features. RME is an instruction theory for the teaching and learning of mathematics that was developed in the Netherlands. A starting point was Freudenthal's (1973) view on mathematics as a human activity, i.e., mathematics should be experienced as meaningful, authentic, sensemaking and real by the students. The following quote stresses that the word "realistic" should not be understood as "real world":

Although 'realistic' situations in the meaning of 'real-world' situations are important in RME, 'realistic' has a broader connotation here. It means students are offered problem situations which they can imagine. This interpretation of 'realistic' traces back to the Dutch expression 'zich REALISERen', meaning 'to imagine'. It is this emphasis on making something real in your mind that gave RME its name. Therefore, in RME, problems presented to students can come from the real world, but also from the fantasy world of fairy tales, or the formal world of mathematics, as long as the problems are experientially real in the student's mind. (Van den Heuvel-Panhuizen & Drijvers, 2014, p. 521).

This starting point is elaborated in some key concepts, including the activity principle, mathematization, and didactical phenomenology. Let me briefly elaborate on each of these three.

- The *activity principle* links to the view of mathematics as a human activity and highlights that students should have the opportunity to explore and to re-invent mathematics, and in this way build up their mathematical knowledge.
- In line with this, *mathematization* refers to the activity of doing mathematics. Treffers (1987) distinguishes horizontal and vertical mathematization. Horizontal mathematization concerns mathematizing reality and the process of formulating a mathematical description, involving the transfer between different domains. Vertical mathematization concerns mathematizing mathematics and the process of reorganization within the mathematical system, involving the genesis of mathematical objects and relations between them.
- A *didactical phenomenology* is an analysis of "how mathematical thought objects can help organizing and structure phenomena" (Van den Heuvel-Panhuizen, 2014, p. 175). It identifies phenomena that beg to be organized with the specific mathematical means that are the topic of the learning, and as such may "show the teacher the places where the learner might step into the learning process of mankind" (Freudenthal, 1983, p. ix). It invites the development of the mathematics at stake and gives meaning to it. As said before, these phenomena can come from different "worlds" as long as they are experientially real to the students (Gravemeijer & Doorman, 1999). Such an analysis on the one hand asks for a thorough analysis of the mathematical topic, and on the other hand for a clear view on the targeted audience of the teaching.

How do these RME principles inform the use of digital technology in mathematics education? First, the interpretation of the word "realistic" in the sense of experientially real suggests that students should experience the activity with the digital technology as meaningful. In line with Ainley, Pratt and Hansen (2006), students may perceive an activity as meaningful if they are aware of its purpose

and its utility, where purpose refers to the activity leading to a “meaningful outcome for the pupil, in terms of an actual or virtual product, or the solution of an engaging problem” (p. 29), and utility to “the ways in which those mathematical ideas are useful” (p. 30). I expect that a certain level of transparency of the tool would foster meaning in terms of experienced purpose and utility.

Second, the activity principle and the human activity view suggest that the digital tool should offer the students opportunities to explore, and to be an actor rather than a passive user. I expect that a degree of ownership and the feeling of being in control may invite this. From a mathematization perspective, being in control also includes the opportunity to easily express yourself mathematically with the amount of freedom that one also has while doing paper-and-pen mathematics. This requires a sound mathematical basis for the tool in use.

Third and final, taking a didactical phenomenology perspective leads me to expect that the phenomena may change in a technology-rich classroom: the digital environment itself may be a meaningful phenomenon to study. For example, if students regularly use digital tools like graphing calculators or software for dynamic geometry, these environments really become part of the classroom environment and as such may elicit inspiring phenomena that invite further investigation. Also, as many students nowadays are familiar with games and tools, digital environments may be quite natural and authentic to them, which offers opportunities to better realize this RME principle.

Let me illustrate these principles through the example of an online lesson series on arrow chains and functions for grade 8 (14-year-old students), implemented in the Freudenthal Institute’s Digital Mathematics Environment<sup>1</sup> (Doorman, Drijvers, Gravemeijer, Boon, & Reed, 2012; Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010). In this lesson series, students first explore chains of operations in meaningful contexts. As an example, they figure out how the breaking distances of different types of vehicles, the distance needed to stop in case of emergency, depend on their velocity. Next, they act out the chaining by standing next to each other, creating an input-output-chain in which each student is responsible for performing one of the operations, to prepare for the work in the digital environment.

Figure 2 shows some snapshots of the work in the digital environment that follows. The first row shows how students can chain operations to calculate the breaking distance in meters of a scooter with an initial velocity of 40 km/hour. Of course, after their previous experience with series of numerical calculations, the construction of these chains should be experienced by the student as a meaningful way to organize these calculations. In the second row, the breaking distance is investigated as function of the initial velocity, and a graph is added. In the third row, these breaking distance functions are compared for scooters, cars and lorries. As the window got too full, the user has collapsed the function chains into single boxes, allowing for a good comparison of the three graphs.

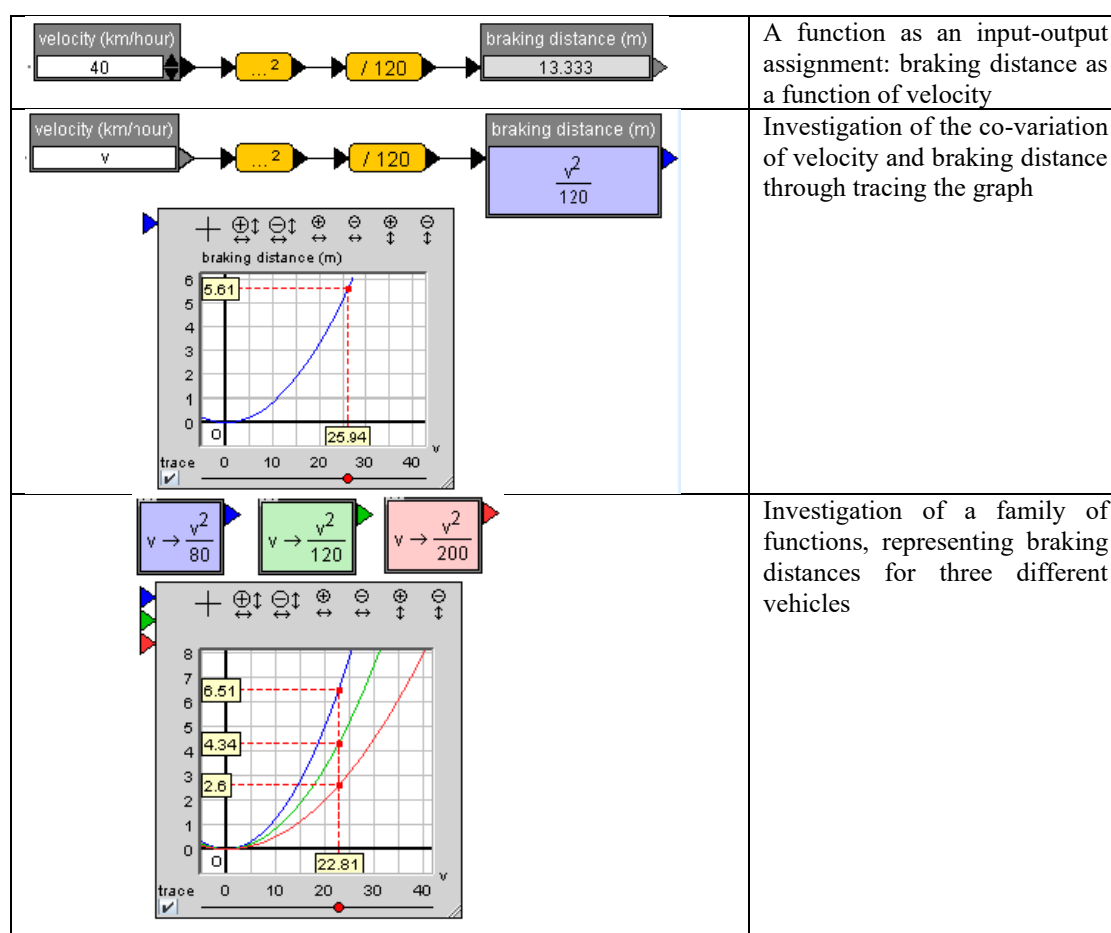

Even if these activities are described only briefly, some RME principles can be recognized. As for the reality principle, the students have been introduced to arrow chains to organize calculations in

---

<sup>1</sup> See <https://app.dwo.nl/en/student/> -> Old -> Secondary education -> Algebra -> Lesson function and arrow chains.

whole-class and paper-and-pen activities, so these have become meaningful ways to capture calculations. The open character of the environment, with a big empty window as exploration room for students, is meant to provide the students with means to freely build, change and organize arrow chains and to be in control of what is happening. Horizontal mathematization is addressed through the task of modelling the arrow chains for the case of the breaking distances, and vertical mathematization comes into play as soon as the three quadratic functions and their relationships are compared, independently from the initial breaking distance problem situation. The option to collapse function chains into boxes is intended to support an object view on function. A didactical phenomenology lens led the designers to consider the breaking distance context as a phenomenon that can very well be organized through mathematical functions and arrow chains.

To summarize, the example illustrates how the general RME principles can be applied to the specific situation of using digital tools in a meaningful way, and as such provide guidelines and criteria for sensible tool use. In this way, the RME lens may offer a nuanced view on using digital technology in mathematics education, even if it is not dedicated to this particular case.

**Figure 2: Snapshots from the Function and Arrow Chains material (from Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013). See <https://youtu.be/OMDjC5yVlr0> for an animation.**

## An instrumental approach

In addition to the general guidelines offered by RME, a more detailed view on the interplay between mathematics and tool use is needed. A first, somewhat naive view on digital tools and their use in mathematics education might be that tools are just “objective” mathematical assistants that help us to carry out tasks, to “do the jobs”: using them reduces solving mathematical tasks to pressing buttons, and as such simplifies our lives. However, things turn out to be not that straightforward. Tools are not as neutral as one might hope, but come with affordances and constraints, with opportunities and obstacles, and as such guide the user’s mathematical practices:

Tools matter: they stand between the user and the phenomenon to be modelled, and shape activity structures. (Hoyle & Noss, 2003, p. 341)

For example, drawing a circle with physical compasses is quite different from drawing it in a dynamic geometry environment such as GeoGebra. In the first case, one really experiences a circular movement, after deciding on the centre and the radius. In the latter case, the focus is on setting the centre and the radius, but while enlarging the radius, the circle is growing, and the circular movement is no longer needed. Different tools lead to different techniques, and as such to different views on the same underlying mathematical concept.

Indeed, in line with Vygotsky (1978), tools mediate between human activity and the environment. As a consequence, using digital tools for learning and doing mathematics is not just a matter of directly transforming mathematical thinking into tool commands. On the one hand, the user shapes the techniques for using the tool, but on the other hand the tool shapes and transforms the user’s mathematical practice. These considerations gave rise to the development of a new theoretical view, called the instrumental approach to tool use. Key in this approach are the notions of artefact, instrument, instrumental genesis, scheme, and technique. Let me briefly explain these notions.

A starting point in instrumental approaches is the distinction between artefact and instrument (Rabardel, 2002; Vérillon & Rabardel, 1995). The artefact is the object that is used as a tool. In our case, graphing calculators or dynamics geometry software are artefacts, even if we also might want to look in more detail, and consider the graphing window in GeoGebra an artefact, or the Solver option in a graphing calculator. An instrument consists of an artefact and “one or more associated utilization schemes” (Vérillon & Rabardel, 1995, p. 87). So, besides the artefact, the instrument also involves the schemes that the user develops and applies while using the artefact for a specific class of instrumented activity situations, in our case often involving a type of mathematical tasks. To summarize this in a somewhat simplified ‘formula’: Instrument = Artefact + Scheme. The process of an artefact becoming part of an instrument is called instrumental genesis (Artigue, 2002; Trouche & Drijvers, 2010).

What are these schemes, key in instrumental genesis? Based on the work by Piaget (1985) and others, a scheme is considered a more or less stable way to deal with specific situations or tasks. Vergnaud claims that “the sequential organization of activity for a certain situation is the primitive and prototypical reference for the concept of scheme” (Vergnaud, 2009, p.84). Referring to the scheme of counting in particular, Vergnaud (1987, p.47) speaks of “a functional and organized sequence of rule-governed actions, a dynamic totality whose efficiency requires both sensorimotor skills and

cognitive competencies.” Later, Vergnaud (2009) prefers to speak about percepto-gestual schemes rather than of sensorimotor schemes, as to go beyond the purely biological level and to highlight the close relationship between perception and gesture on the one hand, and conceptualization on the other. In agreement with these ideas, the term sensorimotor scheme in this rest of this text should be interpreted in this wider sense.

Scheme development involves the intertwined development of sensorimotor skills and cognition. As we see a scheme here as part of an instrument, we speak of an instrumentation scheme. Artigue (2002) highlights the pragmatic and epistemic value of schemes: the pragmatic value in the sense of their productive potential to “get things done”, and the epistemic value in the sense of contributing to the meaning and understanding of the mathematics involved.

The observable parts of an instrumentation scheme, the concrete interactions between user and artefact, are called instrumented techniques. Instrumented techniques are more or less stable sequences of technical interactions between the user and the artefact with a particular goal. As such, an instrumentation scheme consists of one or more observable instrumented techniques, that are guided by the opportunities and constraints the artefact offers, and by the students’ knowledge. In the meantime, the techniques may also contribute to the development of this knowledge. As such, techniques can be seen as actions that reflect students’ knowledge. And, even more important, techniques and knowledge may co-emerge. It is this co-emergence that forms the heart of instrumental genesis and that reflects the main educational potential of using the artefact in a given situation.

In the instrumental approach, a scheme depends on the subject, the artefact and the task. Three comments should be made here. First, this implies that carrying out a similar task with different artefacts is likely to lead to different schemes. The compasses case described above shows that different instrumental geneses will take place. It is interesting to use different artefacts for similar tasks and to confront and compare the different schemes that emerge (Maschietto & Soury-Lavergne, 2013). As a consequence, mathematical practices transform through the use of digital artefacts (Hoyle, 2018). Second, instrumental genesis is not just an individual process, but is part of social learning processes and institutionalization within the specific educational context. Through teachers’ instrumental orchestration (Trouche, 2004), a collective instrumental genesis is taken care of, to assure the convergence towards shared instruments and shared mathematical knowledge. In fact, teachers are involved in a double instrumental genesis, including their personal development of schemes on the one, and schemes for use in teaching their students on the other. Third, some artefacts are more suitable for specific types of instrumental genesis than others. Haspekian (2014) introduced the notion of instrumental distance to stress the change in mathematical practice that may emerge as a result of some type of tool use. If the distance between regular or targeted mathematical practices on the one hand, and techniques invited by the artefact on the other is too big, instrumental genesis might be not productive for the learning process.

The importance of this instrumental view for the use of mathematical tools in mathematics education lies not only in the acknowledgement of the subtlety and complexity of the issue, but also in the concrete guidelines it offers for a fruitful use: as teachers and educational designers, we should set up activities for students and choose appropriate artefacts that together lead to instrumental genesis

processes in which the targeted mathematical knowledge is developed in a meaningful and natural way. A mismatch between the task, the affordances of the artefact, and the mathematical knowledge at stake will not be effective. Outlining these three elements is the game to play; it includes being explicit about the instrumental genesis and scheme development that is aimed for.

**Figure 3: Intersecting graphs to solving equations with two different tools**

As an example of such scheme development, Figure 3 shows two ways in which an equation can be solved graphically through an Intersect procedure, one using a graphing calculator (screens on the left) and one using GeoGebra (screen on the right). This equation,  $\frac{x^2+100}{2x+20} = 4.5$ , appeared in a realistic problem situation in a national examination task in the Netherlands, in which students used a graphing calculator. Technically speaking, the procedure comes down to entering the left-hand side and the right-hand side of the equation separately as functions in the graphing tool. Next, a viewing window should be set so that the two graphs show an intersection point. Then the intersect procedure is called, through selecting the two graphs. This will lead to the coordinates of such an intersection point. Finally, its first coordinate is a solution of the equation. Phrased this way, the technique sounds very straightforward and procedural.

However, several conceptual elements are involved. First, the student needs to be aware of the relationship between solutions of an equation and graphical intersection points. Second, while setting the viewing window dimensions, the student needs to have an idea of where intersection points can be found, which requires some reasoning (or some trial-and-error behaviour). Third, the result consists of not one but two numerical values, and a solution is a numerical, approximated value. Fourth and final, the procedure leads to one, single solution; the procedure needs to be repeated for equations with multiple solutions, that can be visible in the current viewing window, but may also exist outside its boundaries. Again, some reasoning is needed to consider the option of other intersection points outside the current view. Eventually, this technique can be complemented by

zooming in at intersection points, by zooming out to get an overview, or by generating tables of function values.

It is this intertwinement of technical and conceptual elements that makes me speak of an Intersect instrumentation scheme. The development of this scheme impacts on students' view on equation solving in a subtle and somewhat implicit way. Solving an equation is no longer a matter of exact algebraic manipulation while maintaining equivalence, but is replaced by a functional, graphical view that leads to approximated values. As such, the tool use affects the mathematical content. The Intersect scheme, therefore, integrates techniques and mathematical ideas, and this is exactly what instrumental genesis is about.

The instrumentation schemes that students develop depend on the digital tool in use. In Figure 3, the left part shows two screens of a graphing calculator, here a Texas Instruments model (Drijvers & Barzel, 2012). The right-hand side shows a similar screen in GeoGebra, which offers a larger screen and higher resolution. The techniques are also slightly different: GeoGebra does not ask for a starting value, but immediately comes up with a point. This makes the procedure more efficient, but it also makes it harder to find the coordinates of the second intersection point. Also, whether the coordinates are displayed depends on the settings in GeoGebra. The two tools – again, in the default setting – provide the results with different accuracy.

To summarize, this example illustrates the interplay between techniques for using a digital tool, and the related mathematical knowledge involved; an interplay that fundamentally affects the mathematics, but in the meantime is subtle to study. The example shows, to rephrase the quotation by Hoyles and Noss (2003) earlier in this section, that tools and techniques are not neutral, but may highlight or even require specific mathematical views on the task at stake. As a consequence, tool use is less simple than it might seem. Instrumental views are helpful to become aware of this complexity and to identify the interplay between artefacts and tasks, between techniques and schemes. Recognizing instrumental genesis as a path to learning mathematics, and probably also different mathematics, is an important step forward to fostering learning while using digital tools.

### **An embodied view on cognition**

The instrumental approach to tool use has proved valuable in understanding the interplay between the technical and the conceptual when learners use artefacts. So far, however, it focused mostly on higher-level mathematics such as pre-university streams, and on sophisticated digital tools such as computer algebra and dynamic geometry systems. It is maybe due to these foci that mathematics is approached as a cerebral activity, and that the bodily foundations of cognition tend to be neglected. To do justice to the latter aspect, I now consider an embodied view on cognition as a third lens to look at the use of digital technology in mathematics education.

A general starting point here is that body and mind cannot be separated and that a dualistic view on them is inappropriate. Cognition is not considered an exclusively mental affair, but based on bodily experiences, that take place in interaction with the physical and social world (e.g., see Radford, 2009; Lakoff & Núñez, 2000; de Freitas & Sinclair, 2014; Ferrara & Sinclair, 2016). Embodiment “is the surprisingly radical hypothesis that the brain is not the sole cognitive resource we have available to

us to solve problems” (Wilson & Golonka, 2013, p.1). Phrased differently, Alibali and Nathan (2012) claim:

According to this perspective, cognitive and linguistic structures and processes – including basic ways of thinking, representations of knowledge, and methods of organizing and expressing information – are influenced and constrained by the particularities of human perceptual systems and human bodies. Put simply, cognition is shaped by the possibilities and limitations of the human body. (p. 250)

Also for the case of mathematics, often considered a highly abstract and mental subject, cognition is more and more acknowledged to be rooted in sensorimotor activities, and mathematical objects to be grounded in sensorimotor schemes. Two special issues—57(3) and 70(2)—of *Educational Studies in Mathematics*, dedicated to embodiment in mathematics education, testify to the growing interest of mathematics education research in this perspective. Many embodied approaches take “the four E’s” of embodied, extended, embedded and enactive cognition<sup>2</sup> as a starting point. In these terms, the initial views on tool use in this paper highlight the role of tools to extend the body; now the focus shifts towards the other E’s, and to digital technology providing opportunities to create embodied experiences in particular.

At first glance, a tension might seem to exist between this embodied view on cognition and the use of digital technology in mathematics education. Digital tools such as spreadsheets, computer algebra software and dynamic geometry systems embed an impressive amount of mathematical knowledge. As these tools are not transparent, they seem to “hide this knowledge under the hood”, which may create a distance between user and mathematics used. And, even more importantly, ways to interact with these tools have not so far been ‘body-based’, as the interaction mainly took place through keyboard strokes in the more remote past, and through mouse movements in the more recent past. Recent technological developments, however, open up new horizons to do justice to the multimodality of mathematical knowledge. Maybe partly due to the need for embodied experiences, improved user interfaces – think of multitouch screen technology, handwriting recognition, motion sensors, and virtual and augmented reality – have been developed, offering new opportunities to investigate an embodied approach to tool use. For example, some researchers studied students who “walk graphs” using a motion sensor, and in this way create embodied experiences of distance, speed and acceleration changing over time (Duijzer, Van den Heuvel-Panhuizen, Veldhuis, Doorman, & Leseman, 2019; Robutti, 2006).

In line with the didactical engineering tradition within my institute (Margolinas & Drijvers, 2015), the work done in this field by my colleagues and myself within my institute follows an embodied design approach (Abrahamson, 2009; Abrahamson, Shayan, Bakker, & Van der Schaaf, 2016). We use “design genres” (Abrahamson, 2014; Bakker, Shvarts, & Abrahamson, 2019) in which activities in digital environments. In these activities, students can engage in bodily experience and develop mathematical cognition. Let me illustrate this embodied design approach with two examples.

---

<sup>2</sup> <https://4ecognitiongroup.wordpress.com/>

As a first example, Figure 4 shows a task designed by Shvarts (2018) in the Digital Mathematics Environment. The left screen shows a fixed base line and a small, fixed black point. The larger grey dot is projected onto the base line. The three points together define a triangle, which in the left screen is red. The student can move the big grey point with her finger, and the triangle changes accordingly. Suddenly, the triangle becomes green (right screen). The triangle turns green when it is isosceles, otherwise it is red. As a consequence, the triangle is green if the grey, moveable point lies on the parabola which has the base line as directrix and the fixed point as focus. This dashed parabola, however, is not shown to the student, but it is included here for the reader.

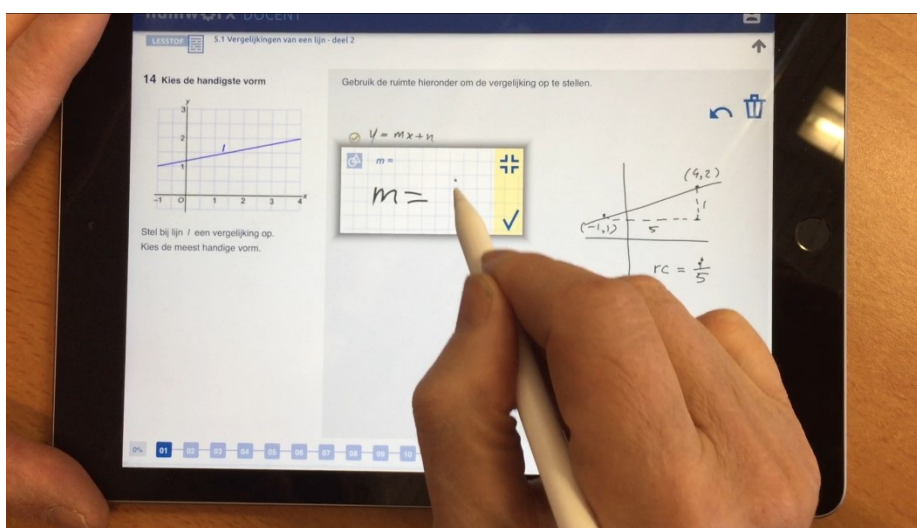

**Figure 4: The parabola task (Shvarts, 2018; Shvarts & Abrahamson, 2019). See <https://youtu.be/JHiHfUGtw> for an animation.**

The task, now, is to constantly move the grey point so that the triangle remains green. When the students become fluent in their movements, they are asked about the rule that determines the colour of the triangle. The task is challenging from different perspectives. From an embodiment perspective, the sensorimotor coordination is quite complex, as the direction to move should be constantly checked with the orientation of the triangle's base. Eye-tracking data indeed show many eye movements jumping between the movable grey point and the midpoint of the base, along the triangle's median (Shvarts & Abrahamson, 2019). These iterative jumps reveal the most important "attentional anchors" (Duijzer, Shayan, Bakker, van der Schaaf, & Abrahamson, 2017). From a mathematical perspective, the property that makes the triangle green is it being isosceles. As one vertex of the triangle is fixed to a point and another runs through a line, this task provides students with sensorimotor experiences that in the future learning might feed the notion of parabola. At a higher mathematical level, and this goes beyond how the example is presented here, one might elaborate this activity towards reflection on the locus of the grey point for the case that the triangle remains green (Shvarts, 2018). As the triangle is isosceles, and one of the sides is perpendicular to the base line (directrix), we can recognize the property of a conic: the distances to the focus and the directrix remain equal, so the locus is a parabola! This example shows how sensorimotor experiences may draw students' attention to the notion of a triangle being isosceles as preparation to the notion of parabola. Of course, many design decisions need to be taken, such as on how to phrase the task, which support to offer (do we display coordinates, or a grid), how to sequence different variations on this task, how to foster the notion of parabola, et cetera. The learning effect of such tasks may to an important extent depend on these

subtle design decisions, but goes beyond the scope of the present example. Digital design is a relatively new phenomenon, which puts high demands on the designers (Leung & Baccaglioni-Frank, 2017).

The second example concerns handwriting recognition. Writing mathematics by hand, whether it is on an old, dusty chalk board or on a tablet, involves hand movements and gestures that may provide a sensorimotor experience to students. Therefore, the Digital Mathematics Environment now has a handwriting recognition module, that allows for the integration of the human experience of hand movements while writing, and the software's intelligence to interpret the handwriting and to evaluate mathematical correctness for the sake of feedback.

**Figure 5: Handwriting recognition in the Digital Mathematics Environment. See <https://youtu.be/YKtrr1IxWAA> for an animation.**

To summarize, the two examples illustrate how an embodied design approach may lead to tasks in which sensorimotor experiences form the basis of mathematical cognition, a view that is not explicitly present in the two views presented earlier.

## Embodied instrumentation

Instrumental and embodied views on the use of digital tools in mathematics education may seem quite different. On the one hand, instrumental approaches in many cases focus on the development of individual, mental schemes – even if collective instrumental genesis is acknowledged –, on high-level conventional mathematics, and on sophisticated digital tools. Embodied views, on the other hand, focus on sensorimotor schemes, on bodily experiences, on basic mathematical ideas, and make use of dedicated software tools; the convergence to conventional mathematical cognition and techniques sometimes receives less attention. From a networking theory perspective (Bikner-Ahsbahr & Prediger, 2014), however, it seems interesting to compare, contrast, combine and coordinate these different views.

The claim I want to make here is that, in spite of these apparent differences, embodied and instrumental approaches both highlight the complexity of user-tool interaction, share some similar theoretical bases, and can be coordinated and aligned in a meaningful way. In line with researchers

who in the past have been exploring the interface between embodied and instrumental approaches (e.g., Artigue, Cazes, Haspekian, Khanfour-Armale, & Lagrange, 2013; Arzarello, Paola, Robutti, & Sabena, 2009; Maschietto & Bartolini-Bussi, 2009), I argue for an embodied instrumentation approach, to reconcile the embodied nature of instrumentation schemes and the instrumental nature of sensorimotor schemes. As such, an embodied instrumentation approach explores the co-emergence of sensorimotor schemes, tool techniques and mathematical cognition, and offers a design heuristic for ICT activities which align the bodily foundations of cognition and the need for instrumental genesis.

As for the shared theoretical basis, embodied and instrumental approaches share a theoretical foundation in ideas from Vygotsky (1978) on tool use and from Piaget (1985) on schemes, and both approaches acknowledge the subtlety of tool mediation in meaningful mathematical activity. In the meantime, the two approaches can be complementary, in the sense that embodied approaches so far have not overstressed the convergence of tool techniques and conventional mathematical notions, whereas instrumental approaches have tended to neglect the sensorimotor view on schemes and the embodied nature of cognition.

Concerning the coordination and alignment of the two approaches, I can image productive learning trajectories on fundamental mathematical concepts, in which the development of sensorimotor schemes may gradually go hand in hand with, or even be part of instrumental genesis. Such a trajectory might lead to schemes in which embodied experiences still form the basis, and through a process of reflective abstraction (Abrahamson, Shayan, Bakker, & van der Schaaf, 2016) lead to instrumental genesis. In this way, embodied and instrumental approaches might be aligned: the process of instrumental genesis is fostered by embodied activities. As students advance in a learning trajectory, the tool techniques and mathematical knowledge emerge from an instrumental genesis process, and the embodied basis may move more to the background. Ensuring coordination between the development of sensorimotor schemes and instrumental genesis might be a strong design heuristic for technology-rich tasks in mathematics teaching.

**Figure 6: MIT-T tasks (Alberto, Bakker, Walker-van Aalst, Boon, & Drijvers, 2019). See <https://youtu.be/1eOU4XyyHmg> for an animation.**

Let me illustrate this embodied instrumentation approach in a final example. Figure 6's left screen shows the so-called MIT-T app, where the abbreviation stands for Mathematics Imagery Trainer – Trigonometry (Alberto, Bakker, Walker-van Aalst, Boon, & Drijvers, 2019). It shows a unit circle and a sine graph, with a movable point on each of them. As a first task, students use the multitouch screen to simultaneously move the two points and, similar to the case in the parabola example

presented above, to explore when the frame around the graphs becomes green. This is the case if a correct match is made between the sine of an angle in the unit circle and the function value of the sine in a point on the horizontal axis, so if the two points are at equal height. The activity of “keeping the frame green” clearly invites appropriate sensorimotor coordination of keeping two points at the same height and is expected to induce a “feeling” for the coordination of the two movements. As was the case for the parabola task (Fig. 4), this may lead to many follow-up activities, each requiring design decisions and subtle arrangements of tasks and tools. As a possible end point of such a sequence, Figure 6’s right-hand screen shows the additional tool of a horizontal line, which can be moved up and down through the central big grey point with label its height, 0.5, thus implementing the coordination that just was enacted. Now both the unit circle and the sine graph can be used to solve the equation  $\sin a = 0.5$ : in the unit circle, one can move the point to meet the intersection of circle and line, and similarly in the graph. Of course, these two techniques need to be coordinated as well: if the two intersection points do not match, the feedback frame will not become green. In a later phase, one might want to drop the unit circle and focus on the sine graph. At that stage, the task in fact comes down to graphically solving equations of the form  $f(x) = c$ , which is exactly the example shown at the end of the instrumental view section (see Figure 3).

To summarize, this example illustrates how embodied and instrumental approaches may be coordinated and aligned in a learning trajectory. In this design, the embodied experiences mediated by digital tools prepare for instrumental genesis. Of course, more research is needed to decide whether such alignments would lead to higher effect sizes than the ones reported earlier. Speaking in general, both the common theoretical bases of embodied and instrumental views, and their complementarity make exploring their potential alignment, as expressed in the notion of embodied instrumentation, a highly interesting enterprise.

## Conclusion

In this paper, I first outlined a taxonomy for the didactical functionality of digital technology in mathematics education. This taxonomy guided a second-order meta-analysis, the results of which suggest that the effect sizes of technology-rich interventions are significantly positive, but small to moderate. This led to the idea of looking in more detail at three views on tool use in mathematics education. As a first lens, Realistic Mathematics Education theory highlights that students should experience mathematics as meaningful. Applied to tool use, this implies that tools should be transparent and should provide the students with authentic ways to express themselves mathematically. More specifically focusing on tool use, the second lens of instrumentation stresses the intertwinement of techniques for using the tool and the mathematical knowledge involved. Techniques and mathematical meaning co-emerge in processes of instrumental genesis. The third lens of embodied cognition claims that sensorimotor activities form the basis of cognition, and, more than the other two approaches, highlights the need to root mathematical knowledge in bodily experiences.

A key guiding principle shared by all three approaches is mathematical meaning, even if each approach stresses different aspects of it: RME highlights the idea of mathematics being “experientially real”, instrumentation theory points to the mathematical meaning embedded in techniques for using tools, and embodied views see sensorimotor schemes as the foundation of

mathematical meaning. This stress on meaning makes sense: if we do not manage to incorporate digital technology in students' mathematical practices in a way that they experience as meaningful, it is a useless enterprise.

As a conclusion, in my opinion the three views have much to offer for technology-rich mathematics education. The RME view provides some important general guidelines, which may inform instrumental and embodied approaches. As for the interplay between embodied and instrumental views, I strongly believe that the two can be coordinated and aligned in a so-called embodied instrumentation approach. Embodied and enacted experiences, so present in the embodied cognition approach, can form the basis for learning. As such, these experiences are the foundations on which instrumental genesis can build; a bodily-based instrumental genesis during which tool techniques and mathematical cognition co-emerge.

Of course, this argument for an embodied instrumentation approach needs further elaboration on several aspects. First, the RME lens may reveal possible tensions between its reality principle and the instrumental approach's focus on tool techniques. Similarly, the alignment of sensorimotor schemes and tool techniques is a subtle one, even if the examples in Figures 4, 5 and 6 provide some possible approaches. Also, a body of empirical evidence for positive effects of such an embodied instrumentation approach is lacking so far. In spite of these limitations, I do believe that the three lenses do justice to three main elements in the "landscape" of mathematics education: the world around us, our bodily interaction with it, and the tools we use to facilitate this interaction. As such, I suggest that embodied instrumentation, seen as an integrated embodied and instrumental approach in which sensorimotor schemes, tool techniques and mathematical cognition co-emerge, deserves priority in the research agenda of those interested in the use of digital technology in mathematics education.

## Acknowledgment

I thank Rosa Alberto, Arthur Bakker, Peter Boon, Alison Clark-Wilson, Michiel Doorman, Anna Shvarts, and Luc Trouche, as well as the CERME IPC reviewers, for their input on previous versions of this contribution.

# History and pedagogy of mathematics in mathematics education: History of the field, the potential of current examples, and directions for the future

Kathleen M. Clark

Florida State University, School of Teacher Education, Tallahassee, Florida USA; [kclark@fsu.edu](mailto:kclark@fsu.edu)

*The field of history of mathematics in mathematics education—often referred to as the history and pedagogy of mathematics domain (or, HPM domain)—can be characterized by an interesting and rich past and a vibrant and promising future. In this plenary, I describe highlights from the development of the field, and in doing so, I focus on several ways in which research in the field of history of mathematics in mathematics education offers important connections to frameworks and areas of long-standing interest within mathematics education research, with a particular emphasis on student learning. I share a variety of examples to serve as cases of what has been possible in the HPM domain. Finally, I propose fruitful future directions that call for the contributions of both established and emerging scholars in the field.*

*Keywords: History of mathematics, mathematics education research, primary historical sources, qualitative research.*

## Introduction

George Sarton (1884–1956), a Belgian-born American historian of science, said:

The main duty of the historian of mathematics, as well as his fondest privilege, is to explain the humanity of mathematics, to illustrate its greatness, beauty and dignity, and to describe how the incessant efforts and accumulated genius of many generations have built up that magnificent monument, the object of our most legitimate pride as men, and of our wonder, humility and thankfulness, as individuals. The study of the history of mathematics will not make better mathematicians but gentler ones, it will enrich their minds, mellow their hearts, and bring out their finer qualities. (Sarton, 1936, p. 28)

Putting aside that to Sarton—in this example—only men experienced this “legitimate pride” (perhaps due to the academic fabric of the 1930s), he beautifully captures one of the often-cited effects of studying the history of mathematics: that such a use of history<sup>1</sup> of mathematics has the ability to humanize the subject, by way of appealing on some aesthetic or non-academic level to the added value of the discipline.

I first experienced this humanistic element of studying the history of mathematics from the desire to provide a different perspective regarding mathematics for my students. At the time some 20 years ago, I was teaching mathematics to students in grades 11 and 12 at a publicly-funded residential school for academically talent students in Mississippi in the United States. I was most concerned about the content that would comprise a history of mathematics course that I was tasked to teach as part of the school’s mathematics course electives. In preparation for teaching the course I became

---

<sup>1</sup> As part of the plenary talk (and paper), I plan to highlight the different notions of “use of history” —as the variants of “use” (e.g., “incorporate,” “include,” etc.) may be a point of contention for some.

involved with the Institute of the History of Mathematics in its Use in Teaching (IHMT), and my world of mathematics changed forever. As a result of that experience, I not only gained access to materials that would inform the first history of mathematics course I taught, I also acquired a new lens on teaching mathematics in general. Although I was teaching students who chose to attend a school focused on mathematics and science (e.g., *the Mississippi School for Mathematics and Science* in Columbus, MS), not all of the students had a positive relationship with mathematics. For many, they had become trained to view mathematics as a set of procedures to acquire a numerical answer for a “problem.” As a high school mathematics teacher, I felt that I was living the embodiment of what Glaisher (1848–1928) described: “I am sure that no subject loses more than mathematics by any attempt to dissociate it from its history” (1890, p. 466). However, continued participation in IHMT and my eventual doctoral work would provide me with new perspectives, tools, and a community with which to view, study, and teach mathematics. Therefore, in this talk, I hope to share with you a small part of the development of the community—its history, if you will—as well as its exciting present and promising future.

### **Plan for the plenary paper**

In this paper, I will first situate the field of history of mathematics in mathematics education—often referred to as the history and pedagogy of mathematics domain (or, HPM domain) within mathematics education, with careful attention to the development leading up to establishing the International Study Group on the Relations between the History and Pedagogy of Mathematics (HPM Group) in 1976. Precipitated by the creation of the HPM Group, research in the HPM domain has continued to grow in last 40-plus years, and includes all levels of learners and teachers. Part of this growth has been marked by the creation of a thematic working group on history in mathematics education, beginning with CERME6 in 2009. Next, I will provide examples of approaches and frameworks that are useful in empirical research in the HPM domain and I will highlight a collection of specific examples in which research on the use of history of mathematics contributes to the broader landscape of research in mathematics education and will do so with respect to two frameworks useful to mathematics education research. As a first example, I will discuss contributions of working with primary historical sources on pre- and in-service teachers’ mathematical knowledge for teaching. As a second example, I discuss the application of Sfard’s (2008) thinking as communicating framework in research, including work by colleagues in Denmark and Brazil, as well as that currently undertaken within the *Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources* (or, TRIUMPHS) project in the United States. Finally, after a brief analysis of ongoing discussions for calls to strengthen empirical work in the HPM domain in light of certain pitfalls and dilemmas facing the field, I will propose directions for future research and the ways in which various CERME thematic working groups can contribute to bridging research in this important field with the broader mathematics education research community

### **Development of HPM: A study domain and a group**

What is now known as HPM was established as part of the second International Congress on Mathematical Education (ICME) in 1972 in Exeter, UK, first as an official working group there (EWG 11) and then as an official study group (with the onerous original name of International Study Group on Relations between History and Pedagogy of Mathematics, cooperating with the

International Commission on Mathematical Instruction; simplified to the HPM Study Group and later as just the HPM Group) subsequent to ICME3 in Karlsruhe, Germany in 1976. The principle aims of the group were perhaps a description of the culmination of efforts focused on integrating or using history of mathematics in teaching in different contexts around the world since the end of the 19<sup>th</sup> century. In particular, the principle aims given by the HPM Study Group were:

1. To promote international contacts and exchange information concerning:
  - a. Courses in History of Mathematics in Universities, Colleges and Schools.
  - b. The use and relevance of History of Mathematics in mathematics teaching.
  - c. Views on the relation between History of Mathematics and Mathematical Education at all levels.
2. To promote and stimulate interdisciplinary investigation by bringing together all those interested, particularly mathematicians, historians of mathematics, teachers, social scientists and other users of mathematics.
3. To further a deeper understanding of the way mathematics evolves, and the forces which contribute to this evolution.
4. To relate the teaching of mathematics and the history of mathematics teaching to the development of mathematics in ways which assist the improvement of instruction and the development of curricula.
5. To produce materials which can be used by teachers of mathematics to provide perspectives and to further the critical discussion of the teaching of mathematics.
6. To facilitate access to materials in the history of mathematics and related areas.
7. To promote awareness of the relevance of the history of mathematics for mathematics teaching in mathematicians and teachers.
8. To promote awareness of the history of mathematics as a significant part of the development of cultures. (Fasanelli & Fauvel, 2006, p. 2; originally in May, 1978, p. 76)

It is important to note that the essence of these eight aims have remained relevant and present in subsequent HPM-related meetings and remain a source of motivation for research and practice for many in the field today. It is also important to note that when appropriate, the aims apply to all levels of learners and teachers (e.g., primary (elementary), secondary, tertiary, and teacher education).

After the establishment of the HPM Study Group in 1976, the community continued to grow in important ways, including a focus on practitioners (e.g., school teachers) who wished to humanize mathematics in school teaching but to also engage students with historical materials, methods, and problems in their learning of mathematics. A classic example of the recommendations that were offered to teachers are given by Fauvel (1991) and which resulted from a brief historical look through curriculum documents for school mathematics teachers in the UK. In his introduction, Fauvel noted that for “decades if not centuries now, a few voices in each generation have urged the value and importance of using history in teaching mathematics—but so far without this insight taking firm and widespread root in the practice of teaching” (p. 3). National curriculum documents echoed a similar call for history of mathematics in both the UK and US in 1989:

Pupils should develop their knowledge and understanding of the ways in which scientific ideas change through time and how the nature of these ideas and the uses to which they are put are

affected by the social, moral, spiritual and cultural contexts in which they are developed. (*Science in the National Curriculum*, 1989; as cited in Fauvel, 1991, p. 4).

Students should have numerous and varied experiences related to the cultural, historical, and scientific evolution of mathematics so that they can appreciate the role of mathematics and the disciplines it serves.... It is the intent of this goal—learning to value mathematics—to focus attention on the need for student awareness of the interaction between mathematics and the historical situations from which it has developed and the impact that interaction has on our culture and lives. (NCTM, 1989, pp. 5–6)

However, policy statements and reform efforts tell only one side of the story and to actually enable teachers with materials, techniques, skills, etc., is quite another. Still, in the decades since the HPM Group's establishment, the community grew in ways that brought together different stakeholders—mathematicians, mathematics historians, mathematics teachers, mathematics education researchers, and others—for the purpose of sharing research, historical materials, and examples of pedagogical practice in which history of mathematics informed the teaching of mathematics. The first HPM Group satellite meeting (associated with an ICME) took place in 1984 at the Stuart campus of the University of Adelaide, and the satellite meetings have taken place every four years (as with ICME) since then. Additional supports to the international community were also established. For example, also in 1984, a meeting took place at University High School in San Francisco, CA, in which the creation of an Americas Section of the HPM Group was planned. The aim for an “HPM Americas” section was to “have a more active presence in the mathematics education community than was forthcoming from the international organization” (Fasanelli & Fauvel, 2006, p. 6). In 1993, the first of regularly-occurring meetings called European Summer University (ESU), were organized by the Institutes of Research in Mathematics (IREM) and took place in Montpellier, France. The ESU was held every three years until 2010<sup>2</sup>, when it was decided that they would occur every four years and would be staggered by two years from the quadrennial ICME/HPM satellite meeting pair.

### **HPM within CERME**

Of course, the inclusion of a working group on history of mathematics in mathematics education at CERME may be the international venue of most interest to the present audience. The working group made its first appearance at CERME6 (Working Group 15: Theory and Research on the Role of History in Mathematics Education), and since then, it was established as Thematic Working Group (TWG) 12, History in Mathematics Education. The TWG has focused on a wide array of concerns to the field, which are represented by nine overarching themes taken from the “call for papers” since 2009:

1. Theoretical, conceptual and/or methodological frameworks for including history in mathematics education;

---

<sup>2</sup> There was a five-year gap between the 1999 ESU-3 held in Leuven and Louvain-la-Neuve, Belgium and the 2004 joint ESU-4 and ICME-10 satellite meeting of HPM held in Uppsala, Sweden.

2. Relationships between (frameworks for and empirical studies on) history in mathematics education and theories and frameworks in other parts of mathematics education [this point featured only from CERME 7 onwards];
3. The role of history of mathematics at primary, secondary, and tertiary level, both from the cognitive and affective points of view;
4. The role of history of mathematics in pre- and in-service teacher education, from cognitive, pedagogical, and/or affective points of view;
5. Possible parallelism between the historical development and the cognitive development of mathematical ideas;
6. Ways of integrating original sources in classrooms, and their educational effects, preferably with conclusions based on classroom experiments;
7. Surveys on the existing uses of history in curricula, textbooks, and/or classrooms in primary, secondary, and tertiary levels;
8. Design and/or assessment of teaching/learning materials on the history of mathematics;
9. The possible role of history of mathematics/mathematical practices in relation to more general problems and issues in mathematics education and mathematics education research. (Jankvist & van Maanen, 2018, p. 242)

Table 1 provides the titles and authors of sample papers (and the CERME meeting in which they were presented) corresponding to the nine themes given, as a way to exhibit the variety and context in which work in HPM is conducted within the CERME community.

TWG 12 <sup>3</sup> theme	Sample paper
1	“The Teaching of Vectors in Mathematics and Physics in France During the 20th Century” (Ba & Dorier; CERME6)
2	“Uses of History in Mathematics Education: Development of Learning Strategies and Historical Awareness” (Kjeldsen; CERME7)
3	“The Role of History of Mathematics in Fostering Argumentation: Two Towers, Two Birds and a Fountain” (Gil & Martinho; CERME9)
4	“Mathematical Analysis of Informal Arguments: A Case-Study in Teacher-Training Context” (Chorlay; CERME10)
5	“Teaching the Concept of Velocity in Mathematics Classes” (Möller; CERME9)
6	“Designing Teaching Modules on the History, Application, and Philosophy of Mathematics” (Jankvist; CERME7)

---

<sup>3</sup> Again, for CERME6 only, this was Working Group 15.

7	“The Implementation of the History of Mathematics in the New Curriculum and Textbooks in Greek Secondary education” (Thomaidis & Tzanakis; CERME6)
8	“The Development of Place Value Concepts to Sixth Grade Students via the Study of the Chinese Abacus” (Tsiapou & Nikolantonakis; CERME8)
9	“Lessons from Early 17th Century for Current Mathematics Curriculum Practice” (Krüger, CERME7)

**Table 1: Sample collection of CERME papers presented in TWG 12**

Jankvist and van Maanen (2018) noted that TWG 12 seeks to “create a forum and a platform for fostering empirical studies in the field of history in/of mathematics education *and to also better link research in this field with research in mathematics education in general*” (p. 241, emphasis added). In the examples that follow, I especially focus on themes 2, 3, and 4 in the list summarized by Jankvist and van Maanen.

### **History in mathematics education: A very brief history of early research**

Early scholarship<sup>4</sup> (e.g., conducted before 2000) in the field of history in mathematics education was primarily focused on (a) anecdotal reports of interventions used with students; (b) historical research on topics that could serve as the focus of classroom instruction; and (c) survey research, including research on students’ or teachers’ attitudes and beliefs related to history of mathematics. A classic example of empirical research is that of McBride and Rollins (1977), in which, as part of McBride’s doctoral dissertation, they examined the effects of studying mathematics history on attitudes of college algebra students toward mathematics. The research was motivated by the lack of research reports (available at the time) that studied “the problem of determining the effectiveness” (p. 57) of “incorporating items from the history of mathematics into classroom discussions of mathematical topics” (p. 57). For McBride and Rollins, the “incorporation” of items was restricted to the use of vignette material to introduce or comment on mathematical topics in the college algebra curriculum. The authors found a significant increase in attitude (particularly since the attitudes of the treatment group increased and the those of the control group decreased); however, several limitations were identified, including the notion that the teacher effect may have been significant. Limitations aside, the McBride and Rollins contribution represented two impacts for subsequent research in the field of history in mathematics education. First, it placed the potential of history in mathematics education on the radar of future researchers (myself included). And, their use of existing research—that on attitudes towards mathematics by Aiken (such as his early work in the *Journal for Research in Mathematics Education* in 1974)—exemplified the fruitful connections for research on history in mathematics education within the broader landscape of mathematics education research. In more recent years, scholarship has begun to shift to capitalize on empirical methods that are more mainstream, and for which researchers seek a broader application of the interventions that have been the focus of their research. In the following, I discuss more recent examples of different approaches

---

<sup>4</sup> Apologies to my colleagues around the globe: for the purposes of this plenary talk (and paper), I focus on English-language scholarship.

and frameworks that are useful in empirical research in the HPM domain, including mathematical knowledge for teaching and thinking as communicating.

## Mathematical knowledge for teaching and HPM

Mathematical knowledge for teaching (MKT) is a practice-based theory of the domains of knowledge that are considered necessary for the work of teaching mathematics. The framework itself (often relegated to the “egg model” diagram; see for example, Ball, Thames, and Phelps (2008)) has been applied in a variety of research contexts around the world since the early 2000s and has its foundation in the work of the Learning Mathematics for Teaching (LMT) Project. However, it is important to keep in mind that rather than taking the egg model too literally (as in, trying to situate all relevant and possible knowledge for teaching mathematics into the original six domains of knowledge), the practiced-based theory of MKT comprises two key aspects: knowledge of content in the discipline of mathematics and the recognition that teaching is at the core, and this brings with it the notion that mathematics teaching can be decomposed into tasks of teaching, of which there are many.

In my own early work with prospective mathematics teachers (PMTs), I was struck by the idea that the MKT framework could provide ways to problematize (or clarify) the ways in which studying history of mathematics informs PMTs’ knowledge of topics they would soon teach. In one study (Clark, 2012), I analyzed reflection journal entries of 80 students enrolled in a “Using History in the Teaching of Mathematics” course, across four semesters. In the particular investigation, I examined 15 weeks of journal entries for each of the 80 students for their reference to solving quadratic equations using completing the square. In the course, students worked with English translations of primary source material as part of investigations designed to engage them with the historical development of a mathematical concept, and which would provide them with opportunities to expand their mathematical and pedagogical knowledge, and to consider ways in which student learning may benefit from incorporating content similar to what they worked with in the “Using History” course. The source excerpt was taken from Fauvel and Gray (1987, p. 229):

*Roots and squares are equal to numbers:* for instance, ‘one square, and ten roots of the same, amount to thirty-nine dirhems’; that is to say, what must be the square which, when increased by ten of its own roots, amounts to thirty-nine? The solution is this: you halve the number of the roots, which in the present instance yields five. This you multiply by itself; the product is twenty-five. Add this to thirty-nine; the sum is sixty-four. Now take the root of this, which is eight, and subtract from it half the number of the roots which is five; the remainder is three. This is the root of the square you sought for; the square itself is nine. [...]

When students elected<sup>5</sup> to discuss course tasks from al-Khwarizmi’s text on solving quadratic equations in their reflection journals, they revealed what it contributed to their mathematical learning and how they would consider incorporating such content in their future teaching. Brad’s reflection of

---

<sup>5</sup> For the reflective journal assignments, students made the choice of what to include in their journals. However, regardless of content selection (typically driven by course readings, tasks, and assignments), PMTs needed to respond to at least one of six fixed reflection prompts, e.g., *In what ways has your understanding of {mathematical topic} changed as a result of considering the history of the topic?*, or, *In what ways do you envision being able to incorporate the history of {mathematical topic} in your teaching?*

his prior and current experience (with respect to his mathematical learning) was representative of the tenor of the PMTs' reflection of the al-Khwarizmi tasks:

I remember learning the quadratic formula in 8th grade. I was in Algebra I and Mrs. Horst had *politely drilled* the “opposite of  $b$  plus or minus the square root of  $b$  squared, minus four  $ac$ , all over two  $a$ ” routine into our heads. All I recall knowing is that I could apply *this formula* to solve polynomials of a 2nd degree. [T]he lesson and activity we completed...were particularly influential to my understanding. This was essentially the *first proof of any sort* that I've experienced relevant to the formula itself. It was *this part where I really had the “a-ha” feeling*. As I began to compose the area relationships using algebraic notation, I could see the beginnings of the quadratic formula; I realized that this was actually going to work! More importantly I began to view the quadratic equation as less of an algebraic equation and more of a *geometric relationship*. (Clark, 2012, p. 78)

From another view, Hillary described her idea for the ways in which she might consider history of mathematics informing her future teaching:

If I were going to use this in my classroom I would be sure to explain to them how al Khwarizmi used his vast knowledge of many subjects to work with these numbers and develop a similar quadratic formula, one that is like that of ours today, except for the use of the negative numbers. I would show them that with a few simple manipulations and algebraic transformations, we would have the same equation and we could even have groups each try a different method but with the same equation, then compare answers; that way students can find which method suits them the best.... I feel that math has so many possibilities, so many ways in which something can be taught and or understood, so why not provide those so the students can make sense of what to them might be complicated mathematics. (Clark, 2012, p. 80)

As a result of studying PMTs' reflections of course content and engagement with materials using history of mathematics in teaching, I claimed that the work on the part of teachers to incorporate history of mathematics in teaching is a component of the “something else” that Ball and her colleagues (2008) described as knowledge for teaching beyond the obvious knowledge of “topics and procedures that [teachers] teach” (p. 395). As part of their definition of *horizon content knowledge*, Ball et al. concentrated on “how teachers need to know that content” (p. 395) and they sought to “determine what else teachers need to know about mathematics and how and where teachers might use such mathematical knowledge in practice” (p. 395). My study of PMTs' work to develop knowledge of history of mathematics—and, therefore of mathematics that they were tasked to teach—pointed to the strong potential of the history of mathematics to contribute to the “what else” described by Ball et al. and how this specialized knowledge contributes to PMTs' future practice. I also made the claim, by using Boero and Guala's (2008) component of the “cultural analysis of the content to be taught” (p. 223), that engaging in the mathematical, historical, and cultural aspects of a mathematical concept is an important way in which teachers need to know the content that they teach. Thus, although the call to “focus attention on the need for student awareness of the interaction between mathematics and the historical situations from which it has developed and the impact that

interaction has on our culture and lives” (NCTM, 1989, p. 6) seems to be a distant memory<sup>6</sup>, situating an analysis of what PMTs’ claim as a contribution to their mathematical knowledge within the MKT framework enables researchers to make decisions regarding the development of prospective mathematics teachers, as well as the role that history of mathematics plays in that important work. There are still too few studies that capitalize on investigating the role that the study of history of mathematics, organized in meaningful and powerful ways to inform not only PMTs’ disciplinary content knowledge but the multiple forms of tasks of teaching that they will perform in their future teaching. However, the contribution of history of mathematics on the MKT of practicing teachers is also productive for research in mathematics education.

### **Additional contexts for the application of MKT**

There is further potential for the application of MKT in the HPM domain. Recent scholarship reveals multiple contexts and applications in which the linkages between MKT and the use of history of mathematics in the development of prospective and practicing teachers further contribute to research on teacher knowledge and the work of mathematics teachers. Two examples are worth noting here. Smestad, Janviskt, and Clark (2014) investigated components of horizon content knowledge (HCK) within MKT in relation to curricular demands that teachers experience in general, and with regard to curricular transition periods in particular; that is, when the transition taking place involves “the inclusion of elements of history of mathematics in new curricula and accompanying textbooks” (p. 180). We approached the three cases of interest with a focus on a dual aspect of HCK. For example, “concrete inclusions of history of mathematics...calls for an already developed [HCK] of a teacher” (p. 174), which can be considered “a priori HCK.” Yet this inclusion of history of mathematics in a teacher’s practice may itself contribute to [a] teacher’s HCK—which might then be referred to as “a posteriori HCK.”

The three cases (Denmark, Norway, and the US) discussed in Smestad et al. (2014) each stemmed from concrete directives (yet still considered rhetoric) calling for the inclusion of history of mathematics in school curriculum, and which represented a continuum of curricular demands for teachers in delivering their instruction while heeding the various directives. These particular transitions—for example, shifting the extent to which inclusion of elements of history of mathematics in new curricula or textbooks—impact a teacher’s HCK. For example:

In the transition phase from one curriculum not including elements of history of mathematics to another which does, in-service teachers often lack the associated CCK, KCC<sup>7</sup>, etc. And, at this particular time, in this particular transition period while implementing the new curriculum and training in-service teachers, a priori HCK comes to play a more crucial role. (p. 180)

This example highlights the dynamic nature of a model (MKT) for understanding the nature of the practice (and perhaps, the purpose) of mathematics teaching. Furthermore, there is a synergetic

---

<sup>6</sup> By 2000, when NCTM issued its new *Principles and Standards for School Mathematics*, what was originally recognized as a goal for learning mathematics was now reduced to identification of a feature of mathematics, *Mathematics as a part of cultural heritage*: “Mathematics is one of the greatest cultural and intellectual achievements of humankind, and citizens should develop an appreciation and understanding of that achievement...” (p. 4).

<sup>7</sup> Common content knowledge (CCK), knowledge of content and curriculum (KCC), etc.

relationship between research on history of mathematics in teacher education and the evolution of models for understanding teacher knowledge. As Jankvist, Mosvold, Fauskanger, and Jakobsen (2015) observed, “the MKT framework provides a powerful language to communicate results from research on the uses of history of mathematics to researchers in other areas of mathematics education research” (p. 495).

### Thinking as communicating and HPM research

In an attempt to resolve certain quandaries related to mathematical thinking and learning, Sfard (2008) operationally defined thinking as a personalized version of communication. Given the collective nature of communication, she introduced the term *commognition* to highlight the communicative nature of activities in our minds, emphasizing that individual cognitive processes (thinking) and interpersonal communication are “but different manifestations of basically the same phenomenon” (Sfard, 2008, p. 83). Using this communicative, or discursive lens, Sfard (2008) determined that “mathematics begins where the tangible real-life objects end and where reflection on our own discourse about these objects begin” (p. 129). That is, what identifies the objects of communication in mathematics is their discursive nature: they come to exist as we talk about them. Thus, taken from this viewpoint, mathematics is seen as a highly situated human activity which generates itself. As a result, the learner of mathematics faces an interesting and paradoxical situation: How can a person join a discourse for which familiarity with the discourse is a precondition for participation in that discourse?

Yet further complications exist. Sfard (2008) noted that participation in any discourse requires adopting the rules that govern that discourse, in addition to becoming familiar with the objects of the discourse. She referred to the former rules as *meta-level*, or *metadiscursive*, and the latter as *object-level*. For instance, asserting that a particular function is differentiable constitutes an object-level narrative about functions. However, a student’s method of justifying this assertion (e.g., sketching a graph versus an  $\epsilon - \delta$  proof) would be indicative of the metadiscursive rules that govern her discourse about functions. Despite the usual implications of the word *rule* as being invariable and strictly deterministic, metadiscursive rules are subject to change in time and space, and they possess certain characteristics; they are tacit, contingent, constraining, flexible, value-laden, and are difficult to change. Sfard posits that these characteristics render meta-level learning possible only through direct encounters with a new discourse that is governed by meta-level rules different from those governing the learner’s current discourse (p. 256). Furthermore, such encounters generally entail a *commognitive conflict* when the discursants unknowingly operate under completely different meta-level rules.

Given their role in governing the actions of the participants in a mathematical discourse, researchers have paid particular attention to factors that affect the learning of metadiscursive rules in mathematics. In a number of these studies, the history of mathematics, and primary source readings in particular, emerged as an instructional approach with strong potential to promote such learning.

### Example from Denmark

In their study of university mathematics students, Kjeldsen and Blomhøj (2012) showed that a careful selection of historical sources can help students learn about the metadiscursive rules that govern mathematicians’ discourse about functions and can allow them to recognize that these rules changed

during the development of that concept. This meta-level learning, they argued, fostered students' learning of mathematics at the object-level as well. The authors shared an in-depth analysis of project reports produced by two groups of students, which were based on project work designed and carried out as part of the mathematics bachelor's and master's programs at Roskilde University. The reports result from semester-long work in which students operate within particular project constraints; in the case of the two projects described by Kjeldsen and Blomhøj, these belong to the "mathematics as a discipline" constraint. The projects exemplified were "Physics' influence on the development of differential equations and the following development of theory" and "Fourier and the concept of a function – the transition from Euler's to Dirichlet's concept of function." In their analyses of student projects, Kjeldsen and Blomhøj brought attention to the incongruent discourses of their students when compared to the primary source texts. For example, for the group whose project was "Physics' influence...", students read and studied three original sources from the 1690s:

In order to answer their questions, the students had to read and understand the sources within the mathematical discourse of the time. On one hand, this is a difficult task because the students' points of departure in dealing with the sources are their own mathematical discourses, which are different from the discourse of the authors of the sources. On the other hand, this is exactly the reason why history, and working with original sources, can serve as an effective method for meta-level learning. (p. 336)

In their discussion of students' project work—for both project examples—Kjeldsen and Blomhøj (2012) beautifully situate the power of primary historical sources to promote students' ability to reflect upon metadiscursive rules of mathematics:

Didactically, it is important to find and identify historical sources that are suitable for provoking discussion in classrooms among students and with their teachers about different meta-discursive rules. Likewise, it is important to perform research about how this can be done, how teaching activities that support such discussions and reflections can be designed and how the effectiveness of such teaching and learning situations can be evaluated in practice. (p. 347)

### **Example from Brazil**

In a similar way and drawing upon the work of Kjeldsen and Blomhøj (2012) and Kjeldsen and Petersen (2014), as well as Sfard's theory of thinking as communicating, Bernardes and Roque (2018) conducted two experiments with a small group of undergraduate students in a mini-course focused on the topic of "Different roles of the notion of matrix in two episodes of the history of matrices" (p. 219). The course included two teaching modules which introduced students to original source materials from J. J. Sylvester (1814–1897) and Arthur Cayley (1821–1895). In a similar way to Kjeldsen's empirical work with colleagues, Bernardes and Roque's research consisted of three goals, in which they sought to investigate:

- (1) how historical sources encourage reflections about metarules related to matrices and determinants;
- (2) how reflections about metarules impact students' conceptions about matrices and determinants; and
- (3) the development of a historical consciousness in the students. (p. 211)

In their analysis, Bernardes and Roque (2018) found that students were able to discuss and reflect on the historical metarules present in the primary source texts; as well, they identified three metarules in the student participants' discourse. Furthermore, Bernardes and Roque highlighted the occurrence of commognitive conflicts – that is, “conflicting narratives in which the...participants and the historical sources were guided by different metarules” (p. 224). The combination of these outcomes prompted the researchers to question the order in which they teach topics in a Linear Algebra course. For example, they questioned whether it is appropriate to begin such a course with the “concept of a matrix as an object in itself” (p. 226). In their proposal for a future instructional sequence, Bernardes and Roque observed that historical episodes showed that the introduction and development of the concept of matrix was driven by a need for such a representation (e.g., introduction of multiplication of matrices in conjunction with composition of linear transformations). Thus, in addition to the use of primary sources promoting students' reflection of metalevel rules governing their mathematical discourse, such an innovation has the potential for guiding instructional changes which can serve to impact students' mathematical learning.

### **Example from the United States: The TRIUMPHS Project**

As part of a large grant project, several colleagues and I have begun a study to further investigate the potential that “history can have a profound, perhaps even indispensable, role to play in teaching and learning mathematics from the point of view of learning proper meta-discursive rules” (Kjeldsen and Blomhøj, 2012, p. 328). Before describing features of that work, it is perhaps helpful to describe the greater context in which the research is taking place.

In 2015, the National Science Foundation (NSF) in the United States funded a seven-institution collaborative project to design, test, and evaluate curricular materials for teaching standard topics in the university mathematics curriculum via the use of primary historical sources. The goal of the project is to assist students in learning and developing a deeper interest in and appreciation of mathematical concepts by creating educational materials in the form of Primary Source Projects (PSPs) based on original historical sources written by mathematicians involved in the discovery and development of the topics being studied. The project, *Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources*, or TRIUMPHS, is developing PSPs which contain (1) excerpts from one or several historical sources, (2) a discussion of the mathematical significance of each selection, and (3) student tasks designed to illuminate the mathematical concepts that form the focus of the sources. PSPs are designed to guide students in their explorations of these original texts in order to promote their own understanding of those ideas.

The numerous PSPs are indeed the life force of the TRIUMPHS project. During the grant-funded effort, the principal investigators (PIs) promised that some 50 PSPs (which span the undergraduate mathematics curriculum, from basic statistics and trigonometry, to real analysis, abstract algebra, and topology) will be developed, tested, and evaluated. Of the 50 PSPs, 20 are planned to be “full-length” and 30 are what we refer to as “mini-PSPs.” Full-length PSPs are designed to typically encompass at least two to four class sessions, which represents the same amount of time that it normally takes to teach the mathematical topic of focus within the PSP. However, among the full-length PSPs there

are also longer ones that could be used by instructors to comprise an entire course's content<sup>8</sup>. Alternatively, “mini-PSPs” can be completed in one to two class sessions and each of the mini-PSPs have been developed to teach a particular topic or concept in mathematics that would normally be addressed in a single class session, but which will be done via a primary historical source. To date, 33 full-length PSPs and 28 mini-PSPs have been developed. Though we have exceeded our commitment to develop 20 full-length PSPs, there are additional full-length PSPs in development, as well as the remaining, promised mini-PSPs.

In Fall 2015 the first PSPs were tested<sup>9</sup> in two undergraduate mathematics classrooms in the United States; in Year 3 (academic year 2017–18), 46 distinct site testers tested one or more PSPs in undergraduate mathematics classrooms. However, in total, by the end of Year 3, 53 instructors have site tested PSPs as part of the TRIUMPHS project, with some one-third of those serving as repeat testers. In the first semester of Year 4, we have 20 student data collection site testers; again, of these, we have several repeat site testers, where 13 are new to site testing TRIUMPHS PSPs.

Whereas this progress across almost four years of a large NSF grant project may seem to some as modest, it is important to note that as only one of three such grants ever funded on this level in the United States, this represents significant progress with regard to efforts designed to promote the teaching of undergraduate mathematics via primary historical sources. The two previous grants – to which three of the seven TRIUMPHS PIs and one of the advisory board members contributed – also produced a number of primary source projects. Table 2 summarizes the origin and availability of these projects.

Years	Name of funded project (URL)	Number of projects developed (and tested in classrooms)
2003–2006	Teaching Discrete Mathematics via Primary Historical Sources; Pilot Grant ( <a href="https://www.math.nmsu.edu/hist_projects/">https://www.math.nmsu.edu/hist_projects/</a> )	14
2008–2012	Learning Discrete Mathematics (LDM) and Computer Science via Primary Historical Sources; Expansion Grant ( <a href="https://www.cs.nmsu.edu/historical-projects/">https://www.cs.nmsu.edu/historical-projects/</a> )	20
2015–present	Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources; Collaborative Grant ( <a href="http://webpages.ursinus.edu/nscoville/TRIUMPHS.html">http://webpages.ursinus.edu/nscoville/TRIUMPHS.html</a> )	61, to date

<sup>8</sup> In fact, this was done recently (Spring 2018) by Janet H. Barnett, in an Abstract Algebra course.

<sup>9</sup> By “tested” we mean that we collected student data from the implementation of PSPs in these classrooms.

**Table 2: PSP development, 2003–2018**

There are two features unique to TRIUMPHS when compared to the two previous grants. First, it was difficult to recruit site testers for the projects that were developed. The Pilot Grant (2003–2006) involved only five total site testers and in the Expansion Grant (2008–2012), a total of 10 site testers participated. However, in the TRIUMPHS project we have developed mechanisms to recruit site testers through a variety of outreach efforts, including presentations at conferences, three-day TRIUMPHS-focused workshops (particularly focused on instructors who might not have previously included primary sources in their teaching), mini-courses and short workshops at conferences, and listserv announcements via professional organizations with members who may share interests in history of mathematics and its use in teaching<sup>10</sup>. In advance of each autumn and spring semester we advertise the site testing opportunity and accept applications for two different site tester streams: those who will serve as student data collection site testers and those who will serve as instructor-only data collection sites.

The second feature unique to TRIUMPHS (when compared to the previous grant efforts) is the evaluation-with-research (EwR) component of the grant project. The two previous grants included only an evaluation component, which resulted from the analysis of surveys completed by students at the beginning and end of courses at the particular participating institutions “in any course in which a historical project could be used, regardless of whether a project [was] actually used or not” (“Instructions for testers,” LDM, n.d.). The surveys asked students to respond to approximately 30 questions: 18 “Need for Cognition Scale” items, 10 “Understanding Computer Science Scale” (and/or Mathematics, depending upon the course) items, and two open-ended items:

In your opinion, what are the benefits of learning Mathematics (and/or Computer Science) from historical sources?

In your opinion, what are the drawbacks of learning Mathematics (and/or Computer Science) from historical sources?

Thus, in the evaluation of the funded grant projects just prior to TRIUMPHS, assertions were made only with regard to students’ self-reported understanding of mathematics or computer science concepts broadly and beliefs about their problem solving and cognitive efforts. That said, student responses to the two open-ended items did provide the PI team with confirmation that the use of primary historical projects was a worthwhile inclusion in the teaching of mathematics and computer science courses. Typical student responses (LDM, n.d.) include:

I really enjoyed it. I found it to be very intriguing.

As a student you get to see where the math we do today came from and engage in the kind of thinking that was necessary to create it.

It’s a perfect way to given math some context in the world. Historical sources teach you the math while simultaneously fitting math into history and give you meaning for why the math was and is

---

<sup>10</sup> We have also advertised training opportunities and site testing via inquiry-based learning (IBL) audiences, since mathematics faculty interested in active learning strategies in undergraduate mathematics courses may find PSPs provide useful materials for promoting active learning, particularly in upper-division mathematics courses.

important. Historical sources also break up the monotony of textbooks, making math more accessible for a wider variety of students.

I think that it gives the student a [deeper] understanding of the subject.

### **The TRIUMPHS Project: Metadiscursive rules investigation (MDRI)**

It is important to point out that the EwR component of the TRIUMPHS project was built after the formulation of the main focus; that is, the development and dissemination of the PSPs was the primary focus of the grant effort. Therefore, evaluation questions were constructed that would enable the PI team to report several metrics to the funding agency (in this case, the NSF in the US) regarding the successful completion of the goals and sub-goals of the project. However, developing research questions about what can be learned from TRIUMPHS—given that the design of the development of the PSPs was fixed first—proved difficult in both the development of the grant proposal and the “pilot year” of the project. In particular, the PIs working on the EwR component<sup>11</sup> strongly believe that TRIUMPHS provides a unique opportunity to contribute to mathematics education research more broadly, especially given the potential that a large collaborative grant project affords, including working with a variety of university teaching contexts (e.g., two-year colleges and four-year colleges and universities) and student populations. And, in response to the NSF prior to receiving funding, we highlighted the importance of the development of communication skills—and all modes of this: written, verbal, reading—as part of students’ mathematical learning was an area of potential impact. After several iterations, the EwR working group decided that the thinking as communicating framework (Sfard, 2008) would provide the most fruitful lens for our research.

Our investigation builds on prior research concerning the potential of primary source readings for mathematics education (e.g., Bernardes & Roque, 2018; Kjeldsen & Blomhøj, 2012) that has been conducted within the framework of Sfard’s participationist theory of “learning as discourse” (Sfard, 2008). In particular, we focus on the role played within that framework by the metadiscursive rules which govern the actions of the participants in a mathematical discourse. When considering the research literature available which contains similar emphases with regard to using primary historical sources in the teaching and learning of mathematics, we have been empowered with a strong conviction—as have others—that, under the right conditions, the use of history does promote the learning of metadiscursive rules in mathematics. Our goal, within the EwR component of the TRIUMPHS project, is to contribute to the important work of identifying what occurs for student learning under what conditions, work which is important to both the researcher who is interested in, for instance, how the learner is thinking along the way, and to the practitioner, for whom the educational setting that motivates meta-level learning opportunities for students is of paramount importance.

Thus, we launched a metadiscursive rules investigation (MDRI), in which we posed the following research questions:

---

<sup>11</sup> There are actually three foci of the EwR component of TRIUMPHS: “student change,” “faculty expertise,” and “development cycle.”

What is the evidence of students' progress in "figuring out" (Sfard, 2014, p. 201) the meta-level rules that govern a new mathematical discourse as a result of studying specific mathematical concepts when using primary source projects?

To what extent do students' actions (e.g., verbal, written), both during and after engagement with the primary source projects, provide evidence of their acceptance of a new discourse?

The construction of our research questions was heavily influenced by Sfard's (2014) observation that university mathematical discourse is "far removed from what the student knows from school as a discourse can be" (p. 200). Thus, in our work, we investigate an alternative to lecturing that makes use of the history of mathematics (e.g., via PSPs) in order to provide a learner with the opportunities for "watching a mathematician in action and imitating his moves while also trying to *figure out* the reasons for the strange things he is doing" that Sfard suggests "may be the only way to come to grips with [the] objects [that she is supposed to operate upon]" (Sfard, 2014, p. 202; emphasis added).

We are also strongly influenced by the agenda articulated by Kjeldsen and Blomhøj (2012):

Didactically, it is important to find and identify historical sources that are suitable for provoking discussion in classrooms among students and with their teachers about different meta-discursive rules. Likewise, it is important to perform research about how this can be done, how teaching activities that support such discussions and reflections can be designed and how the effectiveness of such teaching and learning situations can be evaluated in practice. (p. 347)<sup>12</sup>

In particular, our MDRI research draws upon three semesters of undergraduate mathematics instruction that took place at one institution during the Autumn 2016 (Introduction to Analysis; 11 consenting students), Spring 2017 (Number Theory; 8 consenting students), and Spring 2018 (Abstract Algebra; 15 consenting students). The contexts, student populations, and PSPs used are somewhat different across the three semesters<sup>13</sup>. However, the data sources were similar in each instance, and included:

- Video recordings of all class sessions;
- Audio recordings of each group during small group work;
- Students' written work on all PSPs implemented during the courses and related "Reading and Study Guides" (RSGs);
- Instructor class notes;
- Pre- and post-PSP student interviews<sup>14</sup>; and
- Responses to four surveys per student (pre- and post-course surveys, and two post-PSP surveys).

---

<sup>12</sup> This passage was previously quoted in this paper, but it bears repeating here because it is particularly critical for the MDRI work as part of TRIUMPHS.

<sup>13</sup> However, there was a small subset of students (8) who participated in two of the three courses.

<sup>14</sup> Not all consenting students were interviewed pre- and post-PSP, due to students' class and work schedules.

An example from the Autumn 2016 course (*Introduction to Analysis*), which contained source material “suitable for provoking discussion in classrooms among students and with their teachers about different meta-discursive rules” (Kjeldsen & Blomhøj, 2012, p. 347), was the first PSP of the semester (and which students met during the second week of the course): *Why Be So Critical: Nineteenth Century Mathematics and the Origins of Analysis* (Barnett, 2017a). This project explored the question of: *Why, after nearly 200 years of success in the development and application of calculus techniques, did 19th-century mathematicians feel the need to bring a more critical perspective to the study of calculus?* – and did so through selected excerpts from the writings of the nineteenth century mathematicians who led the initiative to raise the level of rigor in the field of analysis (Barnett, 2017a, p. 1).

The project includes excerpts from four mathematicians: Bolzano, Cauchy, Dedekind, and Abel. In the PSP, Barnett (2017a) provided oriented students to the various primary sources with: “...these mathematicians expressed their concerns about the relation of calculus (analysis) to geometry, and also about the state of calculus (analysis) in general. As you read what they each had to say, consider how their concerns seem to be the same or different” (p. 1). For example, Figure 1 displays an excerpt from Dedekind.

**Richard Dedekind, 1872, *Stetigkeit und irrationale Zahlen* (Continuity of irrational numbers)**

My attention was first directed toward the considerations which form the subject of this pamphlet in the autumn of 1858. As professor in the Polytechnic School in Zürich I found myself for the first time obliged to lecture upon the elements of the differential calculus and felt more keenly than ever before the lack of a really scientific foundation for arithmetic<sup>7</sup>. In discussing the notion of the approach of a variable magnitude to a fixed limiting value, and especially in proving the theorem that every magnitude which grows continually but not beyond all limits, must certainly approach a limiting value, I had recourse to geometric evidences. Even now such resort to geometric intuition in a first presentation of the differential calculus, I regard as exceedingly useful, from the didactic standpoint, and indeed indispensable, if one does not wish to lose too much time. But that this form of introduction into the differential calculus can make no claim to being scientific, no one will deny. For myself this feeling of dissatisfaction was so overpowering that I made the fixed resolve to keep meditating on the question until I should find a purely arithmetic and perfectly rigorous foundation for the principles of infinitesimal analysis.

**Figure 1: Excerpt from Barnett, 2017a (source: Dedekind, 1901)**

In keeping this excerpt in mind, we found evidence that such sources can prompt classroom discussion around the metadiscursive rules that we see at the time of Dedekind—which constituted a shift from what had been in place—and that are different still from what students were trying to reconcile.

Some weeks later—approximately seven weeks into the course—students spent approximately two weeks working on the second PSP in this analysis course: *Rigorous Debates over Debatable Rigor: Monster Functions in Introductory Analysis* (Barnett, 2017b). In the project, students are introduced to the correspondence between Gaston Darboux (1843–1917) and Jules Houël (1823–1886), in which

Houël has requested feedback on early drafts of his intended textbook on differential calculus. Throughout the correspondence, however, Darboux “offered various counterexamples in a (vain) attempt to convince Houël of the need for greater care in certain of his (Houël’s) proofs” (Barnett, 2017b, pp. 2–3). Examples of this correspondence are provided in Figures 2 and 3.

Here is what I reproach in your reasoning which no one would now find rigorous. When we have

$$\frac{f(x+h) - f(x)}{h} - f'(x) = \epsilon,$$

$\epsilon$  is a function of two variables  $x$  and  $h$  that approaches zero when,  $x$  remaining fixed,  $h$  approaches zero. But if  $x$  and  $h$  [both] vary as they do in your proof, or worse yet, if to each new subdivision of the intervals  $x_1 - x_0$  there arise new quantities  $\epsilon$ , then I find it altogether unclear and your proof has nothing but the appearance of rigor. [Darboux, as quoted in (Gispert, 1983, p. 99)]

**Figure 2: Excerpt (A): Darboux correspondence with Houël (Barnett, 2017b, p. 6)**

Yes, I admit as a fact of experience (without looking to prove it in general, which might be difficult) that in the functions that I treat, one can always find  $h$  satisfying the inequality  $\frac{f(x+h)-f(x)}{h} - f'(x) < \epsilon$ , no matter what the value of  $x$ , and I avow to you that I am ignorant of what the word derivative would mean if it is not this. . . . I believe this hypothesis is identical with that of the existence of a derivative. [Houël, as quoted in Gispert 1987, pp. 56 – 57].

**Figure 3: Excerpt (B): Houël correspondence with Darboux (Barnett, 2017b, p. 6)**

Two project tasks related to these excerpts were:

Do you agree with Houël about this being what the word ‘derivative’ means? Why or why not?

How does what Darboux said in the excerpt (A) seem to be different from what Houël is saying here [excerpt (B)]?

The intensive work on how to analyze the data in order to address our original research questions is just beginning. We produced a preliminary report on an initial discussion of methodological issues that we experienced in our first review of the Autumn 2016 data. In our report (Can, Barnett, & Clark, 2018), we addressed two questions:

1. How can we characterize the nature of students’ participation in mathematical discourse in their written work related to primary source projects?
2. What constitutes evidence of students’ noticing of meta-level rules in this written work?

Since our research report was quite preliminary (and page-limited), we focused on analyzing students’ written work from just one PSP<sup>15</sup> (and associated RSGs) that was implemented in the *Introduction to Analysis* course we studied in Autumn 2016. We sought to document evidence of

---

<sup>15</sup> For the purposes of the preliminary report, we focused on the PSP, *Rigorous Debates over Debatable Rigor: Monster Functions in Introductory Analysis* (Barnett, 2017b).

students' noticing of metadiscursive rules in the form of meta-level reflections of two kinds: on either the mathematical objects under discussion (what we called *object-reflection*) or the discourse itself (what we called *discourse-reflection*). In the sample student's reflection (given in Figures 4a, 4b, 5a, and 5b), we identified the student's 'talk' as object-reflection, in which she provided meta-level narrative about mathematical objects (i.e., derivative).

2. Complete Task 3 part (a):

Do you agree with Houël about this being what the word 'derivative' means? Why or why not?

I disagree with Houël about  $\frac{f(x+h)-f(x)}{h} - f'(x) < \epsilon$  is the derivative because we use  $f'(x)$  to define derivative & you would have to find this first before even using the equation above.

How does what Darboux said in the excerpt at the bottom of page 4 seem to be different from what Houël is saying here?

It's a way to describe what Houël trying to do but is not a derivative; they use the derivative in it.

**Figure 4a: Student object-reflection (meta-level)**

Do you agree with Houël about this being what the word 'derivative' means? Why or why not?

I disagree with Houël about  $\frac{f(x+h)-f(x)}{h} - f'(x) < \epsilon$  is the derivative because we use  $f'(x)$  to define the derivative & you would have to find this first before even using the equation above.

How does what Darboux said in the excerpt at the bottom of page 4 seem to be different from what Houël is saying here?

It's a way to [describe] what Houël [is] trying to do but is not a derivative; they use the derivative in it.

**Figure 4b: Transcription of task and student response given in Figure 4a**

1. Read the three excerpts (two from Darboux, one from Houël) on pages 4 – 5.

Write at least one question or comment about these three excerpts.

Darboux really seems to hate Houël's proof.  
The third excerpt, however, was a bit confusing for me, especially when it says "Hypothesis is identical with that of the existence of a derivative."

**Figure 5a. Student discourse-reflection (meta-level)**

Write at least one question or comment about these three excerpts.

*Darboux really seems to hate Houël's proof.*  
*The third excerpt, however, was a bit confusing to me,*  
*Especially when it says "hypothesis is identified with that*  
*of the existence of a derivative."*

**Figure 5b: Transcription of task and student response given in Figure 5a**

We intended the further application of our definitions for object-reflection and discourse-reflection to serve as tools to characterize the nature of students' participation in mathematical discourse in other course artifacts (e.g., small group work, whole-class discussion, interviews), but we have since found that we need an analytical framework that includes at least two components. One component of the analytical framework is the set of metadiscursive rules that we have identified for each of the PSPs that students used in a given course; it is imperative that our analysis attends to and is informed by the relevant metadiscursive rules present in the PSPs used. The second component is the criteria for evidence of students' "figuring out" the meta-level rules governing a new mathematical discourse. We believe these two components in tandem will enable us to capture a critical perspective in the work surrounding the role of primary sources (and in this case, specifically, the PSPs); that is, the implemented PSPs were intended to promote the mathematical learning goals of a given course. And, given the nature of the *Introduction to Analysis* course curriculum, these included both object- and meta-level learning goals. That said, the data analysis for the research described here is ongoing, and our particular struggle at the moment is figuring out what we mean by "figuring out," as suggested by Sfard (2014, p. 202), in order to move forward through our data to determine not only the progress made by students but what such progress could signal for changing instructional practice at the undergraduate level. This work is complex and draws upon multiple perspectives from mathematics, history, and mathematics education, and consequently, possesses ample opportunity for future collaborations and contexts in mathematics education research.

## **Calls for the future: Future contributions**

### **Need for collaboration**

There has been exciting progress in research conducted in the HPM domain in the last 40 years, and in the last 20 years, this is particularly true. As I shared earlier in this paper, at some point not so many years ago, empirical work (available in the English language) in the field of history in mathematics education was predominantly anecdotal in nature. With the growth of professional conferences—HPM, ICME, ESU, and now CERME—collaboration with colleagues around the world has not only afforded but has increased the demand for ways in which research on history in mathematics education can inform and be informed by research in mathematics education more broadly.

To this end, I would like to end with proposing two areas of research that I believe are particularly important and interesting (and necessary?), which draw upon the themes of different CERME thematic working groups and which present opportunities for fruitful collaboration in the future.

### **History of mathematics in mathematics teacher education**

An overarching question that requires careful and thorough study is:

*How does a historical perspective contribute to the mathematical and pedagogical development of mathematics teachers (at all levels, and both pre-service and in-service)?*

And, there are numerous questions it motivates, including:

*What are the different ways in which history of mathematics is used in the education of teachers?*

*What are the different challenges (e.g., historical, mathematical, attitudinal, philosophical, methodological, institutional) for each?*

*Are the outcomes of teachers' study of history of mathematics seen in their classroom practice in explicit ways, and if so how? If not, why? Are the implicit ways equally meaningful?*

Although these questions represent only a small sample of what is yet unknown to any extent in the HPM domain, the collaboration with other domains represented by CERME TWGs could provide the means to increase efforts to conduct research in concerted ways. Some of the TWGs, in addition to contributions from TWG 12, well poised to do so include:

TWG 18: Mathematics Teacher Education and Professional Development

TWG 19: Mathematics Teaching and Teacher Practice(s)

TWG 20: Mathematics Teacher Knowledge, Beliefs and Identify

TWG 22: Curricular Resources and Task Design in Mathematics Education

TWG 23: Implementation of Research Findings in Mathematics Education

### **History of mathematics in the teaching and learning of mathematics**

Research on the many ways in which history of mathematics can be used in the teaching and learning of mathematics seems boundless. There are many open questions in the field, yet when considering educational standards set by different countries around the globe and the persistent (primary and secondary) teacher lament that “there is not enough time to teach history of mathematics”<sup>16</sup> in mathematics lessons, addressing the questions through different research efforts can be problematic. Part of the issue with conducting research on the use of history in teaching and learning mathematics is the need to make clear the potential for student learning that research in the HPM domain has shown. Thus, a question of particular interest is: *How do we encourage, enable, and enlighten large-scale research on the ways in which using history of mathematics in teaching impacts learning?*

Similar to proposing research on history of mathematics in mathematics teacher education, inquiry on teaching and learning of mathematics informed by history of mathematics can be addressed by the expertise represented within several CERME TWGs. For example, for research focused on how

---

<sup>16</sup> Many classroom teachers perceive of “using history” as being equivalent to teaching the history of mathematics. However, this is often a misguided idea. That is, many who propose to use history of mathematics call for robust ways to do so, such as using historical methods to solve problems and to help make sense of the procedures many students find difficult, or reading, interpreting, and applying historical sources in learning mathematics, and not to simply teach who was the first to discover a particular mathematical concept.

history of mathematics can contribute to student learning and engagement with mathematics, collaboration amongst the following TWGs (again, in addition to TWG 12) is valuable:

TWG 1: Argumentation and Proof

TWG 2: Arithmetic and Number Systems

TWG 3: Algebraic Thinking

TWG 4: Geometry Teaching and Learning

TWG 8: Affect and the Teaching and Learning of Mathematics

TWG 14: Undergraduate Mathematics Education

Furthermore, investigating ways in which history of mathematics can connect tools and technologies in the teaching and learning of mathematics may benefit from the expertise of:

TWG 6: Applications and Modelling

TWG 9: Mathematics and Language

TWG 15: Teaching Mathematics with Technology and Other Resources

TWG 16: Learning Mathematics with Technology and Other Resources

And, finally, under the purview of TWG 21 (Assessment in Mathematics Education), there are considerable opportunities to address concerns held by many regarding whether teaching mathematics informed by history of mathematics *actually* contributes to student learning.

### **An additional consideration: Flipping the research perspective**

A large proportion of research conducted on questions regarding the use and impact of history of mathematics has been focused either pre-service or in-service teachers (at the elementary and secondary level) and their students. However, investigating another population of teachers is a promising direction to pursue: teachers of teachers (e.g., university educators). Povey (2014) conducted research conversations with four university instructors designed to address the following research question: What can studying the history of mathematics with initial teacher education students offer us? (p. 148). In her analysis, Povey determined four broad themes, two which seem aligned with affective dimensions and two which are situated more with content and mathematical understanding. The thematic categorizations of the instructors' responses were:

- to deepen mathematical understanding;
- to broaden and humanize mathematics;
- to develop critical thinking; and
- to provide motivation and fun for learners. (Povey, 2014, p. 148)

Povey (2014) provided the foundation for what I believe could promote research that focuses on educators of teachers, who can provide opportunities “for studying history of mathematics [that] sets up a productive relationship with the subject and deepens mathematical understanding” (p. 154). From application and further extensions of existing frameworks such as MKT and Mathematical Knowledge for Teaching Teachers (MKTT; see for example Jankvist, Clark, & Mosvold, 2019),

mathematics education research and history in mathematics education can both capitalize on what many in the field *know* (as in, instinctually know): that historical content, problems, and perspectives in mathematics teaching “requires the development of such critical skills and can develop disposition towards enquiry based on questions posing and evidence” (Povey, p. 155). However, it is imperative that researchers seek to legitimize what has been known for decades, and to do so in concrete and robust ways so that mathematics educators, teachers, and learners can benefit from ways of knowing mathematics to which history of mathematics uniquely contributes. An interesting “flipping” of the research perspective begins with extending research that Povey began with teacher educators, and from what is learned, it is possible to build on these new perspectives coupled with guidance from existing frameworks to develop new knowledge. We may find, as Jo (one of the teacher educators) did:

[finding out about the history of mathematics] has made me realise that there are many more questions to ask than I ever thought about before and there’s probably no end to that, and I think that’s a good thing for maths teachers to know. (Povey, 2014, p. 155)

More importantly, once teacher educators experience this shift, it can permeate their practice with pre-service teachers, which can in turn be impactful in *their* future practice. The greatest imperative, however, is that we must make research in history in mathematics education part of the research landscape, as much as say, how the field has investigated the educational benefit of use of technology in teaching and learning mathematics, or ways to improve concept building in learning algebra.

### **Wanted: A few good researchers**

As previously described, there are numerous perspectives from which researchers can approach important questions regarding teaching and learning of mathematics, of which an historical perspective is just one. Though empirical literature in the field of history of mathematics in mathematics education is much more prevalent today than some 40 years ago, there are several approaches, frameworks, and methodological lenses that are can and should be employed in order to strengthen and expand current examples.

In addition to the examples I have provided, there are other calls for research that have recently been issued and investigated to some degree. However, the potential for future research is significant and importantly, within the field of history in mathematics education, there are applications across age of learners, level of teachers, and mathematical concepts. For example, there are examples for which design-based research seems well-suited, as in the study described by Wang, Wang, Li, and Rugh (2018), in which they proposed a framework to make sense of “how to help teachers...who lack experience in [integrating the history of mathematics in teaching] IHT, use historical materials in their teaching” (p. 135). Wang et al. concluded that

Although the framework provides a new pathway for teachers’ professional development in IHT and a new opportunity for the theoretical development of IHT, *it still requires further empirical studies to confirm its educational value in the future. It is also essential that researchers closely collaborate with teachers and historians* as suggested by the dynamic pyramid model. (p. 153, emphasis added)

In closing, I have attempted to provide a broad landscape of questions, approaches, and collaborative contexts in which educational research of interest to the CERME community is possible and motivated by the field of history of mathematics in mathematics education. I challenge mathematics education researchers to embrace and pursue these questions, approaches, and contexts and to contribute to the expanding perspectives that move teaching and learning of mathematics forward.

## Acknowledgments

The author wishes to thank the International Programme Committee and the Local Organizing Committee for their invitation for me to serve as a plenary speaker for CERME11. The research conducted as part of the TRIUMPHS project was funded by the National Science Foundation's (United States) IUSE Program under grant number 1523561. Any opinions, findings, or recommendations expressed in this paper are those of the author and do not necessarily reflect the views of the National Science Foundation.

# Extensions of number systems: continuities and discontinuities revisited

Sebastian Rezat

Paderborn University, Institute for Mathematics, Paderborn, Germany; [srezat@math.upb.de](mailto:srezat@math.upb.de)

*The extension of number systems from natural to rational and real numbers and related arithmetic is a prominent theme in mathematics from primary to upper secondary education. In parallel to the development of the number concept and the extension of number systems, students need to proceed from arithmetic to algebra. Students' difficulties in mastering both, the extension from one number system to another and the progression from arithmetic to algebra are well documented. The paper focuses on the extension from natural numbers to integers with a particular interest in the relationship to the progression from arithmetic to algebra. Continuities and discontinuities in the alignment of these two parallel curricular developments are analyzed from three different perspectives, namely an epistemological, a psychological, and a pedagogical perspective. This analysis will include work from TWG02 "Arithmetic and Number Systems", which gives a flourishing account of the multifaceted issues related to the teaching and learning of different number systems since its foundation at CERME7 in 2011 and also draws on the work of TWG03 "Algebraic Thinking". Finally, conclusions will be drawn from the analysis of the relationship between the extension from natural numbers to integers and algebraic thinking in terms of the construction of a more coherent curriculum regarding these two developments.*

*Keywords: number systems, integers, negative numbers, algebraic thinking, coherence*

## Introduction

From the beginning of their lives and throughout schooling, students have to develop their number concept and related number sense. The extension of number systems from natural numbers to rational and real numbers<sup>1</sup> and related arithmetic is an endeavor that students are involved in from primary to upper secondary education in mathematics. In parallel to the development of the number concept and the extension of number systems, students need to proceed from arithmetic to algebra, i.e. from operating with known quantities to operating with unknowns, from the particular to the general, from numbers to symbols.

A large body of research shows that learners experience gaps and discontinuities related to both, the learning of number systems (Van Dooren, Lehtinen, & Verschaffel, 2015) and the learning of algebra (Hodgen, Oldenburg, & Strømskag, 2018; Kaput, 2008). In terms of the development of the number concept the transition from natural numbers to non-negative rational numbers (i.e. fractions and decimals) has received much attention. Research has unraveled the problems students encounter at

---

<sup>1</sup> There are ambiguities in the use of the terms *natural number*, *rational number*, and *integers* in the literature. I use the term *natural number* to refer to set  $\mathbb{N} = \{1, 2, 3, \dots\}$ . The term *integer* is used to refer to the set  $\mathbb{Z}$  comprising positive natural numbers including zero and their additive inverses, while with the term *rational number*, I refer to the set  $\mathbb{Q}$  comprising all positive and negative fractions and decimals respectively (and therefore also  $\mathbb{N}$  and  $\mathbb{Z}$ ).

this transition. In particular, it shows that the extension from natural numbers to non-negative rational numbers requires changes in the basic understanding of what numbers can do and what effect operations have on numbers. The problems at this transition exemplify that natural number knowledge on the one hand is a prerequisite for the learning of other number systems, but on the other hand has manifold adverse effects (Vamvakoussi, 2015). This phenomenon is so pervasive that it has been termed the *whole* or *natural number bias* (Ni & Zhou, 2005). Consequently, students' prior knowledge that was developed with respect to the set of natural numbers has to be reorganized in such a substantial way that Vosniadou and Verschaffel (2004) speak of a “conceptual change” that is necessary at the transition from natural numbers to non-negative rational numbers.

In terms of the transition from arithmetic to algebra, the difficulties that students experience with operating on the unknown led Linchevski and Herscovics (1996) to speak of a “cognitive gap” between arithmetic and algebra. Kaput (2008) calls the separation of arithmetic and algebra in terms of “a computational approach to school arithmetic and an accompanying isolated and superficial approach to algebra” the “algebra problem”. The answer to this problem has been to foster what has been termed *algebraic thinking*, *relational thinking*, *functional thinking*, or *early algebra* in the context of arithmetic, in order to provide students with ways of thinking that are crucial for school algebraic contexts.

Both of these long-term developments require a careful construction of the curriculum in order to facilitate students' understanding of these central mathematical ideas. However, researchers criticize the lack of a coherent vision for the teaching and learning of number systems and related transitions (Bruno & Martinon, 1999). This also seems to be the case for the link of the extension of number systems and the progression from arithmetic to algebra. Both, the discourse on the extension of number systems and the discourse on algebraic thinking only seem to be loosely related. This is also noticeable in CERME in that negative numbers are rarely considered in TWG03 on algebraic thinking.

Therefore, the goal of this paper is to unfold the relationship between the extension of number systems and the progression from arithmetic to algebra in order to analyze continuities and discontinuities in the alignment of these two curricular progressions. For reasons that will become obvious later, I will focus on the extension from natural numbers to integers in my analysis. In particular, I seek to answer the following questions:

- 1) What is relationship between the development of the negative number concept and algebra?
- 2) How could the teaching and learning of the extension from natural numbers to integers be aligned with the teaching and learning of algebraic thinking?

In order to answer these questions, I will analyze the transition from natural numbers to integers from different perspectives: a) epistemological; b) pedagogical; and c) psychological. The epistemological perspective will mainly serve to answer the first question. I will show that the development of the negative number concept and the development of algebra were mutually related. In fact, negative numbers play a crucial role in these two developments. The pedagogical and psychological perspective will yield answers to the second question.

Based on my analysis of the relation between the extension from natural numbers to integers and the progression from arithmetic to algebra from the three different perspectives, I will draw conclusions regarding the construction of curricula, in which both, the extension of number systems and the progression from arithmetic to algebra are more coherently aligned.

## Epistemological perspective

In this section, I will show that the same cognitive achievements which underlie the development of algebra were also crucial for the development and acceptance of the negative number concept. I start with a summary of the main cognitive achievements that have been pointed out as characteristic and crucial for the development of algebraic thinking. I will then show, how these cognitive achievements also have been crucial for the development of the negative number concept. However, I will not be able to give a comprehensive overview of this mutual related historical development of the negative number concept and algebra. An analysis of the obstacles in the historical development of the negative number concept was provided by Glaser (1981). Schubring (2005) gives an overview of the historical development of the negative number concept and its relation to the development of algebra.

Hodgen et al. (2018) regard algebraic thinking as the human activity from which algebra emerges. It focuses on generalization and the expression of generalization in increasingly systematic and conventional symbol systems as one core aspect of algebra rather than on syntactically guided actions on symbols (Kaput, 2008). The main cognitive achievements that have been pointed out as being characteristic and crucial for the development of algebraic thinking and algebra are:

1. Algebra deals with objects of *indeterminate* nature (unknowns, variables, parameters) (Radford, 2010)
2. Indeterminate objects are dealt with in *analytic* manner (Radford, 2010).
3. The development of algebraic thinking is characterized by a transition from an operational to a structural or relational perspective, i.e. by “reification” (Sfard 1995) or “objectification” (Radford, 2010) of processes into mathematical objects.
4. The new mathematical objects are detached from their original content meanings and achieve a formal character.

In the development of algebra and algebraic thinking, these four aspects are mutually related and difficult to consider in isolation. However, for the sake of clarity I elaborate on them separately.

### Algebra deals with objects of indeterminate nature

The epistemological development of algebra is closely related to dealing with objects of indeterminate nature. These indeterminate objects yielded the concepts of variable and parameter. It was also in the realm of dealing with indeterminate objects in the context of solving (systems of) equations that negative numbers became relevant (Gallardo, 2002; Glaser, 1981; Hefendehl-Hebeker, 1991). According to Damerow (2007, p. 49) the use of variables “opens a potential means of representation for a higher level of meta-cognitive insights such as the recognition that the natural numbers can be complemented with negative numbers to the system of whole numbers”. Diophantus was one of the first who solved equations based on transformation methods. Applying these methods also yielded

negative solutions. For example, in his *Arithmetica*, Diophantus referred to the equation  $4 = 4x + 20$  as absurd, since it would give the solution  $x = -4$ .

It was not until the second half of the 19<sup>th</sup> century that negative numbers were accepted as autonomous mathematical objects. However, in solving equations they were already accepted as auxiliary means, which had to be interpreted correctly after the equation was solved. A famous example is the problem discussed by D'Alembert in the article *Négatif* from Diderot's *Encyclopédie*:

suppose that we are looking for the value of a number  $x$  which when added to 100 yields 50. According to the rules of algebra; we have  $x + 100 = 50$ , so that  $x = -50$ . This shows that the magnitude  $x$  is 50 and that instead of being added to 100 it must be subtracted. This means that the problem should have been formulated as follows: find a magnitude  $x$  which when subtracted from 100 leaves the remainder 50; if the problem had been formulated in this manner, then we would have  $100 - x = 50$  and  $x = 50$ , and the negative form of  $x$  would cease to exist. Thus, in computations, negative magnitudes actually stand for positive magnitudes that were guessed to be in the wrong position. The sign “-” before a magnitude is a reminder to eliminate and to correct an error made in the assumption, as the example just given demonstrates very clearly. (D'Alembert as cited in Hefendehl-Hebeker, 1991).

D'Alembert does not except the existence of a magnitude with value “-50” in his argumentation. To him, this solution only indicated an error made that had to be corrected.

Another way of making sense of negative solutions was to interpret them metaphorically by the opposite magnitude. This metaphorical interpretation of negative solutions by the opposite magnitude developed into the concept of opposite quantities, which cancel each other out:

“Quantities of the same kind which are considered under conditions that one diminishes the other shall be called opposite quantities. E.g., assets and debts, walking forward and walking backward. One of these quantities, as one likes, shall be called positive or affirmative, and its opposite negative or denying” (Kästner as cited in Schubring 2005, 134).

A similar understanding as “something being opposed to something familiar” was also crucial for the development of the concept of variable. There, it was the dualistic opposition to a known or constant quantity. This concept of variable was first overcome by Euler, who replaced this dichotomy by the universal concept of variable (Schubring, 2005). Similarly, the concept of negative quantity was for a long time conceptualized as an opposite quantity and had to be overcome by the formal concept of number.

### **Indeterminate quantities are dealt with in analytic manner**

As a second important characteristic of algebraic thinking, Radford (2010) points out that indeterminate quantities are dealt with in an analytic manner, i.e. it is calculated with these indeterminate quantities as if they were known by referring to their mutual relationships and the relationships to known quantities. (Hefendehl-Hebeker & Rezat, 2015; Radford, 2010).

As negative numbers occurred in the context of solving equations they result from calculations in which indeterminate quantities were treated as if they were known by referring to their mutual relationships and the relationships to known quantities. This aspect is especially apparent in the

formulation of the rules for calculating with negative numbers. For example, although not accepting negative solutions, Diophantus formulated the rules *minus times minus gives plus* and *plus times minus gives minus* (Tropfke, 1980). However, these rules were derived from calculating with complex expressions, such as  $(a - b)(c - d)$ , by analyzing the internal relationships. The explanation of the rule for subtracting negative numbers by Bernard Lamy (1640–1715) is a revealing example. He explains that when subtracting complex quantities like  $c + f$  and  $b - d$ . One did not want to subtract from  $c + f$  the entire  $b$ , thus  $c + f - b$ , but somewhat less. One thus had to change the algebraic sign of  $d$  from  $-$  into  $+$ , so as to perform the operation  $c + f - b + d$  (Schubring, 2005, p. 76). Consequently, the expression  $-(-b) = +b$  in solving the brackets is given sense in its relations to  $b$  and of  $(b - d)$  to  $(c + f)$ .

### Reification and Objectification

It has been pointed out that “reification” (Sfard, 1994, 1995) or “objectification” (Radford, 2010) of operations or—more generally—processes into mathematical objects had been crucial in the development of algebra. Just as the expression  $4x + 20$  can be seen either as a sequence of operations or as a mathematical object such as a representation of a number or as a function, the expression  $a - b$  can be seen as the operation of subtracting  $b$  from  $a$  or as the number resulting from this subtraction. From this perspective, the construction of negative numbers as autonomous mathematical objects required a transformation of mathematical processes into mathematical objects, which is visible in the step from carrying out the “hypothetical” subtraction  $a - b$  omitting the restriction  $b \leq a$  and accepting the negative number as an own entity. In fact, it may be regarded as one of the cognitive roots of negative numbers (Hefendehl-Hebeker & Rezat, 2015; Sfard, 1994, 1995) that carrying out fictive operations such  $50 - 100$  was actually considered as a possibility. Peacock refers to this generalization of operations as the move from arithmetical to symbolical algebra (Chiappini, 2011). While in arithmetical algebra the operations on symbols underlie the same restrictions as in arithmetic (of natural numbers), the operations with symbols in symbolic algebra are defined according to the properties of the operations.

According to Schubring (2005), it was Euler who first constructed the series of negative numbers by “perpetually subtracting unity”. Later, Hankel used the term  $a - b$  to construct negative numbers (Tropfke, 1980). It was also Hankel who noticed that it is sufficient to use  $a = 0$  and name the resulting number by  $-b$ .

### The new mathematical objects are detached from content meanings and achieve a formal character.

Descartes’ achievement to develop a symbolic language, which primarily relied on the relationships among the symbols and not on justifications through arithmetic or geometry is regarded to be a crucial step in the development of the symbolic language of algebra (Scholz, 1990). This can be understood as a detachment of the mathematical objects from content meanings.

Although at a very different time, the detachment of the number concept from content meanings was crucial for the acceptance of negative numbers. Schubring (2005) points out that the separation between numbers on the one hand and quantities or magnitudes on the other is decisive for understanding the historical development of negative numbers. He shows that in the history of

mathematics the epistemological limitation of the concepts of quantity and magnitude impeded the generalization of operations and thus the development of the negative number concept. As long as the concept of negative numbers was subordinated to that of magnitude, negative magnitudes were not accepted as autonomous mathematical objects. As already shown in the example by D'Alembert, the problems and their solutions were reinterpreted in the domain of positive numbers in order to avoid negative solutions. This view restricted the applicability of negative numbers to operations with “subtractive” or “opposite” quantities, which have a “natural element of opposition as giving and taking” (Schubring, 2005, p. 106). According to Schubring (2005), Euler was the first to consistently present algebra as a science of numbers and to conceptually separate numbers clearly from quantities and magnitudes. However, it was not until the 19th century that these obstacles imposed by the subordination of number to the concept of quantity and magnitude were overcome by a shift of view: The change consisted in the transition from the concrete to the formal viewpoint, which was advanced by Ohm, Peacock and Hankel. Subsequently, the concept of number could be introduced in a purely formal manner without consideration of the concept of magnitude. Hankel, who advanced this viewpoint argues:

Thus, the condition for the construction of a general arithmetic is that it be a purely intellectual mathematics detached from all intuition, a pure science of forms in which what are combined are not quanta or their number images but intellectual objects to which actual objects, or relations of actual objects, may, but need not, correspond (Hankel as cited in Hefendehl-Hebeker, 1991)

Accordingly, the underlying epistemology of justification changed from realism to that of internal consistency (Pierson Bishop et al., 2014). While operating with negative quantities and the related rules were known and used confidently already for a long time, the consistent system of rules for manipulating negative numbers is not deduced from reality, but from the basic rules of natural number arithmetic based on the permanence principle.

Hefendehl-Hebeker (1991) argues that the “separation of the construction of number systems from content considerations did not mean that the extended number systems were detached from content meanings” (p. 31) and provides some examples where negative numbers were successfully applied to real phenomena. The difference is that in these cases the concept of magnitude is subordinated to that of number and numbers are used as modelling tools for real-life situations.

In summary, I argued that the development of the negative number concept and the development of algebra are mutually related. The cognitive achievements, which have been emphasized as being crucial for the development of algebra, also underlie the development of the negative number concept. In particular, these are the possibility of carrying out fictive operations with indeterminate quantities in analytic ways, the “reification” (Sfard, 1994, 1995) and “objectification” (Radford, 2010) of mathematical processes, and the detachment of mathematical objects from content meanings and related formalization. According to Schubring (2005, p. 149), negative numbers “challenged the traditional first understanding of mathematics, its first ‘paradigm’ in Kuhn’s terms, its understanding of being a science of quantities: of quantities that, while being abstracted to attain some autonomy from objects of the real world, continued at the same time to be epistemologically legitimized by the latter” until a formal algebraic introduction and justification of these numbers and their operations

was achieved. Therefore, from the epistemological perspective, negative numbers seem to play a crucial role in the development of number systems aligned with the development of algebraic thinking. This is the reason, why I focus on the case of negative numbers in my analysis of the relation between the extension of number systems and the transition from arithmetic to algebra.

## Psychological perspective

Although negative magnitudes are nowadays a natural part of our daily life as relative magnitudes on thermometers and other scales, research has shown that students struggle with the same obstacles that characterize the epistemology of negative numbers. Gallardo (2002) observes the same levels of acceptance of negative numbers that she found in the historical development in students understanding of the concept. However, she points out that the levels of acceptance do not follow a strict chronological order in the students and that the same student might show different levels of understanding dependent on the context of the task. In line with the historical development of negative numbers, Pierson Bishop et al. (2014) identify the magnitude-based perspective on numbers together with their understanding as cardinal numbers as an obstacle, because then negative numbers are perceived in a non-tangible way as less than nothing. This is also an obstacle for the understanding of operations with negative numbers.

Different studies show that students have difficulties with the order of integers. Students exhibit more difficulties in tasks that involve only negative numbers than in tasks with positive and negative numbers (Bofferding & Farmer, 2018). The main problem is that the size of a negative number is determined based on the absolute value or the opposite magnitude respectively. For example, students regard  $-10$  as ‘bigger’ than  $-5$ , because  $-10$  is colder than  $-5$ . This mirrors the understanding of negative numbers as opposite magnitudes, which was persistent throughout the historical development of the negative number concept. The extent to which these difficulties are shown also depends on the language used in comparison tasks (hottest/most hot/least cold vs. coldest/most cold/least hot) (Bofferding & Farmer, 2018). Schindler, Hußmann, Nilsson, and Bakker (2017) and Yilmaz and Isiksal-Bostan (2017) argue that it is important to consider students reasoning related to their answers. Their studies show that even correct answers might be based on faulty reasoning, which builds on prior experiences from the natural numbers.

Students also have difficulties with the different meanings of the minus sign. While in the set of natural numbers the minus sign only denotes subtraction, it additionally obtains a unary function as a structural signifier to denote a relative number and a symmetrical function as an operational signifier to denote the inverse in the set of integers. Vlassis (2004) shows that students do not assign any other meaning to the minus sign than that of subtraction in polynomial expressions. Their procedures of simplifying polynomials can be understood as strategies of making sense of the expressions and being able to carry out simplifications by adhering to this one meaning of the minus sign that originates from the natural numbers. When solving equations students have difficulties to find negative solutions in particular in situations with two successive signs, such as  $-6 \cdot x = 24$  (Vlassis, 2008).

In summary, as in the case of the transition from natural numbers to fractions, a natural number bias is also apparent at the transition from natural numbers to integers. The empirical findings of students’ difficulties in understanding the negative number concept mirror the obstacles that characterize the

epistemological development of the negative number concept. However, the studies aiming at identifying students' obstacles vary in the degree, in which they consider students' prior experiences when learning negative numbers. The participants of many studies already learned integer arithmetic. Consequently, how they were introduced to negative numbers might have an effect on their understanding of them. In order to unveil continuities and discontinuities in the learning of the number concept, it would be important to understand how the obstacles that students experience in the learning of the negative number concept relate to the way they have been introduced to the concept and to their prior experiences in the set of natural numbers. Referring to the results from the epistemological analysis, the effects of early algebra on the learning of the negative number concept would be a matter of particular interest. However, studies analyzing students' understanding of negative numbers usually do not control for prior experiences.

## **Pedagogical perspective**

In the epistemological analysis I have shown that there are parallels in the development of algebraic thinking and the negative number concept. Therefore, it seems natural to align the teaching and learning of the extension from natural numbers to integers with ideas of algebraic thinking. From the psychological perspective, it is not yet clear, if the teaching and learning of the negative number concept aligned with ideas of algebraic thinking has positive effects on students' understanding of the concept.

Algebraic thinking is promoted in mathematics curricula for the elementary grades across the world and thus has become an important goal in the teaching and learning of natural number arithmetic (Cai, Ng, & Moyer, 2011; Venkat et al., 2018). The vast majority of tasks, learning trajectories and studies related to algebraic thinking is carried out in the domain of natural numbers. Only rarely are integers and other number systems considered related to algebraic thinking. As already mentioned in the introduction, the scientific discourses on the extension of number systems and on algebraic thinking only rarely seem to be related to each other.

Approaching the transition from natural numbers to integers from a pedagogical perspective, I seek to answer the question how the teaching of the transition from natural numbers to integers could be aligned with the teaching of algebraic thinking. In my presentation, I focus on two aspects: 1) didactic models, which align the extension of number systems and algebraic thinking; and 2) number sense as an important goal related to natural number arithmetic and algebraic thinking.

## **Didactic models for integers and algebraic thinking**

Within the scope of this article, I can only briefly sketch my understanding of didactic models. Space does not allow to elaborate on the rich theory behind it. I refer to an understanding of didactic models as representations of abstract mathematical concepts or structures. Thus, they reflect essential aspects of the mathematical concepts or structures. By allowing students to act upon the tangible or symbolically represented mathematical objects, they are used as tools in the meaning of cultural artifacts (Wartofsky, 1979; Wertsch, 1998) to foster students' conceptual development. I adopt the broad notion of models in Realistic Mathematics Education, in which models have different manifestations. From this perspective hands-on-materials, sketches, paradigmatic situations, schemes, or diagrams can serve as models (Van den Heuvel-Panhuizen, 2003). An important aspect

with regard to transitions is that didactic models need to be flexible in order to be applied to more advanced, sophisticated or abstract levels and thus support vertical mathematization (Van den Heuvel-Panhuizen, 2003).

Different categorizations of didactic models for integers have been suggested. Janvier (1983) distinguishes number-line-models and equilibrium models. While number-line models depict negative numbers and related operations on one continuous number line, equilibrium models introduce two separate (magnitude) representations for positive and negative numbers, e.g. black and red stones. These equilibrium models refer to the meaning of negative numbers as opposite quantities. Operations in equilibrium models are based on the principle of compensation between positive and negative numbers, i.e. the neutralization of equal amounts of opposites, e.g. of black and red stones. Another categorization of didactic models for integers has been suggested by Steinbring (1994). He distinguishes three categories: 1) real-life context as modelling structures; 2) models based on geometric or arithmetic permanence; 3) models providing autonomous representations of negative numbers. Temperatures, assets and depths, elevation, and the elevator model are typical examples of the first category. Freudenthal (1983) was a proponent of models of the second category, which aim to provide plausible reasons for the expansion of rules from the natural numbers to integers. The two categories distinguished by Janvier (1983) both belong to Steinbring's (1994) third category.

As Fischbein (2002) points out, there is no didactic model of negative numbers, which at the same time is intuitive and consistently represents all the algebraic properties of negative numbers. A model, which consistently represents the algebraic properties of negative numbers always needs to build on artificial conventions. Therefore, research has tried to identify the affordances and constraints of particular models in learning integer arithmetic (Hativa & Cohen, 1995; Linchevski & Williams, 1999; Stephan & Akyuz, 2012). Many researchers prefer the number line model for representing operations with integers (Altıparmak & Özdoğan, 2010; Bruno & Martinon, 1999; Hativa & Cohen, 1995). Other research highlights the power and importance of contextual knowledge from real-life situations for the understanding of negative numbers (e.g. Linchevski & Williams, 1999; Stephan & Akyuz, 2012). However, in real-life situations the understanding of negative numbers as opposite magnitudes is also identified as an obstacle (Schindler & Hußmann, 2013). Students need well developed mental networks that relate the opposite magnitudes and their order (Schindler & Hußmann, 2013; Yilmaz & Isiksal-Bostan, 2017).

Due to the artificial conventions that are necessary to develop didactic models for negative numbers (Fischbein, 2002), there is a tendency to develop games (e.g. Hattermann & vom Hofe, 2015; Linchevski & Williams, 1999) and artificial contexts (Altıparmak & Özdoğan, 2010; Streefland, 1996) as didactic models. As opposed to real-life contexts, artificial contexts and games facilitate the implementation of formal rules. On the contrary, most recent textbooks introduce negative numbers in real-life contexts such as temperature, assets and debts, or elevation in order to support the understanding of the negative number concept (Whitacre et al., 2015). Whitacre et al. (2015) show that students solve problems in the context of assets and debts without using negative numbers, but most of them were capable to relate negative numbers to the context if asked to do so.

Only rarely are didactical models for integers discussed in terms of their affordances to foster algebraic thinking. A few examples are Chiappini (2011); Gallardo (2002); Peled and Carraher (2008); Rezat (2014); and Schumacher and Rezat (in press). These authors exploit the potential of particular didactic models for the learning of integers aligned with algebraic thinking. Linchevski and Williams (1999) do not explicitly relate to algebraic thinking, but address reification as a main problem of learning integers, which was shown as being equally important for both, algebraic thinking and understanding the negative number concept. Therefore, their approach is also relevant in the present context. I will exemplify the different approaches by providing an example of each.

Gallardo (2002) builds on the historical-critical method as described by Filloy, Puig, and Rojano (2008). This approach is characterized by recurrent movements between the analysis of historical texts and empirical work in the classroom. Learning sequences are developed based on the historical analysis of the development of concepts. In her study, Gallardo (2002) uses word problems from historical sources, e.g. D'Alembert's problem.

Peled and Carraher (2008) criticize that most word problems, which involve negative numbers do not require the formal rules for manipulating negative numbers and consequently can be solved correctly while circumventing operations with negative numbers. Their main approach may be characterized by generalizing arithmetic problems in the realm of real-life contexts as modeling structures. They adjust problems using real-life contexts in order to foster algebraic thinking when learning integers and illustrate how these algebraic problems are more suited than arithmetic problems to promote meaningful learning of negative numbers.

An example from Peled and Carraher (2008, p. 309f) may illustrate their approach. The example juxtaposes two formulations of the same problem: an arithmetical formulation and an algebraic formulation.

*An arithmetical trip:* Anne drove 40 kilometers north from her home to an out of town meeting. She then drove back going 60 kilometers out to another meeting. After both meetings were over, she called home asking her husband, Ben to join her.

- a) How far will Ben have to go and in what direction?
- b) Write an expression for writing the length of Bens' trip.

*An algebraic trip:* Anne drove *a certain number of* kilometers north from her home to an out of town meeting. She then drove back going 60 kilometers out to another meeting. After both meetings were over, she called home asking her husband, Ben to join her.

- a) Write an expression for writing the length of Bens' trip.
- b) *Could Anne have driven less than 60 kilometers north on her first trip? If not, explain why. If she could have, give an example and explain its meaning.*

The example shows that the main idea is to formulate real-life problems in a generalized way in order to foster algebraic solutions which comprise negative numbers. Referring back to my epistemological analysis, their algebraic didactical model seems to be closer to the epistemological roots of negative numbers than the arithmetical counterpart. There, I pointed out that negative numbers became meaningful in the context involving subtractions with variables such as  $x - 60$ .

Chiappini (2011) exemplifies how the number line model can be used in a digital environment to foster algebraic thinking. He presents the algebraic line in the digital tool AlNuSet as a didactic model, which is supposed to mediate reification (Sfard, 1994) or objectification (Radford, 2010) of negative numbers in the context of the operation  $a - b$ . Different values of  $a$  and  $b$  can be chosen by dragging the corresponding points on the number line. The corresponding value of the expression  $a - b$  is shown by the system as a point on the number line (Fig. 2).

**Fig 2: Algebraic line from AlNuSet (Chiappini, 2011, p. 433)**

This didactical model focuses on the core operation, which led to the introduction of negative numbers in the history of mathematics and offers a representation for the result. However, it is not clear how this model is to be extended to other operations with integers.

Linchevski and Williams (1999) use the double abacus related to a real-life problem and a dice game. They conclude that by recording scores of a dice game on the double abacus and by operating on them „integers are encountered as objects in social activity, before they are symbolized mathematically, thus intuitively filling the gap formerly considered a major obstacle to reification“ (Linchevski & Williams, 1999, p. 144).

Rezat (2014) exploits the potential of a model building on the permanence principle. In an ongoing design research project, Rezat (2014) and Schumacher & Rezat (in press) developed a learning trajectory for the learning of integers and the operations with them. In the learning trajectory, they aim to implement a didactical model based on the permanence principle building on pattern generalization tasks. In this learning trajectory, negative numbers are introduced through the idea of counting backwards beyond zero. Based on this idea and the representation of negative numbers on the number line, the order of integers and the operations with integers are consecutively introduced in the following order:

1. Introduction of negative numbers
2. Order of negative numbers
3. Subtraction of positive numbers from negative numbers
4. Addition
5. Subtraction of negative numbers from negative numbers
6. Multiplication

Each section has an analogous structure. It begins with pattern generalization tasks followed by analyzing and exploring task relations within and among operations. Finally, the rules of calculating with integers are abstracted from these explorations. I will provide a more detailed account of this structure using the example of subtracting negative numbers.

Each chapter starts with pattern generalization tasks such as represented in Fig. 3.

<p>a)</p> $\begin{array}{rclcl} 3 & - & 2 & = & \underline{\hspace{1cm}} \\ 3 & - & 1 & = & \underline{\hspace{1cm}} \\ 3 & - & 0 & = & \underline{\hspace{1cm}} \\ 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}} \\ 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}} \\ 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}} \end{array}$	<p>e)</p> $\begin{array}{rclcl} 3 & - & (-1) & = & \underline{\hspace{1cm}} \\ 2 & - & (-1) & = & \underline{\hspace{1cm}} \\ 1 & - & (-1) & = & \underline{\hspace{1cm}} \\ \underline{\hspace{1cm}} & - & (-1) & = & \underline{\hspace{1cm}} \\ \underline{\hspace{1cm}} & - & (-1) & = & \underline{\hspace{1cm}} \\ \underline{\hspace{1cm}} & - & (-1) & = & \underline{\hspace{1cm}} \end{array}$
...	

**Fig. 3: Pattern generalization tasks for the subtraction of integers**

Pattern generalization tasks are widely incorporated in German textbooks for primary level. The aim of these tasks is to foster students' recognition of patterns and their understanding of number relations. By generalizing the patterns, students can discover basic rules of arithmetic, e.g. that a difference remains constant when both, minuend and subtrahend are lowered or increased by the same number. Pattern generalization tasks are widely acknowledged to foster algebraic thinking (Radford, 2008; Rivera, 2013). Freudenthal (1983) also proposed to use them for learning the operations with integers. Although they are already used in this context, their full potential has only rarely been exploited. In their learning trajectory, Rezat (2014) and Schumacher & Rezat (in press) make intensive use of these tasks in order to support the learning of integer arithmetic aligned with algebraic thinking.

Students are supposed to analyze the relation of the tasks, complete the empty fields in the tasks, solve the tasks, and describe the structure of the pattern. The first three tasks in Fig. 3 a) should be easily solvable for students since they ask students to perform a simple natural number subtraction. Whereas in the fourth task, students encounter the subtraction of a negative number from another number for the first time. It is expected that students draw on their prior knowledge of this task type and derive the solution of this unfamiliar task from the pattern that the minuend remains constant, the subtrahend is lowered by one, and consequently, the result increases by one. In these patterns, students encounter the difficult situations, which incorporate two successive signs (Vlassis, 2008). Drawing on the structure of the pattern, they should be able to conjecture that  $3 - (-1)$  equals 4. In that, the prior knowledge of the task type provides a tool for solving tasks involving the subtraction of negative numbers. After more exploration and related reflection, a conjecture about the rule for the subtraction of negative numbers that is consistent with their prior knowledge should be possible. Deeper reflection reveals also new insights, such as that subtraction does not always lower the result. In other structures of task sequences students can encounter the different cases of the subtraction of negative numbers, such as the subtraction of a negative number from a negative number as shown in Fig. 3 e).

In our empirical investigation of students' behavior when working on these tasks we find both, students who solve the tasks correctly based on the pattern (Fig. 4, left) and students, who solve each

task separately and show a natural number bias, which relates to the lowering effect of subtraction (Fig. 4, middle and right):

Fig. 4. Three exemplary student solutions of the task in Fig. 3.

After completing these pattern generalization tasks students are supposed to transfer these tasks into a table such as depicted in Fig. 5.

-												
						5 - 0 = 5	5 - 1 = 4	5 - 2 = 3	5 - 3 = 2	5 - 4 = 1	5 - 5 = 0	...
	4 - (-5) =	4 - (-4) =	4 - (-3) =	4 - (-2) =	4 - (-1) =	4 - 0 = 4	4 - 1 = 3	4 - 2 = 2	4 - 3 = 1	4 - 4 = 0	4 - 5 = -1	...
						3 - 0 = 3	3 - 1 = 2	3 - 2 = 1	3 - 3 = 0	3 - 4 = -1	3 - 5 = -2	...
						2 - 0 = 2	2 - 1 = 1	2 - 2 = 0	2 - 3 = -1	2 - 4 = -2	2 - 5 = -3	...
						1 - 0 = 1	1 - 1 = 0	1 - 2 = -1	1 - 3 = -2	1 - 4 = -3	1 - 5 = -4	...
						0 - 0 = 0	0 - 1 = -1	0 - 2 = -2	0 - 3 = -3	0 - 4 = -4	0 - 5 = -5	...
						-1 - 0 = -1	-1 - 1 = -2	-1 - 2 = -3	-1 - 3 = -4	-1 - 4 = -5	-1 - 5 = -6	...
						-2 - 0 = -2	-2 - 1 = -3	-2 - 2 = -4	-2 - 3 = -5	-2 - 4 = -6	-2 - 5 = -7	...
						-3 - 0 = -3	-3 - 1 = -4	-3 - 2 = -5	-3 - 3 = -6	-3 - 4 = -7	-3 - 5 = -8	...
						-4 - 0 = -4	-4 - 1 = -5	-4 - 2 = -6	-4 - 3 = -7	-4 - 4 = -8	-4 - 5 = -9	...
						-5 - 0 = -5	-5 - 1 = -6	-5 - 2 = -7	-5 - 3 = -8	-5 - 4 = -9	-5 - 5 = -10	...
	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮

Fig. 5: Subtraction table for negative numbers

The table shown in Fig. 5 is an extension of the rotated diagram shown in Fig. 6 to the negative case. Tables such as the one shown in Fig. 6 are recommended by German mathematics educators in order to display the relations between all the tasks with summands up to 10 and to support effective memorization of the basic tasks in the early primary grades (Schipper, Ebeling, & Dröge, 2015; Wittmann & Müller, 1997). The structure of the table is supposed to foster students' understanding

of task relations. Based on their understanding of this structure, students should be able to derive the result of a task from a task, which is memorized as a basic fact. For example, the solution of the task  $5 + 4$  might be derived from the (memorized) doubling task  $5 + 5$  by diminishing the result by one, since one of the summands is also diminished by one.

**Fig. 6: Basic addition-table (Wittmann & Müller, 2012)**

Similarly, students are supposed to complete the table in Fig. 5 by drawing on number relations and thus deriving the contents of the empty fields from adjacent fields. Again, the tasks relate to familiar tasks from the set of natural numbers and students can relate the “new” numbers to their prior knowledge by relying on number relations.

In order to explicate the rules for subtracting negative numbers, students explore number relations in excerpts from different tables as shown in Fig. 7.

$5 - (-5)$ $= 10$	$5 - (-4)$ $= 9$	$5 - (-3)$ $= 8$	$5 + 3$ $= 8$	$5 + 4$ $= 9$	$5 + 5$ $= 10$
$4 - (-5)$ $= 9$	$4 - (-4)$ $= 8$	$4 - (-3)$ $= 7$	$4 + 3$ $= 7$	$4 + 4$ $= 8$	$4 + 5$ $= 9$
$3 - (-5)$ $= 8$	$3 - (-4)$ $= 7$	$3 - (-3)$ $= 6$	$3 + 3$ $= 6$	$3 + 4$ $= 7$	$3 + 5$ $= 8$

**Fig. 7: Comparison of subtraction and addition table excerpts**

By comparing tasks and results, they can find, for example, that the two tasks  $5 - (-5)$  and  $5 + 5$  both equal ten. By exploring and analyzing adjacent tasks they can identify the same phenomenon. Therefore, they can conjecture that  $5 - (-5) = 5 + 5$ . After confirming this relation with more tasks,

they are asked to generalize their findings and formulate a rule for the subtraction of negative numbers.

The learning trajectory by Rezat (2014) and Schumacher and Rezat (in press) was evaluated in a comparative study with a learning trajectory based on real-life contexts as modelling structures. Results are going to be published elsewhere.

Comparing the presented didactical models that introduce negative numbers aligned with algebraic thinking reveals that all of them relate to important cognitive achievements in the epistemology of negative numbers. Chiappini (2011) directly relates to the generalization of the expression  $a - b$  and its representation on the number line, which played a crucial role in the epistemological development of negative numbers. Gallardo (2002) uses historical problems and Peled and Carraher (2008) argue for generalizations of word problems. As was shown in the epistemological analysis, problems of this type and their solution played an important role in the historical development of negative numbers. Rezat (2014) and Schumacher and Rezat (in press) relate to the permanence principle, which was the cognitive achievement that led to the formal understanding of negative numbers and their final acceptance as numbers.

While Chiappini (2011) and Peled and Carraher (2008) only present some isolated examples, which might be incorporated in a learning trajectory for negative numbers, Gallardo (2002) as well as Schumacher and Rezat (in press) present didactic models, which consistently make use of one core idea to foster the learning of negative numbers aligned with algebraic thinking.

The epistemological analysis has shown that it was crucial in the development of the negative number concept to overcome the understanding of negative numbers as magnitudes. The understanding of negative numbers as opposite magnitudes was persistent whenever negative numbers appeared in the solution of real-life-problems. It was not until the formalization of the number concept in the 19<sup>th</sup> century that negative numbers were accepted as autonomous quantities. Therefore, it is questionable if the teaching of the negative number concept solely based on real-life contexts as modelling structures is an appropriate approach to develop an algebraic understanding of negative numbers. According to genetic epistemology it might be appropriate to introduce negative numbers in such contexts, but it equally seems important to proceed towards an algebraic understanding of negative numbers and their operations based on the permanence principle as Rezat (2014) and Schumacher and Rezat (in press) suggest. However, learning trajectories that coherently align the development of the negative number concept and algebraic thinking are still missing in the research literature.

### **Number sense**

So far, I have analyzed the epistemological relation between the negative number concept and algebra as well as didactic models for negative numbers that explicitly relate to algebraic thinking. I will now turn to *number sense*, a construct that is of interest for the scope of this article for two reasons: 1. Like early algebra, number sense usually relates to children's abilities with natural numbers and is rarely used in the context of other number systems; 2. Number sense and algebraic thinking share some commonalities, which are rarely related. In order to unveil continuities and discontinuities in the learning of the number concept, I will firstly elaborate on the question, whether it makes sense to

consider number sense in other number domains. Secondly, I will briefly analyze the relation between number sense and algebraic thinking.

The development of number sense is a commonly shared goal for the learning of natural numbers. It is mentioned about 50 times in the publication of the 23<sup>rd</sup> ICMI Study on whole numbers in the primary grades (Bartolini Bussi & Hua Sun, 2018). Many papers in TWG02 “Arithmetic and number systems” at CERME stress that the presented research is devoted to the development of number sense.

The very *number sense* is used to denote different concepts (Rezat & Rye Ejersbo, 2018). Number sense in the meaning that is commonly shared in the psychological community refers to a persons’ foundational innate core systems to process quantities. Verschaffel elaborated on the facets of this psychological notion of number sense in his plenary talk at CERME 10 (Verschaffel, Torbeyns, & De Smedt, 2017). In mathematics education, number sense broadly refers to “the well-organized conceptual network that enables one to relate number and operation properties and to solve number problems in flexible and creative ways” (Sowder, 1992, p. 381).

There is a fundamental difference between the two perspectives. While the psychological perspective considers children’s innate abilities, which are not subject to learning, the perspective on number sense in mathematics education relates to abilities that children can develop through learning. Sayers and Andrews (2015) integrate three different perspectives on number sense and offer a model that comprises different conceptualizations of number sense at different stages in children’s learning history. In this paper, I refer to the didactical perspective on number sense.

An aspect that has been discussed repeatedly in TWG02 at CERME related to number sense is flexible and adaptive use of strategies in mental calculation (Carvalho & da Ponte, 2013; Morais & Serrazina, 2013; Rezat & Rye Ejersbo, 2018). Flexibility and adaptiveness in mental calculation require a deep understanding of number and operation relationships and knowledge of basic facts. These are core aspects of number sense (Threlfall, 2002; Rathgeb-Schnierer & Green, 2013). Therefore, number sense is regarded as both, a prerequisite and a goal for flexible and adaptive strategy use in mental calculation (Rezat & Rye Ejersbo, 2018).

Number sense and flexible and adaptive mental calculation usually relate to children’s abilities related to natural numbers. According to the definition by McIntosh, Reys, and Reys (1992) it seems desirable to develop number sense in other number domains. In their framework of number sense, McIntosh et al. (1992) include the understanding of the effect of operations with fractions and decimals. However, flexible mental calculation and number sense have been rarely investigated in other number domains. A slightly increasing interest in these issues related to fractions is noticeable (Markovits & Pang, 2007), which was also discussed in TWG02 at CERME (e.g. Carvalho & da Ponte, 2013). In terms of mental calculation related to number sense these studies differentiate between rule-based or instrumental / procedural strategies and number-sense or conceptual strategies, which are based on equivalence, numerical relationships and properties of operations (Lemonidis, Tsakiridou, & Meliopolou, 2018; Yang, Hsu, & Huang, 2004). Reys, Reys, Nohda, & Emori (1995) and Carvalho & da Ponte (2013) find that students tend to apply rule based strategies, where students perform the formal rule mentally. On the contrary, Yang et al. (2004) show in an intervention study how students are able to develop number-sense mental calculation strategies, which are based on

equivalence, numerical relationships and properties of operations. Rezat (2011) also explored students' strategies in mental calculation tasks with integers. He also finds that students transform the problem with integers into a problem with natural numbers and determine the sign of the result separately applying a procedural and rule-based strategy for calculation with integers. Consequently, all mental calculation tasks including integers were solved referring to mental calculation strategies from the set of natural numbers.

These findings give rise to the question of the relevance of mental calculation in other number sets than the natural numbers. If mental calculation in other number sets is reduced to the mental application of the rules for calculating in these domains and by transformation to problems with natural numbers the relevance for fostering number sense has to be questioned. However, Yang et al.'s findings indicate that it is possible to foster students' number-sense based mental calculation strategies related to fractions. Further investigation of mental calculation strategies, which are associated with number sense is needed. In general, the meaning and conceptualization of number sense related to fractions and integers requires further clarification and differentiation.

I will now turn to the relation of *algebraic thinking* and *number sense*. These two constructs are rarely related. While number sense is situated in the discourse of the development of the number concept, algebraic thinking is situated in the discourse of the development of algebra. However, in the latter context, constructs such as *structure sense* (Hoch & Dreyfus, 2004, 2006) and *symbol sense* (Arcavi, 1994, 2005), which seem to relate to number sense, have been suggested. Within the scope of this article, I am not able to analyze the relationship between number sense, structure sense, and symbol sense. I can only briefly outline some similarities between number sense and algebraic thinking.

McIntosh et al. (1992) have provided a framework of generally agreed components of basic number sense, which gives an account of the richness of the construct. This framework distinguishes between three major areas of number sense: 1. Knowledge of and facility with numbers; 2. Knowledge of and facility with operations; and 3. Applying knowledge of and facility with numbers and operations to computational settings. Each of these areas is divided into several categories.

Among the categories that characterize basic number sense we find several aspects that are repeatedly used to characterize algebraic thinking. In particular, these are related to knowledge of and facility with operations. A number of studies on early algebra focuses on students understanding of operations in terms of relational thinking (Bastable & Schifter, 2008; Carpenter, Colm, & Franke, 2003; Empson, Levi, & Carpenter, 2011; Russell, Schifter, & Bastable, 2011), i.e. "using fundamental properties of number and operations to transform mathematical expressions rather than simply calculating an answer following a prescribed sequence of procedures" (Carpenter, Levi, Franke, & Zeringue, 2005). An example, Carpenter et al. (2003, p. 4) provide to illustrate relational thinking is Robin's solution of the open number sentence  $18 + 27 = [ ] + 29$ : "29 is two more than twenty 27, so the number in the box has to be two less than 18 to make the two sides equal. So it's 16". This way of applying associativity in this context is exactly what would be expected from a child, who exhibits number sense.

Due to the similarities of number sense and algebraic thinking in terms of relational thinking, Pittalis, Pitta-Pantazi, and Christou (2016, 2018) argue that number sense has an innate algebraic dimension.

They have empirically validated a model of the structure and development of basic number sense by incorporating an algebraic dimension, which refers to algebraic arithmetic and quantitative relations. In their study, they validate their model, in which number sense is conceptualized as a second order theoretical construct made up of three first order latent factors, namely (a) elementary number sense, (b) conventional arithmetic, and (c) algebraic arithmetic.

This is a first and important step in understanding the relationship between number sense and algebraic thinking. Further research needs to deepen this understanding by also taking constructs like structure sense and symbol sense and their relation to number sense into consideration.

## Conclusions

I have focused on the relationship between the extension from natural numbers to integers and the transition from arithmetic to algebra. From an epistemological perspective on this transition, I have shown that the development of the negative number concept is closely linked to core algebraic ideas, such as indeterminate objects and their analytic treatment, reification and objectification, and a detachment from content meanings in order to proceed to a formalized view.

The psychological analysis showed that the same obstacles characterize students' learning of the negative number concept regardless of their prior knowledge and their prior experiences in the set of natural numbers. So far, the effects of early algebra on students' understanding of negative numbers has not been investigated.

The analysis from the pedagogical perspective has shown that two important goals related to the learning of natural numbers, namely the development of algebraic thinking and the development of number sense, are rarely considered in the domain of integers. I presented a few didactical models that have been suggested in the research literature in order to align the learning of integers and the development of algebraic thinking. However, the alignment seems to be quite loose so far and is rarely developed into coherent learning trajectories for the learning of integers. An analysis of didactic models of negative numbers and their potential to foster algebraic thinking in textbooks might complement the analysis and draw a more comprehensive picture.

In the introduction, I mentioned that the extension of number systems and the transition from arithmetic to algebra are two long-term developments that require a careful construction of the curriculum and related learning-trajectories. Many scholars stress the importance of curricular coherence in the construction and implementation of curricula in general (Confrey, Gianopulos, McGowan, Shah, & Belcher, 2017) and in particular related to goals of the number curriculum (Bruno & Martinon, 1999; Van den Heuvel-Panhuizen, 2008). Curricular coherence is defined differently according to the principles that are used in order to provide it (Confrey et al., 2017). While, for example, Bruner (1960) and Schmidt, Wang, and McKnight (2005) refer to the structure of the discipline as the means to provide curricular coherence, Confrey et al. (2017) argue for learner-centered curricular coherence, which they define as

an organizational means to promote a high likelihood that each learner traverses one of many possible paths to understanding target disciplinary ideas. The goal is that students achieve demonstrable and justifiable proficiency in the meanings, relationships, and utility of those target

ideas by building on and continuously broadening and modifying their ideas and experiences. (p. 719)

Looking at the curriculum in terms of the extension of number systems and the transition from arithmetic to algebra yields that there is a close relation of arithmetic and algebraic thinking in the set of natural numbers. However, this close alignment does not seem to be coherently continued in the extension of number systems. Further development of algebraic thinking in the domain of integers (and also in the domain of fractions) seems to be almost suspended. In terms of curricular coherence, it could be important for the learning of the negative number concept and for the learning of algebra to continuously foster algebraic thinking throughout the extension of number systems. Continuously unfolding number sense aligned with algebraic thinking throughout the extension of number systems might also be a means to provide continuity in a content domain where students' experience of discontinuity has been substantiated by a large body of research.

The general aim of the panel was to offer a reflection on the genesis and the contribution of the European Society for Research in Mathematics Education (ERME) to research in mathematics education, regarding its past, present and future. After a short introduction, the panel focused on three topics: The ERME society, presenting a historical and present view; YERME and YESS, highlighting history and current developments related to supporting young researchers; the ERME book, focusing on its evolution, spirit and results. Each topic started with an input by two panel members who also answered questions by participants of CERME 11 sent in advance or raised during the panel. The panel was concluded by the president and the two co-chairs of the panel.

*Keywords: Europe, mathematics education, collaboration, cooperation, communication, quality, inclusion, promoting young researchers*

### 1 Introduction (Hanna Palmer and Konrad Krainer)

An important step for establishing a European Society for Research in Mathematics Education (ERME) was done in a meeting in Osnabrück (Germany) from 2 to 4 May 1997. Representatives from 16 European countries met in Haus Ohrbeck (Figures 1 and 2). The aim was to establish a new society, ERME, that promotes communication, cooperation and collaboration in mathematics education research in Europe. It was also decided that ERME will launch periodical conferences (CERME). At CERME 1, again held in Osnabrück, from 27-30 August 1998 (coordinated by Elmar Cohors-Fresenborg and Inge Schwank), the foundation of ERME took place. In 1999, the three volumes of the first CERME proceedings were published (Schwank 1999a,b; Krainer, Goffree & Berger, 1999). In 2018, the ERME book (Dreyfus, Artigue, Potari, Prediger & Ruthven, 2018) appeared on the occasion of the 20<sup>th</sup> birthday of ERME. The ERME anniversary panel was held during CERME 11 in Utrecht (The Netherlands) in the Dom Church (Figure 3) on February 2019.

**Figure 1 (E. Thoma):**  
Haus Ohrbeck, Osnabrück

**Figure 2 (private photo):**  
Elmar Cohors-Fresenborg, Host

**Figure 3 (free photo):**  
Dom Church, Utrecht

In preparation for the panel, the community was asked to send questions about ERME research, questions about ERME itself (its role, its possible activities ...) and to share memories on ERME (anecdotes, narratives, pictures ...) by using twitter or mail (Figure 4). The aim with this was to make the panel as dynamic as possible with discussions between speakers, high-level scientific content mixed with narratives and anecdotes about CERME experiences.

**Figure 4 (H. Palmér): Examples of pre-sent tweets**

Some of the anecdotes included memories from those who had participated at almost every CERME. During the introduction of the panel, those who had participated at the first CERME in Osnabrück, 1998, were asked to stand up and there were actually about 12 people. In many anecdotes, CERME was described as a conference where people met others and became friends and research colleagues. Through the years there has been a substantial number of research collaborations initiated at CERME. Many people first visited CERME during their PhD and valued the welcoming atmosphere with its dynamic mix of experienced researchers and newcomers.

After a short introduction, the panel focused on three topics: The ERME society, presenting a historical and present view; YERME and YESS, highlighting history and current developments related to supporting young researchers; the ERME book, focusing on its evolution, spirit and results. Answers to present questions were addressed in the pre-prepared presentations of the panel speakers and further questions were provided by the audience at the conference.

In the following, we elaborate on these three topics (for a summary of relevant data about ERME see also Section 10).

**Figure 5 (personal photos): The first board members of ERME - Paolo Boero, Marianna Bosch, Elmar Cohors-Fresenborg, Jean-Philippe Drouhard, Konrad Krainer, Jarmila Novotná, João Pedro da Ponte, Leo Rogers and Julianna Szendrei (see details in Section 10)**

## 2 The ERME society: A historical view (Barbara Jaworski)

Probably the first thing to say in the history of ERME is that ERME is an AMAZING success story! From early times to the present it has proved attractive to researchers throughout Europe and beyond and it has blossomed and grown.

The very first meeting in Osnabrück, in 1997, set the scene for what has followed, and the conceptualizations emerging from that meeting have been established and faithfully preserved while simultaneously developing in scale and extent.

In response to an open invitation by German colleagues, representatives from 16 European countries discussed what a European society might involve. We saw here democracy in action as the delegates from across Europe presented their ideas and debated possibilities. Clearly, we were focusing on research in Mathematics Education – our name would be ERME – European Society for Research in Mathematics Education. We wanted there to be a conference, every two years, and we wanted very strongly to support new researchers who should be the future of our society.

There was much debate about the nature of the conference. We already had a range of conferences in our community – particularly PME and ICME – the ERME conference should be different with a more European identity. We wanted a research conference, to be called CERME – Conference of ERME – to enable the sharing, understanding and working together of/on research in mathematics education: three principles emerged

- Communication with our colleagues throughout Europe
- Cooperation in and around research topics
- Collaboration in designing and doing research together

These principles quickly became known as “The Three Cs” and “The CERME Spirit”: they were the foundation on which our community was based and on which our conference developed. The conference should enable participants really to *work* on areas of research, forming research groups, with a significant amount of time to communicate their research and develop cooperative and collaborative relationships. Also, ERME should provide a means of educating and supporting young researchers and research students – bringing young researchers centrally into the community.

In the early years of ERME, an ERME board was initiated to guide developments in ERME, and the conference, CERME, was introduced to take place every two years. For young researchers in ERME, the YERME group was initiated.

The first CERME took place appropriately in the same location as our founding meeting, in Haus Ohrbeck in Osnabrück (Germany). There were around 50 participants and just seven working groups – the groups would have 12 hours for their work over the days of the conference. It was a time of getting used to this new kind of conference environment.

At the beginning of this first conference, a well-known researcher asked “what are we going to do with 12 hours? How are we going to use all this time?” At the end of the conference, she said “I am amazed. The time just disappeared as we discussed our work and debated issues in research.” It was clear that we were learning in practice about possibilities and ways of working; trying out ideas and developing (or rejecting) them in practice.

Thus, CERME was planned as a different kind of conference (from PME, ICME and others). It became a working conference with small working groups in research areas led by ‘experts’ in the field (at least 12 hours). It should be open and inclusive to all researchers in the field. It should have published proceedings of high scientific quality. There should be quality support for, and education of research students, with a dedicated day before each conference.

The importance placed on educating research students led to the provision of summer schools in years alternating with CERME. These were led by ‘experts’ in key research areas (The YESS – YERME Summer Schools) and should be open, inclusive and encouraging full participation.

Key words in planning and development were *Quality* and *Inclusion*. Principles of openness and inclusion permeated principles and practice. ALL researchers in mathematics education (from anywhere in the world) should be welcome participants – no barriers to inclusion. The working language would be English – but sincere attempts should be made to include other languages where necessary. There should be principles of high quality in scientific exchange and publication. Group leaders should ensure the highest quality of academic engagement and publication.

These principles led to issues and questions relating to practices in the working groups regarding quality and inclusion,

- Should ALL papers submitted to a group be accepted? Do principles of inclusion require this?
- What if papers are not of a sufficiently high standard? How can group leaders ensure that what is published is of the high quality we seek?

By the time of CERME 6 in Lyon, France, these issues had become central and potent. Thus, a small group from within the initiating team were tasked by the ERME board to do some research to establish the views of CERME participants. A survey was designed and conducted, and interviews were held with CERME participants. The results of this analysis exposed a wide range of views and highlighted the main issues (see Jaworski, da Ponte & Mariotti, 2011). Clearly the majority wanted to maintain both quality and inclusion, but practical suggestions were made as to how this could be possible. It became practice that most papers submitted for presentation would be accepted to include as many researchers as possible, but there would be additional reviews after the conference through which only papers of high quality would be selected for published proceedings. As CERME has grown in size beyond these early conferences, it has become necessary to review how quality and inclusion can continue to be maintained in practice.

### 3 The ERME society: A present view (Susanne Prediger)

20 years after the founding of ERME, we can be very happy that ERME has succeeded in establishing the three C's:

- *Communication* is consequently established in the Thematic Working Groups due to the great work of the TWG leaders and co-leaders. Even in a conference with 26 TWGs (and 8 subgroups), communication was guaranteed by the rule of “30 minutes per contribution”. Additionally, we extended the opportunities for communication by ERME Topic Conferences (ETC, see Section 10), six of them have already taken place.
- *Collaboration* was initiated and is evidenced by many joint publications among ERME members (see overview in Dreyfus et al., 2018). However, we feel that collaboration can still be fostered more.
- also *Cooperation* takes place in more stable contexts, for example in joint research and PD projects (funded by EU Horizon 2020 or Erasmus or bilateral foundations such as the German-Israeli foundation). For further deepening also the institutionalized cooperation across European countries, initiating collaboration and following it up is crucial, for the future.

Within the last twenty years, the ERME policy of inclusion and quality has successfully been installed, especially the TWG leaders and co-leaders do an enormous job in enhancing quality. During these years, inclusion has been interpreted as allowing all interested people to participate. However, ERME has not yet achieved to include all European countries, as we still have regional unbalances and emerging communities which are not yet present at the conference.

At the same time, CERME has experienced a massive growth, from 550 participants in 2013 to more than 900 in 2019 (see Figure 7). This success shows that the founders' choice to design CERME as a „thematic working space" (with the possibility of improving submitted texts before and after the conference) is very appreciated, not only in Europe, but also within the world community of mathematics educators. Among the 900 participants at CERME 11, 150 came from other continents. Thus, the founders' idea of offering CCC opportunities to researchers has been successfully spread to other continents, with the possibility of enriching exchanges. On the one hand, we can celebrate this as a huge success that more and more researchers from all over the world are interested in participating in the conference. However, *CERME's success is ERME's challenge*, as the growth of the conferences endangers both, quality and inclusion. That is why the ERME board has taken the decision that eternal growth is not desirable, and 900 participants is the maximum we can take. For the next conference, the ERME board and the IPC will develop new review procedures for selecting papers.

**Figure 7: Increasing number of participants for the last conferences**

This new situation requires a new interpretation of inclusion in the ERME policy: We must overcome a mainly *quantitative* interpretation of inclusion (as allowing every interested person to participate). Instead, the future inclusion strategies will focus on the heterogeneity of participants and develop approaches for supporting underrepresented groups for finding new balances

- between novices and experts
- between countries
- between well-established communities and newly emerging communities.

At the same time, we will enhance the interpretation of quality: In the future we will not only work on quality of individual contributions, but also on enhancing the three C's. Especially, we will search for new ways of supporting collaboration and cooperation across countries and research groups.

#### 4 YERME and YESS: A historical view (Paolo Boero)

**YESS 1 at Klagenfurt in 2002 was my first international experience in math education, I have visited it as postdoc and immediately found my international family.**

**Figure 8 (H. Palmér): Example of pre-sent tweet**

This spontaneous contribution to our panel from an ERME member well represents the “YESS spirit” and its aims, and more generally the orientation of all the ERME initiatives (YESS, YERME, the YERME day) addressed to people who enter the domain of research in mathematics education.

From the very beginning, one of the main ERME goals was to create a community of young researchers, who might grow up as EUROPEAN researchers in the WORLD context, each of them bringing the richness of her cultural, educational and research traditions, to be acknowledged as relevant contributions by the colleagues, each of them being willing (and able!) to Communicate, Collaborate and Cooperate with the other EUROPEAN and WORLD researchers. This goal was coherent with the general perspective, according to which ERME was founded (the “CCC spirit”). At CERME 2 in Mariánské Lázně, a meeting of young researchers was initiated where 22 of them

(mostly PhD students) and six senior researchers met in order to discuss young researchers' recent situation and to allocate suggestions to improve the situation. Finally, the young researchers were invited to meet as a group during the conference and to formulate their ideas and needs. A subgroup (Michele Cerulli, Petra Frantova and Jukka Törnroos, supported by Konrad Krainer) met, negotiated essential basic points and finally presented them at a plenary discussion at the end of the conference. For example, it was fixed that the group of young researchers was named YERME, that it will have three contact persons and will produce a contact list. It was recommended that, in the future, CERMEs could have a young researchers' day; in addition, a summer school (with workshops and feedback sessions) was proposed. In both cases, young researchers offered to be active in programme committees. Based on these suggestions, the ERME board started to design a summer school for young researchers (later named YESS) to be held every two years (starting 2002) and to start each CERME with a YERME day (starting 2005, formally decided 2003 at CERME 3).

### **YESS 1 and its design**

The first summer school was planned in a meeting held in Klagenfurt in June, 2001 (see reports by Borromeo Ferri, Roth & Reinhold, 2002; Krainer, 2003). Two representatives of YERME were there, together with three members of the ERME board and three members of the University of Klagenfurt (which offered to host the first summer school). The design of the summer school was based on the following guidelines:

- The Working Group (WG) structure as the main feature of the summer school, and the request to all WG participants to prepare a written contribution related to the advancement of their research projects. These choices were coherent with the original planning of CERME, based on thematic WGs. A common theme would have allowed WG participants to better share experiences, readings, method and content choices. The request of a 4-6 pages summary on the personal stage of PhD studies (be it initial, or near to the conclusion, or even post-doc) was conceived with three aims: To favor a personal balance of the acquisitions and the needs, in the perspective of sharing them with the other participants; to let participants know in advance the interests and research orientations of the other WG members; to let the expert in charge of the WG prepare suggestions, references, etc. for each member, and plan the WG sessions, in order to tackle common or near problems/topics in each session.
- The role of the "expert" in each WG: Strong expertise in research and in the supervising of newcomers in the field was necessary. But it was not sufficient. An expert had not to be conceived as PhD super-supervisor! She had to play another, complex role: To provide the newcomers in the field with the opportunity of communicating their projects, preliminary results, needs in a CCC climate; to favor productive exchanges between participants; to provide them with "method" and "content" helps and suggestions (according to her research experience); to ensure a pluralistic vision on theoretical and method choices.

### **YESS, YERME and the YERME day**

The interactions between experts, organizers and students in YESS 1 (2002) allowed the ERME board to better focus (and take precise decisions) on two kinds of needs, that had already been considered in more generic terms in the previous years:

- There was a challenge to create and prepare discussion spaces, within YESS and in the occasion of ERME conferences, where participants with interests in different areas of mathematics education could meet together and with experts to deal with topics related to the level of advancement of their PhD studies (e.g. how to choose and read a research paper? How to choose and formulate a research problem and the related research questions? What about the theoretical framework? How to choose a research methodology to deal with the research questions? How to write a research paper? Etc). This need brought to plan in advance Discussion Group sessions within YESS (in order to share the task of better coordinating and supporting them among the experts and the more experienced members of the programme committee); and to implement the idea of the YERME day (it was finally decided that it should consist of two half days of work for young participants in CERME, before the starting of CERME). The first official initiative involving young researchers took place in CERME 3 (2003) as a YERME meeting within the conference; the name YERME day was adopted for the two half days that preceded CERME 4 (2005) and all the subsequent CERMEs. In the two cases (YESS Discussion Groups and YERME day before CERME), the aim is to provide participants with occasions for dealing in depth, with the support of experts, on subjects (like those listed above, gradually made more precise and specific in the programme of subsequent summer schools) of common interest in each stage of the development of PhD studies and research projects. New formats will be found for the future, for example, the ERME Topic Conferences (ETC) can be opened with a YERME day, for discussing individual projects or a survey of the topic at stake, available before an ETC, as an introduction to the conference.
- There was a constant work on further developing YERME, with its autonomy, its tasks related to YESS and the YERME day, and also to CCC specificity for young researchers and to career needs (e.g. information on research jobs opportunities). During YESS, two time slots are dedicated to special Discussion Groups organized and led by the YERME representatives within the programme committee. The discussions concern the participants' challenges as PhD students, as participants in YESS, and their perspectives as regards the post-doc employments. During the YERME day, a special event is the plenary speech of a young researcher who recently entered a research career. She presents an account of the problems met by her during her PhD studies, of how she tackled them, and of how she succeeded in finding an employment opportunity after her PhD.
- At CERME 7 (2011), the ERME general assembly decided to strengthen the YERME voice in the ERME policy making. The ERME byelaws were modified to include two YERME representatives for four years, each from CERME 8 (2013) on.

## Conclusion

The increased number of applicants to YESS (from 47, almost all from Europe, in the case of YESS 1, to more than 110, including those from America, Africa and Asia in the case of YESS 5, to 136 in the case of YESS 9 – always with candidates from other continents) encouraged the organizers to maintain and strengthen the original features of YESS. The number of WGs was increased from five in YESS 1 to six; the accepted participants have been 72 in the last editions, and will be 84 in YESS 10. In particular, participation of students from other continents is considered as an added value for

YESS (the same as for ERME!). Indeed the participation of young researchers from other research traditions, and with different cultural needs, was, is and will be an occasion for putting into practice the original reason for the existence of ERME (and YESS as well): A community of researchers, based on the positive evaluation of the rich European diversity, and coherently open to the constructive dialogue with other diversities in the CCC spirit.

**Figure 9 (personal photos): Some mentors of YERME - Paolo Boero, Konrad Krainer, Dina Tirosh, João Pedro da Ponte and Viviane Durand-Guerrier**

### **5 YERME and YESS: A young researcher's view** (Simon Modeste)

As a young researcher and a participant in CERME, YERME and YESS events, I would like to describe my trajectory, as a testimony for this panel and illustrating the previous section.

My first contact with ERME and the YERME group was in CERME 7 in 2011. I was in the topic group on “Proof and argumentation”. Looking at the “famous” names in the participants of the group (Paolo Boero was one of them), I was quite intimidated. I think this is the case for many young researchers before their first CERME. Fortunately, I had the opportunity to participate in the YERME day. This day, before the conference, is very important for newcomers. It allows young researchers to meet together, as a small group, to discuss, start knowing each other, share experiences and benefit from experts’ workshops. Paolo Boero was one of the experts (for many generations of young researchers, Paolo is associated to YERME activities) and I attended his “famous” workshop on writing articles, where he makes you analyse and criticize one of his first articles. This is YERME spirit, and contributes to make you more comfortable as a young researcher in the community. Another important thing is that YERME day is oriented towards stimulating communication (in particular regarding the language issue for non-native English speakers). After the YERME day, you can join the conference and the working groups with much less stress. You meet known faces from the YERME day during the conference and can share experiences from the various groups. You have the feeling that you are part of the group of the European young researchers in mathematics education.

In 2012, I participated in YESS 6 in Faro (Portugal). It was six months before my PhD defence, and my dissertation was not written yet. I was very stressed, and meeting with other young researchers, benefiting from the pieces of advice from the expert of my workgroup, sharing experiences during the Discussion Groups have been very comforting and motivating. And I went back to work on my PhD with more energy.

Participating in YESS is sharing a week with young researchers and experts from ERME, where you feel like cut off from the rest of the world, focused on scientific activities. This is very pleasant and it is a luxury in a young researcher's life. The truth is that I don't know any event for young researchers which would be equivalent to YESS.

I also want to write briefly about the network of YERME. It is through this network that I was aware of post-doc positions and got the opportunity to be a post-doc researcher in another country. This permitted me to discover another school system, and another research culture. It brought me an international experience. I think that this is exactly the kind of opportunities that YERME wants to foster, by promoting international collaborations.

In 2018, I had the possibility to contribute to YERME activities, by organizing YESS 9. I was very proud to organize it after my rich experience from YESS 6. In collaboration with the ERME board and the scientific committee, I tried to base on this experience as a young researcher in the ERME community, to implement an organization that stimulates the interactions between young researchers. During the summer school, I have seen the group bonded, and the YERME community has strengthened during the week.

At YESS 9 in Montpellier, we had 136 applications for 72 places (6 working groups of 12), experts from different parts of Europe. The participants came from many countries in the world, representing all continents (of course, the majority from Europe). Figure 10 shows the whole group of participants at YESS 9.

**Figure 10 (S. Modeste): Participants of YESS 9, Montpellier**

Finally, I would like to summarize some important aspects of YESS, YERME and YERME day, and to add some new information (<http://www.mathematik.uni-dortmund.de/~erme/>). Essentially, YERME activities comprise two main events, each recurring every two years: The YERME day, and the YERME summer school (YESS). Each YESS has a programme committee, which consists of a scientific coordinator, two ERME Board representatives, three YERME representatives, two representatives from local organizers. Up to now, ERME has organized 9 YESS, the tenth is already fixed (see Section 10). Other YERME activities comprise participation in the ERME board and communication about YERME and relevant activities for young researchers. Two young researchers have seats in the board of ERME to represent the interest of YERME. Recently, these members are Dorota Lembrér, Norway (term ends in 2023) and Andrea Maffia, Italy (term ends in 2021). YERME is active on social media, in particular Facebook and Twitter. The official Facebook page for YERME is: <https://www.facebook.com/YoungResearchersERME>, a Twitter account with the same information can be found at <https://twitter.com/YERMEeurope>.

## 6 ERME book: Evolution, spirit and results (Tommy Dreyfus)

Upon the initiative of João Pedro da Ponte, the ERME board and its president Viviane Durand-Guerrier (Figure 11) decided that ERME should, on the occasion of its 20<sup>th</sup> anniversary, publish a book presenting ERME to mathematics educators world-wide.

**Figure 11 (personal photos): The initiators - João Pedro da Ponte, Viviane Durand-Guerrier and the 2015 Board**

The board named Tommy Dreyfus, Michèle Artigue, Despina Potari, Susanne Prediger and Kenneth Ruthven as editors (Figure 12), with Tommy as coordinating editor and Susanne as liaison person to the ERME board.

**Figure 12 (personal photos): The editors - Tommy Dreyfus, Michèle Artigue, Despina Potari, Susanne Prediger and Kenneth Ruthven**

The editors met in September 2015, and decided that the aim of the book shall be to present the most important directions, developments and trends of European Research in Mathematics Education in a highly readable text. Hence the book shall report on the main lines of development in ERME in the course of the past 20 years, showing the spirit of communication, cooperation, collaboration in the process;

- showcase past and current European research for audiences inside and outside Europe;
- and establish shared understandings in which to ground future European research in mathematics education.

Since the scientific interaction in ERME happens in the TWGs, a book structure was designed with an introduction by the presidents of ERME, 18 core chapters reflecting the work of the TWGs, and commentaries by two eminent scholars from outside Europe, Marcelo Borba and Norma Presmeg (Figure 13).

**Figure 13 (personal photos): The commentary chapter authors - Marcelo Borba and Norma Presmeg**

The editors chose a writing team for each chapter from among the leaders of the relevant TWGs – overall more than 60 authors contributed. It is notable that every single person who was asked accepted to contribute, and that the writing teams were very responsive to our editorial suggestions. They were also exemplary in keeping the schedule; this was especially crucial toward CERME 10, where the chapters were discussed in the relevant TWGs, so that the process of writing the book was a paradigmatic case of CCC.

The work on the book, and the commentary chapters in particular, raised some general comments and questions about ERME and research within ERME. A few of them will be raised here.

Borba, in his commentary, describes the dynamics of the creation, life and, in some cases disappearance of TWGs in ERME as a response to crises, for example crises in algebra learning and teaching, the integration of technology in classroom, or the low presence of modeling in school mathematics. He observed that some themes like the philosophy of mathematics education, distance education, and assessment were not or under-represented at CERMEs. While in the case of distance education, this may be due to the geographical nature of Europe, and in the case of assessment a TWG has recently been created, there does not seem to be an obvious reason for the absence of the philosophy of mathematics education.

A striking and possibly typically European phenomenon is that all 18 core chapters relate to theories or models. This begs the question whether the theoretical work of each TWG feeds back to the crisis Borba sees at the origin of the TWG? And it has led Presmeg to ask, in her commentary, whether ERME makes an effort to link the work of different TWGs, and whether theories can possibly serve to link the work of different TWGs, for example if one TWG attempts to understand what other TWGs mean by theory.

Presmeg also noted that the CCC spirit may support such links: Theories are designed in a specific context; they express particular world-views. A common research agenda, on the other hand, implies spelling out research paradigms, theories and methodologies, and therefore requires one to suspend or step outside of one's "natural" attitude (or habits). Work in ERME thus led researchers to use different theories as complementary lenses that provide alternative views of the same phenomenon. But it led far beyond this: A paradigmatic case of CCC with respect to theories was realized within ERME: The theory TWG was initiated at CERME 5; at a serendipitous meeting on the last day of the conference, a group of members of this TWG decided to further explore the issue of connections between theories – a case of *communication*. That group has then *cooperated* over 8 years, at CERME conferences and elsewhere; they developed *collaboration* on four case studies of links between theories, links of different kinds and strengths; and a book resulted from their efforts (Bikner-Ahsbahs & Prediger, 2015). This book would have fit very well into a book series under ERME's auspices.

Finally, is ERME international? And in what ways does ERME offer a distinctly “European” perspective on research in mathematics education? While there is no definitive answer to this, international participation at CERME grows from conference to conference; on the other hand, some specifically European aspects of work within ERME have been pointed out in the previous paragraphs; in particular, research traditions that have grown nationally have undergone a process of networking. ERME presents a healthy tension between national, European and international contributions.

The ERME book titled *Developing Research in Mathematics Education: Twenty Years of Communication, Cooperation and Collaboration in Europe* (Figure 14) appeared with Routledge (a division of Taylor and Francis) in 2018, on ERME’s 20th anniversary. In parallel to the creation of the book, the ERME board has decided to launch an ERME book series (e.g. including volumes initiated by researchers at ERME topic conferences). Hence, the “ERME book” has become the inaugural volume of the ERME book series.

Figure 14: The ERME book

Figure 15 (H. Palmér): Example of pre-sent tweet

The editors hope that the book shows readers from Europe and beyond how research in ERME has developed, that book chapters are useful to introduce young researchers to areas active in ERME, that the ways in which ERME promotes research through CCC emerge, and that the book will serve as a close companion to each ERME member in their research. The tweet in Figure 15 is a small indication that these hopes are at least to some extent realistic.

## 7 ERME book: A young researcher’s view (Jana Žalská)

The ERME book “Developing research in mathematics education” will serve as an enriching volume to any researcher in the field of mathematics education. As a young researcher and a participant in CERME, YERME and YESS events, I appreciated especially its value in providing the valuable sense of context (historical, geographical and cultural), and of the organic and dynamic aspects of the field’s epistemic development.

### Making sense of the context

The introductory chapter of the book helps to situate ERME’s endeavors in research, introducing the roots and development of ERME, and explaining not only its guiding values and principles but also the rationale behind them.

Secondly, the core chapters provide overviews on specific areas of research, so they might establish a context for a research question we may pursue. The texts often refer to the geographical (national) context of particular research developments in specific areas of mathematics education, use and developments of concepts and theoretical frameworks etc.

Thirdly, reading about comparable contexts gives us a notion of our own local (e.g., national) context, even when not specifically mentioned through the chapters. It may be an essential contribution to understanding, identifying and describing our own local educational and research context in a similar way.

All of the above contextual notions are vital in determining the direction we envision in participating in the research endeavors within ERME. At the same time, the two commentary chapters bring the activities and principles of ERME under a broader lens, that is to say, zooming out on the bigger picture and reminding us of its current limits and shape.

### **Organic growth and inclusiveness**

The sense of organic growth of the body of knowledge in the community permeates each of the book's content chapters. Finally, Chapter 20 reassures us that striving for "unity in diversity" (Dreyfus et al., 2018, p. 285) is attainable through such an endeavor. For me as a young researcher, this means encouragement in the belief that my own research matters, and the confidence that I, too, am part of this process.

Finally, this book has succeeded in making a significant step toward molding further an identity of a unique community. The book's strong emphasis on reflection and the process of convergent thinking is a tremendous effort of this community to understand itself as much as to understand its subject of research.

## **8 Conclusion and further directions (Susanne Prediger)**

The discussion was insightful and provided hints to promising future activities of ERME in all areas of work, initiating communication, collaboration and cooperation, promoting young researchers, strengthening the visibility of European mathematics education research and increasing inclusion by supporting underrepresented countries. We will think about

- how to keep all the good traditions that were praised by so many members
- how to enhance the CERME programme structure for initiating collaboration
- how to strengthen the three C's between conferences
- how to engage young researchers in the work of the TWGs and to
- elaborate our contacts to mathematicians
- especially, we will explore how to support mathematicians to enter the field of mathematics education research.

Future directions might be as listed in Figure 16.

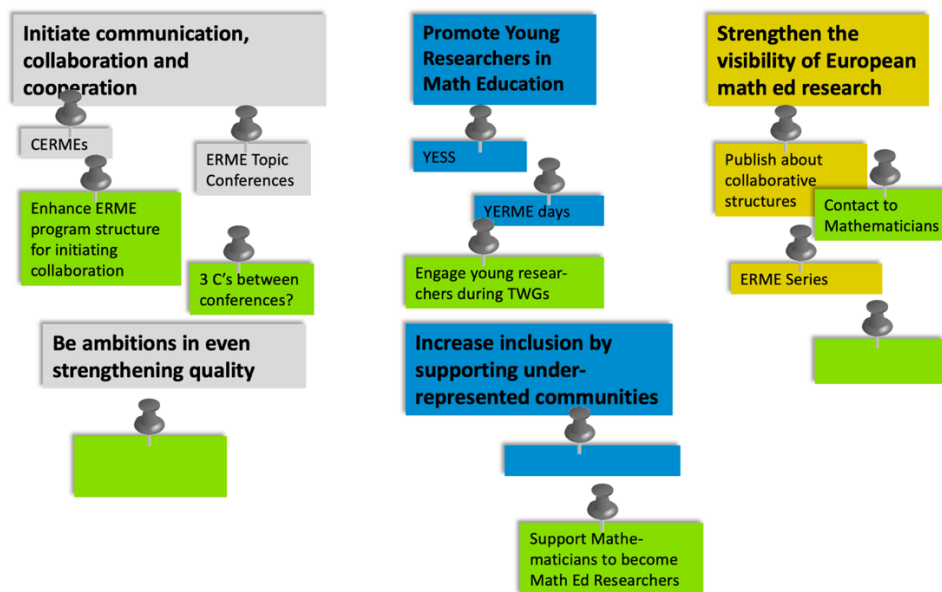

Figure 16: Future directions for ERME work (S. Prediger's final slide from the panel)

## 9 Resume (Hanna Palmér and Konrad Krainer)

The panel was ended as it started, by concluding that ERME, CERME and YERME are AMAZING success stories. Through these events the community share, work on and develop research in mathematics education. Thus, the initial three C's have been kept,

- Communication *with our colleagues throughout Europe, but also beyond*
- Cooperation *in and around research topics*
- Collaboration *in designing and doing research together*

This fantastic history is presented in all CERME proceedings and also in the ERME book. During the panel a new C was introduced – Challenge. The challenges raised were connected to inclusion, quality, regional unbalances, emerging communities and, maybe also the initiative to use twitter to increase the dynamics of the panel. However, it was concluded that challenges only become obstacles if we bow to them.

The success of ERME, YERME, CERME and its publications has many fathers, mothers, sisters, brothers, friends, etc. A whole network of engaged people and organizations is needed.

The most important people are the participants, YOU! In addition, we need people who take responsibility for working groups, thematic conferences or a CERME itself. Without group leaders, subgroup leaders, IPCs and LOCs, a society cannot live. The young people will shape the future, all others need to take actions that they can do that! Without a strong YERME, we don't will have a good future. A society needs relevant others, like our home institutions like universities, and sponsors etc.; but we need institutional friends like ICMI, PME and other organizations. This means to enact the CCC spirit not only on the individual level, but also on an organizational level.

And of course, we need people who take responsibility for the whole, for ERME as a scientific society. The board has both, the task to live our goals, but also to further develop it, in continuous negotiation with its members.

Having observed the development of ERME from the very beginning, we feel that we can hopefully look into the future! All of you have contributed to the success!

## 10 Some relevant data about the ERME society (Konrad Krainer and Susanne Prediger)

A variety of background information about ERME can be found at <http://www.mathematik.uni-dortmund.de/~erme/> (ERME, 2019). In the following, some relevant data are presented:

### ERME conferences (for proceedings see ERME website)

- CERME 1 in Osnabrück, Germany (1998)
- CERME 2 in Mariánské Lázně, Czech Republic (2001)
- CERME 3 in Bellaria, Italy (2003)
- CERME 4 in Sant Feliu de Guíxols, Spain (2005)
- CERME 5 in Larnaca, Cyprus (2007)
- CERME 6 in Lyon, France (2009)
- CERME 7 in Rzeszow, Poland (2011)
- CERME 8 in Antalya, Turkey (2013)
- CERME 9 in Prague, Czech Republic (2015)
- CERME 10 in Dublin, Ireland (2017)
- CERME 11 in Utrecht, The Netherlands (2019)
- CERME 12 will take place in Bolzano, Italy (2021)

### YERME summer schools

- YESS 1 in Klagenfurt, Austria (2002)
- YESS 2 in Poděbrady, Czech Republic (2004)
- YESS 3 in Jyväskylä, Finland (2006)
- YESS 4 in Trabzon, Turkey (2008)
- YESS 5 in Palermo, Italy (2010)
- YESS 6 in Faro, Portugal (2012)
- YESS 7 in Kassel, Germany (2014)
- YESS 8 in Poděbrady, Czech Republic (2016)
- YESS 9 in Montpellier, France (2018)
- YESS 10 on Rhodes, Greece (2020)

### ERME topic conferences

- ETC 1 on Anthropological Theory of the Didactic in Castro-Urdiales, Spain (2016)
- ETC 2 on University Mathematics Education in Montpellier, France (2016)
- ETC 3 on Mathematics Teacher Education in Berlin, Germany (2016)
- ETC 4 on Mathematics and Language in Dresden, Germany (2018)
- ETC 5 on Mathematics Education in the Digital Age in Copenhagen, Denmark (2018)
- ETC 6 on University Mathematics Education in Kristiansand, Norway (2018)
- ETC 7 on Language in the Mathematics Classroom in Montpellier, France (2020)
- ETC 8 on University Mathematics in Bizerte, Tunisia (2020)
- ETC 9 on Arithmetic and Number systems in Leeds, United Kingdom (2020)
- ETC 10 on Mathematics Education in the Digital Age in Linz, Austria (2020)

## ERME book series

- Volume 1: Dreyfus, Tommy, Artigue, Michèle, Potari, Despina, Prediger, Susanne & Ruthven, Kenneth (Eds.). (2018). *Developing Research in Mathematics Education: Twenty Years of Communication, Cooperation and Collaboration in Europe*. London: Routledge.
- Volume 2: Bosch, Marianna, Chevallard, Yves, García, Francisco Javier & Monaghan, John (Eds.). (2020). *Working with the Anthropological Theory of the Didactic in Mathematics Education: A Comprehensive Casebook*. London: Routledge.
- Volume 3: Zehetmeier, Stefan, Ribeiro, Miguel & Potari, Despina (Eds., in prep.). *Mathematics Teaching, Resources and Teacher Professional Development*. London: Routledge.
- Volume 4: Durand-Guerrier, Viviane, Hochmuth, Reinhard, Nardi, Elena & Winsløw, Carl (Eds., in prep.): *Research and Development on University Mathematics Education* (preliminary title). London: Routledge.
- Volume 5: Planas, Nuria, Schütte, Marcus & Morgan, Candia (Eds., in prep.): *Classroom Research on Mathematics and Language*. London: Routledge.
- Volume 6: Clark-Wilson, Alison, Donevska-Todorova, Ana, Fagiano, Eleonora, Trgalova, Jana & Weigand, Hans-Georg (Eds., in prep.): *Mathematics Education in the Digital Age: Learning, Practice and Theory*. London: Routledge.

The ERME book series editors are Viviane Durand Guerrier, Konrad Krainer, Susanne Prediger and Nad'a Vondrova.

## The first ERME board members

- 1998-2005 Paolo Boero (Italy)
- 1998-2005 Marianna Bosch (Spain)
- 1998-2005 Elmar Cohors-Fresenborg (Germany)
- 1998-2001 Jean-Philippe Drouhard (France)
- 1998-2003 Konrad Krainer (Austria)
- 1998-2003 Jarmila Novotná (Czech Republic)
- 1998-2001 João Pedro da Ponte (Portugal)
- 1998-2001 Leo Rogers (United Kingdom)
- 1998-2003 Julianna Szendrei (Hungary)

## ERME presidents

- 1997-2001 Jean-Philippe Drouhard (France)
- 2001-2005 Paolo Boero (Italy)
- 2005-2009 Barbara Jaworski (United Kingdom)
- 2009-2013 Ferdinando Arzarello (Italy)
- 2013-2017 Viviane Durand Guerrier (France)
- since 2017 Susanne Prediger (Germany)

### Introduction

The role and importance assigned to argumentation and proof in the last decades internationally has led to a variety of approaches to research in this area, which is reflected in the growing number of submissions to Thematic Working Group 1 (TWG1) on “argumentation and proof”. The 30 papers and 11 posters presented in TWG1 come from 16 countries and offer a wide spectrum of perspectives. These contributions intertwine educational issues with explicit references to mathematical, logical, historical, philosophical, epistemological, psychological, curricular, anthropological, and sociological viewpoints.

Taking into account this diversity, the paper contributions were presented and discussed in working sessions (some of which were parallel) organized under the following themes: (1) argumentation and proof at the school level, (2) argumentation and proof in teacher education, (3) tools for analysing argumentation and proof, (4) task design in argumentation and proof, (5) theoretical and philosophical issues of argumentation and proof, (6) assessment issues of argumentation and proof, and (7) intervention studies on argumentation and proof. Since the themes are intertwined, a paper could be assigned to multiple themes. Therefore, the assignment of papers to themes was guided by a “best fit” approach, as well as practical considerations.

In this introductory chapter, we organize our subsequent discussion across three broad topics that emerged from the discussions we had in our TWG and cut across the aforementioned themes. These topics are the following: (1) argumentation and proof in the society, (2) argumentation and proof in school, and (3) argumentation and proof in research. We will briefly discuss each topic separately. In our discussion, we will refer to a few papers that help illustrate broader points, but it was not our intention here to refer to or discuss all the papers. Rather, we hope that this discussion will spark the readers’ interest to explore all the papers in the Proceedings under TWG1.

### Discussion of Papers

#### Argumentation and proof in the society

Argumentation and proof can be considered within a purely mathematical realm, but such a view might be limited when one considers a larger purpose for *the role of argumentation, reasoning, and proof in the society*. These considerations would ultimately affect the teaching and learning of proof as a way to achieve certain societal goals. However, a first step in this direction is clarifying what

we mean by argumentation and proof. This critical question has been historically addressed by TWG1 members since the group was established back in 1998, however the focus of the discussion has shifted from trying to reach a consensus towards identifying key features and factors that affect our understanding of the concepts of argumentation and proof. Specifically, the group discussed the cultural origins of our perception of proof, including cultural differences in what types of arguments are considered as proof. In this regard, the role of proof by contradiction has been a focus of several group discussions fostered by the papers of Turiano and Boero, and of Hamanaka and Otaki.

Another key feature of argumentation and proof addressed by the group participants was the *relationship between logic and proof with connection to socio-cultural linguistic structures*. The different grammar and/or syntax of different (natural) languages may affect the transition between oral and written communication, influence how students understand statements, their proofs, as well as the relationships between definitions and proofs. These issues were reflected in the works of Hein, of Kempen, Tebaartz and Krieger, and of Dilberoglu, Haser, and Cakiroglu. Furthermore, the influence of culture and language on the perception of proof was considered broadly in the TWG1 discussions, as initiated by various papers, including those of Stubbemann and Knipping, of Asenova, and of Shinno, Miyakawa, Mizoguchi, Hamanaka, and Kunimune. Reference was made not only to the differences between countries and languages, but also to the differences between formal and informal uses of argumentation and proof, as well as to the use of natural logic in everyday life contrasted with academic settings that require greater formalism. Further distinctions were made with regard to its use in pure mathematical courses and in teacher preparation courses.

It is important to consider the relationships of argumentation and proof with society, in particular, when considering the goals of teaching proof to pre-university students who are the citizens of the future societies. Why foster proof? Is our goal mainly technical or do we, as a society, seek to influence students' thinking about how (mathematical) truths are established and, hence, do we mean to foster critical reasoning (for example, when making inferences about statistical data as illustrated in the study of Krummenauer and Kuntze)? Though the group seemed to agree that logical reasoning, argumentation, and proof might provide students with valuable tools for active citizenship, the question of appropriately developing those reasoning competencies to foster a harmonious transfer within and outside of mathematics remains open.

### **Argumentation and proof in school**

The second broad topic, argumentation and proof in school, was a common theme in many of the papers and posters presented in the group, but from different perspectives. In particular, the following four perspectives were raised in the discussions across the presentations.

*Why foster proof?* Besides the above-mentioned societal considerations and the fact that proof is central to modern mathematics, the explanatory role of proof, as discussed in the paper of Müller-Hill, is also prominent in school mathematics. The reasoning behind teaching mathematical proof to all students, however, needs to be more clearly conceptualized and justified.

*What is proof?* There are different understandings of what proof is or can be, depending on personal experience, but also on factors such as specific area of mathematics considered and/or the educational level – primary school students' reasoning (see for example Jablonski and Ludwig's contribution) is very different from secondary school students' work on geometry. Proof requires

mathematical meta-knowledge (see, for example, Stubbemann and Knipping's paper), and our group discussed that it would be valuable to develop instructional approaches that promote learners' meta-mathematical knowledge in proving.

*Role of the teacher.* It is the teacher who, implicitly or explicitly, implements different socio-mathematical norms in a classroom, highlights key ideas in work with proof and can assign value to certain perspectives in mathematics. The studies of Lee, of Bersch and of Lekaas take up different aspects of teachers' views on the role of argumentation and proof in, respectively, Hong Kong, Germany and Norway, while Larsen and Østergaard discuss how teachers' questioning influences students' opportunities to reason. Moreover, the role of the teacher with respect to both the official and shadow education systems was considered in the study by Moutsios-Rentzos and Plyta. Despite the teachers' efforts, proving is difficult for students to learn and master, and, as a result, students often struggle with it and may not value work on proof in mathematics classrooms. Studies in TWG1, such as the one by Yan and Hanna, provide an insight into students' views about proofs.

*Task design – how can it foster proof?* There are several critical questions to be considered in designing of proof tasks: For whom? For what purpose? In what culture? Tasks need to be designed in order to foster the need for arguments, as discussed for example in the study presented by Cramer. Kempen, Tebaartz, and Krieger examine in their study how the phrasing of a proving task influences students' proof productions, while Komatsu, G. Stylianides, and A. Stylianides propose principles for the design of tasks that promote assumptions in mathematical activity. However, promoting reasoning and proving in school demands more than good tasks, as for example shown in the study of Buchbinder and McCrone. To support teachers' practices, there is a need for appropriately designed material that help teachers to enact the tasks in classroom.

### **Argumentation and proof in research**

During the conference, there were many discussions on argumentation and proof in mathematics education research. A main issue concerns *methodological challenges* and the choice of *theoretical models* in approaching the proof and proving phenomena, including theorising and analysing. Toulmin's model has been used widely in mathematics education research projects on proof and proving (see paper by Jablonski and Ludwig). Due to its frequent application, the reasons for using this model in a given research are not often discussed. We collectively agreed on the importance of justifying methodological decisions for several reasons. First, the epistemic dimension of the mathematical subject area involved in the research and the role of data in the model are depending on the subject area (e.g. statistical versus geometrical reasoning). Finally, Toulmin's model has not been developed to be applied specifically for mathematics. While an advantage of this model lies in its opportunities to connect everyday argumentation to mathematical argumentation, in some cases (e.g. for looking at logical relations) other models more mathematically-oriented might be more suitable. These questions have been discussed in this TWG in previous CERMEs, as presented in Chapter 6 of the ERME anniversary book, *Developing research in mathematics education*, where the authors recall the proposal by Boero and his colleagues to articulate Toulmin's model with Habermas's rationality model (for the latter see Boero and Turiano's paper). Considering proof at the interface between mathematics and computer sciences raised also the need for appropriate methodological tools such as that developed in the paper by Modeste, Beauvoir, Chappelon, Durand-Guerrier<sup>1</sup>, León, and Meyer.

When we move to *proof at elementary school level*, new questions arise, necessitating to reconsider the definition of proof and the possibility to identify students' practices that can be qualified as proof and proving. Epistemological considerations motivate the consideration of proof at the elementary school level: looking for what is invariant is at the core of doing mathematics and, thus, proof is important at all grades. Nevertheless, we need to conceptualize proof in a broader meaning to discuss its role and possibilities in elementary school mathematics. In this respect, the work by Balacheff on the Theory of Didactical Situations and Lakatos' work on Proofs and Refutations may offer an appropriate proof development from the empirical to the intellectual through the generic. There seem to be few studies recognizing and investigating opportunities for proof and proving in the elementary school (see, for example, the works of Arnesen, Enge, Rø, and Valenta, and of Datsogianni, Ufer, and Sodian).

## Conclusions and Future Directions for TWG1

We believe that the TWG on argumentation and proof has offered the participants the richness of diversity in this research domain and the opportunity for fruitful discussions. In the last session of the TWG, the participants engaged in a discussion to identify areas in which they would like, and hope, to see more research in future CERMEs. The following areas were identified:

*The teaching of proof and argumentation* in both school and university settings, including in teacher education with particular emphasis on argumentation and proof at the elementary school level. This area covered also developmental perspectives and learning trajectories, the study of the classroom implementation of tasks rich in argumentation and proof, and how teachers can be prepared to scaffold students' learning and to respond to unexpected student responses to help develop all students' learning of argumentation and proof.

*Issues of language in argumentation and proof*, including: the role of representations, structure, oral and written language, the relationship between mathematical language and natural language, as well as the relationship between the grammatical aspects of language and logic. Due to the complexity of this question, this could be studied in an international group emerging from CERME, in collaboration with colleagues involved on this topic in the TWG9 -Mathematics and Language, and with linguists.

*Argumentation and proof in policy documents and curriculum frameworks*, including the place and role of argumentation and proof in them, expectations and recommendations, and whether these are research-informed, etc.

The identification of these broad areas is aimed at describing the state of the art of the field, without suggesting prioritizing certain areas of research. The TWG1 is committed to representing the diversity of perspectives and research areas on argumentation and proof in future CERMEs.

# Understanding geometric proofs: scaffolding pre-service mathematics teacher students through dynamic geometry system (dgs) and flow-chart proof

Lathiful Anwar<sup>1,2</sup> and Martin Goedhart<sup>1</sup>

<sup>1</sup>University of Groningen, Faculty of Science and Engineering, Groningen, Netherlands

<sup>2</sup>Universitas Negeri Malang, Malang, Indonesia; [l.anwar@rug.nl](mailto:l.anwar@rug.nl)

*The objective of this paper is to discuss the pedagogic potential that is offered by the use of a flow-chart proof with open problems and a Dynamic Geometry System in understanding geometric proofs by pre-service mathematics student teachers at an Indonesian university. Based on a literature review, we discuss aspects and levels of understanding of geometric proof and how to assess students' understanding of the structure of deductive proofs, and how the use of a Digital Geometry System may support students' understanding of geometric terms and statements, including definitions, postulates, and theorems. The pedagogic focus consists of exploiting the semiotic potential of a DGS, especially the use of GeoGebra tools that may function as tools of semiotic mediation to understand the geometry statements and the scaffolding potential of flow-chart proof with open problems in identifying the structure of deductive geometry proofs.*

*Keywords: Understanding, geometry, proof.*

## Introduction

Proof plays essential roles in mathematics and mathematics education. Proofs help mathematicians understand the meaning of statements or theorems and their validity within a framework. Through the process of proving, mathematicians discover or create new results or meanings (Samkoff & Weber, 2015; Zaslavsky, Nickerson, Stylianides, Kidron, & Winicki-Landman, 2012). In the context of mathematics learning, understanding proof is an essential component of mathematics competence as it offers powerful ways of developing and expressing mathematical understanding (NCTM, 2000). However, research has demonstrated that students at all levels have difficulties to deal with understanding and constructing proofs (Doruk & Kaplan, 2015; Güler, 2016; Knapp, 2005; Weber, 2002).

This paper presents some findings of the literature review we conducted aiming at developing a theoretical framework, which will underpin the design of a learning intervention. This intervention will foster understanding of Euclidean geometry proof by mathematics preservice teacher students. The students are first year students at an Indonesian university and will become teachers for secondary school. In this stage, students start to learn formal mathematical proof for the first time. This paper describes the aspects and levels of understanding of geometric proof and elaborate the use of a digital geometry system (DGS) and flow-chart proof representation as scaffolds in order to understand the structure of proof based on our literature review findings. We focus on these issues because they are relevant for our research project regarding the topic (geometric proof in undergraduate level), context and characteristics of participants, Indonesian university students, who have a little mathematical proof background.

## Method

This paper presents some parts of the outcomes of our literature study which focuses on the understanding of proof and the use of DGS and flow-chart proof to support students' understanding of proof. The methodological process of the literature study is *anasynthesis* (coined from the words analysis and synthesis) adapted from Legendre's method (as cited in Jeannotte & Kieran, 2017). First, we create a corpus from a search in three databases of research, namely ERIC, MathEduc, and Web of Science, and select articles/papers having mathematical proof as keywords or associated keywords by entering 'mathematic\* proof' or 'mathematical prov\*' and 'geometric\* proof' or geometrical prov\*' as keywords. It is followed by selection and un-doubling. To assure the quality of the sources, we characterized the papers regarding their relevance of method and findings for education, quality of author (the number of citations) and quality of journal (impact factor). By the end of the process, 32 English texts (books, chapters, articles, and research reports in proceedings) constituted the corpus (modified corpus).

Secondly, the resulting corpus is *analyzed* for relevant information, namely definitions of mathematical proof, structure of proof, learning difficulties, interventions, role of teacher, successful approaches. In order to analyze, we created a matrix of the resulting corpus consisting of four main aspects: source, research context, method, outcomes/conclusions. Thirdly, the information is then *synthesized* to check convergences, divergences, and to identify the theoretical gaps. Underpinned by this research, we developed a framework and prototype for a teaching intervention to foster prospective teacher's geometrical proof competence. We present this process of analysis and synthesis as linear, but the reader should consider that it is a cyclical process, see Figure 1.

**Figure 1: Cyclic process of an Anasynthesis (adapted from Jeannotte & Kieran, 2017)**

## Framework underpinning understanding of geometrical proof

While the ability to understand, construct and validate proofs is central to mathematics, student difficulties with understanding of proof are well-recognized internationally. In order to help students to understand, teachers need to know levels of understanding to be achieved by their students, and also potential tools and tasks scaffolding their thinking. This information is helpful for the teachers/researchers in designing their learning goals and a sequence of learning activities fostering students' understanding of proofs. As a result of our literature review, we present, in this part, our framework regarding aspects and levels of understanding as frameworks to develop an assessment model to capture students' understanding of geometrical proof, and, next to that, potential tools and methods which can be implemented in the classroom intervention to scaffold students' thinking in constructing geometric figure, emerging the meaning of geometric concepts, axioms and theorems.

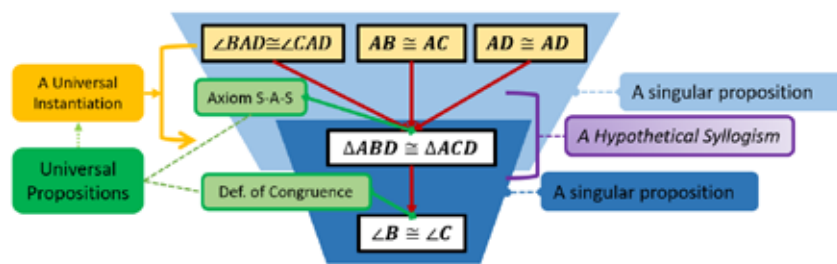

## Understanding of geometrical proof

Based on literature on reading comprehension of geometry proofs (Yang & Lin, 2008), the assessment model of proof comprehension for undergraduate students (Mejia-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012), and students' understanding of the structure of deductive proof (Miyazaki, Fujita, &

Jones, 2017), we distinguish three essential aspects in understanding proofs, namely a *functional aspect*, a *structural aspect*, and a *communicative aspect*. These three aspects are inspired by three main aspects of proof and proving proposed by Miyazaki et al. (2017): “*understanding a proof as a structural object, seeing proof as intellectual activity and the role, functions, and meaning of proof and proving*” (Miyazaki, Fujita, & Jones, 2017, page 225).

First of all, the *functional aspect* regards roles or functions of proofs. The ‘*function*’ of proof means the meaning, purpose and usefulness of a proof. In the context of learning, students should regard proof as a meaningful activity, experiencing the functionality (usefulness) of the activities, they are involved in. Second, the *structural aspect* refers to the deductive structure of proofs. Miyazaki et al. (2017) see the structure of a proof as a network of *singular* and *universal propositions* between *premises* and *conclusions*, connected by *universal instantiation* and *hypothetical syllogism*, see Figure 2. That means that the singular propositions are *universally instantiated* from universal proposition and then these singular propositions are connected by a *hypothetical syllogism*. Students need to know the meaning of these terms and statements (e.g. axioms, theorems) involved in a proof, recognize the status of the statements (e.g. premises, conclusions), to be able to justify the claim.

**Figure 2: An example of flow-chart of proof visualizing the structure of proof**  
(adapted from Miyazaki, Fujita, & Jones, 2015)

The last aspect, the *communicative aspect* regards to students’ intellectual activity to read and comprehend proofs, and to justify and persuade others about the validity of a proof. Through a *validating process*, students determine the truth of a proof by line-by-line checking or step-by-step checking of multi-step proofs using their understanding of the structure of deductive proofs. We interpret that this level of understanding relates to a holistic comprehension of proof where the proof is understood in terms of main ideas, methods and applications in other contexts.

Related to the level of understanding, we elaborate two models of understanding of proofs by Mejia-Ramos and colleagues (2012) and by Miyazaki and colleagues (2017). In their model of levels of structural proof understanding, Miyazaki and colleagues distinguish three levels of understanding of proof structure, namely ‘*Pre-structural*’ level, ‘*Partial-structural*’ level, and ‘*Holistic-structural*’ level. Then, they break down the second level into two sub-levels, ‘*Elemental*’ and ‘*Relational sub-level*’. At the first level (*Pre-structural*), students see a proof as a collection of meaningless symbolic objects. When students start to consider the components, they are at the second level, particularly the *Partial-structural Elemental* sub-level. At the *Partial-Structural Relational* sub-level, students understand hypothetical syllogisms and universal instantiations and are able to use theorems, axioms and definitions as supporting their reasoning. At the third level of understanding (*holistic-structural*),

students understand the components, inter-relationships between those components and how to connect them. Then, they are able to reconstruct the proof and become aware of the hierarchical relationship between theorems and will be able to construct their own proofs.

Mejia-Ramos et al.(2012) have developed a model of assessment for proof comprehension in undergraduate mathematics. They distinguish two levels of understanding of proof, namely a *local* and a *holistic understanding*. The local understanding refers to knowing of basic terms and statements in the proof, knowing the logical status of statements in proof and the logical interrelationship between them and the statement which will be proved, and able to justify oh how the claims in the proof follows from the previous statements. Meanwhile, the holistic understanding regards being able to summarize the main idea of the proof, to identify the sub-proofs and the logical relationship between them, to adapt the idea and procedures of proof to solve other proving tasks, and to illustrate the proof regarding its relationship to specific examples.

### **A semiotic potential of the use of dynamic geometry system (dgs)**

In terms of the structural aspects of understanding proof, several studies confirmed that the use of a Dynamic Geometry System (DGS) may help students not only solve construction problems but also helped them to understand geometrical postulates, definitions and theorems of Euclidean geometry, which are elements of the structure of proof (Jiang, 2002; Mariotti, 2012, 2013). Mariotti (2013) summarized that the semiotic potential of the features of DGS relates to specific mathematical meanings, namely “(1) the dragging test can be related to the theoretical validation of a geometric construction, (2) specific tools can be related to specific elements of the corresponding geometry theory: postulates, theorems; (3) actions concerning the management of the DGS’s menu can be related to fundamental meta-theoretical actions concerning the construction of a theory, such as the introduction of a new theorem or a definition.” (Mariotti, 2013, pp. 444-445). In the following paragraph, we elaborate two studies about the use of DGS in supporting students’ ability in proving.

A study by Jiang (2002) investigates learning processes of two pre-service teachers, Lisa and Fred, in exploring geometry problems using the dynamic geometry software Geometer’s Sketchpad (GSP) to develop mathematical reasoning and proof abilities. They use a constant comparison approach in order to analyze participants’ pre-tests, post-tests, and teaching interviews indicating that the geometer’s Sketchpad can not only encourage students to make conjectures but also enhances students’ mathematical reasoning and proof abilities. Particularly, the use of a Dynamic Geometry System (DGS) improves students’ level of geometric thinking in terms of van Hiele levels (e.g. Lisa’s level increased from level 3 to level 4) and positively changes students’ conceptions of mathematics and mathematics teaching. Jiang argues that pre-service teachers’ experience in using DGS to foster their mathematical reasoning and proof abilities helps them to recognize the need to improve students’ knowledge of geometry, to develop their own mathematical power and their ability to develop teaching innovations.

A theoretical study by Mariotti (2012) discusses the potential offered by the use of DGS in supporting and fostering 9<sup>th</sup> and 10<sup>th</sup> grade student’s proof competence in geometry. The theoretical framework used to support the use of DGS, Cabri Geometer, is her own Theory of Semiotic Mediation (TSM). In this context, students’ personal meanings emerge and then evolve from personal meanings towards

mathematical meanings, when students use an artefact for accomplishing a task through social interaction. Particularly, the specific DGS tools can also be related to geometrical axioms and theorems. Meanings emerging from the use of virtual drawing tools for solving geometry tasks can be related not only to the theoretical meaning of geometry construction but also the meaning of theorems.

Mariotti (2012) argues that the DGS could support not only the conjecturing process, but also mediate the mathematical meaning of conjectures, particularly premises/singular propositions in the context of geometry proofs. Particularly, the dragging feature provided by DGS (Cabri software) supports the emergence of different meanings related to the notion of conjecture as a conditional statement relating a premise and a conclusion. Mariotti also discusses findings by Baccaglioni-Frank (2010) focused on the analysis of the process of exploration that can be expected by using Maintaining Dragging (MD). Baccaglioni-Frank's teaching experiment involves students from three high schools (aged 15-18), which used Cabri in the classroom. Mariotti concludes that this teaching experiment indicates that the DGS tools and dragging activities help students to solve construction tasks and to understand the notion of theorems; particularly the mathematical meaning of conditional statements such as expressing the logical dependency between premises and conclusions.

GeoGebra as another DGS is an open-source well-developed tool with a stable interface familiar to many users and works in any operating system. The software has a number of features such as dynamic geometry which can help students in steps of problem solving towards a proof (Botana et al., 2015). Botana et al. (2015) conclude that GeoGebra tools provide some useful features. Firstly, GeoGebra could not only give yes/no answers but could also show step-by-step explanations. Secondly, GeoGebra could identify properties on the construction of geometric figures. Thirdly, GeoGebra could give a counterexample to check the truth of a statement. However, research findings by Doruk, Aktumen, and Aytakin (2013) show that some preservice teachers highlighted some limitations, such as difficulties in translating mathematical expressions into GeoGebra. Preservice teachers thought that GeoGebra is a complicated program and that it would take a long time and needs a big effort to become competent in GeoGebra.

### **A scaffolding potential of the use of flow-chart proof form with open problems**

A flow-chart proof form is a means to visualize the deductive connections from premises to conclusion by identifying singular and universal propositions in the chart, see Figure 2. Flow-chart proofs show a storyline of the proof starting with premises from which the conclusion is deduced and includes the theorems or/and axioms being used, how the premises/hypotheses and conclusion are connected, and so on (Miyazaki et al., 2015). Gardiner (2004, cited in Miyazaki, Fujita, & Jones, 2017) claims that this format is a good starting point to learn other formats of proofs such as narrative proofs and two-column proofs.

Miyazaki, Fujita, and Jones (2012) developed a learning progression based on flow-chart proving aimed at providing a basis for introducing the structure of proof in Grade 8 school geometry. Based on the theoretical underpinning of the design, researchers proposed three phases of learning progression: (1) constructing flow-chart proofs in an open problem, (2) constructing a formal proof by reference to a flow-chart proof in a closed situation, (3) refining formal proofs by placing them

into a flow-chart proof format in a closed situation. The term ‘*open*’ refers to a situation where students can construct more than one suitable proof. In the open problem task, students are given a conclusion of the proof in the form of flow-chart proof format, and they are asked to determine the suitable statements to fill in the blank boxes of the flow-chart so the proof is complete. Based on three phases of learning progression, the authors designed nine lessons considering open/closed situations, varying steps of deductive reasoning, and different problems and contexts. The results from a Math test of Japanese Survey Item shows that students who followed the nine lessons are more likely to plan and construct a proof in accordance with their plan. This is due to (a) their experience with open problems that encourage them to think backward and forward to identify assumptions and conclusions in proof, (b) they could grasp the structure of proofs better through using flow-chart proofs.

Another research by Miyazaki et al. (2015), as follow-up of their previous study (Miyazaki, Fujita, & Jones, 2012), showed the role of *flow-chart with open problem* as scaffolding to support Grade 8 students’ learning about geometrical proofs. The results of data analysis of students’ activities during a classroom intervention indicates that flow-chart proof with open problems as scaffolding enhances students to understand the structure of proof by providing a visualization of both the connection between singular propositions (via hypothetical syllogism) and the connections between a singular proposition and the necessary universal proposition in the form of universal instantiation.

## Concluding Remarks

We distinguish two levels of proof understanding which are proposed by Mejia-Ramos et al.: *a local understanding* related to knowing the definition of basic concepts/terms, knowing the logical status of statements in proof, knowing how and why each statement connects to previous statements. and *a holistic understanding* when students are able to summarize the main idea of the proof, to identify the sub-proofs and how these relate to the proof structure, to transfer the idea of proof to others, and instantiate the proof with examples (Mejia-Ramos et al., 2012; Miyazaki et al., 2017). Classroom interventions, supporting students’ activities in understanding the structure of proofs including the elements of proofs such as singular propositions (premises/geometric statements), universal proposition (geometric definition, axioms, theorems) and hypothetical syllogism (the inter-relationship of these elements), are needed to help students reach both levels of proof understanding.

Several studies confirmed that the use of a Dynamic Geometry System (DGS), such as Geometer’s Sketchpad, Cabri and Geogebra, may help students not only solve construction problems but also may help them identify properties on the construction of geometric figures, understand geometrical axioms, definitions and theorems of Euclidean geometry, which are elements of the structure of proof, and universal propositions (Botana et al., 2015; Jiang, 2002; Mariotti, 2012, 2013).

The use of the flow-chart proof form may provide opportunities for students to understand the structure of proof and may help students identify the components of proofs and the inter-relationship among the components (Miyazaki et al., 2015; Miyazaki et al., 2017). The use of open problems provides an opportunity for students to construct multiple solutions by deciding about the given statements and intermediate propositions necessary to deduce a given conclusion. This ability promotes student thinking forward and backward interactively when constructing a proof under the flow-chart proof format (Cheng & Lin, 2007; Heinze et al., 2008).

A study by Miyazaki et al. (2017) suggests that the level of understanding of the structure of proof as a part of local understanding should be taken into consideration in designing an effective learning intervention. Mariotti (2012) also recommends future research to better describe how the complex web of meanings emerging from activities with the DGS may be transformed into mathematical meanings such as geometric definitions, axioms and theorems. Hence, the findings presented in this paper indicate our future promising research direction for the study on designing a learning intervention which implements the use of DGS, GeoGebra, as semiotic tools and flow-chart proof format as a scaffolding tool to support a local and holistic understanding of prospective mathematics teachers who have little mathematical proof background.

# Initial participation in a reasoning-and-proving discourse in elementary school teacher education

Kristin Krogh Arnesen, Ole Enge, Kirsti Rø and Anita Valenta

Norwegian University of Science and Technology; anita.valenta@ntnu.no

*Based on a commognitive framework, we analyse the reasoning-and-proving processes of two teachers, and we identify the actions and routines that are visible when working on a given task. The data consist of video recordings of the teachers' attempts to validate a stated hypothesis involving multiplicative reasoning. Six categories of what characterises the teachers' initiation into a reasoning-and-proving discourse are identified. The findings reveal that some actions related to substantiation routines seem to be applicable for novice teachers. Examples of this include questioning validity and the use of words related to deductive reasoning. However, the teachers' participation in the discourse is characterised by ritualised actions, as in their use of visual mediators. Furthermore, the analysis discloses the teachers' tendency to use construction-related actions in what was designed to be a validating activity.*

**Keywords:** mathematical discourse, reasoning and proving, elementary school teacher education

## Introduction

Reasoning and proving are central aspects of mathematics as a discipline, and many researchers have argued that they should be a central part of school mathematics at all grades and in all topics. In this paper, we use a broad definition of the word proof (Reid, 2010), to denote mathematical reasoning involved in the process of making sense of and establishing mathematical knowledge. Hence, we follow Stylianides (2008), who used the term 'reasoning-and-proving' to denote the activities involved in this process: identifying patterns, making conjectures and providing arguments.

The reasoning-and-proving process is difficult to learn and difficult to teach. In exploring ways to teach proof, a number of studies have shown the crucial role that a teacher plays in helping students identifying the structure of a proof, presenting arguments and distinguishing between correct and incorrect arguments (see e.g. Stylianides, 2007). Researchers have found that elementary school teachers tend to rely on external authorities, such as textbooks, college instructors or more capable peers, as the basis of their conviction. They also believe it is possible to affirm the validity of a mathematical generalisation using a few examples (see Martin & Harel, 1989). Similarly, Stylianides, Stylianides, and Philippou (2007) revealed that pre-service teachers had two main types of difficulties with proof: the lack of understanding of the logic mathematical underpinnings of different modes of argumentation and the inability to use different modes of representations appropriately.

As exemplified above, research in mathematics education has shed light on different aspects of pre-service teachers' work on reasoning-and-proving, such as their beliefs related to proofs and proving, the challenges they face when deducing proofs and their use of modes of reasoning. However, more knowledge is needed about how pre-service teachers learn to teach reasoning-and-proving, as well as how teacher education can support their learning. A vital part of teachers' learning how to teach reasoning-and-proving is learning how to reason and prove in school-relevant mathematical areas (e.g. multiplicative reasoning). That learning is the topic of our study.

We examine two elementary school teachers' work on a reasoning-and-proving task during a professional development course. Like Remillard (2014), we consider mathematics to be a specific type of discourse where reasoning-and-proving is essential. Thus, mathematics learning is seen as participation in the discourse (Sfard, 2008). The two teachers whose work we analyse have limited experience of reasoning-and-proving in mathematics, and we are interested in their initiation into that discourse. Our research question is: What characterises two in-service teachers' initial participation in a mathematical discourse on reasoning-and-proving in elementary school teacher education?

## Theoretical framework

Within a commognitive framework<sup>1</sup>, Sfard (2008) take the position that learning mathematics is learning to participate in a specific discourse. Here, discourse is a special type of communication within a specific community that is made mathematical by that community's use of words, visual mediators, narratives and routines. The use of *words* in mathematics includes the use of ordinary words that have a special meaning in mathematics, like function and proof, and mathematical words, like fraction and axiom. Furthermore, people participating in mathematical communication use *visual mediators* to identify the object about which they are talking. These visual mediators are often symbolic, but they also include graphs, illustrations and physical artefacts. Within a discourse, any sequence of utterances, spoken or written, that describes the properties of objects or the relationships between objects is called a *narrative*. Mathematical narratives can be numerical, e.g. " $\frac{1}{2}$  is equivalent to  $\frac{2}{4}$ ", or more general, e.g. "addition is commutative". Narratives are subject to endorsement or rejection, that is, being labelled as true or false, based on specific rules defined by the community. Endorsement of narratives is the main goal of the mathematics discourse; this includes the processes of constructing new endorsable narratives, substantiating them and recalling them in new situations.

*Routines* are well-defined practices that a given community regularly employs in a discourse. Sfard (2008) describe routines as patterns that are guided by two sets of rules: those telling the participants *how* to act, and those indicating *when* to do the given action. In contrast to rules on the object-level, which describe regularities on actions on and relations of objects, routines describe the participants' patterns of actions in a given discourse, and they can be considered to be rules on a meta-level. Lavie, Steiner, and Sfard (2019) emphasise the role of routines when participating in a specific discourse, and they suggest that learning routines can be seen as the routinisation of actions in a given discourse. Thus, on their way to new routines, learners must pass, if only briefly, through the stage of ritualised performance or imitation (Sfard, 2008). Here, *rituals* are understood to be socially oriented; they are acts of solidarity with co-performers. At this transitory stage, learners may become very familiar with the *how* of the new routine, but they will be much less aware of *when* it is used.

Our research question focuses on participation in a mathematical discourse on reasoning-and-proving, involving the processes of identifying patterns, making conjectures and providing arguments for whether or not conjectures are true. Hence, from a discursive stance, we are primarily interested in the routines associated with the construction and substantiation of narratives. New narratives are constructed mainly through operations on previously endorsed narratives. To substantiate a constructed mathematical narrative, one produces a proof—a sequence of endorsed narratives, each

---

<sup>1</sup> The term "commognition" is a combination of the words "communication" and "cognitive", and it stresses that thinking is a way of communicating with oneself and others.

of which is deductively inferred from previous ones, the last of which is the narrative that is being endorsed. Thus, learning to reason and prove in mathematics is about individualising both the *when* and the *how* of the construction and substantiation routines. In this paper, we focus on substantiation routines as framed by a task in which a hypothesis is already given.

To obtain insight into how individuals learn about reasoning-and-proving, it is useful to delineate the possible patterns of the processes and actions involved in constructing and substantiating narratives. Applying a commognitive perspective, Jeannotte and Kieran (2017) have developed a conceptual model of mathematical reasoning based on exhaustive analyses of mathematics education research. They propose the following definition of mathematical reasoning through commognition lenses: “Mathematical reasoning processes are commognitive processes that are meta-discursive, that is, that derive narratives about objects or relations by exploring the relations between objects” (Jeannotte & Kieran 2017, p. 9). Because their notion of mathematical reasoning involves proving, it coincides with our use of reasoning-and-proving. However, we use the latter to indicate that we look at a special kind of reasoning that is used when validating mathematical hypotheses, as mathematical reasoning *per se* does not necessarily include proving. Furthermore, Jeannotte and Kieran (2017) distinguish between processes related to the search for similarities and differences and processes related to validating. Searching for similarities and differences includes generalising, conjecturing, identifying a pattern, comparing and classifying. All these processes infer narratives about mathematical objects or relations (although on a partly different basis); thus, they are related to the routine of constructing narratives (Sfard, 2008). The processes related to validating include validating, justifying, proving and formal proving (defined inclusively, with an increasing degree of deductive structure and stringency). These processes aim to change the epistemic value (e.g. true, false) of a given narrative; therefore, they are related to substantiation routines (Sfard, 2008).

This study investigated two teachers’ initial participation based on their utterances and actions in a mathematical discourse on reasoning-and-proving in elementary school teacher education. We aim to illustrate how key concepts from the commognitive framework proposed by Sfard (2008) can provide insight into how mathematics teachers learn about the process of reasoning-and-proving.

## Method

The two elementary school teachers, Sandra and Nora (pseudonyms), who participated in the research study, were part of a professional developmental course in mathematics for teachers in grades 1–7 in Norway that was held by two of the authors of this paper. Both teachers are 45-50-year-old females, and both completed general teacher education with less than 15 ECST credits in mathematics education. Sandra and Nora represent typical teachers attending the course, due to their age, educational background, gender and having more than 10 years of experience as general teachers.

The course contained materials on mathematics and mathematics education, and it was organised as six, three-day seminars distributed over one year, in addition to the teachers’ individual work on literature and assignments. The topics were sense-making in mathematics, pattern seeking and exploration, use of different representations (e.g. the array model for multiplication) and reasoning-and-proving (in particular, representation-based proofs). The participants noted that the coursework invited them to use new ways of thinking about and working with mathematics. This paper presents an analysis of the data collected through video recordings (in total 24 minutes) of Sandra and Nora

working on a task (Teddy's hypothesis, see Figure 1) on the second day of the fourth seminar of the course. The day before data collection, the topic was multiplication: different properties, strategies, models and reasoning-and-proving.

The task was chosen for the purpose of reasoning-and-proving, starting with a hypothesis proposed by Teddy, an imaginary student (Figure 1). The first step of the task (part a) involves validation of the hypothesis; the second step of the task (part b) entails both stating and validating the new hypotheses. In our analysis, we study validation processes, as exemplified by Sandra and Nora's work on the first step of the task (part a).

Teddy is a grade 5 student. He and his classmates are working on square and cubic numbers. After completing some tasks, Teddy says to the teacher: "Look here, if you multiply ... take two numbers and multiply... and both numbers end with 5... then the result also will end with 5".

- a) Give a proof that shows that Teddy's observation is correct for all such numbers.
- b) The situation can be used to propose and solve other problems, for instance:
  1. Is it only when both numbers end with 5 that the result ends with 5?
  2. Does the result hold only for 5, or when two numbers ending with the same digit are multiplied, does the product also end with that same digit?
  3. Which digits can square numbers end with?

**Figure 1. Teddy's hypothesis task (adapted from Skott, Jess, & Hansen, 2008, pp. 223–224)**

Teddy's hypothesis can be proved by using a generic example and array model of multiplication. Given any two numbers, both ending with 5, say 125 and 35, one can use the array model for multiplication to represent the multiplication  $125 \times 35$ , as shown in Figure 2.

	100	20	5
30	$100 \times 30$	$20 \times 30$	$5 \times 30$
5	$100 \times 5$	$20 \times 5$	$5 \times 5$

**Figure 2. The array model for multiplication used in a representation-based proof of the hypothesis**

Every cell in this array, except the cell with  $5 \times 5$ , is a multiple of 10. Thus, these cells do not contribute to the ones in the product. Only the cell with  $5 \times 5$  does, and since  $5 \times 5$  equals 25, we find that the product ends with 5. There is nothing special about the two numbers (35 and 125) in the example. The product of any two numbers both ending with 5 will have the same structure; thus, the number resulting from such a multiplication will end with 5.

## Data analysis

The video recordings of Sandra and Nora's work on the task were transcribed, and then coded. The coding was guided by the research question. The aim was to describe the actions and utterances in the teachers' work, rather than to evaluate the mathematical and logical correctness of their arguments. Four researchers made a descriptive coding of the collected data, individually (Miles & Huberman, 1994). Next, the researchers compared and contrasted their coding and grouped the codes into six categories describing the two teachers' reasoning-and-proving efforts. The following categories were agreed upon: *confirming*; *proposing hypotheses*; *questioning validity*; *warranting*; *searching for patterns*; and *making drawings*.

To illustrate the categories and our findings, we present the teachers' work from part a of the hypothesis task. However, the above-mentioned categories apply to the teachers' discussions on all

the given tasks. The teachers' utterances are sometimes imprecise and difficult to interpret, and we tried to preserve this in the translation. In the analysis presented below, we use italics to emphasise the categories.

Sandra and Nora start their work by reading the hypothesis proposed by Teddy.

- 1     N:            It is true, what he says.
- 2     S:            Yeah.
- 3     N:            So, the argument is correct.
- 4     S:            Yes, it is, eh; but it's more. It works for all odd numbers; so, the answer is 5.
- 5     N:            Yes, exactly.
- 6     S:            As long as one is a 5, one of ...
- 7     N:            Yes, in the 5 times table, no matter what you multiply with something with a 5 in, then you'll get a 5 at the end of the answer.
- 8     S:            Yes, ehm ...
- 9     N:            But, that's also because 5 is an odd number.
- 10    S:            Yeah, but do you have an argument that shows that Teddy is correct? Yes, it is, but is it ... is it enough? Now, we have actually, sort of gone further.

The category *confirming* in our analysis is a social act of support. Examples of this are seen in turns [2] and [5]. Furthermore, two new *hypotheses are proposed* in this excerpt of the discussion, one in turn [4] and another in [7]. Both hypotheses are related to Teddy's, but they are partly different, as [4] is more general than Teddy's hypothesis and [7] concerns properties of the 5 times table. In turn [9], the teachers *warrant* the hypothesis stated in turn [7]; in turn [10], they *question the validity* of Teddy's hypothesis. A few turns later, the discussion continues, as follows:

- 17    N:            Because, eh, when you, right, in the 5 times table [S: Yeah], when you multiply with an odd number, you'll always end with 5, [S: Yeah] the answer will, the sum will always end, the answer will always be 5, thus ...
- 18    N:            And, anything that ends with 5 is an odd number, so if you multiply... 35 is an odd number, right.
- 19    S:            Yes, yes, because of the 5.
- 20    N:            Yes, so because of the 5 there it will be an odd number.
- 21    S:            Yeah.
- 22    N:            And, therefore, it will end with 5.
- 23    S:            Yeah.
- 24    S:            Yeah, but, but, if one should have made such a, representation-based proof for it, is that what they want? Or is it enough that we ... it is probably not enough that we say this. [N: [laughs]] Believe me [in English].

In the utterance in turn [17] a new *hypothesis is proposed* (stating that when multiplying any odd number by 5, the product always ends with 5), which can be seen as a generalisation of the hypothesis proposed in turn [7]. At the same time, the purpose of the utterance in turn [17], and also several other utterances in this excerpt ([18, 19, 20, 22]), is *warranting*, as recognised by their use of the words "because" and "therefore". The utterance in turn [24] *questions the validity* of the argument given ("is it enough"). Following her own request for a representation-based proof, Sandra is *making drawings* of arrays on a sheet of graph paper (Figure 3).

- 26 S: Yeah, but if you have a, 1-2-3-4-5, [N: Yes] (draws a 1x5 array on the sheet), that's there. How do I draw this here, then? Eh ... So, you have ... (draws a 2x5 array)
- 27 N: So, each 5 you'll get... Now, there it is an even number. [S: Yeah (draws a 3x5 array)] Then, there is an odd number.
- 28 S: Yeah, do we get a ... pattern? (draws a 4x5 array)
- 29 N: Yes... even number.
- 30 S: Yeah (draws a 5x5 array).

**Figure 3. Sandra's drawings for part a of the hypothesis task**

- 31 N: Odd number.
- 32 S: Yeah. But it's a ... eh, even number (writes e below the 1x5 array). No, (corrects to the letter o below the 1x5 array) odd number. Odd number plus odd number is always ... even number [N: even number, yeah] (writes o+o=e below the 2x5 array. And here it's [N: odd number] odd number plus odd number plus odd number, equals odd number (writes o+o+o=o below the 3x5 array, then o+o+o+o=e below the 4x5 array)
- 33 N: And five is an odd number.
- 34 S: Yeah, ... Shall we drop this now, and try the next question?

While drawing the arrays, the teachers are *searching for patterns*. The patterns they discuss concern even and odd numbers in the 5 times table [32]. After turn [34], the teachers leave the task in step a, and proceed to step b. It is not clear if they are dissatisfied with the pattern discovered or if they are finding it difficult to identify a way to use the pattern to prove the hypothesis in turn [17] or Teddy's hypothesis, when they choose to leave the task.

## Results and discussion

Our analysis shows that Sandra and Nora use several actions related to construction and substantiation routines. According to Sfard (2008), one of the distinct characteristics of discourses is the keywords that are used. In a mathematical reasoning-and-proving discourse, these keywords relate to deductive reasoning, which is “the only form of reasoning that can change the epistemic value of mathematical knowledge from likely to true” (Jeannotte & Kieran, 2017, p. 8). Sandra and Nora use words that are distinctive of a reasoning-and-proving discourse, namely their warranting of statements by their use of the word “because” followed by “then” or “therefore”, as seen in excerpts [18–23]. Moreover, the teachers question the validity of the arguments they provide, and they make drawings and search for patterns. In general, the use of drawings as visual mediators is one of the main aspects of mathematical discourse, and its role in reasoning-and-proving was emphasised in the professional development course. Sandra and Nora's drawings and their search for patterns is initiated by their act of questioning the validity of the arguments, which is part of the process of convincing (oneself or another) and is fundamental to mathematical reasoning (Jeannotte & Kieran, 2017).

At the same time, Sandra and Nora's explicit reference to representation-based proving (as seen in statement [24]), within the framework of Sfard (2008) and Lavie, Steiner, and Sfard (2019), indicate

that the teachers' participation is ritualised. As previously explained, rituals are understood to be socially oriented; they are acts of solidarity with co-performers or authorities. With their questioning of validity, Sandra and Nora express what they assume to be expected by the community, i.e. the teacher educators, regarding substantiation routines ("is that what they want?" [24]). The making of drawings and the search for patterns emerge in the teachers' work as a result of stating this question. This stands in contrast to questioning validity on the basis of the given hypothesis and a discussion of what narratives can be considered to already be endorsed by the community. Apart from the question referring to the teacher educators, Sandra and Nora also frequently confirm each other's contributions. Because their questioning of the validity and confirming each other's statements appears to be an attempt to gain social acceptance rather than their need to support and strengthen their substantiation of Teddy's hypothesis, their initial participation in the reasoning-and-proving discourse appears to be ritualised.

Our analysis also reveals ritualised participation in terms of *how* to act, in particular, how to use drawings. As shown in Figure 3, Sandra has made a drawing based on her own request for a representation-based proof of Teddy's hypothesis. The drawing and the following search for a pattern are related to the teachers' hypothesis (as seen in [17]), and not Teddy's hypothesis. Nevertheless, the chosen drawing does not advance the teachers' reasoning-and-proving process.

Sandra and Nora's actions related to construction and substantiation of narratives also indicate ritualised participation in terms of *when* to do a given action. As previously discussed, meta-discursive processes of reasoning-and-proving can be divided into processes of searching for similarities and differences (constructing narratives) and validating processes (substantiation of narratives). Throughout Sandra and Nora's conversation, these processes seem to intersect: several actions that they use, e.g. proposing hypotheses and searching for patterns, are mainly related to the processes of construction of narratives, and they are not appropriate for modifying the epistemic value of a narrative from likely to true. In a substantiation routine, a sequence of endorsed narratives is used, each of which is deductively inferred from previous narratives. Sandra and Nora propose several *new* hypotheses during their work (e.g. in [17]), and they are not explicit about whether the new narratives are (or can be seen to be) endorsed by the community and how they connect to Teddy's hypothesis. Moreover, Sandra and Nora search for patterns related to even and odd numbers, and it seems that the aim of this action is proving a hypothesis given in [17]. However, their search for patterns does not help them validate the hypothesis, and they leave the task. It is worth noting that the teachers' use of actions related to the construction of narratives happens, even though the Teddy's hypothesis task was designed to direct the teachers to participate in the validating process.

## Conclusions and implications

Ritualised participation and challenges in knowing how and when a given action can be used are not surprising results when studying novices' initial participation in a given discourse (Sfard, 2008). Yet, within the frames of commognition, we have highlighted that some reasoning-and-proving actions seem to be more visible and applicable for novice participants than other actions; thus, they are easier to imitate. The teachers in this study employed several actions that are not directly related to substantiation but are regularly applied in a mathematical discourse. They search for patterns, propose a hypothesis and make drawings. They also perform actions related to substantiation routines, such as warranting and questioning validity. Yet, other actions related to substantiation of narratives seem

to be more hidden. For example, being critical is central to substantiation routines; however, Sandra and Nora continuously confirmed each other's contributions.

Moreover, the analysis discloses the two teachers' tendency to use construction-related actions (searching for patterns, proposing hypotheses) in what was designed to be a validating activity. Thus, the findings imply a need in teacher education to be more explicit about what actions are specific for reasoning-and-proving, and also, to be explicit about changes in actions when moving from construction to substantiation of narratives.

In this paper, we have reported on the characteristics of two in-service teachers' learning of reasoning-and-proving in a professional development context in the field of elementary education. Nevertheless, our study is limited by the number of participants, and further research from a commognitive standpoint is needed to shed more light on elementary education teachers' learning of reasoning-and-proving. For example, longitudinal studies are needed to learn more about teachers' evolving routines. Another topic for further research is the role of visual mediators in a reasoning-and-proving context, and how participants can routinise the use of visual mediators in the discourse.

*Keywords: Proof, epistemological obstacles, to convince, contradiction, semiotic.*

## Introduction

Bachelard (1938) identifies in the act of knowing the causes of stagnation of the evolution of scientific thought; he calls the psychological causes of inertia in this evolution *epistemological obstacles*. According to the author (Bachelard, 1938), the epistemologist must endeavor to grasp the scientific concepts in an actual, i.e. in a progressive, psychological syntheses, establishing, concerning every notion, a scale of concepts, which shows how one concept has produced another; moreover, the epistemologist must necessarily take a normative point of view, while the historian usually has to avoid it, and what must attract his attention and guide his research is the search for rationality and construction in the evolution of scientific thought. “The epistemologist must take the facts as ideas, inserting them into a system of thoughts. A fact misinterpreted in an era remains a fact for the historian. It is, at the discretion of the epistemologist, an obstacle, it is a counter-thought” (Bachelard, 1938, p. 17). It is clear that in the construction of the epistemological trajectory it will not be possible to provide (nor would it make sense to ask for) a proof of uniqueness; what such a reconstruction can produce is an argument, effective because of its coherence and its explanatory capacity, which testifies in favour of its one existence.

Brousseau (1989) gives to the concept of epistemological obstacle the meaning of knowledge (not a lack of knowledge) that has been effective previously, in a given context, which at a certain point begins to generate answers judged to be false or inadequate and produces contradictions. Moreover, an epistemological obstacle has the characteristic of being resistant and of presenting itself sporadically even after having been overcome; its overcoming requires the passage to a deeper knowledge, which generalizes the known context and requires that the student becomes explicitly aware of it (Brousseau, 1989). According to Brousseau (1989), this reasoning can be applied to analyse either the historical genesis of knowledge or its teaching or the spontaneous cognitive evolution of student's conception. The search for epistemological obstacles can occur using two approaches: the first is, according to Bachelard, based on historical research by adopting an epistemological lens; the second one is based on the search for recurring errors in the learning process of a mathematical concept; the two research lines are intertwined: the historical-epistemological evolution can help in the identification of possible hidden models and can provide suggestions on the construction of appropriate learning situations to overcome a given obstacle; on the other hand, students' errors and recurring difficulties can suggest the presence of epistemological obstacles. Given students' enormous difficulty in understanding proof, it seems to us that the identification of

possible epistemological obstacles can be useful in teaching and learning practice and, even before, in teachers' training, providing awareness of teachers' own epistemology and of the possible gap between their own and students' conceptions.

The historical-epistemological investigations on the concept of proof are not new in Mathematics Education. Barbin (1994) traces briefly a history of proof, highlighting its different meanings in different eras. The author identifies two fractures, one relative to the convincing-explaining contrast and one relative to the role of contradiction, but does not clearly highlight the origins of proof as a conviction from an epistemological point of view; moreover, in the identification of the second fracture, she assumes that modern axiomatization is the result of a need for greater proof rigor, while we intend to show that it arises from the very nature of mathematics. Barbin concludes that deduction constitutes an obstacle and that its overcoming can be achieved through the revaluation of proof as a method. Another historical analysis that takes at times interesting epistemological aspects is that of Grabiner (2012), in which the author mainly aims to highlight the non-absoluteness of the concept of rigor and proof, without however proposing an evolutionary trajectory in which, as Bachelard states, it should become clear how one conception follows from the other (Bachelard, 1938). A last contribution that we take briefly into consideration is that of Longo (2012), in which the author emphasizes the pre-eminence of two fundamental principles for mathematical proof, which have cultural and historical roots: symmetry and order, and highlights the need for an approach in opposition to Hilbert's formalism, which should avoid recourse to actual infinity. Longo's approach is interesting but it is posed in a perspective of synthetic philosophy, which is not however the one on which the current foundation of mathematics is based.

None of the contributions examined searches explicitly for epistemological obstacles, taking at the same time a position in line with the current foundational aspects of mathematics, which are those on which teachers' training is based on and which are transposed in textbooks. Our aim is to understand if there is a path in the epistemological evolution of the object proof in the ancient Greek (and then the Western) tradition that could show changes in the modes proof was considered able to provide knowledge and about the characteristics of that knowledge.

## **The epistemological evolution of the concept of proof**

### **Ancient Greek tradition**

One of the most interesting aspects of proof in the path of ancient Greek tradition is related to its origin in an axiomatic system. Even when analyzing various other aspects, Grabiner (2012) identifies at least the reason of what she calls "a logical proof", in Greek mathematicians' need to be able to prove things that are not evident: "[...] visual demonstration did not suffice for the Greeks. [...]. Such proofs are necessary when what is being proved is not apparent." (Grabiner, 2012, p. 148). We believe that from an epistemological point of view the answer of the question is a bit more complex and should be searched upstream, in Eleatics' rejection of the epistemological validity of the experience of the senses, which led them to assume logical indicators of clarity and necessity as criteria of truth. We will explain our point of view in the next paragraph, following the original sources.

According to Parmenides, the Being is the only reality and the convincement, in the sense of persuasion through thought, is the only way that allows us to acquire reliable knowledge. Parmenides' conception of thought is that of reasoning, of logos, of what can be called "logical reasoning", which

produces *necessary* true conclusions, because when investigating truth (i.e. the Being), we start always from the Being which is not only an unchanging, indestructible whole, but is also connected: “observe how what is far away is reliably approached by your mind because it [the mind] will not separate the Being from the context of Being, nor in such a way that it [the Being] loosen anywhere in its structure nor in such a way that it masses together. Then Being is indeed connected, regardless of where I start [the research] that’s where I’ll be back again.” (Diels, 1906, p. 116). The last sentence shows exactly the conception of knowledge acquirement in Parmenides: logical reasoning, starting from necessary true premises is convincing and this kind of convincement is the only way that leads to knowledge of truth. Instead the way of investigating the Not-Being, which is not necessary, is the way of opinion linked to the senses: “the only thinkable ways of research are the following: the way of Being, which is and which is impossible but be, is the way of conviction (since it follows the truth); but the other one, that it [the Being] isn’t and that this Not-Being is necessary, is a completely inscrutable path since the Not-Being cannot be neither recognized (it is in fact unfeasible) nor pronounced” (Diels, 1906, p. 116). The fundamental Eleatic dialectic is then the dialectic between certain knowledge (and the way of convincement which allows to acquire it) on the one part, and opinion (and the way of the senses which allows to acquire it) on the other part.

Eleatics used different modes of conviction to carry out Parmenides’ “way of truth”: Zeno of Elea used the proof by *reductio ad absurdum* (or proof by contradiction) as method to destroy the arguments of the opponents showing that their premises led to contradictions, while other Eleatics, like Melissus, tended to prove arguments also starting from undoubtedly certain premises. (Cambiano, 2004). Zeno’s way of *reductio ad absurdum* is coherent with the Eleatic philosophy because there is not only a distinction of Being (real, true) and Not-Being (not real, false), that excludes the possibility of a third value, but also the fact that for the Being not be is impossible, that represents the double negation. Like outlined by Antonini and Mariotti (2008), in the past, starting from 16<sup>th</sup> and 17<sup>th</sup> centuries and up to the 20<sup>th</sup> century, there was a debate about the fact that proof by contradiction collides with the Aristotelian position that causality should be the base of scientific knowledge and that such a proof cannot reveal the causes since it is not based on true premises. We state that in the perspective of Eleatic philosophy, proof by contradiction fits perfectly with the role it has in this philosophy: the role to get knowledge of the truth of a statement by following a convincing logical thought that shows that it is necessarily so and it cannot be in another way. This is just what Zeno probably wanted to do, using such proofs, because they are not suitable to explain, but they are suitable to convince.

The Eleatic dialectic was of great importance for the subsequent development of philosophy and science. Plato’s thinking was strongly influenced by Parmenides (Cambiano, 2004) and so all the Western philosophy.

Other important aspects in the epistemological evolution of proof are the roles played by the Megarian school and by the Sophists. The Megarian philosophical school flourished in the 4<sup>th</sup> century BCE and some of the successors of Euclid of Megara, its founder, developed logic to such an extent, maintaining the Eleatic epistemological assumptions about the importance of conviction in knowledge acquirement, that they became a school in its own (Cambiano, 2004).

In the 5<sup>th</sup> century BCE the Greek society experienced a period of rapid socio-cultural transformation that led to a new politic system based on democratic principles; in this new society the need to provide

education for the children of the emerging classes arose and Sophists satisfied it (Cambiano, 2004). The ability to convince was considered one of the most important abilities for the citizen who wanted to participate in the political life of the *polis*. Sophists wanted to show that with the art of rhetoric and dialectic, even “weak” speeches could be made “strong”, since it would have been possible to reject even the most evident statements. This was a turning point to relativism with respect to Eleatic doctrine because Sophists negates the existence of absolute truth: truth is a form of knowledge always related to the subject and its experience; they are as multitude of truths as subjects. The dialectic methods used by the Sophists for their argumentations were the same used by the Eleatics: confirmation by proof conducted in rigorous logic steps and refusal by proof of the falsity of the antithesis, but Sophists perfected them; dialectic influenced deeply rhetoric, shifting attention to the persuasive force of speeches.

The Sophists’ relativism pushed many philosophers, e.g. Plato, to look for a transcendent objective basis on which to base behavior and moral conduct but also influenced the way of exposing scientific knowledge, particularly the mathematical one. It becomes clear that the Euclidean axiomatic system was developed at a time when it was necessary to place mathematical knowledge on unquestionable bases. This point of view is clearly expressed for instance by Clairaut: “this geometrician [Euclid] had to convince obstinate Sophists who were proud to reject the most obvious truths” (Clairaut, 1741, pp. 10–11). Hoüel remarks furthermore that Euclid’s frequent recourse to indirect proofs is also motivated by the need to prevent critics due to Sophists’ relativism: “[...] hence his [Euclid's] habit of always proving that a thing cannot be, instead of showing that it is” (Hoüel, 1867, p. 7).

The need to avoid any critic as the tread in organizing the mathematical knowledge can also be detected in the attention placed by Euclid on avoiding arguments which involve concepts that might leave some room for criticism, instead of using direct proofs which involve only subjects conceptually close to the statement to be proved. An example in this sense is the proof of proposition CXVII of book X of the *Elements* which states that in a square the diagonal and the side are incommensurable. In order to prove the statement Euclid uses an indirect proof that involves not only geometrical but also arithmetical arguments (e.g. concepts of odd and even number, of divisibility etc.) instead of using the proposition II of book X, introduced just before, which applies to segments the arithmetical method used in book VII to establish if two numbers are coprime (Barbin, 1994). A proof conducted using the latter method would be direct and would refer only to geometric concepts, but the problem is that it would involve an infinite procedure and might be exposed to the criticism of who asked what is, for example, the limit of the succession of squares that is built.

According to Barbin (1994) we can state that Euclid’s main concern is to be able to persuade and to avoid considerations that might leave room for critiques; an axiomatic system is a good solution to do this. Of course, the methods that could be applied to isolate the axioms might have already been highlighted by Hippocrates of Chios, “who wrote the best logically structured *Elements of Geometry* until Euclid wrote his own *Elements* 150 years afterwards” (Grabiner, 2012, p. 150), but the real motivation to do this should be detected in the philosophical and cultural environment of the time.

In our analysis we cannot avoid to mention Aristotle because of his influence in shaping medieval scholarship, not only in the Western but also in the Islamic world. Aristotle, starting initially from a Platonist position, reversed later in a certain sense the ontological question advocated by the Eleatics and then by his master Plato. Aristotelian ontology, like the Platonic one, distinguishes between

Universal and Particular, but while for Plato universal forms are separate from particular manifestations, for Aristotle the Universal is in the Particular and the only way to access the Universal is through the Particular, using the perception of the senses, in particular the eye, because in perceiving the world we prefer the sight to all the other senses (Aristotle, 1973). One might wonder why the Aristotelian doctrines have not changed the idea of proof and why there is no trace of them in the *Elements* and why the concept of proof contained in the *Elements* remained the prototype of (not only) mathematical proof for a lot of time. We can say that while the ontological aspect is reversed, Aristotle's epistemology remains similar to the Platonic one. Indeed, both, Plato and Aristotle, are interested in the knowledge of Universals though the way to reach them is different: Aristotle's empirical approach is linked to exploration, which can also refer to induction or abduction, but its aim is to arrive at "true" knowledge; this last way is nonetheless deductive and proof is the final step of the process of knowledge acquirement (Cambiano, 2004).

### **Enlightenment and the “small steps”: the first crisis**

Until the 17<sup>th</sup> century the concept of proof in mathematics remained linked to the idea of proof in an axiomatic system such as that of geometry presented in Euclid's *Elements*, even if, due to the lack of adequate mathematical tools, attempts to axiomatize other fields of mathematics remained sporadic and ineffective for a long time (Lolli, 2004). The 17<sup>th</sup> century was a particular historical and cultural period during which there were a lot of important discoveries and innovative and courageous stances in science. Alongside of Galileo's scientific method, new general mathematical methods were developed in order to satisfy the need to describe the physical phenomena, like Cavalieri's principle of indivisibles, the Cartesian method, Newton's method, Monge's projective method etc. In these rapid innovations the ancient Greek writings, first of all Euclid's *Elements*, were exposed to a hard criticism by the mathematicians. They accused ancient Greek geometer to be more interested in persuasion and in validation than in explanation and discovery. What is criticized is not the content but the form, the setting and the role attributed to proof. In Arnauld's and Nicole's *La logique ou l'art de penser* the authors expose the widespread feeling among their contemporaries summarizing as follow the errors attributed to Greek geometers: (1) to pay more attention to certainty than to evidence and to the conviction of the mind than to its enlightenment; (2) to prove things that have no need of proof; (3) to demonstrate by impossibility; (4) to conduce far-tetched demonstrations; (5) to pay no attention to the true order of nature; (6) to employ no divisions and partitions (Arnauld & Nicole, 1850). The critiques are basically two. The first, which contains the first four errors, concerns the single results and can be summarized in the question: "Is it more important to convince or to enlighten?". The second, which involves the whole structure of the text, is the accusation of a lack of method (the sixth error can be regarded as the consequence of the fifth one).

With regard to the new methods elaborated by mathematicians during the 17<sup>th</sup> century there was an important epistemological aspect that mathematicians of the time were already asking themselves: the problem of the validity of the new methods. Barbin summarizes as follows the doubt in this regard: "these methods illuminate, clarify the spirit, as they show the way to which we have passed and lead to evidence [...] but what is made evident can be considered as demonstrated?" (Barbin, 1994, p. 223). Thus, for example, Cavalieri's method of indivisibles, which already carried the idea of the integral, aroused some suspicion because of its resort to actual infinity, despite its operational superiority compared to Archimedes' method of exhaustion.

One method that initially does not raise suspicion was instead the Cartesian method which essentially led to a general algebraic conception of proof. The method described by Descartes in his *Discours de la Méthode* (1966), his *small steps*, his *long chains of reasons*, *all simple and easy*, were the attempt to provide a method of discovery to mathematics which quickly imposed itself on a large scale even though it posed some practical difficulties and mathematicians found it difficult to resort to it in practice (Lolli, 1988). We should however keep in mind that there are two different layers of evidence in Descartes' conception: the one is related to the physical evidence of the axioms in Euclidean geometry, which is the basis of mathematics and that remains undisputed; the other is related to the evidence of the starting point and of the "small steps" of reasoning that should be so simple and evident to be intuitively accepted by anybody without any doubt about their correctness. Both these evidences will be questioned by the subsequent development of mathematics.

### **Mathematical proofs, physical reasons and the second crisis**

At the end of 17<sup>th</sup> and beginning of 18<sup>th</sup> centuries, with the growing of Analysis, it becomes more and more clear that the algebraic conception of proof was insufficient for the type of investigation mathematics was going to face [see for instance the need to deal with functions and infinitesimals and in general with infinite entities (Lolli, 1988)] and that requires a purely mathematical definition of the involved objects. Furthermore, the development of abstract algebra allowed a new, structural organization of mathematical knowledge. All these reasons allow the take-off of pure mathematics which does not (should not and could not) refer to physical evidence. On the other hand, the birth of non-Euclidean geometries led to a subsequent loss of authority of geometry as foundation of mathematics, based before on the physical evidence of its axioms. The birth of general theories with multiple interpretations and the need to give a unitary organization of mathematics led to increasing awareness of the importance of the definition of mathematical objects through interrelations of formal axioms, which allows multiple interpretations; all this finally led to the modern axiomatic model.

Axiomatization implies an important change of perspective: a change in concept and role of contradiction: in ancient Greek mathematics the contradiction intervened in a social act and was used to convince: to prove means to convince; the modern conception of contradiction is very different: contradiction intervenes in a system of mathematical propositions and it is used for producing mathematical results: to prove means to make evident the non-contradictoriness of a statement within an axiomatic system. The concept of evidence makes no sense in this formalistic conception of mathematics: the objects are *real* inasmuch they are defined by the relations between them; there is no need for physical or metaphysical reality to refer to. The only way to deal with such abstract formal objects is formal reasoning: implicit definition and formal logical principles are needed for the new conception of proof, based on non-contradictoriness; the new axiomatic model is not due to a perverse and arbitrary will of formalization but to the formal character of mathematics (Lolli, 2015).

### **Modern axiomatization and the need for interpretation**

Modern axiomatization underpins and highlights the special ontological condition of mathematical objects to which an ostensive cross-reference is impossible and shows clearly the essentially semiotic nature of mathematical activity; but it poses an important problem: in a formal axiomatic conception of mathematics asking for meaning of mathematical objects makes no sense. The only way to give meaning to them is dealing with them in an interpretation of the formal theory. An interpretation

needs a language that allows to express the relations of the objects occurring in it. Bourbakism rendered clear that set theory is a formal language which is most similar to natural language and that allows to construct mathematical discourses, giving a meaning to mathematical activity. Experts in mathematics are able to give a meaning to a discourse in set-theoretical language (they are able to use it, enriching its expressivity by natural language without losing its mathematical meaning) and so they are usually convinced of the unity between mathematical and natural languages; but this competence is only the confirmation of the fact that the metalanguage (natural language) has successfully fulfilled its role as constructing tool for the object language (mathematical language).

## Conclusions

Our analysis shows three epistemological obstacles which forcefully impose themselves in the examined path: (1) the belief that the proof concept in Euclidean Geometry may be used to *explain* mathematical reasoning; (2) the belief that contradiction in mathematics has the role of convincing and that to prove means to convince somebody of the truth of an utterance and not the role to establish the consistency in an axiomatic system, i.e. to establish its validity; (3) the supposition that mathematics is not a discourse in itself but one that is telling something about something that really exists and that to prove means to prove the truth of a statement and not its validity in a metalanguage as well the subsequent supposition of the unity between natural language and mathematical language and the consequent lack of awareness of the complex relation between them.

All three obstacles represent important topics related to the teacher's epistemological beliefs and the way in which teachers implement the didactic transposition of the mathematical object "proof". Moreover, we stress that against the third obstacle, the whole teaching of modern mathematics collides. Without the awareness of the latter, at school we will continue to teach only Euclidean mathematics and the concept of proof present in it, believing that the modern axiomatic method is only a generalization of the Euclidean one.

Furthermore, while the first two obstacles can be considered as obstacles already crystallized in Western culture, the third is an obstacle of very recent formation and it is still little perceived and not recognized. This obstacle also places the cultural aspect in the foreground as it can have very different cultural declensions. Indeed, while the general semiotic aspects might have a general characterization, semiotic aspects related to the natural language can be specific (Lolli, 2015). While the overcoming of the first two obstacles requires the entry into a certain culture of mathematical thought (which has its roots in ancient Greek tradition), the overcoming of the third obstacle requires a specific transposition, dependent on the peculiarities of the natural language of reference.

Concerned to the usefulness of the epistemological obstacles in Mathematics Education, we can say that within Brousseau's (constructivist) theory of didactic situations, acquiring knowledge means adapting to a specially designed situation that has that given knowledge as optimal solution (Brousseau, 1989); it is therefore worth to identify the epistemological obstacles in order to help teachers to construct situations in which the student is forced to use a type of knowledge that leads her/him to overcome the obstacles, supported by teacher's mediation choices. In a socio-cultural perspective, instead, the interpretation of the notion of epistemological obstacle could present some difficulty because of the specificity of mathematical cultural production (D'Amore, Radford, & Bagni, 2006). Nevertheless, also in a socio-cultural perspective, the institutional meaning of

mathematical objects refers to a certain cultural tradition which could hide eventual epistemological obstacles.

# Teachers' perspectives on mathematical argumentation, reasoning and justifying in calculus classrooms

Sabrina Bersch

University of Augsburg, Germany; sabrina.bersch@math.uni-augsburg.de

*An interview study on mathematical argumentation (in a broad sense) was conducted with teachers of upper-secondary calculus classrooms. This paper describes the study's methods and its results. By using qualitative text analysis, four major categories were created to depict the current state of mathematical argumentation in calculus classrooms. Two dominant problem areas were revealed: Students' language difficulties and the heterogeneity of students. To address these problems, a learning environment was designed and evaluated in a follow-up study.*

*Keywords: Argumentation/Reasoning/Justifying, calculus, secondary school teachers, semi-structured interviews, learning environment.*

## Introduction and theoretical background

Mathematical argumentation, reasoning, justifying and proof indisputably constitute an important field of mathematical competencies. Nevertheless, the 1995 and 1999 TIMSS Video Studies found that reasoning did not occur frequently in mathematics classes of the examined countries (Hiebert et al 2003, p. 73-75). Since 2003, the *Bildungsstandards* set by the KMK<sup>1</sup> have functioned as an important framework for teaching mathematics in Germany. One of the process-related competences they specify is *Mathematisch Argumentieren* (approximately corresponding to *mathematical argumentation*). This term is used as an umbrella term for working with mathematical conjectures and statements by employing a range of argumentations, from arguments of plausibility through justifications to formal proofs (KMK 2012, p. 14). In the United States, the Principles and Standards for School Mathematics were published by the National Council of Teachers of Mathematics (NCTM) in 2000 as one of the first sets of standards for mathematics teaching. One of the Process Standards set by the NCTM is *Reasoning and Proof*, which also comprises reasoning, proving, using conjectures, argumentation and justification (NCTM, 2000). In this paper, *mathematical argumentation* is used in a broad sense, including all aspects used by the KMK and the NCTM. In addition, pre-formal or semi-formal mathematical activities of argumentation, reasoning and justifying are considered suitable for mathematics in school and useful, necessary steps to formal, deductive proving as an essential mathematical activity. The term *formal* is “referring to the standard language used to talk about mathematics, which encodes the meanings of mathematics” (Barwell 2016, p. 333). Mastering this standard language is considered its own learning item for students. Pericleous similarly states that “explanation, justification and argumentation [...] provide a foundation for [...] developing deductive reasoning” (2015, p. 226). However, the level of formality and deductive reasoning that should be acquired in school is open to debate.

---

<sup>1</sup> The *Bildungsstandards* are Educational Standards set by the Conference of Ministers of Education and Cultural Affairs in Germany (KMK)

Teachers' perspectives on argumentation in class are of great importance, because teachers are responsible for providing learning environments and tasks for students (Buchbinder, 2017, p. 107). They have gained significant experience with students' processes of acquiring competencies. Yet, there is little research on argumentation from a teachers' perspective to date. The discussed study investigates the role and importance of mathematical argumentation in calculus classrooms, explores teachers' attitudes and ideas about mathematical argumentation and reveals problems and difficulties teachers face when training students' mathematical argumentation competencies. Interviews with 14 teachers of different schools teaching upper-secondary students in calculus were conducted and analysed using qualitative text analysis<sup>2</sup>. In a follow-up study, a learning environment was developed and evaluated based on the results of the interview study. In this paper, the interview study is described in detail including its methods and findings. The paper concludes with a short outlook on the follow-up study.

## Methods

There were two main research questions: (1) *Which role does mathematical argumentation play in current calculus classrooms?* (2) *Which problems and difficulties do teachers face with regard to mathematical argumentation in calculus classrooms?* To answer these questions, semi-structured interviews were conducted with 14 upper-secondary school teachers. The interview manual had four parts with different thematic foci. The participants had been informed that the topic would be calculus teaching. However, the emphasis on mathematical argumentation was not mentioned before the second part of the interview, because the first part was about calculus teaching in general and argumentation was only focused on in the other three parts.

14 upper-secondary school teachers, 5 female and 9 male, were chosen from 7 different schools (6 in Bavaria, Germany; 1 in Hesse, Germany), teaching different subjects in addition to mathematics. Their age ranged from 30 to 64 years with teaching experience from 4 to 36 years.

The analysis of the interviews used a combination of methods of qualitative content analysis (Mayring, 2015) and thematic qualitative text analysis (Kuckartz, 2014). First, a selection criterion was applied to detect all passages of the interviews concerning the topic of mathematical argumentation. Then, major categories were created deductively according to the interview guidelines and the research questions. After applying them to the data, they were further differentiated into subcategories inductively using the codes of each major category. Processes of subsumption and clustering were used to establish the final category system with various levels for the analysis.

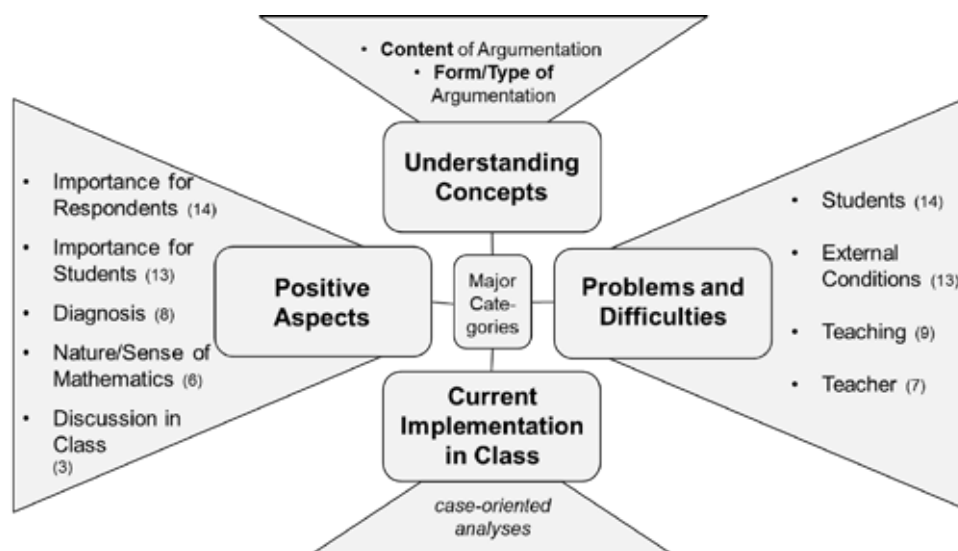

## Results

Figure 1 presents an overview of the category system. The major categories are *Understanding Concepts*, *Current Implementation in Class*, *Positive Aspects* and *Problems and Difficulties*. The numbers in brackets state the numbers of respondents (out of 14) whose statements contained segments for the respective subcategories. Each category is described separately in the following.

---

<sup>2</sup> A rough overview of the interview study is being published in (Scheffler, 2018) and parts of the results have been published in (Scheffler, 2017).

**Figure 1: Major categories of the qualitative text analysis of the interviews**

### ***Understanding Concepts***

The major category *Understanding Concepts* comprises segments from which it can be concluded what teachers mean when speaking of *argumentation*, *reasoning*, *justifying* or *proving*<sup>3</sup>. Segments within this category were categorized throughout all parts of the interviews, because the participants were not directly asked about their understanding of the terms. Various ideas could be found and subdivided into two subcategories: Ideas about the *Content of Argumentation* and ideas about the *Form/Type of Argumentation*. The teachers' statements do not only contain ideas about their actual teaching but also about their general understandings of argumentation. Both subcategories demonstrated a wide range of understandings. The most frequent opportunities for mathematical argumentation mentioned were situations in which students needed to justify their approaches when dealing with any mathematical exercise or task or justify certain mathematical theorems, rules or formulas. In addition, it was described that students reason when working with properties of various functions or when modelling mathematically. More generally, the teachers stated that mathematical relations or issues can be used for mathematical argumentation in class.

In the subcategory *Form/Type of Argumentation*, it is striking that most teachers talked about formal proving but mostly commented on the lacking feasibility of using proofs in class. Other ways of mathematical argumentation mentioned by several teachers were justifying using calculation, explaining or elucidating, verbal justification and justification supplemented by sketches. This results in a varied field of teachers' understandings of how argumentative competencies can play a role in calculus classrooms and what mathematical content can be used for these purposes. These findings

<sup>3</sup> In the interviews, I used the German terms *Argumentieren* and *Begründen* (approximately corresponding to *argumentation* and *justification* in English) as synonyms and avoided the term *Beweis* (*proof*) as it has negative connotations for some teachers. For the category *Understanding Concepts*, all segments of the interviews were used which showed understandings of any of the terms *Argumentieren*, *Begründen* or *Beweisen*.

correspond to the broad understanding of the term used in the German KMK *Bildungsstandards* and in the NCTM standards.

### ***Current Implementation in Class***

Descriptions of what the teachers actually do in class concerning mathematical argumentation are collected in the subcategory *Current Implementation in Class*. Each case was analysed separately by summarising and abstracting the main ideas. The following overall tendencies about the current state of mathematical argumentation and proof in calculus classrooms could be found:

- Tasks in which students are asked to give reasons play a significant role.
- Formal proving, theoretical justifying and systematic derivations only occur occasionally, with most argumentations and justifications being informal, oral and not written.
- Teachers reason and justify more than their students.
- Argumentation and reasoning seem to be opposed to standard techniques which are trained mainly for the final examinations.

These practical tendencies are based on teachers' attitudes towards argumentation and reasoning in calculus classrooms. These attitudes are connected to the reasons teachers have to train their students' argumentative competencies. These reasons can be deduced from positive remarks about argumentation collected in the major category *Positive Aspects*. On the other hand, *Problems and Difficulties* with argumentation in calculus classrooms concern reasons why teachers use fewer opportunities for mathematical argumentation in their classes than they ideally should.

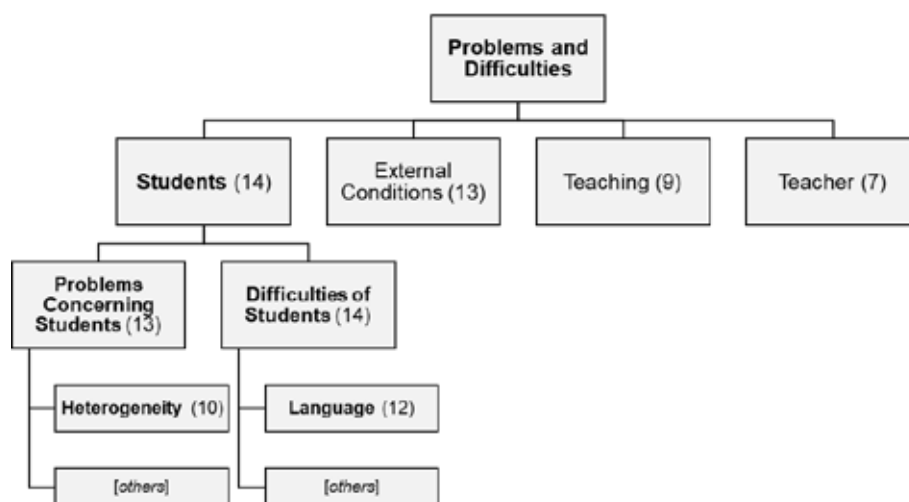

### ***Positive Aspects***

The positive statements about mathematical argumentation in calculus classrooms can be divided into 5 subcategories: Segments showing that mathematical argumentation is important for the teachers themselves (1) or for the students (2), segments explaining that mathematical argumentation is a good way for diagnosing students' skills (3), segments in which teachers state mathematical argumentation to be an essential part of mathematics (4) and segments in which teachers express that employing mathematical argumentation results in good discussions in class (5). The most interesting results can be found in the subcategory *Importance for Students* (2) which includes segments in which teachers explain how mathematical argumentation in class has positive effects for the students. In their opinion, mathematical argumentation is crucial for the students' content-related competence. It is also considered important for the students' future in mathematics and beyond. Teachers point to students who really like reasoning and to more proficient students who can demonstrate their skills with justification tasks.

### ***Problems and Difficulties***

Nevertheless, there are many problems and difficulties with mathematical argumentation in calculus classrooms. As it has been explained above, there is a reluctance to use formal proofs for different reasons which are not focused on in the study. For this reason, remarks stating difficulties and problems specifically with formal proofs were not coded in the major category *Problems and Difficulties*. Emphasis was put on argumentation in general. As Figure 1 and Figure 2 show, 4 subcategories could be created inductively in the major category *Problems and Difficulties*. All

teachers mentioned problems and difficulties concerning the *Students* and nearly all teachers have problems with the *External Conditions* they face. In addition, there are problems and difficulties in the area of *Teaching* and difficulties for the *Teachers* themselves. Notably, difficulties for the *Teachers* themselves all deal with grading mathematical argumentation tasks. Problems with *Teaching* arise because teachers do not consider reasoning and justifying tasks suitable for examinations, and training standard calculation techniques has priority in their teaching. *External Conditions* that cause most problems for teachers are the restricted time available for teaching and the requirements of the centrally organised final examinations.

**Figure 2: Part of the category system with a focus on *Problems and Difficulties***

The subcategory *Students* contains by far the most difficulties and problems that were mentioned by the teachers. It is further subdivided into *Problems Concerning Students* and *Difficulties of Students*. Due to their size, these subcategories were further subdivided:

Firstly, by far the largest subcategory of the subcategory *Problems Concerning Students* is *Heterogeneity*. Segments in this subcategory are about problems that arise because of students' different performance levels. While teachers are of the opinion that low achieving students have serious problems with mathematical argumentation tasks, such tasks are seen as a particular challenge for high achieving students. Consequently, teachers do not know how to cope with the great span and often decide not to use justification tasks in class. An example segment within the subcategory *Heterogeneity* is the following:

First of all, I often think that these justification tasks are only accessible for a part of the students so that another part of the students is left behind by these justification tasks. And for them, it is important to do tasks in which they can use their learnt strategies. So, I would not use 45 minutes just for training argumentation, because after some time I would sit there just talking to five students and the other 20 are looking into the air (Interview 8, paragraph 58, own translation).

Other *Problems Concerning Students* result from students' aversion to argumentation amongst others.

Secondly, within the other subcategory, *Difficulties of Students*, a dominant subcategory evolved as well: *Language*. This subcategory contains segments dealing with problems students have with, for

example, terminology, formulations, and especially writing down argumentations and justifications. An example segment within the subcategory *Language* is the following:

And of course language, that's an important point, whether mathematical language or German language, stringing two sentences together. What is given? So, what can be concluded? That is what causes most problems (Interview 9, paragraph 56, own translation).

Apart from language problems, there are other issues students have problems with when working on argumentation tasks: the general validity of mathematical statements, mathematical precision and accuracy, recognizing the expectations and technical contents amongst others.

The interview study showed that teachers have a wide range of ideas about which aspects of mathematical argumentation exist and their attitude towards argumentation in calculus classrooms is positive to a large extent. However, teachers state that there is little formal argumentation and proof in their classrooms. Training standard techniques is far more important than training argumentation competencies. In addition, many varied problems and difficulties concerning the training of argumentation competencies could be gathered. As *Heterogeneity* and *Language* could be found as being dominant problem areas, developing a proposal for facing these problems was the aim of a follow-up study.

### **Follow-up study: Development and evaluation of a learning environment**

To address the dominant problem areas found in the interview study, students' *Language* difficulties and the *Heterogeneity* of students, a calculus learning environment<sup>4</sup> with justification tasks was designed and given to 15 teachers for application and subsequent evaluation.<sup>5</sup> Language support is provided by a toolbox in two versions, based on ideas of Meyer and Prediger (2012), among others. To cope with the students' heterogeneity, potential for differentiation is given by a task structure orientated towards Bruder and Reibold's concept of *Blütenaufgaben*<sup>6</sup> (2011). To support students who have problems with argumentation in general on the one hand and students with problems concerning language on the other hand, there is a prepended worked-out example. A study of Reiss et al indicates that "self-explaining heuristic worked-out examples are a qualified instrument for improving students' achievement on reasoning and proof in the mathematics classroom" (2008, p. 463).

The learning environment was evaluated using written interviews. The analysis of these interviews showed that the learning environment is suitable for differentiation and the language support works

---

<sup>4</sup> The term *learning environment* is used for a large task with several subtasks embedded in a lesson plan together with instructions and additional material bound together by one central idea. This is based mainly on (Hirt & Wälti, 2008).

<sup>5</sup> The design principles of the learning environment and first results of study 2 have been published in (Scheffler, 2018).

<sup>6</sup> *Blütenaufgaben* (literal translation: *blossom tasks*) open like flower heads, which means their subtasks have different requirement levels and vary from closed to open-ended tasks. The subtasks are independent, though (Bruder & Reibold, 2011).

if a suitable version of the learning environment is chosen. As a result, it is important that teachers have distinct diagnostic competencies to be able to support their students.

## Discussion and Conclusions

This paper presented an interview study with teachers about mathematical argumentation in upper-secondary calculus classrooms. The qualitative and explorative character of the study provided an insight into current practices of argumentation in calculus teaching. The results might be used to generate possible hypotheses which could be examined quantitatively to learn more from the teachers' perspective. Whether the results can be transferred to other sections of mathematics teaching in upper-secondary school, is debatable. The complexity of calculus in comparison to stochastics and analytic geometry indicate that automatic transfer is not possible. What could be shown is that the interviewed teachers have a wide understanding of mathematical argumentation. They include different aspects of argumentation and reasoning in their calculus classrooms, but they hesitate to incorporate justifications in a written way or let students do so. They are also reluctant to use formal argumentations such as proofs, which is a bit surprising because teachers spoke of the upper-secondary level. This, however, can be justified as long as pre- or semi-formal mathematical argumentation is seen as pre-stage to proving, interested students are able to encounter formal arguments as well, and a realistic and representative view of mathematics is conveyed. Although the KMK *Bildungsstandards* have set a framework for teaching mathematics on an upper-secondary level in Germany, argumentation does not seem to play a role in mathematics teaching as much as it ideally should. Teachers basically have a positive attitude towards training argumentative competencies in their calculus teaching, but they also face a wide range of problems and difficulties. Two dominant problem areas could be found: Students have difficulties with language, especially when writing down their justifications, and teachers have problems dealing with the heterogeneity of their students. To work on these problems, a learning environment with differentiating character and language support has been developed and evaluated in a follow-up study. It could be shown that taking action is possible and that it is important for teachers to choose suitable teaching material for their students. More material should be developed to assist teachers and hence to help students develop argumentative competencies. It is a good basis that the interview study suggests that teachers consider argumentation in calculus classrooms important.

# Integrating Euclidean rationality of proving with a dynamic approach to validation of statements: The role of continuity of transformations

Paolo Boero<sup>1</sup> and Fiorenza Turiano<sup>2</sup>

<sup>1</sup>University of Genoa, Italy; boero@dima.unige.it

<sup>2</sup>I. I. S. Arimondi – Eula, Savigliano, Italy; fiorenza.turiano@gmail.com

*During a long-term teaching experiment aimed at developing 10<sup>th</sup> grade students' culture of theorems through a pathway in Euclidean plane geometry, some students' autonomous reasoning moved towards non-Euclidean proofs based on continuity of transformation of geometric figures. Based on the use of existing analytical tools to analyze such episodes, the aim of this paper is to outline a wider scope for synthetic geometry in order to make it more suitable for students' approach to the culture of theorems. Through the introduction of a continuity principle to legitimate such extension, the paper suggests how to exploit students' potential in transformational reasoning, and to bridge the gap between synthetic geometry and analytic geometry rationalities in classroom work.*

**Keywords:** Euclidean geometry, transformational reasoning, continuity principle, rationality.

## Introduction

Since 2016 we are engaged in designing and implementing in 10<sup>th</sup>-grade classes a teaching and learning pathway in Euclidean geometry aimed at promoting students' approach to the culture of theorems (Bartolini Bussi, Boero, Ferri, Garuti, & Mariotti, 2007) – i.e. at developing not only the knowledge of statements, proofs and their applications, but also autonomous proving and the awareness of crucial meta-knowledge about theorems (the role of hypotheses and thesis, the requirements of proof, etc.). Such aim is not easy to attain; the question that originated the study reported in this paper was: is it possible to lessen the students' difficulties with proving by legitimating some spontaneous ways of solving geometry problems and validating statements? Let us consider an episode, a single case of a wider phenomenon observed in the three classes where the experiments on our pathway have been performed. Its role is to put into evidence the potential inherent in students' dynamic approach to solving theoretical problems in geometry. Students have already learnt to construct a circle tangent to both sides of an angle, and to justify the construction. In interaction among them and with the teacher, students have learned to build up the circle with center chosen on the bisector and ray derived from the following construction: to draw the perpendicular line from the chosen center to one side of the angle; to consider its intersection with that side, and the segment joining it with the center as the ray of the circle. They have proved (with the help of the teacher) that the drawn circle is tangent to both sides of the angle through the steps of Euclid' validation of the same construction. Some weeks later they are asked to construct a circle tangent to the three sides of a given triangle. They have at their disposal a worksheet with a drawn triangle, the ruler and the compass.

One student (Ale) draws the bisector of the angle ABC, then he tries to choose a point on the bisector as the center of a circle by taking different points on the bisector and adapting the width of the compass to the sides of the triangle. Finally, he draws the circle S (the arrow and S are added to the original figure). Ale is not satisfied with his drawing. After a while he makes a free-hand drawing of a circle near to B, then other circles more and more near to AC. Finally, he stops and observes the worksheet for several seconds.

**Figure 1**

Then he starts writing: “The solution of the problem is when the circle, which is tangent to the sides of the angle B, meets the third side”. The participant observer (PO: the first author of this paper) starts an interaction with Ale:

PO: May you explain your reasoning to me?

Ale: The tangent circle becomes bigger and bigger, and a certain moment a circle will meet the third side. It will be the solution!

PO: Why? Are you sure that it is tangent to the three sides of the triangle?

Ale: Yes, when I move the center on the bisector the circle is (pause) the circle becomes bigger and bigger, and remains tangent to the two sides of the bisector (pause)

PO: Are you sure that it becomes tangent to the third side?

Ale: Because the circle (pause) if I continue moving the point on the bisector, one part of the circle will go outside the triangle (pause) Therefore there will be ONE (emphasis) point to get the contact, (pause) the tangency with the third side.

PO: And if the circle becomes bigger and bigger?

Ale: It will be no more tangent to the sides of the triangle, but... No, if I come back, the two intersections finally join in the tangency point.

Given that the circle exists (by such continuity considerations) it is easy to prove that its center belongs to the three bisectors - provided that students already know that if a point is equidistant from the sides of an angle, it belongs to the bisector of the angle, and that the tangent straight line is perpendicular to the ray in the point of tangency. Hence the ruler and compass construction may be easily made by using the intersection point of two bisectors and the perpendicular straight line from it to one side of the circle. In this case *the method of construction derives from the reasoning used to prove the existence of the tangent circle* and the knowledge of its properties. Note that performed exploration might result in the construction of a theoretical justification (*cognitive unity of theorems*: see later), once Ale’s reasoning by continuity would be legitimated.

In Book IV of the Elements (prop.4) Euclid describes how to construct a circle tangent to the three sides of a given triangle and provides a theoretical justification for it.

PROPOSITION 4 (book 4, Heath’s translation)

In a given triangle to inscribe a circle.

Let ABC be the given triangle; thus it is required to inscribe a circle in the triangle ABC.

Let the angles ABC, ACB be bisected by the straight lines BD, CD [I. 9], and let these meet one another at the point D; from D let DE, DF, DG be drawn perpendicular to the straight lines AB, BC, CA.

Now, since the angle ABD is equal to the angle CBD, and the right angle BED is also equal to the right angle BFD, EBD, FBD are two triangles having two angles equal to two angles and one side equal to one side, namely that

**Figure 2**

subtending one of the equal angles, which is BD common to the triangles; therefore they will also have the remaining sides equal to the remaining sides;

[I. 26], therefore DE is equal to DF. For the same reason DG is also equal to DF. Therefore the three straight lines DE, DF, DG are equal to one another; therefore the circle described with centre D and distance one of the straight lines DE, DF, DG will pass also through the remaining points, and will touch the straight lines AB, BC, CA, because the angles at the points E, F, G are right.

For, if it cuts them, the straight line drawn at right angles to the diameter of the circle from its extremity will be found to fall within the circle : which was proved absurd; [III. 16] therefore the circle described with centre D and distance one of the straight lines DE, DF, DG will not cut the straight lines AB, BC, CA; therefore it will touch them, and will be the circle inscribed in the triangle ABC. [IV. Def. 5]. Let it be inscribed, as FGE.

Euclid's line of thinking is different from Ale's. Euclid describes how to solve the problem of the circle inscribed in a triangle by *finding candidates to be the center of the circle and three of its rays*, then a *theoretical justification for the chosen solution follows*, which relies on definitions and previously proved theorems, and results in a proof of the existence of the inscribed circle. No continuity or transformational considerations are made.

Based on the above episode and other episodes that will be shortly presented later, and with reference to some constructs in mathematics education literature, integrated with a *principle of continuity to legitimate the widening of the scope of synthetic geometry*, we will present and discuss the potential inherent in students' transformational reasoning (Simon, 2006) in the approach to the culture of theorems, once that principle is assumed.

## Theoretical background

### Transformational reasoning, and the continuity principle

Transformational reasoning was defined by Simon (1996) as:

The mental or physical enactment of an operation or set of operations on an object or set of objects that allows one to envision the transformations that these objects undergo and the set of results of these operations. Central to transformational reasoning is the ability to consider, not a static state, but a dynamic process by which a new state or a continuum of states are generated (p. 201).

In past research of our group this construct was already used, in particular, to characterize one of the types of generation of conditionality of statements (Boero, Garuti, & Lemut, 1999). In this paper it will be used to describe processes of discovery of the reason why a statement is true, or strategies to solve a construction problem in Euclidean geometry.

In our toolkit we will integrate the construct of transformational reasoning with a *principle of continuity*. Continuity provides students not only with hints for the solution of a construction problem or a proving problem, but also, in some cases, substantial elements for the validity of the construction and the proof. For instance, in the episode presented in the Introduction, Ale "by continuity" proves the existence of the tangent circle. Thus a principle of continuity as a criterion for the epistemic validity of a conclusion derived through transformational reasoning might widen the scope of acceptable proofs, with positive consequences for the approach to the culture of theorems (see Discussion). How to formulate the continuity principle within the perspective of synthetic geometry

(i.e. geometry theory based on constructions performed with ruler and compass)? Continuity axioms (including Archimedes' axiom) were among the axioms added by Hilbert to Euclid's axioms (Trudeau, 1987), but it is not easy to formulate a consequence of them which in simple operational terms accounts for the truth of the "existence theorem" proved by Ale. However, it is possible to provide a formulation of the continuity principle in operational terms by making reference to analytic geometry:

The continuity principle guarantees the solution of a synthetic geometry problem through transformational reasoning provided that the translation of the problem and the related transformational strategy into analytic terms (by using algebraic expressions) allows a treatment which brings to the solution thanks to the continuity of the set of real numbers.

As an example, consider the episode presented in the Introduction. As a generic example (Mason & Pimm, 1984) of the situation, we may assume  $B=(0,0)$ ,  $a$  represented by  $x=0$ ,  $b$  represented by  $y=0$ , and the side  $AC$  represented by  $y=-2x+3$ . Then the system  $y=-2x+3$  &  $(x-K)^2+(y-K)^2=K^2$ , will represent the circle centered in the point  $(K, K)$  of the bisector, which is tangent to  $a$  and  $b$ . By varying  $K$  we represent the situations of no intersection with the straight line  $y=-2x+3$ , of tangency (two possibilities, including tangency from the exterior), and of intersection in two points.

We will use the above criterion as a provisional solution for the characterization of the continuity principle; further research (and the analysis of more episodes!) is needed to formulate it in more precise and effective terms.

## Theorems

Mariotti (2001) defined a Theorem as a statement and its proof with reference to a theory (and related inference rules). With reference to Guala & Boero (2017), Mariotti's definition

encompasses theorems related to various kinds of theories throughout history (e.g., Euclid's, as well as Hilbert's, geometry; graph theory, with its crucial reference to visual objects; 19th-century classical probability theory as well as Kolmogorov's axiomatic theory, etc.), together with the different ways of considering proof since the Greeks (Grabiner, 2012) along with the cultures these ways came from (Siu, 2012) (p. 210).

In this paper we use the construct of Theorem to consider different, possible ways of proving the same theorem with reference to different theories and different inference rules.

## Cognitive unity of theorems

After having found some cases of theorems (in geometry, and in elementary arithmetic) for which students behaved in a similar way, Garuti, Boero and Lemut (1998) defined "cognitive unity of theorem" what happens for some theorems when:

during the production of the conjecture, the student progressively works out his/her statement through an intensive argumentative activity functionally intermingled with the justification of the plausibility of his/her choices. During the subsequent statement-proving stage, the student links up with this process in a coherent way, organizing some of the previously produced arguments according to a logical chain (p. 345).

The cognitive unity construct was also extended to the case of the relationships between the exploratory phase of proving a theorem, and the subsequent construction of a proof for that theorem (Garuti et al., 1998): indeed, the exploratory phase of proving shares some common aspects with

conjecturing (as re-construction of the meaning, and appropriation, of a statement; and identification of elements for its validity).

The cognitive unity construct may be used to account for what happens when students produce, thanks to transformational reasoning, arguments that may be re-arranged in a proof (be it Euclidean, or based on a continuity principle: see the episode in the Introduction).

### **Rationality**

Many cultural activities (including mathematical ones) may be described as discursive activities sharing some common features: First, criteria to establish truth and falsity of propositions, and validity of reasoning. Second, strategies to attain the goal of the activity, which can be evaluated. Third, a specific language for social interaction and self- dialogue.

The *rationality* construct elaborated by Habermas (1998) may be exploited to move from such a superficial description to a deeper treatment of discursive activities. According to Habermas' construct, rational behavior is characterized by: conscious taking in charge of truth and validity criteria (*epistemic rationality*), of strategies to attain the goal (*teleological rationality*), and of communication means (*communicative rationality*); and by dynamic links between knowing, doing and communicating in the rationality perspective (for a discussion of potential and limitations of Habermas' construct as it was adapted to mathematics education, see Boero & Planas, 2014).

### **Where the episodes come from**

We think that it is important to put into evidence some salient features of the long term teaching experiment that provided us with the elements for the theoretical elaboration of this paper (in particular, Ale's and other episodes like those presented here); in particular we agree with Simon (1996) when he says that transformational reasoning is a natural way of thinking, which needs to be "nurtured" - thus suitable cultural and educational choices must be performed in order to allow students to develop it.

### **A teaching-learning pathway to the culture of theorems**

We have chosen to base the approach to the culture of theorems in grade X of high school on the Euclid's plane geometry for the following reasons: First, in Italy, since the end of the XIX century and for several decades Euclidean geometry was the main subject intended to allow secondary students to meet theorems, proofs, proving. Second, Euclidean geometry offers the possibility to approach different kinds of proof (including proof by contradiction – the preferred indirect proof in Euclid's Elements). Third, through the alternation of "theorems" and "constructions to be validated" in Euclidean geometry the teacher is offered the opportunity of stressing the relevance of theoretical thinking in mathematics – in particular the distinction between a drawing and a geometric figure, and the need of moving from visual truth to theoretical truth (even if in Euclid's elements the goal of going beyond visual evidence to validate statements is not completely accomplished: see Trudeau, 1987. However, in our design we have not followed any path taken as such from Euclid's Elements; we have chosen only some constructions and some theorems. In the case of theorems with a thesis consisting of more than one claim we have chosen only one claim (this is in the case of the theorem considered in the second and third episodes below).

## The educational context of the episodes

The episodes presented in this paper happened within a pathway to the culture of theorems in the domain of Euclidean geometry that had been experimented for the first time in the year 2016-17 in a 10<sup>th</sup>-grade class of a scientific oriented high school, and in the year 2017-18 in two 10<sup>th</sup>-grade classes of the same school, with two 50' lessons per week from October to May (out of 5 hours devoted also to other mathematics subjects: algebra, probability and statistics). Classroom activities were based on an alternation of individual activities, in some cases preceded by a constructive interaction with the teacher, and collective activities. Individual activities concerned six kinds of tasks: solution of construction problems, conjecturing, proving, analyzing, evaluating and improving some schoolfellow's productions, close activities regarding proof texts. Collective discussions were orchestrated by the teacher and in most cases concerned the comparison and the critical analysis of a few students' individual productions selected by the teacher. According to the aim of developing competencies related to the culture of theorems, the assessment method consisted of: the individual revision of individual work at the end of each of the three parts in which the pathway was divided, with careful identification and remediation of "what does not work" in each individual production, and an overall synthesis on the individual itinerary concerning difficulties met, still obscure points, reasons for mistakes, emotional problems, etc. This evaluation method was derived and adapted from a similar method currently adopted in several Genoa University courses for pre-service teacher education aimed at developing professional competencies of cultural analysis of the content to be taught (see Guala & Boero, 2017, for more information on the assessment method and its motivations).

## Further episodes

We have chosen three further episodes. Like that presented in the Introduction, they concern relations among circles and straight lines. They show different roles that may be played by transformational reasoning and continuity in the field of plane geometry, and how to legitimate them within the proposed theoretical framework, in particular through the continuity principle.

### The rolling circle

Students are requested to find if it exists a position of a given circle, such that the circle is tangent to two sides of an angle, and to justify the answer. Some students imagine to roll the circle on one line towards the second line and they discover that "Yes, it exists, because there is a moment in which the rolling circle starts to touch the second line; in that moment it is tangent to both lines". This intuition of the rolling circle facilitates also the discovery that, in the found position of the circle, the center of the circle is the point of intersection of the two straight lines that are parallel to the sides of the angle at the distance of the ray of the circle. Students "see" the movement of the center of the circle in parallel with the first line, and (after the tangency position) with the second line.

By considering the generic case of the straight lines  $y=0$  and  $y=x$  and of the rolling circle  $(x-K)^2+y^2=1$ , the continuity principle may be applied to legitimate the solution found by the students.

All this suggests a way both to find the center of the circle when it is tangent to both lines (a heuristic function for the solution of a construction problem), and to explain why in that position it is tangent to both lines (a proving function, once the continuity principle is adopted) – in a perspective of cognitive unity of theorems.

## Comparing the length of the chords of a circle

The diameter of a circle is its longest chord, and the length of the chord increases when its middle point approaches the center of the circle.

This is part of proposition 15 of Book 3 of the Elements:

Of straight lines in a circle the diameter is greatest, and of the rest the nearer to the centre is always greater than the more remote.

Euclid proof is rather complex- it needs the proof of 6 intermediate statements.

Figure 3

A student produces a reasoning that may be reported this way: he fixes a point on the circle and considers a chord on that side of the circle “which is opposite to it”, with corresponding angles at the center of the circle. He imagines to move the chord towards the center and he observes that the nearer the chord is to the center, the bigger is the corresponding angle –till when the chord becomes the diameter by collapsing on the two aligned rays. This is not yet a proof of the theorem, but the student’s line of reasoning might be integrated with elements that allow to prove that the length of the chord increases when the chord approaches the diameter. Indeed, the triangles obtained by joining the extremities of the chord with the center of the circle have two sides of equal length (the ray of the circle) and the width of the angle between them increases, thus also the length of the side opposite to the center increases. This may suggest to exploit the triangular inequality –the chord is shorter than the sum of the rays– to prove that the diameter (two rays long) is the longest chord; and it may suggest also to use Pythagoras’ theorem in order to prove that the length of the chords increases when the distance between the chord and the center of the circle decreases, or to find the length  $2\sqrt{1-K^2}$  of the chord intersected by  $y=K$  on the generic circle  $x^2+y^2=1$ : the length of the chord attains its maximum value 2 when  $K=0$ , i.e. when the chord becomes a diameter.

## Tangency between a straight line and a circle.

By composing two statements of Euclid’s Elements, we get the following statement:

Given a circle centered in C and a straight line a intersecting the circle in the point T, the straight line a is tangent to the circle (i.e. T is their only common point) if and only if the straight line is perpendicular to CT.

While trying to prove the “if” part of the statement, students were suggested by the teacher to reason by contradiction; they were also invited to consider a second point of intersection T’. Some students reacted to the discovery of a contradiction (an isosceles triangle with two rectangular angles) by imagining to make CT’ collapse on CT by rotating it around C. This movement might be exploited to expand their reasoning through the consideration of the isosceles triangle TCT’ and its height CH. The identity  $CH = \sqrt{(CT^2 - TH^2)}$  (Pythagoras theorem) allows to prove (by continuity) that TT’ is 0 (i.e. there is only one point of intersection – which means tangency) if and only if the height CH of the triangle collapse on CT, i.e. if and only if CT is perpendicular to the straight line a.

In this case transformational reasoning produced by some students might play a double heuristic role: first, to suggest the *necessity* of the condition of perpendicularity for the tangency while proving its *sufficiency*; second, to suggest the way to get a proof (by the continuity principle) of the “if and only if” statement – still, cognitive unity might allow to arrange a valid, simple proof.

## Discussion

Transformational reasoning combined with the continuity principle may play three roles for the approach to the culture of theorems and, more generally, for the development of students' mathematical rationalities: first, it may help solving a construction problem and simplifying its proof, in comparison with the Euclid's proof (like in the episode presented in the introduction). Second, it may play a heuristic function by suggesting a method of proving in Euclidean geometry, or eventually a method of proving by relying on the continuity principle (like in the last two episodes). Third, it may allow to compare different ways of proving the same theorem in synthetic geometry, thus contributing to the development of the culture of theorems and at the same time to an initial understanding of the fact that a theorem may be tackled with different strategies and according to different criteria of truth and of validity of proving methods. Concerning the second and the third role, we may observe how the adoption of a principle of continuity would imply changes in the rationality of the discursive activity of proving, in comparison with Euclidean rationality. On the epistemic side: a new criterion of truth is introduced. On the teleological side: for a construction problem, the existence of the solution may be got through transformational reasoning; for the proof of a theorem, transformational reasoning in several cases (see our episodes) guarantees the possibility of the cognitive unity between the exploration phase and the proving phase. On the communicative side, new verbs and expressions are necessary to account for the specificities of transformational reasoning, in comparison with the language of Euclidean geometry. In the perspective of rationality, the principle of continuity might allow to compare (for some theorems) methods of proof corresponding to Euclid's ones with methods of proof which depend not only on Euclid's axioms and theorems, but also on the additional principle, thus contributing to the culture of theorems and prepare students to move to other theories – in particular, Analytic geometry – and help to “cross the borders” between the two domains (and the inherent rationalities: see Boero, Guala, & Morselli, 2013). We observe how, in the problem situations of our episodes, the principle of continuity may be easily related to the algebraic modelization of the situations at stake. For instance, in the case of the last episode we may consider the circle of center (0,0) and ray 1, whose equation is  $x^2+y^2=1$ , and its intersections with the straight line of equation  $y=kx+1$ , which meets the circle in the point (0,1). The algebraic treatment of the system of the two equations offers an immediate answer to the problem of tangency by discussing the solutions of the second degree equation:  $(1+k^2)x^2+2kx=0$  derived from the system. The equation has the solutions (x-coordinates of the intersection points)  $x=0$ ,  $x=k/(1+k^2)$ . They are coincident (i.e. tangency, in terms of analytic geometry) for  $k=0$ , i.e., when the straight line of equation  $y=kx+1$  becomes perpendicular to the ray of the circle with extremities (0,0) and (0,1). Conversely, including the principle of continuity in synthetic geometry might allow to give sense to the algebraic expressions that are used in the algebraic modeling process of geometry problems, particularly as regards the role of the variable(s) – which not only are signs to be dealt with according to the syntactic rules of the algebraic language, but also represent dynamic phenomena (in our case, geometric transformations).

In this section we have used the expressions “may”, “might allow” several times to outline possible directions for studies, intended to develop the culture of theorems in the classroom on the reflective and on the operational sides, once the continuity principle (possibly, after further elaboration) is assumed to legitimate an extension of the scope of synthetic geometry and the inherent rationality.

# The role of the teacher in the development of structure-based argumentations

Fiene Bredow

University Bremen, Germany; bredow@uni-bremen.de

*Keywords: Argumentation, teacher influence, symbolic language, algebra.*

## Motivation

It is a desideratum that mathematical argumentation should be integrated into today's mathematics teaching. In reality, opportunities for learning mathematical argumentation are infrequent. Algebraic language is often understood only as a series of signs that can be transformed according to certain rules and the same applies to algebraic argumentation (Pedemonte, 2008). Such argumentations present an epistemological challenge for students because they are detached from concrete examples. The integration of mathematical argumentation into teaching and the appreciation of different types of arguments is therefore of crucial relevance. The role of the teacher in this needs to be clarified.

The aim of my PhD project is to investigate the role of the teacher in the development of structure-based argumentations in classroom practice. What kind of support can teachers in mathematics education give their students in order to guide their argumentation from concrete examples to general structures? How does this support influence the students' argumentation and their conception of algebraic language? For this purpose, a learning environment at the transition from arithmetic to algebra was designed and implemented in three eighth-grade classes in Germany. The main ideas of my teaching design and learning environment will be presented in this poster.

## Theoretical framework

Sfard (1991) distinguishes between an operational and a structural conception of mathematical objects. In an operational conception, mathematical objects are perceived as a process. In a structural conception mathematical objects are conceived as static constructs, objects. Reification is necessary to conceive mathematical objects structurally. There are different types of mathematical arguments. Structure-based arguments use properties of the involved objects instead of only calculation-oriented transformations of algebraic expressions without relation to the content. Mason (1996) describes that, as a first step, learners should investigate examples and their structure in order to be able to develop general arguments using symbolic language. This idea guided the construction of the learning environment in my project. Connections between the conception of algebraic language and the development of structure-based argumentations are examined as well.

All in all, the teacher has an important role in mathematical argumentation. Conner, Singletary, Smith, Wagner and Francisco (2014) describe three different types of support for collective argumentation by teachers: "Direct contributions to arguments", "Asking questions" and "Other supportive actions" (e.g., evaluating, repeating). In addition to that, it is interesting how teachers enact written tasks in classrooms. This can lead students to an interpretation of tasks that can provide rich opportunities for argumentation or create obstacles. Whether and how this support can affect the arguments of pupils has been researched little so far and is a focus of this study.

## Research project and methodology

First, tasks for eighth-grade classes and teacher prompts are theoretically constructed, which are supposed to stimulate a structure orientation and provide opportunities for mathematical argumentation. Then, a learning environment is designed and empirically enacted. Two interviews with teachers are conducted to get insights into the teachers' understanding of mathematical argumentation and into their experiences with the designed learning environment. Then, from transcripts of the lessons, argumentation processes and students' conceptions are reconstructed and analysed with a focus on the prompts of the teacher that promote a structure orientation. All this will inform a revision of the learning environment. The following research questions guide my study: How can teachers constructively support their students in developing structure-based argumentations? How do a teaching design and a learning environment for the development of structure-based argumentations in mathematics lessons look?

## Structure of the learning environment

An intervention of four lessons (90 min each) was designed and performed. All tasks provide opportunities for mathematical argumentation. The teaching environment and tasks are designed in a way that allows students to build on concrete examples, examine the structure of these examples, and finally develop structure-based arguments. All tasks support this strategic approach to argumentation: 1. Observe; 2. Assume; 3. Analyse and check; 4. Justify. Learners are not simply asked to do calculations in the tasks, but to observe and reflect the mathematical structures of the numbers to support structure orientation (see Wittmann, 1985; Mason, 1996). In the first two lessons, the students get to know four different types of arguments (explanatory arguments in form of a dot pattern; generic examples; algebraic and narrative arguments) and have to solve conjecture-and-proving tasks. In the third and fourth lesson, the students learn to argue in a new format and more sophisticated arguments are demanded in context of “arithmogons”: the sum of two corners is a side (Wittmann, 1985).

All in all, this learning environment should provide students opportunities to learn mathematical argumentation and to establish a structure orientation. How teachers enact this learning environment, support their students and which impact this support has will be analysed in my study.

## Prospective teachers enacting proof tasks in secondary mathematics classrooms

Orly Buchbinder<sup>1</sup> and Sharon McCrone<sup>1</sup>

<sup>1</sup>University of New Hampshire, Unites States; [orly.buchbinder@unh.edu](mailto:orly.buchbinder@unh.edu), [sharon.mccrone@unh.edu](mailto:sharon.mccrone@unh.edu)

*We use a curriculum design framework to analyze how prospective secondary teachers (PSTs) designed and implemented in local schools, lessons that integrate ongoing mathematical topics with one of the four proof themes addressed in the capstone course Mathematical Reasoning and Proving for Secondary Teachers. In this paper we focus on lessons developed around the conditional statements proof theme. We examine the ways in which PSTs integrated conditional statements in their lesson plans, how these lessons were implemented in classrooms, and the challenges PSTs encountered in these processes. Our results suggest that even when PSTs designed rich lesson plans, they often struggled to adjust their language to the students' level and to maintain the cognitive demand of the tasks. We conclude by discussing possible supports for PSTs' learning in these areas.*

*Keywords: Reasoning and Proving, Preservice Secondary Teachers, Lesson Plans, Task Design*

Integrating reasoning and proving in secondary schools has been an elusive goal of the mathematics education community. Despite agreement of the importance of reasoning and proving in school mathematics among scholars and policy makers, proof has been shown to be a “hard-to-teach and hard-to-learn” concept (Stylianides & Stylianides, 2017, p. 119). Areas that have been identified as being persistently difficult for students, but also critically important for proof production and comprehension, are the following: (1) understanding the role of examples in proving including recognition of the limitation of supportive examples as proofs and the role of a single counterexample as refuting evidence, (2) conditional statements, (3) argument evaluation, and (4) indirect reasoning (e.g., Antonini & Mariotti, 2008; Durand-Guerrier, 2003). We term these areas “proof themes”. Our choice of these four proof themes stems from the literature and our own experience as instructors observing prospective secondary teachers’ (PSTs’) challenges in university coursework. Our study rests on the assumption that these proof themes can be integrated into secondary school mathematics in “intellectually honest” ways that are true to the discipline of mathematics and honor students as learners (Bruner, 1960; Stylianides, 2007). Towards this end we developed and systematically studied a capstone course *Mathematical Reasoning and Proving for Secondary Teachers*, which intended to support PSTs in developing robust knowledge and pedagogical skills for integrating proof in their classroom practices.

The course aimed to increase PSTs’ awareness of the logical aspects of proof and the place of proof in secondary curricula, expose PSTs to common student difficulties with proof, and provide PSTs with pedagogical tools to create or modify tasks that integrate reasoning and proving. In the practical component of the course, PSTs developed lessons on each of the four proof themes and taught them in local schools. In this paper, we focus on two PSTs’ lessons plans that successfully integrated the conditional statements proof theme and analyze how these lessons were enacted in classrooms. Our analysis reveals the aspects of lesson enactment that were successful and those that posed challenges to PSTs. In the discussion, we contemplate potential reasons for these challenges and how we, as

teacher educators, can further support PSTs in the process of integrating proof in their teaching practices.

## Theoretical Perspectives

We adopt Stylianides and Stylianides' (2017) definition of proof as “a mathematical argument for or against a mathematical claim that is both mathematically sound and conceptually accessible to the members of the local community where the argument is offered” (p. 212). By “proving” we mean processes such as conjecturing, generalizing and making valid arguments grounded in mathematical deductions rather than authority or empirical evidence (Ellis, Bieda, & Knuth, 2012). Implicit in this definition is that students must develop understanding of what a deductive argument is, and that teachers must provide opportunities for students to develop such understanding through instructional activities. Teachers, on their part, rely on curriculum materials to facilitate student learning of proof.

Stein, Remillard and Smith (2007) distinguish between the *written curriculum*, which includes written artifacts that teachers and students use, the *intended curriculum*, which is the teacher's lesson plan, and the *enacted curriculum* that is the lesson as it unfolds in the classroom (Fig. 1).

**Figure 1: Phases of curriculum. Adapted from Stein, Remillard, & Smith, 2007, p.322**

From the perspective of a secondary teacher aiming to integrate reasoning and proof into the mathematics curriculum, we find that each element of this model (Fig. 1) presents unique challenges. First, written curricula in the United States, such as textbooks, offer limited proof-related tasks outside high-school geometry (e.g., Thompson, Senk, & Johnson, 2012). Thus, it becomes the work of the teacher to design tasks and develop an intended curriculum. Next, as the teacher enacts the lesson in the classroom, he/she must use appropriate language and conceptual tools that are within the reach of secondary students to highlight mathematical ideas. Here, again, curriculum materials offer little guidance to teachers on how to enact proof tasks in classrooms (Stylianides, 2008) in ways that support development of students' conceptions which are in line with conventional mathematics. Thus, much of the curriculum design and implementation around proof rests on teachers' own knowledge and beliefs about the importance of proof for their students' mathematical learning.

Supporting PSTs in developing such knowledge and productive dispositions towards proof were the goals of the capstone course. In Buchbinder and McCrone (2018) we describe the course structure and its theoretical underpinnings. Here, we illustrate the design features of the course that were intended to support PSTs in development and enactment of a lesson on conditional statements. We use conditional statements as an example, but our analyses apply to all four proof themes mentioned.

## Setting

The course *Mathematical Reasoning and Proving for Secondary Teachers* contains four modules, each addressing one of the proof themes. In the Conditional Statements module, PSTs first engaged in activities designed to strengthen their knowledge of conditional statements. This knowledge includes understanding that a conditional statement has the form: *If P then Q* ( $P \Rightarrow Q$ ), where P is

a hypothesis and  $Q$  is a conclusion; how to determine truth-value of such a statement; its equivalent forms such as a contrapositive ( $\sim Q \Rightarrow \sim P$ ) and non-equivalent forms, such as a converse ( $Q \Rightarrow P$ ).

PSTs then examined excerpts of hypothetical student work related to conditional statements, analyzed students' conceptions, and contemplated ways to address students' difficulties. Next, the PSTs reviewed a sample of mathematics textbooks to examine where conditional statements appear in the school curriculum. These activities aimed to equip PSTs with the background for creating their own lessons integrating conditional statements with mathematical topics taught in local schools.

During the lesson development stage, PSTs shared ideas and received feedback on their lesson plans from their peers and the course instructor. The lessons were 50-minutes in length, and were intended for small groups of 5-8 students rather than the whole class. All lessons were videotaped with 360° cameras to capture both the PSTs' actions and the students' participation. PSTs then watched their videos and wrote a reflective report. Sharing lesson plans with peers was intended to support PSTs' enactment of their lesson, while reflection reports and instructor's feedback on it aimed to serve as a mechanism for future improvement. Despite multiple means of support embedded in the course design, PSTs experienced challenges in developing and enacting lessons on conditional statements, as we will show in the results section.

## Methods: Participants, Data Sources and Analysis

Fifteen PSTs in their last year of university studies took part in the research. Prior to the capstone course the PSTs completed most of the required courses in mathematics and pedagogy.

The data sources for the analysis reported in this paper comprise the PST-developed lesson plans on conditional statements, the video recordings of the enacted lessons, and PSTs' reflective reports. The lesson plans were analyzed in terms of their focus on the conditional statements proof theme, and assigned a rating of high, medium or low. The *low* focused lesson plans included no more than 3 conditional statements and the activity only required students to determine their truth value. For example, Chuck's (all names in the paper are pseudonyms) 8<sup>th</sup> grade lesson on exponents had three true or false questions, such as: "*If a negative number is raised to an even power, the result will be a positive number.*" This question offers opportunities to discuss what is needed to prove or disprove such a statement and use the rules of exponents to produce a generic proof accessible to 8<sup>th</sup> graders. Yet, Chuck's plan merely expected students to produce a "proof" by example, such as  $(-2)^2 = (-2)(-2) = 4$ , missing the opportunity to attend to a misconception about the limitations of empirical evidence as proof and even enforcing it. Lesson plans with *high* focus on the proof theme contained more than three conditional statements along with a clear plan on how they would be used to advance students' knowledge of conditional statements (as examples in the results section will show). A lesson plan with *medium* focus would be located between these two extremes, for example, Rebecca's lesson on logic riddles dealt with reasoning and justifying, but the place of conditional statements was unclear.

The classroom videos were analyzed using Schoenfeld's (2013) *Teaching for Robust Understanding* (TRU) rubric which was slightly modified to reflect aspects of teacher work and student interaction that are specific to proving. The revised rubric had five dimensions, four related to teacher actions: (a) Accuracy, language, and connections, (b) Explicating reasoning and proof theme, (c) Actions to promote student engagement, (d) Maintaining cognitive demand; and one dimension related to (e)

Student engagement. Each video was divided into thematic episodes, no more than 5 minutes long, and each episode was assigned a score of 3 (high), 2 (medium), 1 (low) on each dimension. In the results section we illustrate the different dimensions of the rubric and the scoring system.

## Results

### The intended curriculum: Lesson plans

The analysis of the lesson plans in terms of prevalence of the conditional statements revealed 3 plans with low focus on the proof theme, 1 medium and 11 high. Below are examples of two lesson plans with a high focus on the conditional statements theme, developed by Bill and Dylan for students in grade 10. We chose these lessons to illustrate creative integration of conditional statements with regular content in algebra and geometry; as well as the challenges that PSTs encountered while enacting the lessons in classrooms.

Bill's lesson plan integrated conditional statements with triangle geometry. Each pair of students had two sets of notecards: yellow cards had hypotheses written on them (e.g., a triangle is equilateral), and green cards had conclusions (e.g., a triangle is isosceles). Students had to create conditional statements by matching hypotheses to conclusions. Bill intended to use student-produced statements in a whole class discussion to introduce such concepts as *domain* of a statement and a *counterexample*. Bill also planned to have students physically switch between hypothesis and conclusion cards as a way to introduce a *converse*. The lesson plan did not contain any exposition about what a conditional statement is, how it is structured, and what is needed to prove or disprove it. Bill hoped that these ideas would come out naturally as the students engaged in and discussed the card-matching activity.

Dylan's lesson integrated conditional statements with evaluating expressions and solving simple algebraic equations. First, the concept of conditional statements and key vocabulary such as truth value, domain and proposition (in lieu of hypothesis and conclusion) was introduced through non-mathematical examples such as "If a motor vehicle has four wheels then it's a car." Next, students practiced identifying domain, proposition and determining the truth-value of four statements: (1) If a number is divisible by 10, then it is divisible by 5; (2) If a number is not divisible by 10, then the number is not divisible by 5; (3) If a number is not divisible by 5, then it is not divisible by 10; and (4) If a number is divisible by 5, then it is divisible by 10. Notating the first one as  $P \Rightarrow Q$ , the other statements have the forms:  $\sim P \Rightarrow \sim Q$ ,  $\sim Q \Rightarrow \sim P$ , and  $Q \Rightarrow P$ , respectively, which allows making interesting connections. The third task had students identify domain and proposition in statements related to evaluating expressions, such as: "If we have the equation  $11x - 12 = 1$ , then the solution of  $x$  is a whole number", or "If the side length of a cube is a whole number, then the volume is also a whole number." The students worked on these tasks in pairs and then discussed as a group.

Both lesson plans meaningfully integrated conditional statements with the mathematical topics Bill and Dylan planned to teach. The tasks in the lessons were of high cognitive demand (Silver et al., 2009) as they required formulating statements, exploring and justifying claims. In the next section we examine the transition from the intended to enacted curriculum in Bill's and Dylan's lessons.

### The enacted curriculum: Classroom implementation

Both Bill's and Dylan's lessons were enacted in 10<sup>th</sup> grade classrooms with a group of 4 students. The description of the enactment below follows the five dimensions of the modified TRU rubric.

**Bill's enacted lesson.** Within the dimension of *Accuracy, language and communication* we distinguish between accuracy related to geometry, in which Bill's performance was impeccable, versus accuracy related to the proof theme. Bill's lesson plan suggested that he intended to build on students' contributions to elicit ideas about conditional statements. Thus, throughout the lesson Bill tried to avoid unfamiliar vocabulary and only used informal language. For example, when introducing the card matching activity Bill instructed students to match "if-cards" with "then-cards" to create "if-then" statements. He never introduced the concept of conditional statement and referred to hypothesis and conclusion as the "if-part" and "then-part" of the statement throughout the entire lesson. The lack of proper mathematical language complicated the classroom communication. Towards the end of the lesson Bill wrote a statement and its converse next to each other on the board and asked the students: "what changed?" One student responded by saying "the 'then' became the 'if'." This is a correct observation on behalf of the student, which signals the lack of language to describe it. While intending to build on student knowledge, Bill missed the opportunity to introduce vocabulary that could help to streamline the communication around conditional statements.

In terms of *explicating the conditional statements* proof theme, Bill seemed to follow a similar strategy of minimizing his input. The mathematical task lent itself naturally to discussing such important ideas as generality of a conditional statement and how to determine if it is true or false. Yet, the only concept Bill introduced in the lesson was a counterexample, which he informally defined as an example that "does not fit the statement and disproves it." Bill initiated a discussion on how to distinguish between examples that support, disprove or are irrelevant to the statement. For the latter point he used the statement: "If an angle in a triangle is 45°, then the measure of the third angle is 45°," and drew a triangle with no 45° angles. Students were initially confused whether this triangle constitutes a counterexample to the statement, so Bill explained that a counterexample must satisfy the "if-part" but not the "then-part". Overall, Bill explicated multiple aspects related to conditional statements, but his insistence on using only informal language kept the discussion at a basic level.

In terms of actions to *promote student engagement*, Bill's lesson was rated very high. He encouraged participation by asking multiple questions, pushing students to provide explanations and justify their thinking. He was attentive to student body language and when he sensed that some students did not follow the discussion, he asked a student to repeat what was said in their own words. Bill made sure that each student contributed something to the conversation, however the level of *student engagement* was rather moderate. Although all students were listening attentively, they appeared uncomfortable when pushed to speak in full sentences, only responding in a few words. As a result, Bill often had to break down his questions to a set of simpler ones, lowering the *cognitive demand* of the tasks. The aggregate scores for Bill along the five dimensions are shown in Figure 2a.

**Dylan's enacted lesson.** Similar to Bill, Dylan's *Accuracy, language and communication* was different when talking about solving equations versus aspects related to conditional statements. The latter was often imprecise or not properly adjusted to the students' level. For example, Dylan said that

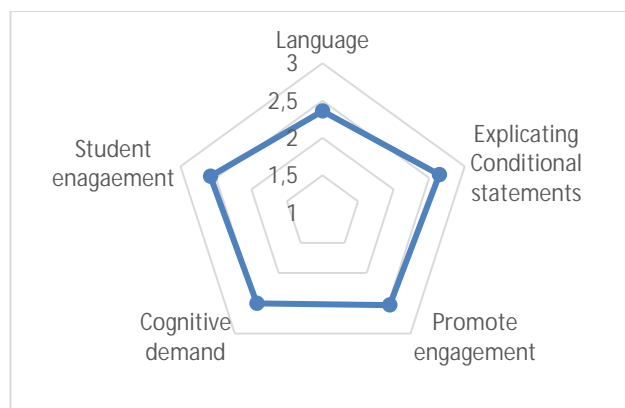

“when we prove the statement is false, we are providing a counterexample - something that does not fulfill the statement.” But since he did not provide a clear explanation of what it means to “not fulfill the statement” students occasionally confused an irrelevant example for a counterexample.

Dylan *explicated the conditional statement* proof theme much stronger than Bill. Dylan introduced some key concepts related to conditional statements, and even some logical notation, e.g.,  $P \Rightarrow Q$ , which contributed to more seamless communication. However, Dylan missed multiple opportunities to draw connections among the concepts. For example, each of the four conditional statements on divisibility by 10 and by 5 was treated as a separate entity during the lesson. We are not claiming that Dylan should have delved deeper into logical notation or introduced a contrapositive, which could have been overwhelming for the students. However, Dylan missed the opportunity to draw students’ attention to the fact that that statements (2) and (4) are disproved by the same counterexample or that statements (1) and (3) require a general proof that uses the same key idea of 5 being a factor of 10. In his lesson reflection Dylan wrote how impressed he was with the students being able to identify the domain and proposition, and correctly justify the truth-value of statements that included negations, the converse, and the contrapositive. However, his lesson plan did not mention any of these connections, suggesting that the missed opportunity occurred at the planning stage.

Dylan did a good job in *promoting students’ engagement* by ensuring that students were on task, following up on students’ input, asking questions and pressing for explanations. For their part, *students participated* in the lesson in meaningful ways such as sharing ideas, responding to prompts, and justifying their work. As the lesson progressed, and its focus shifted to conditional statements involving equations, Dylan payed less attention to the logical aspects, focusing almost entirely on solving equations, possibly because students appeared to have difficulties in this area. While trying to support student thinking, Dylan often took over the explanation, thus lowering *the cognitive demand* of the tasks. The aggregate scores for Dylan along the five dimensions are shown in Figure 2b (four on teacher actions and the fifth on student engagement).

**Figure 2a: Bill's enacted lesson.**

**2b: Dylan's enacted lesson**

Figure 2 allows us to compare the various dimensions of Bill's and Dylan's enacted lessons. Both written lesson plans were rated high on explicating the conditional statements theme, however, Bill's insistence on using informal language resulted in lower scores in the areas of *Language* and *Explicating Conditional Statements*. Also, as described above, Bill put more effort into promoting student engagement, which is reflected in the high score for *Promote Engagement* (Fig. 2a). For the

*Cognitive Demand* dimension, both Bill and Dylan scored about 2.5 on the three-point scale, reflecting the fact that they both tried but did not completely succeed in maintaining the cognitive demand of their intended tasks when enacting their lessons. The *Student Engagement* dimension was also about 2.5 for both Bill and Dylan. We emphasize that in our setting it is not possible to draw direct connections between teacher actions and student engagement. Students' active participation, or the lack of thereof, could be in response to the change in their learning routine, by having a standard mathematics lesson replaced by one taught by a PST. Nevertheless, we include the student engagement dimension in the analysis to show the feasibility of having secondary students participate meaningfully in lessons that integrate conditional statements with the ongoing mathematical topics.

## Discussion

Our goal in this paper was to trace how PSTs who participate in the capstone course *Mathematical Reasoning and Proving for Secondary Teachers* developed and implemented, in real classrooms, lessons that integrate aspects of conditional statements with the regular mathematics curriculum. Our analysis was grounded in Stein et al. (2007) curriculum framework. Overall, we were impressed with the fact that 11 out of 15 PST-developed lesson plans rated high on the prevalence of the conditional statements proof theme in them. This is a non-trivial outcome, especially given the limited access to pre-existing proof-oriented tasks in traditional US mathematics textbooks (i.e., the written curriculum). The majority of our PSTs were able to overcome this limitation, with the appropriate instructional support, and use knowledge and skills acquired in the capstone course creatively to develop lesson plans (i.e., the intended curriculum) that integrate logical aspects of proof with a variety of standard mathematical topics.

Despite many of the lesson plans having high focus on the conditional statements proof theme, the actual enactment of the lesson was often challenging for PSTs, as Bill's and Dylan's lessons illustrate. The main difficulties observed were adjusting the language to the student audience and clearly explicating the proof theme. These difficulties can be due to the fact that the PSTs did not know the students prior to the lesson, which impeded their ability to anticipate how students would respond to the conditional statements content. We addressed this issue in the subsequent iteration of the course, by including a requirement that PSTs provide in their lesson plans a list of mathematical-logical concepts they plan to use during the lesson and write a verbatim description of how they intend to introduce these concepts to students. The intention is to have the PSTs play out these aspects of the lesson plans more explicitly, prior to their enactment, so that their lessons are more likely to match the intended curriculum.

Based on the structure of the course, most PSTs taught a different group of students each time; this lack of continuity impedes our ability to make claims about student learning across time. However, our analysis showed relatively high levels of student engagement with proving during the PSTs' enacted lessons. Although we cannot attribute this completely to the PSTs' pedagogical actions, we assume that, if the content of the lessons was completely outside students' interest or conceptual reach, we would be seeing much lower levels of student participation.

The challenges encountered by the PSTs in our study can be partially explained by PSTs' lack of teaching experience. However, we assert that teaching conditional statements, or proof themes, in

general, is inherently challenging. Identifying specific areas of challenge for PSTs can help us, as mathematics teacher educators, to develop support structures that promote PSTs' competence in enacting reasoning and proof in their future classrooms. Some of these support structures were tested in our course design. Through repeated cycles of planning lessons that integrate proof themes within regular school curriculum, enacting these lessons in classrooms, and reflecting on them, the PSTs gained valuable experiences and developed a sense of feasibility of engaging students in proving.

# Developing Pre-service Mathematics Teachers' Pedagogical Content Knowledge of Proof Schemes: An Intervention Study

Fikret Cihan<sup>1</sup> and Hatice Akkoç<sup>2</sup>

<sup>1</sup> Kirklareli University, Kirklareli, Turkey; [fikret\\_cihan@hotmail.com](mailto:fikret_cihan@hotmail.com)

<sup>2</sup> Marmara University, Istanbul, Turkey; [hakkoc@marmara.edu.tr](mailto:hakkoc@marmara.edu.tr)

*The purpose of this paper is to examine the effects of an intervention study which aimed at improving pre-service mathematics teachers' pedagogical content knowledge (PCK) of proof schemes. Sowder and Harel's (1998) framework of proof schemes constitutes the conceptual framework of this paper. To explore twenty-two pre-service teachers' PCK, we designed a survey using a scenario. The quantitative findings of the study revealed that the intervention had a meaningful and large effect on participants' PCK of proof schemes. The qualitative findings of the study indicated that participants had difficulties identifying especially symbolic, example-based, transformational and axiomatic proof schemes prior to intervention, but they had overcome these difficulties after the intervention.*

*Keywords: Proof, proof schemes, pedagogical content knowledge, pre-service mathematics teachers*

## Introduction

Teaching proof is a extremely difficult matter for teachers to overcome (Heinze & Reiss, 2004). For teaching proof effectively, teachers should be able to determine types of justification used by their students and help them enhance their justification types to be able to reach the axiomatic level. In other words, they should have pedagogical content knowledge (PCK) of proof. In this paper, we are particularly interested in proof schemes which could be described as cognitive characteristics of proving processes (Harel & Sowder, 1998). However, there is a gap in the literature which explores or aims to develop PCK of proof schemes which is crucial for pre-service mathematics teachers. In order to address this problem, mathematics teacher educators should look for different ideas to teach proof in teacher preparation courses (Stylianides & Stylianides, 2017). Lack of such courses and instructional materials in pre-service mathematics teacher education programs call for intervention studies that foster PCK of proof.

## Conceptual Framework of the Study: PCK of Proof Schemes

The conceptual framework of this study adopts two different frameworks: pedagogical content knowledge (Shulman, 1987) and proof schemes (Harel & Sowder, 1998; Sowder & Harel, 1998). Shulman (1987, p. 8) describes PCK as an “amalgam of content and pedagogy that is uniquely the province of teachers”. Various researchers describe different components of PCK. Among them, knowledge of students' thinking has been extensively studied in teacher education literature (Depaepe, Verschaffel, & Kelchtermans, 2013). Knowledge of students' thinking in a specific domain such as proof has a topic-specific dimension in it. With this regard, Lesseig (2016) created the "MKT for Proof" framework by adapting the Mathematical Knowledge for Teaching (MKT) framework developed by Ball, Thames, and Phelps (2008). She defines a subdomain of PCK as the knowledge of content and students (KCS) for proof which involves “knowledge of students' typical conceptions or misconceptions of proof as well as an understanding of developmental sequences” (p. 256). More

specifically, it is the knowledge of “characteristics of external, empirical and deductive proof schemes, students’ tendency to rely on authority or empirical examples, typical progression from inductive to deductive proof” (p. 257). In this study, we focus on PCK of proof schemes, knowledge of students’ proving processes and identifying students’ proof schemes in particular.

Proof schemes are cognitive characteristics of the proving process and describe one’s methods of justification. Harel and Sowder (1998, p. 244) discovered undergraduate students’ categories of proof schemes each of which “represents a cognitive stage and intellectual ability in students’ mathematical development”. They offered three main categories and their sub-categories:

The first category, *external proof schemes*, points out to an external source that convinces the student. Also, students persuade others by referring to these external sources. When this source is an authority (e.g. a teacher or a textbook), it is called *authoritarian proof scheme*. The external source might also be the form or appearance of arguments e.g. proofs in geometry must be in two columns. In this case, it is called *ritual proof scheme*. The last sub-category of an external proof scheme is *symbolic proof schemes* which refer to meaningless manipulations of symbols (Harel, 2007).

The second category is *empirical proof schemes*. For this scheme, “conjectures are validated, impugned, or subverted by appeals to physical facts or sensory experiences” (Harel & Sowder, 1998, p. 252). This could be in two ways: (a) relying on evidence from one or more examples (*example-based proof schemes*) or (b) relying on intuition or perception to convince or to be convinced (*perceptual proof schemes*) (Harel, 2007).

The third category is *analytical proof schemes* which is at the highest level of justification. In this case, conjectures are validated by means of logical deductions. It has two sub-categories: transformational and axiomatic proof schemes. *Transformational proof schemes* have three characteristics: generality, operational thought, and logical inference. (Harel, 2007). Generality is concerned with justifying “for all”. Operational thought takes place when a student “forms goals and subgoals and attempts to anticipate his/her outcomes during the proving process” (Harel, 2007, p. 67). Finally, logical inference requires mathematical justification based on the rules of logical inference. In addition to these three characteristics, in the *axiomatic proof scheme*, proving processes are built upon an axiomatic system, therefore must start from accepted principles (Harel, 2007).

## **The aim of the study and the research question**

This study is part of a PhD thesis which aims to design an undergraduate course for developing pre-service mathematics teachers’ (PSMTs) view, content and pedagogical content knowledge of proof. The aim of this study is to report the findings of an intervention study which aims to develop pre-service teachers’ knowledge of proof schemes. As part of the course, a module on proof schemes, was implemented and our research question is as follows: “How does the module affect pre-service mathematics teachers’ pedagogical content knowledge of proof schemes?”

## **Methodology**

This study used designed-based research (DBR) and specifically ADDIE (Analysis, Design, Development, Implementation, and Evaluation) model (Branch, 2009). In the analysis phase, the needs analysis was made based on the literature. Calls for the design and analysis of interventions

that foster PCK of proof and proving, proof schemes in particular, in the context of pre-service teacher education were considered. The objectives and learning outcomes of the course were determined. One of them was related to proof schemes: “PMTs will be able to describe and identify students’ proof schemes”. In the design phase, a 15-week course consisting of various modules (i.e. modern components of proof, proof methods, identifying proof schemes, student difficulties with proving, reasons behind student difficulties, teaching strategies that can overcome student difficulties) was prepared and expert opinion was taken. In the development phase, learning and teaching situations were organized. For the module on proof schemes, the classification of proof schemes by Sowder and Harel (1998) were explained to participants using two scenarios. Participants worked both individually and in groups to identify students’ proof schemes using the scenarios. After the intervention, the learning outcome related to proof schemes was evaluated using a different scenario. In the evaluation phase, the effect of the module on the learning outcome related to proof schemes was evaluated.

Participants are twenty-two PMTs who are in the second year of a teacher education program in a state university in Istanbul, Turkey. To explore PCK of proof schemes, we designed a survey called Pedagogical Content Knowledge of Proof Survey (PCK-P survey) using a scenario (See Appendix). The scenario includes an excerpt of a hypothetical discussion among a mathematics teacher and ten 9th grade students (age of fifteen). Prior to the intervention the PMTs were asked to describe student thinking; after the intervention, the PMTs were specifically asked to describe students’ proof schemes. The topic is set theory which is a typical topic in 9<sup>th</sup> grade curriculum in Turkey and the class discusses the truth of a proposition. Sowder and Harel’s (1998) proof schemes are illustrated by excerpts of students (See Table 2 for which student has each scheme). For validity concerns, the number of students was chosen to be ten which is bigger than seven (which is the number of proof schemes) to prevent participants from matching students’ work to the proof schemes. The teacher presents a proposition and asks students whether this proposition is true or false and justify their answers: “Let  $X$ ,  $Y$ , and  $Z$  be sets. If  $X \subset Y$  and  $Y \subset Z$  then  $X \subset Z$ ”. The survey includes the following questions concerning the scenario: “Describe how students S1,...,S10 justify their answers to the truth of the proposition. Is the proof correct”. To increase the validity of the findings, the scenario used as data collection tool was chosen to be different from the scenario used during the module. The topic was also different. PMTs filled the PCK-P survey before and after the intervention (fifteen weeks later). In the second implementation, PMTs were directly asked to identify proof schemes of students.

We analyzed qualitative data to explore the effectiveness of the module and obtained quantitative findings which will also be supported with written explanations of participants. Each participant identified ten students’ proof schemes, therefore there is a total of 220 answers. 220 answers from 22 participants were coded as “correct”, “incorrect” or “no response”. We used the Wilcoxon Signed Rank Test (Wilcoxon, 1945) to investigate whether the module significantly affected participants’ PCK. The effect size was calculated using the formula  $r = Z/\sqrt{n}$ .

## Findings

Table 1 below presents the frequencies and percentages for correct, incorrect and no response categories. Percentages were calculated out of a total of 220 answers. As can be seen in Table 1,

findings indicate a development of PCK of proof schemes. The percentage of correct answers is 61.4% before the intervention and it increases to 96.4% after the module implementation. The number of correct answers increased by 77 which represents 35%.

	Correct	Incorrect	No Response	Total
Pre-intervention f (%)	135 (61.4%)	82 (37.3%)	3 (1.4%)	220 (100%)
Post-intervention f (%)	212 (96.4%)	8 (3.6%)	0 (0.0%)	220 (100%)

**Table 1: Frequencies and percentages for answers before and after the intervention**

Mean, standard deviation, minimum and maximum points were also calculated (over 10 which is the number of questions) considering answers to the survey before and after the intervention. The mean value increased from 6.14 to 9.64, minimum value increased from 3.00 to 8.00 and maximum value increased from 9.00 to 10.00. Standard deviation decreased to 0.58 from 1.49.

Student no	Type of Proof Scheme	Correct (Pre-/Post-)	Incorrect (Pre-/Post-)
1	Authoritarian	19/18	2/4
2	Authoritarian	19/22	3/0
3	Perceptual	17/22	5/0
4	Ritual	18/22	4/0
5	Symbolic	0/20	22/2
6	Example-based (a single example of finite sets)	21/22	1/0
7	Example-based (a single example of infinite sets)	13/21	9/1
8	Example-based (multiple)	14/21	8/1
9	Transformational	2/22	19/0
10	Axiomatic	12/22	9/0

**Table 2. Frequencies of answers for proof schemes before and after intervention**

We used the Wilcoxon Signed Rank Test to decide whether differences in PCK scores is significant. A Wilcoxon signed rank test showed that there was a significant difference ( $Z = -4.144$ ,  $p < 0.001$ ) between scores obtained before and after the intervention. Outputs for mean ranks of difference scores and sum of ranks imply that this significant effect is in favor of positive ranks, in other words, post-intervention. In addition, all participants' scores of PCK after intervention are higher than their scores prior to intervention. Effect size ( $r$ ) was found as  $-0.88$ . Since the absolute value of effect size is 0.88 which is greater than 0.50, it can be said that the module has a large effect size on the scores of PCK with regard to proof schemes in favor of post-intervention (Cohen, 1988).

As Table 2 shows, participants had difficulties to identify symbolic, example-based, transformational and axiomatic proof schemes before the intervention. They had overcome most of these difficulties after the intervention. Below, we present examples of these cases.

Student 5 has a *symbolic proof scheme*. He justified his answer considering the number of elements (See the lines 21-22 in Appendix): “ $S(X) < S(Z)$  then  $X \subset Z$ ”. Using this statement which is wrong, Student 5 uses a shallow symbolic manipulation. None of the participants correctly identified that this student has a symbolic proof scheme because participants also thought that it is a valid proof. After the intervention, 20 out of 22 participants identified Student 5’s proof scheme correctly. They used the terminology of proof scheme framework.

In the scenario, we prepared three different cases of an *example-based proof scheme* using (a) a single example of finite sets (Student 6), (b) a single example of infinite sets (Student 7) and (c) multiple examples (student 8). Before the intervention, 21 out of 22 participants noticed that Student 6 relied on only one example. After the intervention, all participants identified the proof scheme of Student 6 correctly. For the cases of (b) and (c), frequencies of correct answers increased considerably after the intervention (See Table 2). For (b), after the teacher called out for a more general example, Student 7 justified his answer using the sets  $N$ ,  $Z$ , and  $R$  which are infinite (See the lines 32-34 in Appendix). We consider this as an “example-based proof scheme using a single example” as in the case of (a) except the fact that  $N$ ,  $Z$ , and  $R$  are infinite sets. However, before the intervention, nine participants could not identify the proof scheme in the case of (b) because they thought that this is a generalization. Since they considered the student’s scheme as a generalization rather than example-based scheme, we coded their responses as incorrect. However, after the intervention, they improved in identifying this scheme (21 out of 22 participants correctly answered).

Student 8 suggested each student find one example so that there would be many examples to justify the truth of the proposition (See the lines 36-37 in Appendix). 8 out of 22 participants could not identify Student 8’s scheme correctly as “example-based” before the intervention. The main reason is that they thought multiple examples are convincing for a generalization:

PMT13: He reaches a generalization by a different example for each one in the class.

PMT17: He justifies by making a generalization and uses many examples that show the truth of the proposition so many times.

After the intervention, 21 out of 22 participants correctly identified Student 8’s justification as “example-based”.

Student 9 has *transformational proof scheme* since he reached a generalization through operational thought based on logical inference (See the lines 42-43 in Appendix). Before the intervention, only two participants could identify the proof scheme correctly, because others did not refer to any components of this scheme (generalization, operational thought or logical inference) in their explanations about Student 9’s justification. After the intervention, all participants identified the proof scheme correctly.

Student 10 has *axiomatic scheme* since he started the proof by using the definition of a subset and successfully completed the proof as can be seen in the scenario in Appendix (See the lines 47-48).

Before the intervention, 12 out of 22 students could identify this scheme. Others just mentioned that it was a mathematical proof. After the intervention, all participants identified the proof scheme correctly because Student 10 used the modern components of an axiomatic system.

## Discussion and Conclusion

Data indicated that the course module had significantly affected participants' scores of PCK of proof schemes. The intervention was effective especially in overcoming difficulties with identifying symbolic, example-based, transformational and axiomatic proof schemes. Before the intervention, participants could not identify students' shallow symbolic manipulation. Instead, they were probably convinced that the proof was valid just because it included symbols. For symbolic proof scheme, the course module included discussions of many examples of meaningless symbolic manipulation. After the intervention, participants improved in identifying this scheme. In the scenario, we expanded the notion of example-based proof schemes and included three cases (a single example of finite sets or infinite sets and multiple examples) and participants performed differently in each case. Before the intervention, participants found it more convincing compared to a proof with a single example which includes finite sets. In sum, although they identified an example-based proof scheme, they had difficulties in identifying proof schemes of students who used infinite sets and multiple examples. These findings indicate the importance of teachers' awareness of how students may view examples and noticing aspects of example use (Tsamir, Tirosh, Barkai, & Levenson, 2017). The module which included different cases of example-based proofs helped them overcome their difficulties.

The module was also effective for overcoming participants' difficulties in identifying transformational proof scheme by focusing on practices of generalizations using rules of logical inference and operational thought. Participants were more successful with identifying axiomatic proof schemes when compared to transformational scheme probably because they were more familiar with the modern components of proof such as definitions and axioms. However, before the intervention, they did not refer to these components to explain students' proving processes.

Considering the potential of scenarios to investigate PCK of proof schemes as implied by the findings of this study, we suggest that future studies could design scenarios focusing on proofs in different content areas. We also suggest that scenarios could be used in transition courses in undergraduate mathematics programs as well as teacher preparation programs. However, one should consider potential limitations of assessing the knowledge of identifying proof schemes using scenarios which could not reflect the complexity of a classroom. The second cycle of intervention could focus on teaching and learning situations in real classroom settings. Using Sowder ve Harel's (1998) notion of proof schemes which is a psychological construct, we focused on the psychological aspects of proof. Future studies could consider epistemological and sociological aspects of a mathematical proof.

## Appendix. The scenario used in the PCK-P survey

**Teacher:** Is the proposition below true or false? If true, why? If false, why? Justify your answer.

Proposition: “Let  $X$ ,  $Y$  and  $Z$  be sets. If  $X \subset Y$  and  $Y \subset Z$  then  $X \subset Z$ ”

**Student 1:** I think, it is false. We've seen a lot of rules about sets. But I don't remember this one.

**Teacher:** OK. We haven't seen it in a lesson. Couldn't it be still true?

**Student 1:** I've never heard of a rule like this. Therefore, I think it's false.

**Student 2:** Teacher, it is true. Because this theorem is in our maths textbook. So, it is definitely true.

**Teacher:** Do you think this is enough for a justification? You didn't write or do anything about it.

**Student 2:** I think it's enough. Why do we need another kind of justification if it's in the textbook?

**Teacher:** It's very important for us to reason about truth or falsity of a proposition.

**Student 3:** Teacher. May I draw a picture?

**Teacher:** Of course, you can.

**Student 3:** I think it's obvious from the picture.

**Teacher:** (heading towards the class) Is it enough for a proof? Just to draw a picture?

**Student 4:** Well, in fact. Every element in  $X$  is also an element of set  $Y$ . Every element in set  $Y$  is also an element of  $Z$ . I can express truth of the theorem. But we should do something mathematical. But I can't do it. Theorems should be proven using mathematical statements. But it shouldn't be. Verbal expressions, like I use, convince me much more.

**Teacher:** How did you come to this conclusion that proofs consist of mathematical statements only?

**Student 4:** Because proofs I've seen so far are just like that.

**Teacher:** Is there anyone who could use mathematical statements?

**Student 5:** If  $X \subset Y$  then  $S(X) < S(Y)$  and if  $Y \subset Z$  then  $S(Y) < S(Z)$ . Therefore  $S(X) < S(Z)$  that is  $X \subset Z$ .

**Teacher:** If the number of elements of a set is smaller than the number of elements of another set, then does it mean that the first set is a subset of the second set?

**Student 6:** I think not. I think that there is an easier way.

**Teacher:** What is that?

**Student 6:** Let  $X \subset Y$  and  $Y \subset Z$ . Let  $X = \{1,2\}$ ,  $Y = \{1,2,3\}$  and  $Z = \{1,2,3,4\}$ .

Since  $\{1,2\} \subset \{1,2,3\} \subset \{1,2,3,4\}$  then  $X \subset Z$ .

**Teacher:** Well. Do you think that this example is sufficient?

**Student 6:** Now it is true. I think it is sufficient.

**Teacher:** (heading towards the class) Do you think that this is sufficient?

**Student 7:** Not that example. But it would be sufficient if we justify with a more general example.

**Teacher:** For example?

**Student 7:**  $N \subset Z$  and  $Z \subset R$ . Therefore  $N \subset R$ .

**Teacher:** That is a more general example. But still, it is not sufficient for generality issue of a proof.

**Student 8:** Teacher! If each one of us in the class finds an example to show the truth (of the proposition), then we can reach a generalization.

**Teacher:** When I talk about a generalization, it means it is true for all  $X, Y$  and  $Z$ . We can reach a generalisation through the rules of logical inference and operational thought. That is, using other rules we should reach a judgement from a hypothesis through operational thought. Is there anyone who could reach a generalization using what we've done in our previous lessons?

**Student 9:** Let  $X \subset Y$  and  $Y \subset Z$ . Considering the rules we mentioned in our lessons, if  $Y \subset Z$  then  $Y \cup Z = Z$ .  $X \subset Y$  then  $X \cup Z = Z$ . If  $X \cup Z = Z$  then  $X \subset Z$ .

**Teacher:** That is correct. However, it is better if we think of the modern components of proof. It is appropriate to start a proof with definitions and axioms. Is there anyone who could prove it using the definition of a subset?

**Student 10:** Let  $X \subset Y$  and  $Y \subset Z$ . In this case, from the definition of a subset, if  $X \subset Y$  then for  $\forall a \in X$   $a \in Y$ . If  $Y \subset Z$  then for  $\forall a \in Y$   $a \in Z$ . Therefore, since for  $\forall a \in X$   $a \in Z$  then  $X \subset Z$ . It's proven.

# Games as a means of motivating more students to participate in argumentation

Jenny Cramer

University of Bremen, Germany; [cramerj@math.uni-bremen.de](mailto:cramerj@math.uni-bremen.de)

*Mathematical argumentation and proof require students to engage in complex thought processes in which they explore logical connections, solve problems, and learn to trust their own assertions. While in most mathematics classrooms there are some students who show an aptitude for trusting their own reasoning and making logical inferences, this does not generally hold true for the majority of students. In the context of playing games, however, many students overcome such obstacles and become motivated to use logical reasoning and argumentation. In this paper I examine the potential of exploiting logical structures in games as a means of fostering the motivation of students to engage in inner-mathematical argumentation. A three-step-approach leading from a board game into argumentation in calculus is introduced and indications towards the usefulness of the approach for fostering students' motivation are presented.*

*Argumentation, logical games, calculus, motivation.*

## Argumentation – a mathematical activity for the few?

Mathematics is a discipline based on logical thinking and inferences, with argumentation and proof at its heart. Proving activities in mathematics provide opportunities to autonomously discover mathematical knowledge and reach a deeper understanding (de Villiers, 1990) and can therefore promote an experience of empowerment to students. They may also teach us how to reason logically outside of mathematics (Grabiner, 2012). The mathematics classroom should thus aim at engaging all students in “suitable mathematical activities of argumentation and proof” (Boero, 2011, p. 1). This demand is even more pressing in the light of existing gaps in the accessibility of high level mathematical activities for students from different backgrounds (Boaler, 2016, p. 173). Argumentation and proof threaten to act as social filters that may increase performance gaps between students of different backgrounds if they are only accessible to few students (Knipping, 2012).

Being important mathematical activities, argumentation and proof have been receiving increasing attention in mathematics education and in school curricula for decades. However, in spite of efforts made to promote argumentation in class, only one in three students reported in the PISA study of 2012 that they like to engage in complex problem solving activities (OECD, 2013, p. 67f), and about 30% of students reported a feeling of helplessness when doing mathematics problems (OECD, 2013, p. 88f). While problem solving is not synonymous to arguing and proving, such tasks almost always rely heavily on logical reasoning, and the results may be taken as an indication for students' attitudes towards argumentation activities: few students appear to enjoy such activities, and a significant number of students is reluctant to engage in them at all. This is surprising, as more than half of the same students questioned for PISA 2012 stated that they sought explanations for things and could easily link facts together (OECD, 2013, p. 67f), and both of these skills are crucial for argumentation.

Mathematical argumentation is a discursive practice, into which students need to be introduced in order to be able to participate (Boaler, 2000). Logical games and puzzles may provide a suitable way of overcoming obstacles to participation, as they require forms of logical, deductive reasoning similar to the reasoning used in mathematical argumentation and proof. Clear rules, balanced starting positions for all players, and the limited scope of knowledge required for argumentation in a game context may help to facilitate students' participation in discourse as they provide circumstances which may support fulfilling discourse ethical requirements (Habermas, 1990). These potential positive aspects of games have been discussed before (Cramer, 2014).

Another positive aspect of games lies in their potential to appeal to the intrinsic motivation of students. High motivation in games can be explained by the needs for competency, autonomy and relatedness postulated by Deci & Ryan's (1993) self-determination theory. The motivational potential of games has been well documented for video games (Rigby & Ryan, 2011), and similar effects may be expected for board games. The *need for competency* describes an inner desire to master challenges and new situations. Games provide such challenges to their players. A fulfillment of the *need for autonomy* is given when we perceive our actions as self-guided. While this is generally difficult to achieve in a school setting, a playful approach may help to fulfill this need. Lastly, the *need for relatedness* describes a need for meaningful social interaction. Board games are characterized by interaction and could prove even more helpful in this area than video games.

### From game to graph: A three step approach

In this paper, a three-step approach to fostering the motivation of students to engage in argumentation is presented. It includes several rounds of the logical game *Uluru*, puzzles in the logical game environment, and puzzles in the area of calculus that aim at finding the graph of a function based on certain requirements. The research was conducted in a regular mathematics class with 15-16 year-old students in their tenth year of education (E-Phase) at a German high school (Gymnasium) over the course of five double lessons on four school days. Results are based on students' responses to three questionnaires at different points of the study. Figure 1 shows a timeline of the intervention.

Fig 1: Temporal overview of the study

#### Step 1: Playing Uluru

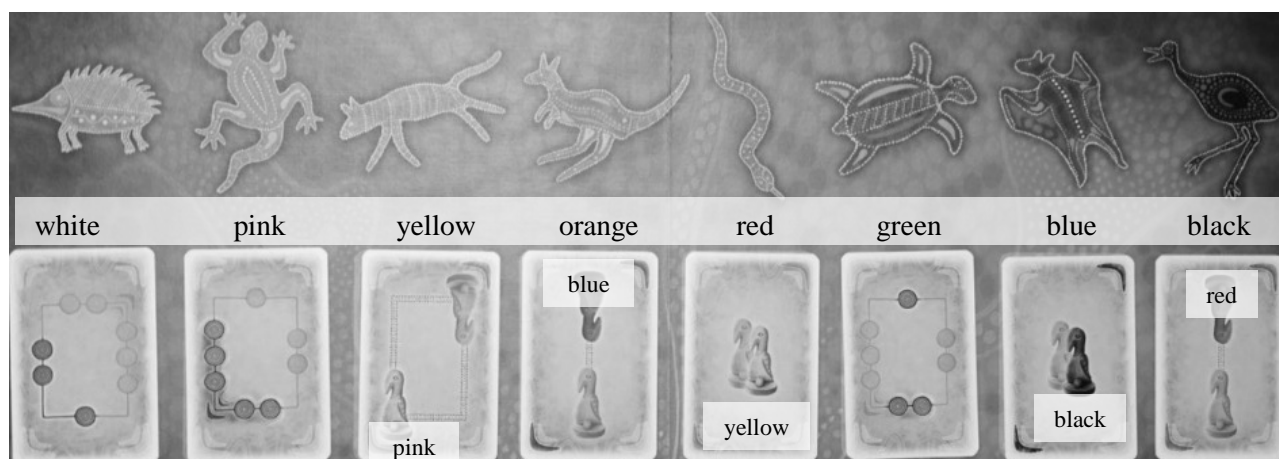

In the first step of the intervention, the game *Uluru* (by Lauge Luchau, published by Kosmos) was presented to the students. In *Uluru*'s scenario, animals in Australia transform into dream birds of different colors (white, yellow, orange, pink, red, green, blue and black) at night and fly towards Uluru (Ayers Rock). There are exactly eight spots around the Uluru on which birds may be placed. Each player receives bird tokens in the eight different colors and a game board. At the beginning of each round, wishes are randomly generated from a set of cards to guide the placement of the dream

birds. The wishes correspond either to positions around the Uluru (e.g. “on the short edge”) or to positions relative to birds of other colors (e.g. “next to the green bird”). Situations can arise in which not all wishes can be fulfilled. All players simultaneously try to place their birds according to the wishes within a set time limit. When the time has run out, points are given to the players according to the number of birds correctly placed. The game is played in several rounds.

The types of arguments generated in Uluru are very similar to typical argumentation patterns in mathematics. When evaluating the positions of the birds that each player has found, it is easy to tell whether the requirements given by the wish for a certain bird have been fulfilled or not, and the only possible results of this evaluation are true or false. Furthermore, the game naturally leads to questions characteristically mathematical, such as: “(Why) is this the only possible constellation?”, “Is it possible to fulfill all wishes?”, or “Why can’t all conditions be met at the same time?”. Thus, the game naturally provokes argumentation between players at the end of each round, especially in situations in which no player found a solution yielding eight points or when different solutions occur.

## Step 2: Solving Uluru puzzles

For the second step of the intervention, I created eight different puzzles in which different wish constellations were depicted. Students were given the task to figure out the maximum of achievable points for each situation. Two of the puzzles could be solved in exactly one way, two could be solved in different ways, three puzzles had a maximum of seven possible points, and in one puzzle six points were the maximum. The students were asked to record and justify their solutions on a protocol sheet. They were allowed to use the game board and the bird tokens to find a solution.

**Fig 2: An example for an Uluru-puzzle (colors annotated)**

In the example puzzle shown in Figure 2, three wishes (white, pink and green) refer to positions around the Uluru and five wishes (yellow, orange, red, blue and black) refer to birds of other colors. This puzzle has a unique solution. Due to the wishes of the red snake and the black emu, red and yellow need to be placed on adjacent spots and the black bird must be placed opposite the red bird. The blue bat’s wish means that black and blue need to be on adjacent spots. The orange kangaroo’s bird must be placed opposite the blue bird and thus on the same side as yellow and red. There is only one side of the Uluru that has three spots (cf. Figure 3). The wishes of the yellow dingo (shared corner with pink) and the pink lizard determine the corner in which these two dream birds must be placed.

Fig 3: Unique solution

Combined with the already discussed wishes of the other animals, there remains only one spot of the places defined by the wish of the white echidna. The green bird token takes the remaining spot.

The students were allowed to work on these puzzles with a partner. They handed in their protocols at the end of the lesson. The examination of students' answers showed that while they were almost always capable of finding the best possible solution, many students had problems with justifying their answers. Before resuming work on Uluru puzzles in the next lesson, a plenary phase was initiated in which proof by exhaustion of cases and proof by contradiction were discussed in the context of Uluru puzzles.

### Step 3: $f(u)$ -luru puzzles

In a third step, the concept of  $f(u)$ -luru puzzles was introduced. In these puzzles, the animals of Australia wished for properties of the graph of a function. The puzzles followed the game design. To develop the graph, the students received a laminated coordinate system in a design inspired by the game board, as well as removable foil pens. Table 1 gives an example for conditions of a puzzle.

white	pink	yellow	orange	red	green	blue	black
$f(-1) = -0.5$	exactly 1 maximum	$f''(0) > 0$	$f(-2) = 0$	$f'(0) = 0$	symmetrical to y-axis	$f(0) = 1$	minimum for $x = -1.5$

Table 1 Conditions in the  $f(u)$ -luru-"lightning puzzle" (simplified design)

For this puzzle, a maximum of 7 points can be achieved. The wish of green combined with the wishes of orange, white and black provide additional points  $f(2) = 0$ ,  $f(1) = -0.5$  and another minimum for  $x = 1.5$ . The blue and red wishes define the y-intercept as a local maximum or minimum. As the black and green wishes define two minima, pink's wish determines that the y-intercept must be a maximum. This contradicts yellow's wish  $f''(0) > 0$ . Thus, not all conditions can be fulfilled simultaneously. As seven is the second largest number of achievable points, this is an ideal solution to this puzzle. Figure 4 shows the solution.

Fig 4: Solution to the puzzle (7 points)

Fig 5: Excerpt from the "wishes"-overview for  $f(u)$ -luru

To help students determine possible solutions and formulate arguments, they received an overview which served to clarify and simplify the possible wishes in the  $f(u)$ -luru puzzles and to make the mathematical task more playful. Figure 5 shows an excerpt of the overview. The students also

received protocol sheets in a design analogous to the protocol sheets for the Uluru puzzles to document their solutions. Like in the Uluru puzzles, the students were again allowed to work in pairs. The puzzles did not ask the students to find an algebraic solution (no functional equations were expected from the students).

### **From game to graph: A three step approach**

To assess motivation, the Intrinsic Motivation Inventory (IMI, McAuley et al., 1989) was used. It is a suitable tool to measure motivation based on the needs postulated by self-determination theory. The questionnaire consists of 18 items and covers the dimensions *interest-enjoyment* (int-enj), *perceived competence* (perc-comp), *effort-importance* (eff-imp) and *tension-pressure* (tens-pres). For each item, agreement or disagreement was measured on a 7-point Likert-scale. Assessments took place at three points during the intervention. All examined tasks target solving a problem involving a variety of conditions that require reasoning and justifying. The students answered to the questionnaires using a pseudonym, allowing them to freely utter criticism (the researcher being their teacher).

Questionnaire 1 (Q1) was given to the students before the intervention to act as a point of comparison for later responses (cf. Field & Hole, 2003, p. 68). It was coupled to a task from the math textbook in which the graph of a function was to be created from certain requirements. This task had briefly been discussed in class in a lesson before the intervention. Q1's purpose was to facilitate capturing students' attitudes towards tasks in the regular mathematics classroom involving reasoning.

The second questionnaire (Q2) was given after the students had played the game Uluru and after they had been working on Uluru-puzzles for approximately one hour. I decided to forego an assessment of motivation after playing so as not to overstrain students with too many questionnaires.

The students responded to the third questionnaire (Q3) after approximately one hour of f(u)-luru-puzzles. This last questionnaire also covered some free text questions and items focusing on an evaluation of the intervention by the students, which were not statistically validated and can thus only give an indication concerning students' attitudes towards the intervention.

The setting of the evaluation is as a repeated measures design (Field & Hole, 2003, p. 183ff) with interdependent data, which necessitates an analysis of variance (Rasch et al., 2010). Nineteen students participated in all three questionnaires ( $n=19$ ). Shapiro-Wilk tests allow the assumption of normally distributed results for all dimensions except tension-pressure ( $p<0.05$ ) in Q2. Levene's test allows to assume homogeneity of variances except in the dimension of perceived competence.

### **Results**

The needs dimension of interest-enjoyment is a measure of perceived intrinsic motivation. Results for this dimension are thus very interesting, as they refer directly to how students perceived the tasks. A non-significant Mauchly-test ( $p = 0.53$ ) and the clearly significant analysis of variance ( $F_{(2,36)} = 7.80$ ;  $p < 0.01$ ) justify the use of t-tests. Bonferroni-corrected values show significant ( $p < 0.01$ ) differences between Q1 and Q2 and between Q2 and Q3. The boxplot in Figure 6 shows a positive shift of means from the first ( $M_1 = 3.63$ ;  $SD = 1.22$ ) to the second assessment ( $M_2 = 5.51$ ;  $SD = 0.83$ ). The third mean ( $M_3 = 4.39$ ;  $SD = 1.06$ ) lies between the others. Interest and enjoyment decreased in f(u)-luru puzzles compared to the Uluru puzzles. However, the histograms of

questionnaires 1 and 3 (Figures 7 and 8) also show a considerable decrease of very negative evaluations (scale range 1–2).

**Fig 6: Boxplot int-enj for Q1-Q3**

**Fig 7: Histogram int-enj Q1**

**Fig 8: Histogram int-enj Q3**

These results can be interpreted as a positive tendency that students preferred the f(u)-luru puzzles over classic mathematical tasks. However, this tendency needs to be treated with care as working arrangements were different for the mathematical task and for the f(u)-luru puzzles.

For the dimension of perceived competence, homogeneity of variances cannot be assumed. A closer look at the data shows that this can be explained by the high mean and small standard deviation in Q2. A comparison of means of questionnaires Q1 ( $M_1 = 3.93$ ;  $SD = 1.85$ ), Q2 ( $M_2 = 5.94$ ;  $SD = 0.77$ ), and Q3 ( $M_3 = 4.4$ ;  $SD = 1.75$ ) shows an increase in perceived competence for the Uluru-puzzles, followed by a decreased for f(u)-luru; the pairwise differences between Q1 and Q2 and Q2 and Q3 are significant ( $p < 0.05$ ). The means for perceived competence did not increase significantly between Q1 and Q3. However, as in the dimension of interest-enjoyment, the distributions of students for the lower scores are instructive. In the classic mathematical task covered in Q1, eight students perceived themselves as scarcely competent (scale range 1–2), whereas only two students gave this response in Q3 for the f(u)-luru puzzles. Taking into consideration that the latter were comparatively harder, this can be taken as an indication that students who otherwise trust little in their abilities might have benefited from the intervention.

Results for effort-importance show significant differences ( $p < 0.01$ ) between Q1 ( $M_1 = 3.8$ ;  $SD = 0.77$ ) and the means of Q2 and Q3 ( $M_2 = 4.95$ ;  $SD = 1.15$  and  $M_3 = 4.7$ ;  $SD = 1.02$ ; Mauchly-test  $p = 0.38$ , ANOVA  $F_{(2,36)} = 7.80$   $p < 0.01$ ). The students appear to have put greater effort into both, solving Uluru-puzzles and f(u)-luru puzzles. These results could point to an increase in students' readiness to get deeply involved in a given task.

Results do not allow to assume normally distributed results for the dimension of tension-pressure in Q2. However, this dimension was rated low in all assessments ( $M_1 = 2.88$ ;  $M_2 = 2.01$ ;  $M_3 = 3.06$ ). The students apparently did not perceive themselves under pressure during the intervention.

The students were asked in Q3 to comment on whether they had liked f(u)-luru puzzles better than classic problems in mathematics. Some notable answers:

I liked the f(u)-luru puzzles more, because it was possible to visualize and understand better.

Yes, because it was something different. Not so “dry”, but another method to do math problems.

I liked it better because for some reason I was more motivated.

The majority of students responded positively. Only one student replied: “I personally liked the Uluru puzzles better, because you didn’t need to show mathematical understanding like in the f(u)-luru

puzzles. The f(u)-luru puzzles were just as tiresome as normal mathematical problems.” While this answer shows that the intervention did not manage to motivate all students equally to engage in mathematics, it underlines the positive effects of the second step of the intervention.

In addition to the IMI-questions, Q3 also covered items aimed at a more direct evaluation of the intervention, which were rated on the same 7-point Likert scale. The students’ answers to these questions show a positive evaluation. Table 3 shows the items and the means.

Item	mean
I had fun playing Uluru (the game)	6.65
I had fun solving Uluru puzzles	6.15
I had fun solving f(u)-luru puzzles	4.9
I was motivated by the game Uluru to make an effort in Uluru puzzles	5.55
I was motivated by Uluru puzzles to make an effort in f(u)-luru puzzles	4.53

**Table 3 Evaluation items in questionnaire 3 and their means**

## Discussion

The three-step intervention described in this paper covered only a brief timespan of five double lessons, so only small effects may be expected. Furthermore, different working arrangements at different stages of the intervention must be considered when examining the results. However, the results presented here may be taken as an indication that game-based approaches may have motivational benefits for students. The quantitative evaluation of students’ answers yields a significant and noticeable increase of motivation for the Uluru-puzzles. While results for the f(u)-luru puzzles are not as unequivocally positive, the distribution of student responses compared to their assessment of the mathematical task in the dimensions of interest-enjoyment and perceived competence allows for the tentative assumption that the f(u)-luru puzzles are more likely to get a larger number of students involved in mathematical thinking than classic problems. Further research is needed, both to determine the effect of the different conditions in this study (e.g. working arrangements, difficulty of the tasks in Q1 and Q3) and to look at potential long-term effects.

While this paper shows potential motivational benefits of game-based approaches, this study did not include an evaluation of students’ argumentation quality in the Uluru puzzles or in the f(u)-luru puzzles. Therefore, it is unclear whether the intervention managed to actually improve mathematical argumentation skills. This question needs to be tackled in future research. For an evaluation in this regard, a consideration of Hintikka logic can prove helpful (Soldano & Arzarello, 2017).

Interventions like the one presented in this paper can be first steps towards a better integration of more students into argumentation discourse in the classroom. Observations in class and student responses to Q3 show that students worked on all given tasks in a highly concentrated way, which naturally included arguments and justifications. Clearly positive reactions of students to the game and the game-based puzzles show that most students like to engage in logical thinking. Exploiting logical games and puzzles as a stepping stone for more students to get involved in mathematical argument

seems a promising path towards more equally distributed student participation and might provide a means of tackling existing gaps in students' access to argumentation discourse.

# **Towards an interactional perspective on argumentation in school mathematics**

Markos Dallas

University of Agder, Faculty of Engineering and Science, Department of Mathematical Sciences,  
Kristiansand, Norway; markos.dallas@uia.no

*This paper discusses theoretical and methodological considerations which have emerged from reviewing the literature related to my PhD research project which adopts an interactional perspective on the development of the argumentation process in primary school mathematics. This led me to distinguish the factors involved in mathematics classroom interaction during the development of the argumentation process, as well as to examine the possible relations and interrelations of these factors. The outcome of this process was, first, to clarify theoretical aspects and, second, to create a preliminary model, called the “Mathematics Classroom Interactional Model” (MCIM), positing two levels of classroom interaction and the possible relations within each of them and between them.*

*Keywords: Socio-mathematical norms, participation, mathematical argumentation, mathematical communication, mathematics classroom interaction*

## **Introduction**

In the field of Mathematics Education, according to the related literature review, the notions of argument and of mathematical argument can be found in two different strands. The first strand relates to socio-mathematical norms and participation in the learning environment (e.g. Yackel & Cobb, 1996; Wood, 2002), mostly based on situated learning theory in the research (e.g. Lave & Wenger, 1991; Greeno, 1997; Boaler, 2000) and the second strand relates to mathematical argumentation and classroom interaction (e.g. Steinbring, 2005; Stylianides, 2007). However, so far, the literature does not seem to have made any clear attempt to develop a coherent theoretical framework and methodological tools emerging from the two strands. Thus, in my study, I focus on the development of the argumentation process in primary mathematics classrooms, considering the norms, the interactions and the role of the participants in learning and teaching practices. In this paper, I discuss aspects related to mathematical argument, argumentation and participation from the two strands of the literature to formulate the preliminary central research questions of the study, as well as to discuss the coherence –both compatibility and complementarity– of the two strands. On this basis, I develop a preliminary model, called the “Mathematics Classroom Interactional Model” (MCIM), of the concepts and their possible relations that will guide the scope of the study.

## **Socio-mathematical norms and participation in the learning environment**

Lave and Wenger (1991) describe learning as a social phenomenon that is constituted in the real world through a process of legitimate peripheral participation in communities of practice which are in development. This means that pupils are members of wider worlds that are socially and culturally formed, so developing links that cross the identities of ethnicity, gender, religion, etc., acts in classrooms, schools and communities and the practices that govern all these environments. The word “knowledge” has been replaced by the word “knowing” that declares an action. This fundamental

shift indicates that activities cannot be considered independent of the context. The “practice” is mainly characterized by the terms “discourse” and “communication” which implies that a pupil should be regarded as a person interested in participation in certain types of activities not only in the accumulation of knowledge (Sfard, 1998).

While the learning process in the current study is regarded in terms of the participation metaphor (Sfard, 1998), what is important is the person’s participation in activities influenced by the context. The underlying theory is that of Vygotsky’s (1978) socio-cultural approach, considering learning as an outcome of interaction with others, while theoretical approaches in situated learning are preeminent in contextualizing and describing classroom communities. These approaches, according to Lave and Wenger (1991) and Bransford, Zech, Schwarz, Barron and Vye (2000), have led to situated learning theories, in which knowledge is situated in particular forms of experience that arise in specific situations, and are understood in a relational way as something shared between people, activities and environments rather than as a fixed, individual characteristic (Boaler, 2000). Hence, mathematical knowledge, as a dynamic process of mathematization, is “still being open and not fixed in advance of the learning and acquisition processes” (Steinbring, 2005, p. 48).

According to Greeno (1997), many researchers based on situated perspectives study the development of classroom activities which involve pupils participating “in the discourse of the subject matter, including formulating and evaluating hypotheses, conjectures, arguments, evidence, examples, and conclusions” (Hatano & Lambert, 1990; Inagaki, 1991; Cobb et al., 1993; Cohen et al., 1993; Schoenfeld, 1994 as cited in Greeno, 1997, p. 99). A situated view suggests that activities of different practices are important, for instance involving pupils in classroom discussions is a way of pupils learning not only the content knowledge but also to participate in discourse practices (Greeno & MMAP, 1998 as cited in Boaler, 2000). Pupils learn not only methods and processes in the mathematics classrooms, but they are trained in mathematics, and the learning of content knowledge cannot be separated from the classroom interaction, as they are two reciprocal components (Boaler, 2000). One question posed in the situated learning theory is whether the pupil’s pattern of participation can be a potential obstacle to his/her membership of the classroom community.

Wood (2002) states that classroom culture consists of a set of social norms, a specific structure of participation, as well as characteristic forms of discourse that support both social norms and the structure of participation. A participatory structure refers to the specific characteristics of the classroom that affect pupils’ participation in the classroom: who is involved, when and how. Wood recognizes three types of culture that characterize a classroom of inquiry and can lead to different patterns of participation. The first relates to the development of alternative resolution strategies, the second relates to a culture of exploration of the strategies developed by their classmates, and the third to a culture of argumentation where social norms require pupils to justify or defend the methods of solution they choose. Wood, Williams and McNeal (2006) investigated primary mathematics classroom interactions and the development of mathematical thinking. One of the most important results was the finding that only in an inquiry/argument classroom culture were there opportunities for all children to be involved in meaning making and shared understanding. Nevertheless, as Klein (2001) points out, participation in cultures such as the above may be problematic for pupils who either have not conquered the tools of defending or challenging ideas through discussion (e.g. language or

norms such as what constitutes a different answer) or lack the self-confidence or self-image expected by an apprentice working in a collaborative learning environment.

Many researchers attach importance to the role of classroom culture, providing cooperative learning opportunities and, in particular, developing the intellectual autonomy of pupils. They focus on socio-mathematical norms and argumentative skills in the constitution of mathematical meaning in the classroom. Yackel and Cobb (1996), investigating the role of communication as a cultural tool, concluded that social norms (e.g. explanation and justification of a solution) directly affect the patterns of participation, a conclusion also supported by Sfard (1998), while socio-mathematical norms (e.g. which answer is considered mathematically different) provide equal opportunities to all pupils in that particular structure and regulate mathematical arguments. Finally, Kazemi and Stipek (2001) recognized, defined and described four categories of social norms and socio-mathematical norms respectively. The authors, in their discussion, emphasize the need for future research with longitudinal data that may reveal other norms, how socio-mathematical norms are created and sustained, and how they influence pupils' mathematical understanding.

The discussion so far led me to consider the connection between social and socio-mathematical norms relating to argumentation in the mathematics classroom. It seems that the mediator in this connection is the specific structure of the patterns of participation that allows (or not) the social norms to be transformed, created and sustained as socio-mathematical norms. Thus, the first preliminary central research question which emerged is: “what social and socio-mathematical norms relating to argumentation are established in the mathematics classroom, and how are these expressed in terms of patterns of participation?”.

## **Mathematical argumentation and classroom interaction**

In the field of Mathematics Education, Krummheuer (2007, 2015) started off using Toulmin's (2003) argumentation scheme to analyse classroom-based mathematical arguments. However, Krummheuer (2007, 2015) used a reduced version (conclusion, data, warrants and backings) of Toulmin's full scheme of argumentation (conclusion, data, warrants, backings, modal qualifier and rebuttal). Many researchers (Yackel, 2001; Hoyles & Küchemann, 2002; Evens & Houssart, 2004; Cabassut, 2005; Pedemonte, 2005; Weber & Alcock, 2005) as cited in Inglis, Mejia-Ramos and Simpson (2007) appear to have followed Krummheuer in using the reduced scheme. While Inglis et al. (2007) concluded that without using Toulmin's full scheme of argumentation it may be difficult to accurately formulate the full range of mathematical arguments, on the other hand Mariotti, Durand-Guerrier and Stylianides (2018) mention that difficulties of pupils to organize arguments in a deductive chain in the form of proof cannot be fully explained by Toulmin's model.

Despite the widespread use and proven usefulness of Toulmin's scheme of argumentation over the last two decades, researchers in Mathematics Education do not use this scheme in a consistent way. Besides different emerging interpretations, limitations can be identified. Thus, I studied further the related literature to find a model created in the field of Mathematics Education that could serve both aspects of mathematical argumentation and classroom interaction.

Stylianides (2007) developed a theoretical framework about proof and proving in the context of K-12 mathematics. “Proof is a mathematical argument, a connected sequence of assertions against a

mathematical claim” (Stylianides, 2007, p. 191). Any given argument can be broken down into three major components: the set of accepted statements, the modes of argumentation and the modes of argument representation. The distinction between base arguments and ensuing arguments could provide the context in which instructional analysis and instructional interventions by teachers influence classroom interactions and vice versa. In terms of this distinction, it is worth to be mentioned that in everyday mathematics classrooms situations, where the learning process is considered in terms of a participation metaphor (Sfard, 1998), the participants could produce a range of arguments, for example, “relatively sophisticated arguments” or “explications of elements of an argument” (Krummheuer, 2015, p. 53). Thus, the basic assumption is that mathematical argumentation can only emerge through interaction and mathematical communication within the classroom culture. Steinbring (2005) developed an analytic framework to examine the relation between mathematical knowledge and mathematical communication. While, “language is the central medium for the creation of possible connections between communication and consciousness” (Steinbring, 2005 p. 53), proof is the communication medium of invisible mathematical objects and the mediator between communication and consciousness (Heintz, 2000 as cited in Steinbring, 2005; Steinbring, 2005).

Instructional school-mathematical interaction is expected to contribute to introducing individuals into mathematical communication practice, and thus to increase these individuals’ ability to participate in (mathematical) communication in the society. (Steinbring, 2005, p. 74)

This interaction could be understood by the term “situational”.

My perspective is situational, meaning here a concern for what one individual can be alive to at a particular moment, this often involving a few other particular individuals and not necessarily restricted to the mutually monitored arena of a face-to-face gathering. (Goffman, 1974, p. 8)

According to Krummheuer (2007), the term “situational” refers not only to a particular situation that could be characterized as “situated”, but to anything that can happen in the interaction between people. Thus, for example, if during a lesson the pupils solve an activity on their own it may be a “situated learning” process (Lave & Wenger, 1991) which is shaped by the pre-knowledge that allows them to face similar activities. The action changes into a “situational” process if the pupils take initiatives to act with their classmates. Levinson (1988) extended the ideas of Goffman (1981) and Krummheuer (2007, 2015) by adapting the concepts of participants’ (speakers’) roles in Mathematics Education: “author”, “relayer”, “ghostee” and “spokesman”. Although Krummheuer’s (2007, 2015) approach to participation in argumentation offers insights on the way that participation is performed in mathematical argumentation, the mechanism of being in one role or another is not obvious and cannot explain the obstacles in pupils’ participation in the developing of mathematical arguments, something also claimed by Cramer and Knipping (2018). Cramer and Knipping (2018) highlight the importance of participation in mathematics classroom argumentation, considering the discursive and social processes that affect argumentation. Thus, participation is not only a discourse but the practice of constructing arguments through the social order of participants’ interactions in the classroom which can be constructed, maintained and transformed. Cramer and Knipping (2018) mention an interesting case of pupils’ implicit participation (pupil’s initially spoken idea developed further in the classroom

discourse but the pupil's voice disappeared), to describe possible obstacles for participation in argumentation and possible interventions by a teacher.

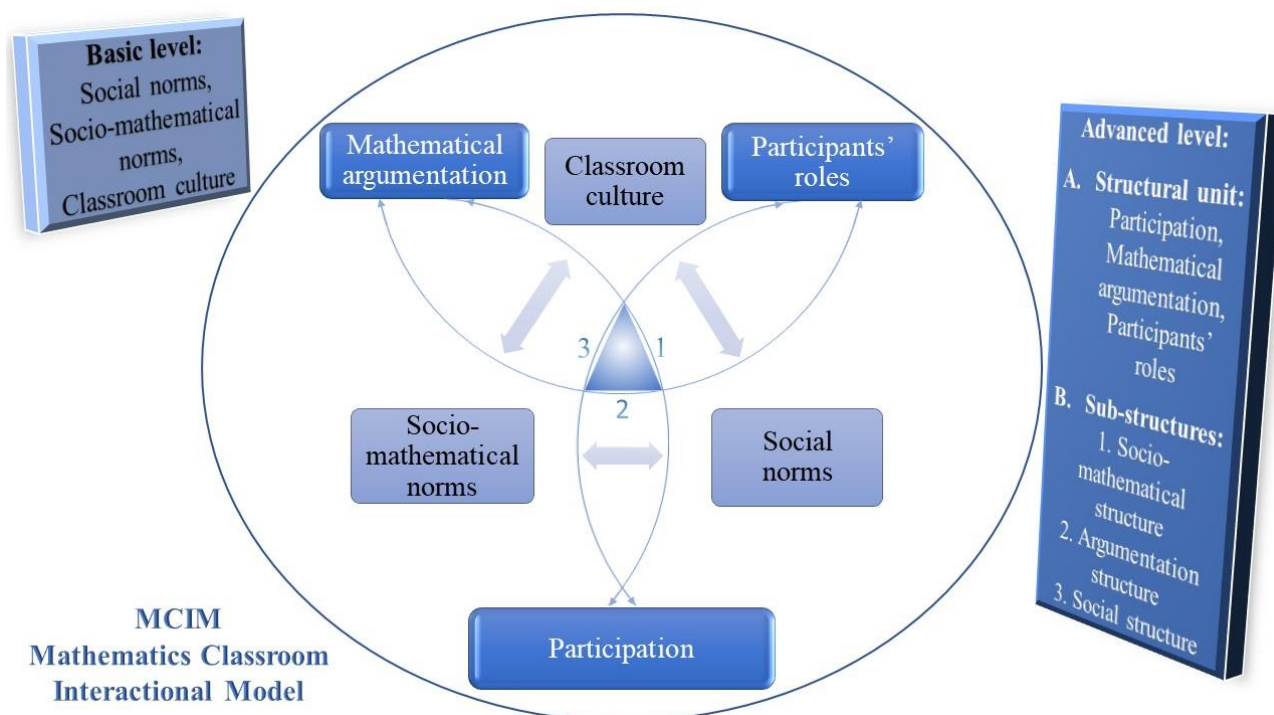

The discussion so far led me to consider the connection between mathematical argumentation and classroom interaction. It seems that the mediator in this connection is the specific role of the participant that regulates the participation in mathematical argumentation. Thus, the other two preliminary central research questions which emerged are: "how do pupils' interactions contribute to the development of the base arguments?" and "how do teachers' instructional interventions influence pupils' activity in the developing of ensuing arguments?".

## Discussion

The ideas about socio-mathematical norms and participation in the learning environment and those about mathematical argumentation and classroom interaction seem to be related. Socio-mathematical norms seem to be a major factor that regulates classroom interaction in developing arguments. Especially, pupils' and teachers' roles in developing base and ensuing arguments are related to socio-mathematical norms that could foster (or not) mathematical argumentation and participation in the classroom. Thus, I decided to create the preliminary MCIM model, of the basic concepts and their relations as considered in the previous two sections and expressed in terms of the three preliminary central research questions.

In this model, Figure 1, I posit two levels of classroom interaction. The first (basic) level of classroom interaction is defined by the relations among the social norms, the socio-mathematical norms and the classroom culture. These are the predominant factors that characterize classroom interaction and are defined fully through the review of the first strand of the literature. The socio-mathematical norms established in the classroom culture are affected by social norms. The second (advanced) level of classroom interaction is defined by the relations among the participation, the mathematical argumentation and the participants' roles. This level includes, A: the three factors as a structural unit (participation, mathematical argumentation, participants' roles) and B: three sub-structures: 1) socio-mathematical structure: participation-mathematical argumentation, 2) argumentation structure: mathematical argumentation-participants' roles, 3) social structure: participants' roles-participation. Each of these (sub)structures presupposes the connection of the factors at the basic level. Thus, the common ground of the structures at the advanced level is the connection among the three factors at the basic level. When a researcher or a teacher in the classroom would like to understand, investigate and further develop the advanced level, they should firstly understand, consider, and develop the connection of the social norms, socio-mathematical norms and the classroom culture, the factors at the basic level.

According to the related literature, the main connection between the two levels rests on social norms and socio-mathematical norms that regulate mathematical arguments, defining participation in the classroom culture (e.g. Yackel & Cobb, 1996; Wood, 2002; Wood et al., 2006). Therefore, in order to define this model with consistency, I consider theoretical and methodological frameworks to get access to mathematical argumentation and classroom interaction.

**Figure 1: Mathematics Classroom Interactional Model (MCIM)**

Stylianides (2007) framework could serve as an analytic tool in order to examine the development of mathematical argumentation and teachers' actions, through the processes of instructional analysis and instructional intervention. Especially, the distinction between base and ensuing arguments and the possible differentiation between them and in each of them could be related with the patterns of participation which emerge through the socio-mathematical norms. Nevertheless, it seems that the focus of the framework is from the teachers' perspectives rather than on pupils' and teachers' interactions and their roles in the classroom culture. Stylianides uses the notion of classroom community in the definition of proof with a perspective different from that usually found in the literature, and from the one I have taken in my study. He regards the pupils as the main members of the classroom community, giving the teacher a special membership status and distinct role, while in my study I focus on the dynamic of the classroom interactions and the power of the relationships that shape the participation in the classroom community. Thus, I elaborate Steinbring's (2005) framework of mathematical knowledge and communication where the interactions and communication among participants are presented as predominant in the classroom. In this context, the reference to the role of the language in mathematical communication and argumentation in the classroom is very interesting and this leads me to consider frameworks through which I could get insights on the utterance of the mathematical argumentation through the participants' roles. Levinson's (1988) categorization of speakers' roles seeks to offer insights on the patterns of participation. However, Krummheuer (2007, 2015) does not seem to undertake or investigate the limitations described by Levinson (1988), where multiplicity and alteration of the participants' roles in some utterance events, as well as new roles, could be recognized, defined and re-defined. Moreover, Cramer's and Knipping's (2018) evidence of implicit participation is an interesting aspect related to participants' roles in mathematical argumentation and could be investigated further, either as forms of participation

or non-participation. Considering the roles of the participants and interactions among pupils and teachers in the classroom culture, it could be possible to examine pupils' interactions in developing base arguments and explain teachers' actions in influencing pupils' activity to develop ensuing arguments.

Finally, the way that the socio-mathematical norms and the social order, related to the development of mathematical arguments and argumentation, are created, sustained and transformed could provide the context of an interactional perspective on argumentation in school mathematics through the MCIM model. However, this model has still to be considered and defined fully through empirical research to be conducted, developing the methodological context and the research protocols that fulfil the goal of the study.

# A pilot study on elementary pupils' conditional reasoning skills and alternatives generation skills in mathematics

Anastasia Datsogianni<sup>1</sup>, Stefan Ufer<sup>1</sup> and Beate Sodian<sup>1</sup>

<sup>1</sup>University of Munich (LMU); [Anastasia.Datsogianni@psy.lmu.de](mailto:Anastasia.Datsogianni@psy.lmu.de),  
[ufer@math.lmu.de](mailto:ufer@math.lmu.de), [Sodian@psy.lmu.de](mailto:Sodian@psy.lmu.de)

*Keywords: Conditional reasoning, alternative generation, mathematics, primary students.*

## Background and rationale

One of the main aspects of logical reasoning is conditional reasoning, i.e. reasoning with if-then statements. Conditional reasoning tasks usually present a rule of the form “if  $p$  then  $q$ ” as a major premise, and a minor premise. Four minor premises differentiate four possible logical forms of inference:  $p$  is true (Modus Ponens, MP),  $p$  is false (Denial of the Antecedent, DA),  $q$  is true (Affirmation of the Consequent, AC), and  $q$  is false (Modus Tollens, MT). Definite conclusions can be drawn for MP (“ $q$  is true”) and MT (“ $p$  is false”), while AC resp. DA do not allow definite conclusions. Even very young children can show conditional reasoning skills in familiar everyday contexts (Markovits & Thomson, 2008). However, a link between conditional reasoning and mathematics has been found only in adolescents and adults in the context of proof (Stylianides & Stylianides, 2007).

According to Mental Model Theories, inferences are drawn by constructing mental models that encode information about specific situations in which the conditional is valid (Johnson-Laird & Byrne, 2002). The reasoners' ability to generate alternative models (beyond a model representing “ $p$  and  $q$ ”) for the given conditional is considered a crucial prerequisite to draw valid inferences. Studies on conditional reasoning in the everyday context (De Chantal & Markovits, 2017) have shown that the alternative generation skills do predict early development of conditional reasoning. This raises the question, if the ability to generate multiple alternative models for a given mathematical premise, has an influence on students' conditional reasoning with these concepts.

## Methods

Our study aimed at examining the relation between primary students' skills in conditional reasoning with mathematical concepts, and their performance on the corresponding, alternative generation tasks. Participants were 55 elementary students (4th graders  $n=13$ :  $M=9.5$  years, 6th graders  $n=42$ :  $M=11.5$  years) from a public school in Cyprus. Their conditional reasoning skills were assessed in two conditional reasoning tasks including mathematical concepts (Datsogianni, Ufer, & Sodian, 2018). Each task contained one item for each logical form (MP, MT, DA, AC). For example, one conditional reasoning task focused on the circumference of rectangles in a context of dwarf houses. It was explained that dwarf houses always consist of several aligned rows, all with the same number of same-sized quadratic rooms. The major rule in this task was “If a dwarf house has exactly 2 rows of 4

rooms each, then it has 12 windows". The alternative generation tasks asked students to generate many examples satisfying the conclusion of the major premise (i.e. "Draw as many dwarf houses as possible, that have 20 windows!").

## Results and discussion

Students' solved 62.7% of the mathematics conditional reasoning items correctly, illustrating early conditional reasoning skills under specific conditions. Regarding the first alternative generation task 62% of students gave 4 to 6 correct alternative solutions ( $M= 3.42$ ,  $Mdn= 4.00$ ). The second alternative generation task seemed to be more difficult since only 20% of students gave 4 to 5 correct solutions ( $M= 1.81$ ,  $Mdn= 1.00$ ). This indicates that the alternative generation tasks are feasible, but not too easy for our target sample. The number of generated alternatives correlated with students' reasoning performance (task 1:  $\rho=0.358$ ,  $Sig.=0.001$ , task 2:  $\rho=0.343$ ,  $Sig.=0.003$ ), supporting our assumption that mathematical conditional reasoning is based on alternatives generation. Some first insights of our main study, which followed the above one, confirm that alternative generation in mathematics predicts correct logical reasoning and especially with AC form.

The results showed that the applied instrument is accessible to students while they replicate early conditional reasoning skills reported in studies from developmental psychology (e.g. Markovits & Thompson, 2008). This study replicates also previous results (De Chantal & Markovits, 2017) regarding the significant relation between alternative generation skills and students' conditional reasoning skills, extending these results to tasks that involve mathematical concepts. The small sample size forbids taking far-reaching conclusions. However, our future research will be based on these developed tasks to describe the role of mathematical knowledge in conditional reasoning with mathematical concepts in more details investigating also whether alternative generation training could be one approach to support students' conditional reasoning in mathematics.

# What do prospective mathematics teachers mean by “definitions can be proved”?

Merve Dilberoğlu<sup>1</sup>, Çiğdem Haser<sup>2</sup> and Erdinç Çakıroğlu<sup>1</sup>

<sup>1</sup>Middle East Technical University, Turkey; [armerve@metu.edu.tr](mailto:armerve@metu.edu.tr), [erdinc@metu.edu.tr](mailto:erdinc@metu.edu.tr)

<sup>2</sup>University of Turku, Finland; [cigdem.haser@utu.fi](mailto:cigdem.haser@utu.fi)

*The research reported here is part of an ongoing study<sup>3</sup> in which prospective middle school mathematics teachers' conceptions of definition are investigated through their responses to semi-structured interview questions about defining quadrilaterals. Here we present findings from their responses to a subset of the interview questions, with the purpose of understanding what they mean by the expression “definitions can be proved”- an expression commonly referenced, and considered as erroneous in the research literature. Analysis of the responses, through using thematic coding and Toulmin's (1958) scheme, revealed that participants attributed two different meanings to the phrase: (1) proving the claim that a written definition accurately designates an intended concept and (2) proving the concept being defined (erroneous). Based on our findings, we point to a reconsideration of the phenomenon by the research community.*

*Keywords: Meta-mathematical knowledge, conception of proof, conception of definition, prospective middle school mathematics teachers*

## Introduction

Most teacher education programs offer college level mathematics courses to strengthen prospective teachers' mathematical preparation. Although these courses provide rich mathematics content and experience of working with definitions and proofs, they do not include explicit information about mathematics at the meta-level (Azrou, 2017). Especially, learning to prove becomes a difficult task for university students (Stylianides & Stylianides, 2009). Previous studies highlight that students at all grade levels experience difficulties related to proofs (e.g., Azrou, 2017; Fiallo & Gutiérrez, 2017), which is most of the time considered as a consequence of an inaccurate understanding of what constitutes a proof (Weber, 2001). Various studies have also informed that prospective teachers lacked an accurate understanding of mathematical definitions (Leikin & Zazkis, 2010; Levenson, 2012). Indeed, that many teachers and students cannot differentiate between definitions and proofs or consider definitions as provable is a robust research finding (Edwards & Ward, 2004; Leikin & Zazkis, 2010; Levenson, 2012).

In this study, we delve deep into prospective teachers' reasoning about if definitions need to be proved or not. In case of occurrence, we investigate prospective teachers' expressions and examples, in order to find out what they mean by the expression “definitions can be/need to be proved.” By using Toulmin's (1958) model of arguments, we look for the existence of concrete claims in participants' proof-related attempts, because their responses to interview questions provide the key information on “what is being proved” in their perspectives. By detecting the actual

---

<sup>3</sup> The research is funded by Middle East Technical University Research Fund GAP-501-2018-2714.

“proven”, we aim to find out underlying reasons of using this erroneous expression; which might be a first step in developing proper ways of remediation in teacher education programs.

We also refer to arbitrariness aspect of mathematical definitions (not of definitions, but of concepts) in answering our research question: What meaning do prospective mathematics teachers attribute to “proving/proof of a definition”? Since defining in mathematics is arbitrarily naming concepts (Vinner, 1991), concepts do not possess inherent truth-values. They are neither true nor false (Edwards & Ward, 2008). However, by “arbitrariness” we do not mean that definitions are adopted on a complete random base. Rather, we acknowledge that they are open to intelligent refinements through successive work of mathematicians (Lakatos, 1976). In this study, we position that both the concepts and definitions are “arbitrary”, in the sense we use the word. Concepts are “agreed upon conventions” (Levenson, 2012, p. 209); that is why they are arbitrarily named. On the other hand, definitions can arbitrarily be chosen among multiple equivalent definitions of a concept. We use the former in the case we report here.

## Background

Two theoretical foundations were employed in this study. The concept definition-concept image distinction and Toulmin’s (1958) model of arguments are introduced in the next sections.

### Concept Definition/Concept Image

*Concept image* is the collection of all mental representations associated with a particular concept in one’s cognitive structure; while the *concept definition* is the mathematical statement that designate that concept (Tall & Vinner, 1981). Although a concept definition is expected to connote the same meaning to everyone, concept image is specific to the individual and may not be fully compatible with the formal definition. In our study, the distinction between *concept image* and *concept definition* is a theoretical keystone for understanding prospective teachers’ hidden claims underlying their use of the erroneous expression “proving a definition”.

### Toulmin’s (1958) Model of Arguments

Toulmin (1958) proposed a schema for describing an argument by identifying three main components. The model describes the connection between the claim (C) - that is desired to be established- and the data (D) - the fact, which can serve as a basis for establishing that claim. For the argument to take the arguer from the data to the claim, another element is defined: The warrant. Warrants can be rules, principles or inference-licenses entitled to “show that, taking these data as a starting point, the step to the original claim or conclusion is an appropriate and legitimate one” (Toulmin, 2003, p.91). The three elements constitute the simplest form of the model. The complete model includes additional elements of backing (B), modal qualifier (Q), and the rebuttal (R). Backing is a further evidence for the connection between data and claim, modal qualifier associates a degree of confidence to the conclusion made; and rebuttal states the conditions under which the conclusion is not valid. However, not all arguments have to contain these latter three elements.

Given that proof is a mathematical argument produced with the purpose of convincing oneself and others of the truth of a mathematical statement (Fiallo & Gutiérrez, 2017), we apply Toulmin’s model on prospective teachers’ productions of exemplary proofs, in order to identify the actual

claims they aim to prove, while expressing it as “proving a definition”. Since our focus is on identifying any existing claims in participants’ examples, we use the simplest form of the model, consisting only of the three elements data (D), claim (C) and warrant (W).

## Method

Basic qualitative research methods were used in this study.

### Context and Participants of the Study

Participants of the study were six senior (4<sup>th</sup>-year) prospective middle school mathematics teachers in a four-year teacher education program. The program, prepared around 40 mathematics teachers each year to teach at the grade levels from 5 to 8, by offering college-level mathematics courses mostly in the first two years and concentrating more on the teaching-related courses in the last two years. Participants were selected based on their active participation in the educational courses, their inclination to express and discuss mathematical ideas and the variation in their knowledge of mathematics, as observed in the teaching related courses by the authors. All six participants volunteered to participate in the study as an out-of-class activity. Since the data were collected through the end of the academic year, they had nearly completed all the courses in the program. Although the program included the study of undergraduate level mathematics courses (offered by the Mathematics Department) in which definitions and proofs played important roles, students had not been offered any specific information about meta-mathematical constructs of definitions and proofs in these courses. Also, it may worth to highlight that a detailed chapter on the geometry terms, especially the hierarchical way of defining quadrilaterals were covered in the mathematics teaching methods course that participants took in their third year.

### Data Collection and Analysis

In semi-structured interviews conducted by the first author in one-to-one settings, prospective teachers responded to a broad range of verbal and task-based questions aimed at revealing their understanding of mathematical definitions. After completing an initial open-ended task about defining quadrilaterals (participants were asked to propose a sequence for introducing quadrilaterals, by supplying their own definitions), they were asked questions such as “What is a mathematical definition for you?” and “Why do we state definitions in mathematics?” One of the questions asked participants to explain their thinking about the relationship between definitions and proofs. They were explicitly asked to indicate if definitions need/have proofs or not, and explain their reasoning. In case of accepting definitions as provable, they were requested to give an example. Participants’ responses were analyzed through thematic coding procedure (Braun & Clarke, 2006) and Toulmin’s (1958) model of arguments was used to describe their examples.

## Findings

Analyses of prospective teachers’ explanations and examples resulted in two different interpretations of the expression “proving a definition”. In particular, prospective teachers considered “proving a definition” as (1) justifying the claim that a written definition accurately designates an intended concept (which would be an appropriate action in the discipline of mathematics) and (2) justifying the concept being defined (which remains ambiguous in meaning).

Table 1 presents a summary of each participant's thinking about the phrase, as inferred from their verbal explanations and concrete examples, which were mostly different from what they explicitly said. A representative quotation from each participant is given in order to reveal their use of words in their conversations. Two separate rows are used for the participant (P5) who displayed both type of interpretations.

PST	Sample Wording PST Used	Meaning Inferred from Further Explanations (through thematic coding)	Meaning Inferred from Example Case (through Toulmin's scheme)
P1	"I am proving the triangle (definition)."	Proving the claim	Proving the claim
P2	"I proved the truth of this definition."	Proving the claim	Proving the claim
P3	"Definitions should be proved."	Proving the claim	(Did not provide)
P4	"I could not understand what you mean?"	Proving the claim (if such a thing exists)	Proving the claim
P5	"By ..., we can prove definitions."	Proving the claim	Proving the claim
P5	"After the shape square has been proved."	Proving the concept	(Did not provide)
P6	"If I am definining a concept, it has nothing to do with proving."	Proving the concept (non-existent)	(Not applicable)

**Table 1: Meaning attributed to the phrase of "proving a definition" in prospective teachers' (PST) explanations and examples**

The two types of interpretation resulting from participants' responses are described in the following sections. In the reporting of quotations and examples, brackets are used for indicating the authors' insertions, and square brackets are used either for indicating excluded parts of the interview (with ellipsis: [...]) or for specifying the components of the participant's arguments (i.e., [data], [claim], and [warrant]).

### **Interpretation I: "Proving a definition" as "proving the claim that a written definition designates the intended concept"**

Four of the six prospective teachers (P1, P2, P3, and P5) indicated that definitions "can be proved" (P1) or "need to be proved" (P3). Although their wording did not reflect the existence of an explicit claim to be proved (e.g., "proving the triangle (definition)" (P1); "I will give a definition and prove it." (P2)), their explanations and examples revealed that what they considered provable was an actual claim. In particular, they were talking about proving that a written definition truly reflects the image of the intended concept in their minds. Following scripts from P1 and P2 illustrate the case.

Researcher: The proof you thought of there... What exactly is that proof of?

P1: Of the triangle (definition), in fact.

Researcher: How is that? Could you open this up a little?

P1: Of the triangle (definition). It is about the shape of the triangle. I mean, in our minds there is a shape about... the shape of the triangle and we are trying to make this definition fit to it. With the proof, we check if it fits the shape or not.

Researcher: Is there a relationship between definition and proof?

P2: Yes. In order to prove that the definition we create is true, we do proofs. I mean I create a definition; but to what extent is that true, when it holds? Maybe under some conditions it does not hold. For proving this, proofs are written.

Their examples were based on proving concrete claims as well. They were basically comparing a written definition with the corresponding concept image in their minds to evaluate their congruence.

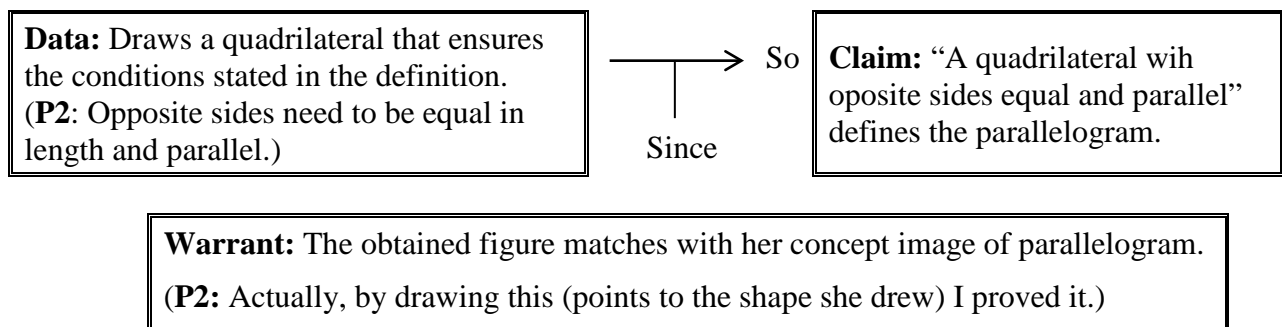

Researcher: Now, what exactly is that you try to prove here? [...] Can you give me an example?

P2: I will give a definition and prove it. Hmm... Let me take the parallelogram. Opposite sides need to be equal in length and parallel (reads the definition she wrote in a previous task), I say. I will prove this. (Draws the figure that satisfies the given conditions.) [data] Actually, by drawing this (points to the figure she drew) [warrant: the figure fits into her concept image] I proved it [claim].

Researcher: What is that you proved here?

P2: Properties of the parallelogram. I try if it does hold for the given definition. I do some trials and then I see that it holds for this definition. And I proved the truth of this definition, I mean.

Figure 1 presents P2's example case of "proving" by using Toulmin's (1958) model arguments.

**Figure 1: An argument schema for P2's example**

On the other hand, the idea of "proof of a definition" did not make any sense to P4 first. However, when she thought over it by the help of an example case, she ended up with the same interpretation as the previous participants:

P4: Let me think about this. Here, I had written something for rectangle (in a previous task). There I have defined rectangle as the parallelogram with a right angle. Now, am I required to prove that this definitely defines the rectangle?

Her exemplary proof attempt provided an accurate representation of the participants' thinking.

- P4: I know what a parallelogram is (Draws a parallelogram-angles very close to  $90^\circ$ ). [data] Now, I should have drawn a real rectangle. It is OK, if I do not. One of the angles is 90 degrees [data], I started here (marks one of the angles with the perpendicularity symbol). I know that in a parallelogram opposite sides are parallel. Then, these (two adjacent angles) add up to 180 degrees. This is also 90 (degrees). [...] Then, its all interior angles are 90 degrees. Opposite sides are parallel, equal and so forth... It satisfies all the properties of rectangle. [warrant][...] I mean, I can prove that this definition is rectangle. [claim]

### **Interpretation II: “Proving a definition” as “proving the concept being defined”**

Two of the prospective teachers perceived “proving a definition” differently. They maintained the odd wording of “proving a concept” in their explanations (e.g., “proving the shape square” (P5)). However, their approaches to this idea were different from each other's. P5 thought that it was a possible action to “prove a concept”. Although she could not elaborate much on this idea of her, since she demonstrated two different meanings at the same time (both proving the claim and proving the concept) it was evident that she was talking about an issue different than proving the claim in the following dialog:

- Researcher: Is there a relationship between definition and proof?
- P5: I cannot say absolutely there is, but I think should be. [...] After the shape square has been proved, it must have fit to its definition. Otherwise, if we do not know what is the thing that we call square, without proving this, we cannot make the definition.
- Researcher: What is it that we prove here?
- P5: Which shapes we call “square”? How does the square come into existence?
- Researcher: Can you give me an example of this?
- P5: I do not know. Now... I can't find.

Immediately after, when she was asked if definitions were provable or not, she demonstrated the same understanding of “proving a claim”, similar to what the previous participants did:

- P5: We draw the multiple shapes of what we do (define), I mean by looking for counterexamples, we can prove definitions.

Her example also supported that she was proving a claim (whether a given definition of square would actually define square or not), although she relied on empirical reasoning in her argument.

- P5: Let me think with square again. More than one person draws its definition [data], because it may not represent the same thing to everyone. We check if it does represent the same thing to everyone. If one person draw a thing that is different from what we try to explain [warrant], then that means the definition we have is not correct or not clear, erroneous [claim]. In this way, I think we can prove it.

Unlike P5, P6 seemed to be aware of the fact that “defining was arbitrarily naming concepts” and hence definitions (concepts) needed no justification.

P6: Of course there may be (a relationship in between), but if I am trying to name something, if it is something like a term... You see, here when I am trying to define the trapezoid, I am not proving the properties of the trapezoid [...] Because I am just giving it a name.

As we consider that they are the concepts which are arbitrary, rather than the defining statements (in our case), we name this second type of interpretation with the phrase “proving the concept being defined”. Both P5 and P6 seem to be thinking about proving “why concepts exist in mathematics as they are”. While P6 correctly rejects this kind of thinking about definitions, P5 seem to consider it as a necessity. Also, P5’s erroneous understanding may still be residing in other participants’ minds, as prospective teachers may not be aware of arbitrariness aspect of definitions.

## Discussion and Implications

Findings of the study provide insights into participating prospective teachers’ conceptions of proof. Although at the first glance they seem to be trying to prove a non-claim, existence of a real claim in their arguments reveals that they have an implicit (because they do not say so) insight about what needs a proof in mathematics. This is an unexpected finding and a positive outcome for teacher education programs compared to previous research findings, because no such claims were proposed by the participants of other studies who communicated that definitions could be proved (Levenson, 2012) or who could not distinguish between a theorem and a definition (Edwards & Ward, 2004; Leikin & Zazkis, 2010). However, this finding does not necessarily mean that participants are also sure of what cannot be proved in mathematics. P5’s explanations displayed that one of the things she tried to prove was a claim (Interpretation I), while the other was not (Interpretation II). The same might be the case for all of the participants of the study, except P6; but might have remained uncovered in our interviews, because no participants other than P6 mentioned the arbitrariness aspect of defining concepts in their responses. They did not reveal any thinking about if concepts were provable or not, as P5 and P6 did. This addresses that while interviewing prospective teachers, handling the nature of proofs and definitions concurrently and from multiple aspects might provide a more complete picture of their meta-mathematical knowledge. Otherwise we might end up with unrealistic judgments of prospective teachers’ knowledge and understandings.

On the other hand, our observation that most of the prospective teachers attributed the same acceptable meaning (Interpretation I) to the principally imperfect phrase of “proving a definition,” have important implications about the common practice of using the words “proof” and “proving” imprecisely. Besides not questioning the misuse of the word “proving” in the question we directed to them (P4 did only); most of the participants consistently used unclear wordings such as “proving the triangle” (P1) in their explanations. Also, the inconsistency between what they do (or think) and how they talk about it was striking; which would probably have a negative influence on their future students’ learning of mathematics at the meta-level. Previous studies acknowledge the need for discussing notions of definition and proof in teacher education programs, along with the other meta-mathematical constructs such as assumptions and axioms, and the interrelationships among them

(Levenson, 2012). Based on the findings of our study, we want to point out to the importance of using the meta-mathematical terms “proof” and “definition” rigorously within such discussions.

## Introduction

Mathematical reasoning (MR) is recognized as one of the fundamental aspects of mathematics learning (NCTM, 2000), however, in the literature, sometimes this concept is not clearly defined. From a review of literature, Jeannotte and Kieran (2017) synthesized converging features of MR and developed a conceptual model for MR in school mathematics. According to these researchers, MR is a process of communication that allows to infer mathematical statements from other mathematical statements and that encompasses five processes regarding students' search for similarities and differences (generalising, conjecturing, identifying a pattern, comparing, and classifying) and three processes regarding students' aim for validation (justifying, proving, and formal proving). In this study, we aim to analyse 5<sup>th</sup> grade students' justifications of a conjecture on the properties of triangles, during a teaching intervention to promote students' MR.

## Theoretical framework

For the purpose of this study, we will use the term *justification* as an argument that guarantees (or disproves) the truth of an statement and uses mathematical forms of reasoning accepted as universal in the classroom community. This way of defining justification is similar to the one by Staples, Bartlo and Thanheiser (2012) but to which we add the focus on the community. Therefore justification consists in the process of searching for data and guarantees that allows the change of the epistemic value of a narrative (Jeannotte & Kieran, 2017) and it is supported by the discourse of the community. However, according to these authors, that change does not occur “necessarily from likely to true” but “from likely to more likely” (p. 12) and, as such, this process does not require a deductive structure. In order to analyze students' justifications, we use in this study a framework based on Balacheff (1988) and Harel and Sowder (1998), with five levels hierarchically organized. At level 1 – *external authority* – the justification is based on an element considered as an authority, which can be the teacher, a colleague or the textbook. At level 2 – *empiricism naïf* – we consider two categories: *perceptual naïf empiricism*, when a justification is based on perceptual observations, showing a drawing or gesturing; and *inductive naïf empiricism*, when a justification is based on the verification of some examples. At the intermediate level – *crucial experience* – a justification is grounded on a carefully selected example, revealing intentionality in the choice. At level 4 – *generic empiricism* – operations are used, based on the properties of objects, for justification, however, the student does

not identify or justify the applicability of the property used in the operation. At the most sophisticated level – *mental empiricism* – the justification is based on the properties and relations between objects.

## Methods

The study was carried out in a 5<sup>th</sup> grade class with 30 students, during a teaching intervention on geometry conducted by the first author. The focus of this poster are the students' justifications of a conjecture presented by one student (Mariana) who stated that "If two triangles have the same perimeter, they are equal", when they were working on the topic of congruence of triangles. Students were asked by the teacher to validate or refute the conjecture individually and then to discuss their ideas with whole class. The methodology of the study is qualitative with data coming from students' written productions and the collective discussion of their work. In this poster we use the 5-level justification framework referred above to analyse the justifications of four students, whose solutions were selected by the teacher to be collectively discussed in order to clarify the refutation of the conjecture and the importance of the counterexample used in this refutation.

## Results

The analysis shows that students' justifications of the conjecture are at the second and third levels according with the adopted framework. At the second level, justifications are based on perceptual or intuitive observations. These students perceive other possibilities of different lengths for the sides of the triangle from which an equal perimeter can result, without the triangles being equal, however, the counterexample they present does not take into consideration the triangular inequality. At the third level, students use carefully selected examples, such as two triangles of different lengths and with the same perimeter, that they draw rigorously using the compass and the ruler, and which they present as a counterexample to refute the conjecture. Still, there is evidence that students are producing arguments that may lead to a more general conclusion by making important connections with triangular inequality to choose the counterexample. The analysis of this classroom episode also emphasizes the importance of the teacher's role in promoting the development of MR processes. The fact that the conjecture was based on a wrong assumption was seen by the teacher as an opportunity to trigger MR validation processes and, more generally, for promoting students' MR.

*The teaching of proof by contradiction involves a didactical paradox: students' efficient use of this proving method is hard to achieve in mathematics classes, although students' argumentation using this method can occasionally be observed in extra-mathematical contexts. To address this issue, Antonini (2003) proposed a task of the non-example-related type that could lead students to produce indirect proofs. The aim of this paper is to propose a new type of tasks and situations related to counterexamples that can lead students to argument by contradiction, not by contraposition.*

*Keywords: Mathematical logic, proof by contradiction, indirect proof, counterexample.*

## Introduction

This paper reports some results of developmental research on the teaching and learning of proof by contradiction. Despite the various studies on the subject, in general, mathematical proving seems to remain difficult to learn for most students over the world, especially regarding proving by contradiction. In Japan, mathematical proof is learned in lower secondary school, while more delicate proof methods are learned in senior secondary school. Proof by contradiction, one such delicate method, can be rather difficult to learn, as reported by several authors (Antonini & Mariotti, 2008; Reid, 1998). In particular, from the didactical and cognitive perspective, it involves curious conflicting aspects. On one hand, it would be far from a desirable understanding of the subject just to learn the fact that proof by contradiction is a correct method and the manner to build such proofs, since students could not be convinced of the conclusions in such proofs unless they understood why this method works. On the other hand, it has been observed that students sometimes spontaneously use the method of proof by contradiction as argumentation in extra-mathematical contexts, even before they develop any notions regarding this method (e.g. Freudenthal, 1973, p. 629).

To manage this paradoxical issue, Antonini (2003) proposed tasks and situations that can help students to generate the idea of indirect argumentations and proof (i.e. tasks involving *non-examples*, which shall be addressed in the second section). This proposal is based on the notion of *cognitive unity*, which emphasizes the similarity between processes of argumentation and proof construction (Garuti, Boero, & Lemut, 1998). The developmental principle of cognitive unity claims the importance of preceding argumentations to produce the conjecture, before the stage of proof construction. In summary, Antonini (2003) conducted a task design for the teaching of indirect proof using of the principle of cognitive unity. Our study follows this same line.

First, we clarify the notion of proof by contradiction especially confirming how it differs from proof by contraposition. Then, we review the preceding result of Antonini (2003) and identify its focus on proving by contraposition rather than by contradiction. Therefore, the main objective of this paper is to propose new tasks and situations that can lead students to argumentation using the idea of proof by

contradiction, beyond proofs by contraposition. We present the task designed for this study and investigate some results of a teaching experiment with this task.

## Preliminary analysis for the design of a new task with proving by contradiction

### The authors' position on proof by contradiction

This section confirms the definition of proof by contradiction and summarizes its relation to indirect proof. As Chamberlain & Vidakovic (2017) point out, some studies do not distinguish proof by contradiction from that by contraposition. While Lin, Lee, & Wu Yu (2003) attribute proof by contradiction to the law of contraposition, Antonini & Maritotti (2008) refer to such proof methods as 'indirect proving', which may also include the method of proof by contraposition. Logically speaking, the method by contradiction to indirectly prove the statement ' $P \rightarrow Q$ ' is to directly prove the statement ' $P \wedge \neg Q \rightarrow \perp$ '.<sup>1</sup> This method is based on the law of excluded middle, which claims that ' $Q \vee \neg Q$ ' is true. In addition, the method by contraposition to indirectly prove ' $P \rightarrow Q$ ' is to directly prove ' $\neg Q \rightarrow \neg P$ '. This method is based on the principle that ' $P \rightarrow Q$ ' and ' $\neg Q \rightarrow \neg P$ ' are equivalent. Here, we observe that  $(P \rightarrow Q) \rightarrow (\neg Q \rightarrow \neg P)$  is true, even in the intuitionistic logic, although  $(\neg Q \rightarrow \neg P) \rightarrow (P \rightarrow Q)$  requires the law of excluded middle. Moreover, it is known that the law of excluded middle can be verified conversely using this contraposition rule with the intuitionistic logic. Thus, from the *logical* perspective, we can consider these proving methods interchangeable, in the sense that adding either the law of excluded middle or the contraposition principle to the intuitionistic logic results in the same classical logic.

In fact, we can show proof diagrams in which the two proving methods, support each other (Figure 1).

$$\begin{array}{c}
 \frac{\neg Q \rightarrow \neg P}{(P \wedge \neg Q) \rightarrow (P \wedge \neg P)} \\
 \frac{(P \wedge \neg Q) \rightarrow \perp}{P \rightarrow Q}
 \end{array}
 \qquad
 \begin{array}{c}
 \frac{\neg Q \wedge (\neg Q \rightarrow \perp) \rightarrow \perp}{\neg Q \rightarrow ((\neg Q \rightarrow \perp) \rightarrow \perp)} \\
 \frac{\neg Q \rightarrow \neg \neg Q}{\neg Q \rightarrow \neg P} \\
 \frac{\neg Q \rightarrow \neg P}{P \rightarrow Q}
 \end{array}
 \qquad
 \begin{array}{c}
 \frac{P \wedge \neg Q \rightarrow \perp}{P \rightarrow (\neg Q \rightarrow \perp)} \\
 \frac{P \rightarrow (\neg Q \rightarrow \perp)}{P \rightarrow \neg \neg Q} \\
 \frac{P \rightarrow \neg \neg Q}{\neg \neg \neg Q \rightarrow \neg P}
 \end{array}$$

Figure 1: Two proving methods mutually supported

However, from the *cognitive* or *epistemological* perspective, we can point out certain differences. How should the argumentation by contraposition against the statement ' $P \rightarrow Q$ ' begin? It would be natural to begin the generation of argumentation by contraposition with the question 'what if  $Q$  is not true?', while it is desirable to begin argumentation by contradiction with the question 'is there any situation where " $P$ " and "not  $Q$ " is possible?'. In addition, the middle processes of both types of argumentations have differences. In the case of contraposition, the argumentation starting from the assumption 'not  $Q$ ' would not result in any contradiction but in the conclusion 'not  $P$ '. Thus, the instances in this argumentation are possible and real under this assumption 'not  $Q$ '. On the other hand, the argumentation starting from the assumption 'if " $P$ " and also "not  $Q$ " are possible' would lead to a contradiction. Therefore, the argumentation in the middle process deals with impossible cases. Moreover, we can see differences in the goal of the argumentations. In the case of contraposition, the conclusion to be reached can be specified as 'not  $P$ ' from the beginning, while, in the case of contradiction, the conclusion can be any type of contradiction. Therefore, the goal of this type of

<sup>1</sup> The symbol  $\perp$  means the contradiction, which is unconditionally false.

argumentation is not specified in the beginning and proof by contradiction seems to be more difficult than that by contraposition.

Despite these differences, both proving methods tend to be integrated as indirect proofs. We believe this to stem from a didactical reason, instead of a reason based on compatibility in logic. The principle of contraposition in the school mathematical context is not an axiom, but a meta-theorem that can be verified somehow. In fact, faced the question of why ' $P \rightarrow Q$ ' can be implied from ' $\text{not } Q \rightarrow \text{not } P$ ', they can possibly use the method by contradiction: 'if  $Q$  is not true under  $P \dots$ '. Thus, it is didactically natural to verify the method of proof by contraposition based on contradiction, although the inverse is verifiable by logic. Therefore, from the didactic and cognitive perspectives, we consider that proof by contradiction is more fundamental and supports the method of proof by contraposition, which can be acknowledged as an application of proof by contradiction.

### **From investigation of non-example to non-existence of counterexample**

As mentioned in the first section, Antonini (2003) proposed tasks involving non-examples against almost the same research question. Given a property  $A$ , non-example is an instance that negates  $A$ , while an ordinary example is one that verifies  $A$ . Antonini (2003) argues that, faced with a question such as 'given a hypothesis  $A$ , what can you deduce?', students tend to generate examples and (or) non-examples and, through the observation of non-examples that verifies  $B$  but does not satisfy  $A$ , students can assume that 'if  $B$  is true,  $A$  is not true'. From this argumentation, students may be led to obtain 'if  $A$  is true,  $B$  cannot be true', which is an indirect argumentation. Although such tasks and processes are reasonable enough, we would like to indicate room for further improvements: the argumentations that would be observed in these processes are proofs by contraposition, not by contradiction. Such argumentations certainly include ways of thinking such as ' $\dots$  if it were not so, it would happen that...'. However, because this argumentation starts from the observation of a non-example (not satisfying  $A$ ), such thinking necessarily has the form 'if  $B$  is true,  $A$  cannot be true', which certainly corresponds to an argumentation by contraposition.

In contrast, our hypothesis is that the *principle of non-existence of counterexample* yields argumentation by contradiction. Generally speaking, the intension to *disprove* some statement may lead to the pursuit of its counterexample. However, it is difficult to prompt disproving activities in mathematics classes, which are usually filled by the requirement for *proof*. In the following subsection, we discuss a favourable condition involving counterexample towards argumentation by contradiction.

### **Judgement of truth and proof by contradiction**

In the former part of this section, we defined the method of proof by contradiction. However, it is written in propositional logic, while there are many propositions of predicative logic that will be addressed in mathematics in upper secondary school or higher. In fact, in Japan, many common propositions to be proved in mathematics are universal propositions. Let  $S$  be a proposition such as 'for any  $x$ , if  $P(x)$  is true,  $Q(x)$  is true', and consider a task such as 'is this proposition  $S$  true?', that is, the judgement of the proposition  $S$ . Facing this type of task, what types of argumentations occur naturally? As a form of naïve argumentation, one may try to verify  $S$  in an empirical way: each instance  $x$  verifying  $P(x)$  is examined to verify whether it satisfies  $Q(x)$  or not. Then, the more

instances one checks, the more plausible  $S$  would be. In addition, this operative work might prompt students to understand what the negation of the statement  $S$  is. If the above examination of each instance  $x$  fails even once, in other words, if one finds an instance  $x$  satisfying  $P(x)$  but not  $Q(x)$ ,  $S$  turns out to be false. In class, the task of proving  $S$  makes it unquestionable, because such a task *implicitly* means that  $S$  is true. However, against the task of judgement, one may suspect its negation quite naturally. Moreover, in this type of task, which will be proposed in the following section, this suspicion is important and can lead students to the idea of proof by contradiction, as this suspicion is the initial point of the proving method by contradiction: if one doubts the truth of  $S$ , he or she can start argumentation from the assumption of the counterexample's existence, that is, an instance  $x$  satisfying  $P(x)$  but not  $Q(x)$ . If this argumentation comes to a contradiction, the non-existence of a counterexample can be deduced; furthermore, it claims the truth of  $S$ , which is an argumentation by contradiction.

Regarding the proving by contradiction, Antonini & Mariotti (2010) point out two difficulties: the treatment of impossible mathematical objects and the link between the contradiction and the statement to be proved. In fact, when proving by contradiction, one should think of impossible and absurd cases and deduce a contradiction. One may not make sense of a contradiction from an absurd assumption that looks trivial and from which nothing is likely to be deduced. This is similar to the low assessment by students of proof of a *trivial* theorem, such as 'the base angles of an isosceles triangle are equal'. Likewise, in proof by contradiction, if the provisional assumption is apparently absurd, the deduced contradiction would make no persuasive argument. Thus, to promote students' argumentation by contradiction, it is important that the provisional situation, where the hypothesis is true but the conclusion is false, is unknown to be possible or impossible, and its possibility should be the focus of the discussion. This is exactly the case in the proposed tasks of judgement.

### Proposal of the task and situations

First, it is necessary to recall the characterisations of a parallelogram (i.e. sufficient conditions for a quadrilateral to be a parallelogram). Although Japanese lower secondary schools do not use the word 'sufficient', they adopt the following five conditions in classes as 'conditions for a parallelogram':

- Two pairs of opposite sides are parallel. (Definition)
- Two pairs of opposite sides are equal in length.
- Two pairs of opposite angles are equal in measure.
- One pair of opposite sides are parallel and equal in length.
- The diagonals bisect each other.

Figure 2: Parallelogram with Labels

Each of these five conditions consists of two conditions out of the following:

- |                                        |                                                 |
|----------------------------------------|-------------------------------------------------|
| – a pair of opposite sides is parallel | – a pair of opposite sides is equal in length   |
| – a diagonal bisects the other         | – a pair of opposite angles is equal in measure |

Apart from the previous five sufficient conditions, various combinations of two out of the conditions specified above are possible. In particular, we adopt the following combination and the task in

connection with it: for a quadrilateral  $ABCD$  with its diagonals crossing at  $M$ , does the condition of  $\angle A = \angle C$  and  $BM = MD$  make this quadrilateral a parallelogram? (See Figure 2.)

Since this condition is actually a necessary condition to make the quadrilateral a parallelogram, the figure of a parallelogram may give an impression that this condition is also sufficient. Thus, one may try to prove its sufficiency directly. In such an attempt to prove it, it would be natural to focus on a congruence of triangles, namely  $\triangle AMB$  and  $\triangle CMD$ . Verifiable facts concerning these triangles from the given condition are  $BM = DM$  and  $\angle AMB = \angle CMD$ . If one could claim that  $AM = MC$ , it is easy to conclude that this quadrilateral is a parallelogram using the congruence of triangles, although no more properties concerning  $\triangle AMB$  and  $\triangle CMD$  can be obtained directly from the assumption.

If this was against the task of proving a statement suggested by a teacher, which would be considered correct previously, then this proving attempt would end here and no further argumentation would hardly continue. However, in the task of judgement, one can proceed this argumentation as such a stagnation of verifying argumentation implies the possibility of a counterexample. A student can suspect the congruence of  $\triangle AMB$  and  $\triangle CMD$ . In particular, if  $AM = MC$  is true, they are congruent and the quadrilateral  $ABCD$  turns out to be a parallelogram. Thus, one can imagine an instance satisfying  $\angle A = \angle C$  and  $BM = MD$ , but  $AM \neq MC$ , or  $AM < MC$ . If one tries to draw a figure of an instance satisfying  $BM = MD$ ,  $AM < MC$  and also  $\angle A = \angle C$ , the impossibility of such an instance comes apparent. This might be seen by intuition (See Figure 3) and can also be verified as follows: if one take  $C'$  on  $MC$  with  $AM = MC'$ , we can see  $\angle A = \angle BC'D > \angle C$  and obtain contradiction. This is proof by contradiction.

Figure 1: Impossibility of a counterexample

## Teaching experiment

In this section, we report a teaching experiment in a typical upper secondary school in Japan. This experiment was mainly designed to investigate the learning about wide logical concepts through inquiries, not limited to the idea of proof by contradiction. The 40 students in our study are first years at a typical upper secondary school in Japan (15-16 years old) and, in general, students in this school are not highly competent in mathematics. The students were about to study logical notions in the small unit of 'sets' and had never studied proof by contradiction, not even the concepts of counterexample, sufficient condition, or necessary condition. They were divided into 12 groups of three or four students each. A main element of this experiment is the inquiry against the following task (Figure 4) given to the groups (cf. Hamanaka & Otaki, to appear).

There is a quadrilateral  $ABCD$  with its diagonals crossing at  $M$ . Find combinations of two out of the following eight conditions as many as you can, each of which makes this quadrilateral  $ABCD$  a parallelogram: (a)  $AB = CD$ , (b)  $AD = BC$ , (c)  $\angle A = \angle C$ , (d)  $\angle B = \angle D$ , (e)  $AM = MC$ , (f)  $BM = MD$ , (g)  $AB \parallel DC$ , (h)  $AD \parallel BC$ .

Figure 2: Task given in the teaching experiment

Among the 28 possible combinations of conditions, 16 are sufficient to make a quadrilateral a parallelogram, while 12 are not. Among the sufficient combinations,  $\{(c), (f)\}$  and  $\{(d), (e)\}$  are relatively difficult to be justified, and their proofs could involve proof by contradiction. The teaching experiment was carried through two teaching terms. While the first term was dedicated to students to do their own inquiries around the task, the second term was devoted to their reflection.

In fact, because of its difficulty, we did not expect the generation of the idea of proof by contradiction at the beginning. However, we could observe the generation of argumentation using that method in their inquiries as we report below. The following is a part of the conversation during the inquiries by a group of three students (A, B, and C) in the first term, which was mainly recorded by a voice recorder and partly by a video recorder. We were not able to identify their voices clearly and the speaker of the speech below was partly unspecified (Indicated as Student X). They were considering the case where  $\angle A = \angle C$  and  $BM = MD$ .

Student X: As these lengths [BM and MD] are specified from the beginning and if we set that these angles [ $\angle A$  and  $\angle C$ ] are the same, I think it must be a parallelogram, right?

Student A: If we change these lengths [AM and MC], these angles [ $\angle A$  and  $\angle C$ ] must also change...

Student A: So, if we change these lengths [AM and MC] and also fix these angles [ $\angle A$  and  $\angle C$ ], these edges cannot meet.

Student A: Wait, yes. If the angles [ $\angle A$  and  $\angle C$ ] are specified and the lengths [AM and MC] are different, it cannot be. Under these conditions [ $\angle A = \angle C$  and  $BM = MD$ ], it is impossible.

Student B: Well, why is it impossible? (A short silence follows.)

Student A: Well, listen. If we change the lengths [AM and MC], they [the edges CD and AD] cannot meet, can they? Let's see, if we keep these angles [ $\angle A$  and  $\angle C$ ] having the same measure, and also if we make this part [MC] longer...

Student C: Oh, they [CD and AD] will not meet... it [CD] cannot reach [D].

The final worksheet did not retain the figures used at the time of the above argumentation. It is assumed that Figure 4 illustrates the situation described by Student A. At that time, she was looking for a counterexample, that is, an instance that satisfies the given condition but is not a parallelogram. This idea led her to the argumentation 'if MC is longer than AM'. Their argumentation continued as follows:

Student B: Then, let's draw the figure (of the considered situation).

Student A: No way. We cannot draw it because it is impossible.

Student B: Oh, right. I see.

Student C: Oh, we cannot draw it...

These protocols clearly show that their argumentation involves contradiction: a situation that can be considered but cannot be possible. Then, she organized her idea, draw a new figure (see Figure 6), and spoke as follows:

Student A: The answer is yes [sufficient] for this case. Because ... Let us use this line [set AC on this line], [under the assumption  $BM=MD$ ] then look at these lengths [AM and MC]. If these lengths are different and if one is even one block longer, then these angles [ $\angle A$  and  $\angle C$ ] cannot be the same in measure. Thus, if we assume that these angles [ $\angle A$  and  $\angle C$ ] are same, these lengths [AM and MC] are *definitely* the same, too!

This shows how confident Student A finally was at the correctness of her argumentation and illustrates the possibility of generating the idea of proof by contradiction through this type of argumentation that judges the truth of a universal proposition.

**Figure 4: The final diagram  
in their work sheet**

## Discussion and conclusion

Although we admit the weakness of our empirical evidence as our teaching experiment was not limited to proof by contradiction, we could observe small but specific data of successful argumentation in the teaching experiment. We would like to discuss how this proposed task relates to the generation of such argumentation. Moreover, this research is highly inspired by the research by Antonini (2003), which also describes that the non-example argumentation is not the only process for the generation of indirect proving. There is also a request for further research that develop other processes and related tasks. Since this paper is one of possible responses to such request, we also compare and discuss the differences between the argumentations by contradiction observed above and the indirect argumentations involving non-examples proposed by Antonini (2003).

As mentioned by Antonini (2003), in the students' argumentations, non-examples may work as generic examples; their observation, which indicates 'if  $B$  is true, it cannot be an example', can be generalized or expanded to the universal proposition of 'for any case, if  $A$  is true,  $B$  cannot be true'. This generalization is possible because the instances in consideration are real. On the other hand, although the proposed argumentation in this paper is also related to a universal proposition, nothing in the argumentation works as a generic example. The principle of this argumentation is the assertion of the non-existence of counterexamples, and it does not involve the effects of generalization or expansion. In fact, they deal with an impossible instance which can hardly be generalized or expanded. Thus, these two types of argumentations are entirely different. This difference comes from the fact that the proposed argumentation is directly based on proof by contradiction, not by contraposition.

In addition, the proposed argumentation essentially requires predicate logic: it is necessary to consider the negation of the predicate statement 'for any  $x$ ,  $P(x)$  implies  $Q(x)$ ', that is, 'for some  $x$ ,  $P(x)$  and

not  $Q(x)$  are true', while, in the non-example argumentation, the phrase 'for any  $x$ ' is hidden or always prepositional. Although it seems rather complex at first glance, such an argumentation is supported by the features of the related task: first, this is not a proving task but a judgement task; second, this task may prompt the empirical verification activity that can stimulate the understanding of the negation of a universal proposition. This fact seems to be a reason of the didactic paradox of proof by contradiction mentioned in the introduction: between spontaneous proving by contradiction in extra-mathematical situations and the difficulty of understanding it in school mathematical situations. In the classroom, both the judgement task (or disproving task) and the empirical verification usually live in a narrower space than the proving task with theoretical ways.

# Student teachers' argumentation in primary school mathematics classrooms

Helene Hauge

Western Norway University of Applied Sciences, Norway; [helene.hauge@hvl.no](mailto:helene.hauge@hvl.no)

*Keywords: Argumentation, student teacher, primary school.*

## Argumentation in mathematics education

In recent years, there has been increased interest in the nature and role of argumentation in mathematics education. Engaging in argumentation can lead to a deeper understanding of mathematics. In the context of mathematics education, argumentation can be defined as:

a term which is generally used to describe the discourse or rhetorical means (not necessarily mathematical) used by an individual or a group to convince others that a statement is true or false. (Stylianides, Bieda, & Morselli, 2016, p. 316)

The teacher plays a key role in establishing mathematical quality of the classroom environment (Yackel & Cobb, 1996). The teachers are representing the mathematical community in the classroom, and their personal mathematical beliefs, values, mathematical knowledge and understanding are important. Research on teachers' knowledge about mathematical argumentation has focused on identifying problems and challenges (for example teachers' lack of mathematical knowledge) rather than finding solutions to these problems (Stylianides et al., 2016).

The Norwegian curriculum is currently under review and in the latest draft reasoning and argumentation is one of six core areas in mathematics (Utdanningsdirektoratet, 2018).

The aim of my PhD research is to investigate preservice primary school teachers' views on, and use of, argumentation in mathematics education. I have three research questions:

1. How do preservice primary teachers argue when evaluating mathematical arguments?
2. How do preservice primary school teachers argue when teaching mathematics in primary school?
3. How do preservice primary school teachers engage primary school students in argumentation when teaching mathematics?

## Method

My study focuses on students enrolled in the Norwegian teacher education for Grades 1 – 7, age 6-12. It is a five-year program with an integrated master's degree. After graduation, these students will be qualified to teach mathematics, Norwegian and one subject of their own choice. The education comprises 30 mandatory credits in mathematics, which equals half a year of full-time study. The mandatory mathematics courses are taught in the second and third semester of the education. Later, the students can choose to do 30 more credits of mathematics, and to do their master's thesis in mathematics education. I will collect data when the students are in their third and fourth semester of their education, i.e. I will follow them in their last semester of mandatory mathematics course and following semester.

The research has a qualitative approach. I will do video observation of student teachers when teaching mathematics during practice training and audio-recorded interviews with both student teachers and their practice training supervisor. The students will be interviewed in their practice training groups. The interview will focus on their mathematical argumentation, and on their argumentation when teaching mathematics. I will give the students a statement and several ways of defending this statement. Through a discussion about what is the best way of convincing others that the statement is true, I will get the data to answer research question 1. I will also interview the students about situations from their practice teaching using video clips. Together with the observations, these data will be valuable when answering research question 2 and 3.

The interviews with the practice training supervisors will aim at finding out what development the supervisor observes, encourages and disapproves with the student teachers. This will give me information about the background for the students' choices, to what extent they are students' own independent choices or a result of the supervisors' guidance.

The recordings will be transcribed and analysed. I will identify the discourse by which the student teachers construct mathematical arguments for themselves and for school students; and what discursive space, including gestures and use of artifacts, they provide for their school students engagement with mathematical argumentation. Processes of argumentation will be analysed with methods that are based on Toulmin's theory of argumentation (Toulmin, 1958), as described by Krummheuer (2015).

## Research result and implications

The research will contribute to a deeper understanding of student teachers' ability to teach argumentation in primary school classrooms. This can form the basis of future research on how to support student teachers to teach argumentation in primary school classrooms.

The poster will present the design of the study and some preliminary results. I find this poster particularly relevant for the Theme Working Group 1 (Argumentation and Proof).

# The interplay of logical relations and their linguistic forms in proofs written in natural language

Kerstin Hein

TU Dortmund University, Germany; kerstin.hein@math.tu-dortmund.de

*The Toulmin model and the systemic functional grammar are combined to analyse logical relations and their linguistic forms in students' written proofs for identifying obstacles and possibilities to foster the understanding of proofs. The qualitative analysis of 63 students' products reveals a parallelism between syntactical and content-related explications and condensations. In particular, the use of conjunctions seems to support more options 1.) to make explicit logical relations between premise and warrant or conclusion, 2.) to combine several steps of a proof, and 3.) to recycle conclusions as new premises. The logical relation from the warrant to the conclusion is often only made explicit using causal prepositions as linguistic condensed forms of relations.*

*Keywords: Formal proof, logical relations, Toulmin model, linguistic analysis*

## Introduction

There is still a lack of knowledge about the concrete language demands for specific topics, although the importance of identifying academic language and the epistemic role of language has been explored (e.g. Schleppegrell, 2004). For these reasons, a linguistic analysis of the classroom discourse to support teaching-learning processes should be pursued for several subjects and topics, in particular mathematics (Schleppegrell, 2007). Especially, for the challenging topic of proof and proofing an analysis of students reasoning is important (e.g. Mariotti, Durand-Guerrier, & Stylianides, 2018, p. 80), in particular, the analysis of logical rules and their linguistic forms, which cannot be translated from formal language directly (Durand-Guerrier, 2004, p. 2). Within the logical structures, the “implicit logical relationships” (Schleppegrell, 2007, p. 141) in their linguistic forms are one of the major challenges in proof. Because of the high density of academic language, it is demanding for the students to be aware of and to understand the academic language. Therefore, it is important to unpack the meanings in more explicit language (O'Halloran, 1998). The suggestion for teachers is to be explicit and to hold syntactic control within their own language during teaching logic (Durand-Guerrier, Boero, Douek, Epp, & Tanguay, 2011).

As a first step, a linguistic analysis is needed for analysing the language demands of logical relations. The structural and linguistic analysis of students' products in this study follows the above mentioned, general suggestions to identify language demands in logical structures, here for logical relations. It pursues three research questions: 1) *How can logical relations and their linguistic forms be analysed?* 2) *Which pattern can be seen in the interplay between the logical relations and their linguistic forms?* 3) *Which linguistic forms of logical relations can be used to make logical relations explicit?* The first two sections present the theoretical background and methodology of the analysis. The outcome of the qualitative analysis of the written proofs is presented afterwards illustrated by case studies of two texts.

## **Theoretical background: Logical relations and their linguistic forms**

In line with Mesnil (2013), the interaction between logic and language and the importance of explicitness of the language in teaching and learning proof is assumed. This study focuses on the logical relations as one challenging part of the language of proof (Schleppegrell, 2007). For this reason, the study aims at identifying the linguistic forms of logical relations.

### **Logical elements**

For the analysis of proofs, the Toulmin model (1958) is often applied, although it was developed to describe everyday argumentations. Within mathematics education the structural analysis with the Toulmin model was also applied to analyse mathematical classrooms (Krummheuer, 1995), the structure gap between argumentation and proofs (Pedemonte, 2007), and for proofs with several steps (e.g. Knipping & Reid, 2015), even if there are limits for the analysis of proofs and proofing (also discussed in Mariotti et al., 2018, p. 78). In the structure model of Toulmin, the function of the logical elements as premise etc., not their relations, is crucial. This becomes more important when it is applied for the logical structure analysis of proof. This article refers to the short versions of Toulmin's model and considers premise, warrant and conclusion as the relevant logical elements within deductive steps. These logical elements are connected more or less implicitly by logical relations, which need to be unpacked, here.

### **Logical relations**

In this article, logical relations are understood as relations between logical elements. In deductive proofs, the relations between premise, warrant and conclusion are crucial (as described by Duval 1991, p. 235), but also within a warrant with the logical form of implication or equivalence (Selden & Selden, 1995). In particular, the logical relation from premise to warrant is crucial for the verification of the premises (Duval, 1991). These logical relations are often implicit in the language, creating an obstacle for students (Schleppegrell, 2007) as they have to be unpacked in order to understand them (Selden & Selden, 1995).

### **Different linguistic forms**

Logical relations are often expressed in natural language by logical connectives such as “because”, “due to” or “if..., then...” (Clarkson, 2004). These logical connectives can be classified as causal-conditional principal markers by the systemic functional grammar of Halliday (1985), describing language from a functional perspective. They have different linguistic forms such as causal conjunctions (“because”), conditional conjunctions (“if... then...”) or causal prepositions (“due to”). However, there is still a research lack of the analysis of the combination of logical relations and their linguistic forms (e.g. Durand-Guerrier et al., 2011; Schleppegrell, 2007).

## **Methodology for the analysis of written proofs**

### **Data collection**

The students' texts of written proofs have been generated within a teaching-learning arrangement on deductive reasoning in grade 8-12 all with angle sets (Hein & Prediger, 2017; Prediger & Hein, 2017). In the teaching-learning arrangement conjunctions were used to express logical relations. The students were also asked to reason why a theorem can be applied (premises are met). In this paper,

the learning process and the effects of the teaching-learning arrangement are not analysed. Instead, it focuses only on the written products of the teaching-learning arrangement in order to investigate the interplay between logical relations and their linguistic forms. The data corpus consists of 63 written texts from 48 students (20 in grade 8, 6 in grade 9, 4 in grade 10, 18 in grade 12). The result section presents the results of two cases with texts of the twelfth graders Linus and Petra.

### Methods for qualitative data analysis

The qualitative analysis of logical relations and their linguistic forms in the written products combines two analysis models: (1) *Toulmin model*: The Toulmin model in its short version (1958) is applied for the logical structure analysis to identify the addressed logical elements (premise, warrant, conclusion) (Pedemonte, 2007) and to disentangle the several steps of the proof (Knipping & Reid, 2015). (2) *Systemic functional grammar*: The linguistic analysis of the logical connectors as language means for logical relations draws upon systemic functional grammar (Halliday, 1985), which can also be used to identify linguistic challenges in mathematics education (Schleppegrell, 2007). The analysis approach systematically identifies lexis used for logically connecting sentences or elements within sentences and classifies their syntactical forms as conjunction (con) respectively prepositions (pre). For these, the English functional grammar (in which the products are presented here) and the German functional grammar (the original language of the products) resonate with each other. For example, causal conjunctions can be described in English and German with conjunctions and prepositions and function in a similar way. Here, first the existence of a logical relation as links between logical elements and then their grammatical form (conjunctions such as “therefore” or preposition such as “according to”) are identified.

Figure 1: Analysis tool with Toulmin for several steps and both linguistic forms for logical relations

### Empirical insights into the cases of Petra's and Linus' written proofs

Petra's and Linus' texts were chosen for illustrating the results because their texts contain typical linguistic forms for the logical relations – condensed and non-condensed – which were also found in many other written proofs about angle sets. The students work on the proof for the sum of angles in a triangle (Figure 2). Before starting to write individually, they discuss the proof, identify which theorems have to be applied and draw the sketch printed in Figure 3 to which both texts refer.

Figure 2: Mathematical statement to be proven by Petra and Linus

Figure 3: Students' joint sketch

Analysis of activated mathematical statements: Both students refer to the same mathematical statements, the alternate interior theorem (Step 1 and 2), supplementary angle theorem (Step 3), calculating with angles theorem (Step 4), but both texts show substantial differences with respect to making the logical relations and their linguistic forms explicit. Presentation of the structural and linguistic analysis: The logical elements are illustrated with colours (green: premises (P); blue: warrant (W), orange: conclusion (C)), both in the text and the graphical representations. Only partly explicated logical elements are illustrated with \* in the text and with dashed boxes in the graphics. The logical relations (R) (conjunctions (con), prepositions (pre)) are illustrated in black and by arrows in the graphical presentations (continuous arrow for conjunctions, dashed arrow for prepositions).

### Linus' text with causal prepositions for the logical relations

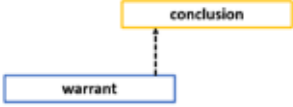

Step	Translated (and original) text	Structural and linguistic analysis
1+2	<p>The triangle ABC has the angles <math>\alpha := \angle CAB</math>; <math>\beta := \angle ABC</math>, <math>\gamma := \angle BCA</math>.  Additionally, a line passes through point B.  Additionally, the angle <math>\pi</math> is located at line k and at <math>\overline{AB}</math> and <math>\delta</math> is located at line k and the side <math>\overline{BC}</math>. (p*: Parallelism of k to BC is missing.)  According to (R/pre) the alternate interior angle theorem (W), the angles <math>\alpha</math> and <math>\pi</math> have the same measure and <math>\delta</math> and <math>\gamma</math> have the same measure. (C)</p> <p>(German Original: Das Dreieck ABC hat die Winkel <math>\alpha := \angle CAB</math>, <math>\beta := \angle ABC</math>, <math>\gamma := \angle BCA</math>. Zusätzlich geht durch den Punkt B eine Gerade. Zusätzlich liegt der Winkel <math>\pi</math> an der Geraden k und an <math>\overline{AB}</math> und <math>\delta</math> liegt an der Geraden k und an der Seite <math>\overline{BC}</math>. Gemäß des Wechselwinkelarguments sind die Winkel <math>\alpha</math> und <math>\pi</math> gleich groß und <math>\delta</math> und <math>\gamma</math> gleich groß.)</p>	 <p>The detailed explicated premises (without parallelism) are not verbally connected with the warrant.</p> <p>With "According to" the warrant (alternate interior angle theorem) is connected with the conclusion.</p> <p>"According to" is a preposition within one sentence.</p>
3	<p>According to (R/pre) the supplementary angle theorem (W), the angles <math>\beta</math>, <math>\pi</math> and <math>\delta</math> sum to 180 degree (C).</p> <p>(German Original: Gemäß des Nebenwinkelarguments sind die Winkel <math>\beta</math>, <math>\pi</math> und <math>\delta</math> zusammen gleich 180 Grad groß.)</p>	 <p>"According to": analysis analogue to Step 1+2</p>
4	<p><math>\pi</math> can be substituted by <math>\alpha</math> and <math>\delta</math> can be substituted by <math>\gamma</math> (P*: Conclusion of step 3 as new premises is missing.).  According to (R/pre) the calculating argument (W), the interior angles <math>\alpha</math>, <math>\beta</math> and <math>\gamma</math> have a measure of 180 degree (C).</p> <p>(German Original: Für <math>\pi</math> kann <math>\alpha</math> eingesetzt werden und für <math>\delta</math> <math>\gamma</math> eingesetzt werden. Gemäß des Rechenarguments sind die Innenwinkel <math>\alpha</math>, <math>\beta</math> und <math>\gamma</math> gleich 180 Grad groß.)</p>	 <p>Linguistically, it is not marked as previous conclusion of Step 1+2 (implicit recycling). Conclusion from Step 3 is not explicitly used.</p> <p>"According to" connects the theorem with the conclusion with a preposition.</p>

Table 1: Analysis of Linus' text

In Linus' first sentences, the premises for the Steps 1, 2 and 3 are almost explicated. In further sentences, the warrants and the conclusions for Step 1, 2, 3 and 4 are explicated. The

Figure 4: Summary of the analysis of Linus' text

recycling of the conclusions from Step 1, 2 and 3 to new premises in Step 4 is not made explicit. However, logical relations between these elements are only explicated from the warrant to the conclusions, whereas the logical relations from the premises to the warrants or to the conclusions are not explicated. In each occurrence of logical connectives, Linus activates prepositions such as “according to”.

### Petra's text with more causal conjunctions for the logical relations

Step	Translated (and original) text	Structural and linguistic analysis
1	<p>A triangle with <math>\alpha</math>, <math>\beta</math> and <math>\gamma</math> is given. The line <math>k</math> is parallel to line <math>k</math> and crosses point B. To identify the measures of the angles <math>\alpha</math> and <math>\gamma</math> (crossed out), at the point B to the angle <math>\beta</math> the angles <math>\pi</math> and <math>\delta</math> are defined (P). Because (R/con) the line <math>k</math> and the side AC are parallel and are crossed by the side AB (P), the angle theorem (W) can be applied. Therefore, (R/con) <math>\alpha = \pi</math> (C).</p> <p>(German Original: Es ist ein Dreieck mit <math>\alpha</math>, <math>\beta</math> und <math>\gamma</math> gegeben. Die Gerade <math>k</math> ist parallel zu der Geraden <math>k</math> und schneidet den Punkt B. Um die Größe der Winkel <math>\alpha</math> und <math>\gamma</math> (durchgestrichen) zu erfahren, definiert man an dem Punkt B zu dem Winkel <math>\beta</math> die Winkel <math>\pi</math> und <math>\delta</math>. Da die Gerade <math>k</math> und die Seite AC parallel sind und durch die Seite AB geschnitten wird, kann man das Winkelargument anwenden. Daraus folgt, dass <math>\alpha = \pi</math>.)</p>	 <p>„Because... can be applied“ connects the premise with the theorem. “Because” is a causal conjunction (within one sentence).</p> <p>“Therefore” connect the warrant (here angle theorem) with the conclusion.</p> <p>“Therefore” is a causal conjunction and connects two sentences.</p>
2	<p>Additionally, the side BC crosses the parallel line <math>k</math> to the side AC (P), therefore (R/con) <math>\gamma = \delta</math> (C) reasoned by (R/prop) the alternate interior angles theorem (W).</p> <p>(German Original: Außerdem schneidet die Seite BC die parallele Gerade <math>k</math> zu der Seite AC, deshalb ist <math>\gamma = \delta</math> begründet durch das Wechselwinkelargument.)</p>	 <p>With „therefore“ (causal conjunction), the conclusion is drawn. “Reasoned by” is used at the end of the sentence to add the logical relation from the warrant to the conclusion.</p>
3	<p>By the fact that (R/prop) <math>\Omega</math> and <math>\delta</math> are supplementary angles (<math>\Omega = \beta + \pi</math>) (P), <math>\beta</math>, <math>\pi</math> and <math>\delta = 180^\circ</math> (C), according to (R/prop) the supplementary angle argument (W).</p> <p>(German Original: Dadurch dass <math>\Omega</math> und <math>\delta</math> Nebenwinkel sind <math>\Omega = \beta + \pi</math>, sind <math>\beta</math>, <math>\pi</math> und <math>\delta = 180^\circ</math>, laut dem Nebenwinkelargument.)</p>	 <p>With „By the fact that...“, the conclusion from the premise is drawn. “By” is a preposition. The premises are condensed to an object with “as a fact” which is explained in a sub-clause. “According to” (preposition) is used at the end of the sentences to add the logical relation from the warrant to the conclusion.</p>
4	<p>So, if (R/ con) <math>\beta + \pi + \delta = 180</math> degree and <math>\alpha = \pi</math> and <math>\gamma = \delta</math> (P), then (R/ con), according to (R/ prop) the calculating argument (W), <math>\beta + \gamma + \alpha = 180</math> degree (C).</p> <p>(German Original: Wenn also <math>\beta + \pi + \delta = 180</math> Grad und <math>\alpha = \pi</math> und <math>\gamma = \delta</math>, dann sind nach dem Rechenargument <math>\beta + \gamma + \alpha = 180</math> Grad.)</p>	 <p>With „If..., then” (conditional conjunction) the warrant is applied to the case. With “so” there is a reference to the previous conclusion, which is used as new premise (recycling). For “According to...”, see Step 3.</p>

Table 2: Analysis of Petra's text

In her text, Petra addresses the premises, the warrant with the name of the theorems and the conclusions as Linus. For making the logical relations explicit, she connects the premises with the warrants or the conclusions with causal conjunctions such as “because” and “therefore”. In one case, Petra

connects the premise with the conclusion by a preposition (Step 3). Petra also uses prepositions such as “due to” by adding the expression “due to the ...-argument” as last part of the sentences after connecting the premise to the conclusion (Step 3 and 4).

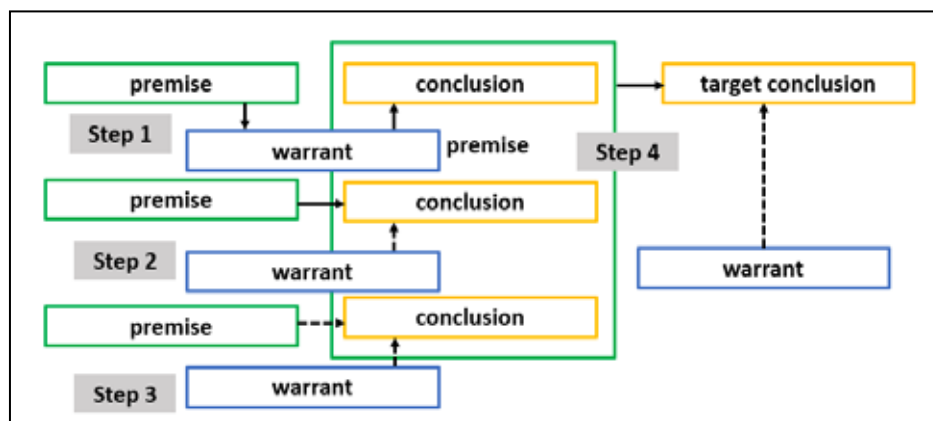

Figure 5: Summary of the analysis of Petra's text

### Comparison of the case studies of Linus and Petra

In both texts, almost all contents of the elements of the short Toulmin Model are explicated, even Linus only mentions the premises partly at the beginning, respectively not completely in Step 4. The conclusions as new premises in Linus' example are not explicated in their function, in particular, the logical relations from the premises to the warrant or conclusion. The linguistic analysis shows that *causal conjunctions* such as “because” and “therefore” of logical relations are only used in Petra's text, where also the logical relations from the premises to the warrant respectively conclusions and the recycling of previous conclusions are expressed. These findings are in line with those of other written products (see Prediger & Hein, 2017). According to Halliday (1985) conjunctions are non-condensed forms for relations as in everyday language (called by him as *coherent*). In this case, these conjunctions were also used to make explicit the logical relations from the premises to the warrant or from the premises to the conclusion. With *causal prepositions* such as “according to”, “due to” or “by”, virtually nothing but the logical relations between the warrant and the conclusion are made explicit. This was also found in other texts (Prediger & Hein, 2017). Only in Step 3 of Petra's text, the relation from the premises to the conclusion is made explicit with a preposition (“by the fact that...”). Here, the content of the premises is expressed by a sub-clause. One reason for virtually explicating nothing but the logical relation from the warrant to the conclusion (exception: Step 3 in Petra's text) may be that prepositions need nominalizations and here only the warrant is condensed to a nominalization by its name and can be easily integrated by a preposition (“due to the ...-theorem”). By adding the phrase with the preposition (“.... according to the ...-argument.”) at the end of the sentences (such as in Step 3 and Step 4 of Petra's text), the logical relations from the premises are also made explicit in the same sentence. In all other cases, in sentences with prepositions only the logical relation from the warrant to the conclusion is expressed. Prepositions are linguistically condensed forms of logical relations (called *metaphorical* by Halliday, 1985). This kind of linguistic phenomena is one of the most important characteristics of academic language to increase lexical density. However, these condensed forms (e.g. prepositions for logical relations) are challenging for students (Martin, 1999) and have to be unpacked first into non-condensed forms

before students can understand their meaning (O'Halloran, 1998, p. 382). In the context of this case study, mainly the logical relations between warrant and conclusion are articulated by condensed forms of prepositions instead of conjunctions. The qualitative analysis shows that the prepositions provide not only challenges to understand the logical relations, they also seem to hinder the explication of logical relations, from the premises to the warrant or to the conclusion or within a theorem. Prepositions also seem to be obstacles for combining several logical elements and steps.

## Conclusion

The analysis of students' products reveals three main findings: 1) The Toulmin model has not only limits for analysing proofs in general (Mariotti et al., 2018, p. 78), but in particular, for capturing the logical relations. 2) The linguistic analysis here suggests that in non-condensed forms some aspects are more often expressed than in condensed forms. This finding can be used to be more explicit on language while teaching proof as Mesnil (2013) has recommended. 3.) For these reasons, it might be useful to first offer non-condensed linguistic forms (conjunctions), before condensed forms (prepositions) are used in the classroom. This approach resonates with Martin's (1999) observations regarding the challenging condensed forms in academic language.

Of course, this case study has significant methodological limits as only 63 texts were analysed, that were produced within the specific setting and content. It has not yet been taken into account how the setting and the content influence the students' articulations. Future research is required to overcome these limits. Furthermore, the texts are written in German and not in English, so every interpretation can only be made in the original.

## Acknowledgment

I would like to thank my supervisor Susanne Prediger for the great support and intense cooperation. The doctoral thesis on which the article is based was carried out with the financial support of the Foundation of German Business.

# Mathematical Arguments in the Context of Mathematical Giftedness – Analysis of Oral Argumentations with Toulmin

Simone Jablonski<sup>1</sup> and Matthias Ludwig<sup>1</sup>

<sup>1</sup>Goethe University Frankfurt am Main, Institute of Mathematics and Computer Science, Germany,  
[jablonski@math.uni-frankfurt.de](mailto:jablonski@math.uni-frankfurt.de); [ludwig@math.uni-frankfurt.de](mailto:ludwig@math.uni-frankfurt.de)

*Being defined as a main learning goal of mathematical education, arguments and argumentative skills are of high relevance. The development of these skills in the context of a deeper understanding is an important aspect for mathematical teaching and the support of mathematically gifted students, whose interest in mathematics should be increased. To focus more in detail on arguments in the context of mathematical giftedness, the paper poses the question whether it exists a relation between mathematical giftedness on the one hand, and mathematical argumentations on the other hand. For this purpose, the arguments of primary students from an enrichment program for mathematically gifted and interested students are gathered in an interview setting and analyzed by means of the Toulmin scheme. The results show that giftedness might influence the content and quality of arguments, but not the need for argumentations.*

*Keywords: argumentation, giftedness, Toulmin*

## Introduction

For curricular, societal and mathematical reasons, argumentative skills are claimed as central learning goals in mathematical education. Especially the view on mathematics as a deductive organized system with theorems and proofs forces fundamental skills in argumentation (e.g. Hanna, 2000). Nevertheless, former research shows that (German) students have deficits in formulating arguments in written and oral form (Cramer, 2011). It is therefore an important aim to support the development of argumentative competences, not solely, but also with regards to mathematical giftedness. The idea that gifted students perform better in the formulation of mathematical arguments seems legitimate, even though the relation is not clear (Fritzlar, 2011). In this context, the study focuses on this relation through analyzing gifted students' oral arguments.

## Theoretical Framework

### Arguments in Mathematical Education

Not only in every day's communication, but also in mathematical education, arguments are of high relevance. The aim of an argumentation is to convince the communication partner with the help of shared respected statements (Cramer, 2011). Nevertheless, real disputes in mathematical education are rare, so that argumentations are best described in the context of a problem solving process as "a type of dialogical or dialectical game [...] that is associated with collaborative meaning-making." (Baker, 2003, p. 48). In mathematical education, the process of an argumentation involves activities such as to formulate assumptions on mathematical characteristics, to reason on relations, as well as to question assumptions (Bezold, 2009). The paper defines the term 'argument' as a product which results from the processes of former described activities. With this product-oriented focus, it is possible to analyze arguments among different categories, e.g. structure and content.

According to Toulmin (1958/2003), every argument can be structured through different functional elements. Toulmin describes *Data* (D) as “facts we appeal to as a foundation for the claim” and *Conclusion* (C) as claim “whose merits we are seeking to establish” (Toulmin, 2003, p. 90). The step from D to C often requires further considerations, asking for “general, hypothetical statements, which can act as bridges, and authorize the sort of step to which our particular argument commits us” (Toulmin, 2003, p. 91). These kind of statements are called *Warrant* (W). Figure 1 presents the core of the Toulmin scheme.

**Figure 1: Core of the Toulmin Scheme (Toulmin, 1958/2003)**

Apart from a structural analysis, it is furthermore necessary to analyze arguments according to their content as the analysis by means of the Toulmin scheme does not state anything on the argument’s quality, e.g. whether a warrant is based on authority or a mathematical rule (Koleza, Metaxas & Poli, 2017). Following Toulmin’s definition, an argument is called *analytic* if W includes all relevant information for the step from D to C (Toulmin, 2003), e.g. mathematical rules or laws that are adequate in the specific context. Arguments that do not fulfil this condition are claimed as *substantial* (Toulmin, 2003). These arguments leave open or fail to answer (further critical) questions (Koleza, Metaxas, & Poli, 2017), e.g. “*My calculation is correct, because Anna has the same result*” could be rebutted by the question “*But what if both of you did a wrong calculation?*” (Fetzer, 2012).

### Mathematical Giftedness

Mathematical giftedness is a complex construct that lacks a standardized definition and diagnosis as it is not directly observable (Bardy, 2013). It is more a potential that might develop into an outstanding mathematical performance by means of an advantageous interplay of genetic and environmental factors (Käpnick, 1998). Therefore, the construct is approximated by means of lists of characteristics, including special skills such as the memorizing and transferring of mathematical structures, creativity and problem solving competences (Käpnick, 1998).

### State of the Art

A main interest of studies on argumentations in the educational context is on the analysis of arguments with help of frameworks and models in order to make characteristics observable (e.g. Nussbaum, 2011). Mostly, studies observe arguments in classroom interactions and collaborative argumentations (e.g. Forman, McCormick, & Donato, 1997). For this purpose, the Toulmin scheme, and especially its core, is often used (e.g. Koleza, Metaxas, & Poli, 2017). Further studies focus on the evaluation of argumentative skills by means of models and methods to improve them (e.g. Bezold, 2009). The studies show quite consistently that arguments in primary school have a low significance and real disputes are rare, so that the teacher has to initiate arguments and show the need for arguments

(Schwarzkopf, 2000). With regards to Toulmin, arguments by primary school children are typically characterized by the missing of a warrant and by substantial arguments (Fetzer, 2012). Koleza, Metaxas & Poli (2017) assume that primary students are able to formulate arguments which can be analyzed using the Toulmin scheme, even though basic elements are not mentioned through a lack of need for argumentation. Focusing on argumentative skills of mathematically gifted students, the relation is not explicitly clarified (Fritzlar, 2011). On the one hand, Fritzlar (2011) assumes that mainly other factors apart from giftedness influence argumentative skills and the need for argumentations. Other models see the potential of gifted students (inter alia through supportive characteristics, such as creativity) to develop outstanding argumentative skills, which can be forced through training (Bardy, 2013).

## Research Questions and Methodology

Based on this theoretical outline and former research findings, the research questions of this paper is formulated as follows: *What are the characteristics of mathematically gifted and interested primary students' arguments? In how far do they differ from general research findings on the arguments of primary students with special regards to the Toulmin scheme and the need for arguments?*

The research question is answered in a qualitative study. The sample is taken from the participants of the extra-curricular enrichment program “Young Math Eagles Frankfurt”. The aim of the program is to support mathematical interested and gifted students and to increase their mathematical interest and joy on a regular and long-term level. In the school term 2017/2018, about 50 students between 8 and 10 years from 14 schools participate in the program after nomination of their teachers.

To focus on the characteristics of the oral arguments of the participants, task-based and problem-orientated interviews are created (Goldin, 2000). This interview form is characterized by the openness of answers while focusing on a special problem. The interview material includes tasks that emphasize arguments and ask primary students to formulate warrants through irritation or the task itself (Bezold, 2009). The task formats focus on number pyramids and numerical lattices with regard to special number relations. The formats can be expected to be known by the primary students and do not ask for difficult calculations. Therefore, the task formats' focus is basically on argumentation and it can be expected that the students are able to use their findings on number relations as basis for warrants that can be analyzed by means of the Toulmin scheme. In each interview, different components of the formulation of arguments are included. In particular, the students are asked to comment on a wrong assumption e.g. through giving a counter example, to argue on different mathematical relations and to generalize their detections.

**Figure 2: Task formats number pyramid (left) and numerical lattices (right)**

One task is to answer the question how the basic stones of the number pyramid/the arrow numbers of the numerical lattices have to be arranged in order to maximize the top of the pyramid/the result of the numerical lattices (see Figure 2). Every interview is done individually and includes four tasks which are done within 15 minutes. To make the interviews comparable, they are directed with help of a guideline. The interviews are transcribed on the basis of an audio recording and an observational protocol.

The task formats, as well as the guideline were tested during the pilot phase regarding their appropriateness in terms of the students' age, needed time and mathematical content. Further, they were analyzed according to the need for argumentations. The results show that the formats are adequate in the named categories. Most students were able to identify relevant mathematical characteristics and some were even able to generalize them to some extent. In all interviews, the students formulated arguments which could be reconstructed with the Toulmin scheme. Therefore, the piloting could confirm that the tasks emphasize arguments, which shows the suitability of the tasks for the research question. Nevertheless, many arguments were initiated by the interviewer. Through these initiation processes in the interview, it is therefore possible to analyze the independence of and need for arguments.

On the basis of the results in the piloting and the theoretical framework, a scheme for the analysis of the arguments within the interviews is created. The analyzed categories within this paper are

- (1) Structure of Arguments: Within this part, it is analyzed which of the elements *Data*, *Conclusion* and *Warrant* could be observed during the focus on the specific task.
- (2) Independency of Arguments: Here the focus is led to whether a warrant is initiated by the interviewer through questions/given after mediation, or given on an independent level.
- (3) Content of Arguments: This part involves a categorization of the warrant in terms of its mathematical content (inacceptable/wrong, substantial, analytic).

The use of the Toulmin scheme as a basis for the analysis can be legitimated as the results are to be compared to former research findings on arguments in the primary age and the Toulmin layout is frequently used in these studies. Through adapting the independency and the content, its limitations apart from a structural analysis for this setting are recognized.

During May and June 2018, 32 participants (all students with parental consent form and presence during the interview dates) were interviewed. Within the interviews, 128 argumentation tasks are analyzed. Beforehand, no special training in the formulation and awareness of arguments or an education on the formulation of analytic warrants took place. Argumentation and reasoning tasks were part of some lessons, but not to a greater extent than the focus on other competences, such as problem solving. First observations within the enrichment program did not seem to show obvious differences in the need for argumentations. Nevertheless, the detection of mathematical findings, might be an important influence on the arguments of gifted children. The following results from the analysis should specify the relation of argument and giftedness on a systematic level.

## Results

Table 1 shows an example of an interview extract with a functional analysis according to the elements of the core of the Toulmin scheme. At the date of the interview, the student (S) was in ten years old. His interview bases on the task format *numerical lattices*. The sample analysis focuses on the task within the interview, in which the participant has to argue in which case the result is the highest. In advance, he does calculations with changed orders of the arrow numbers and concludes that the results change. Through initiation of the interviewer, he gives a substantial warrant for the relation of the basic elements and result. His argumentation bases on the order of the boxes of the numerical lattices and the switch of numbers comparing both tasks.

On the basis of this observation (which is coded as *Data* for the following task), he is able to identify the case in which the result is the highest, namely when the arrow with the higher number shows downwards (see Figure 2). Without initiation, he uses a substantial warrant and through initiation he supports a conclusion through an analytic warrant by transforming it to a general case.

**Table 1: Extract from the transcript (translated from German by the author)**

I: [...] In which case do you receive the highest result? You can use your former calculation.	Introduction of Task
S: When the higher number is taken plus here ( <i>shows on arrow downwards of numerical lattices</i> ).	Conclusion
Because here, there are three and here there are solely two ( <i>shows on boxes of numerical lattices</i> ). [...]	Warrant (substantial)
I: Do you think this is always the case or solely in our example?	Initiation
S: Well, I think this is in every example like this.	Conclusion
I: Can you tell me why this is the case or/?	Initiation
S: ( <i>shows on arrows of numerical lattices</i> ) Because when you calculate here the higher number plus at the arrow downwards, then there is one box more, where you can calculate plus and here on top, there is no more	Warrant (analytic)
and therefore I think, this is always like that.	Conclusion

With the former task as data, a conclusion is drawn and supported through a warrant. The task is therefore coded as *Data – Conclusion – Warrant*. For the warrant, the highest observable category before initiation is *substantial*, and after initiation *analytic*. The development of the warrant after initiation can be observed frequently, so correspondingly, two phases within each interview task are distinguished for the following analysis: Phase 1 describing the argument respectively the warrant on an independent level, and Phase 2 after an initiation of a warrant.

Table 2 shows the results from the structural analysis of all interview tasks through categorization according to the included elements on an independent level, namely without a question as initiation

of reasoning (Phase 1). Without initiation processes, only 24.2% of all analyzed tasks include a warrant on an independent level. In the majority of the tasks, a conclusion is drawn, but ungrounded. Taking those tasks that are coded within the category *Conclusion or Data – Conclusion* on an independent level and in which a warrant was initiated afterwards, in 87%, a warrant could be formulated after being initiated. By combining the independently formulated and initiated arguments, within 98 of all 128 tasks the complete core according to the Toulmin scheme (*Data – Conclusion – Warrant*) could be reconstructed. Nevertheless, within 67 of these 98 tasks, the warrant was only formulated after being initiated.

**Table 2: Structural categorization according to the Toulmin scheme on independent level**

N=128	No Conclusion	Conclusion or Data – Conclusion	Data – Conclusion – Warrant
Argument on an independent level	6 (4.7%)	91 (71.1%)	31 (24.2%)

To focus more in detail on the mathematical content of the arguments, the tasks including a warrant are categorized as *not acceptable/wrong*, *substantial* and *analytic*. Again, the highest observable category is coded, e.g. a task including a substantial and an analytic warrant before initiation is coded as analytic. In Table 3, the independently given warrants from Table 2 are categorized (N=31). In addition to the former finding that in about 75% of all tasks no warrant is coded on an independent level, one can observe that two thirds of the independently given warrants are substantial.

**Table 3: Content-related analysis of the tasks with an independently formulated warrant**

N=31	Not acceptable	Substantial	Analytic
Independent Warrants	3 (9.7%)	21 (67.7%)	7 (22.6%)

In Table 4, a further categorization is made before and after initiation (Phase 1 and 2) for those tasks in which an initiation of a warrant is coded (N=95). Even though in 10.5% of initiated tasks still no warrant is coded, this number decreases significantly after initiation. In addition, it becomes obvious that the proportion of analytic warrants increases after a question on (further) reasoning is posed.

**Table 4: Content-related analysis of the tasks with initiation**

N=95	No warrant	Not acceptable	Substantial	Analytic
Before initiation	77 (81.0%)	2 (2.1%)	15 (15.8%)	1 (1.1%)
After initiation	10 (10.5%)	7 (7.4%)	42 (44.2%)	36 (37.9%)

## Discussion and Conclusion

A comparison of the results with former research findings gives different insights into the arguments of mathematically gifted and interested primary students. On the one hand, the results can confirm

the general conclusion by Schwarzkopf (2000) that arguments have to be initiated at least partly. In two thirds of all tasks including a warrant, the warrant was only mentioned after initiation of the interviewer. Therefore, one can assume that gifted primary students do not seem to have an exceptionally sensible need for reasoning and arguing. Without initiation processes, the research findings by Fetzer (2012) on the lack of a warrant in primary students' arguments seem to be accurate for this sample. Also the independently formulated warrants are mostly substantial what fits the findings by Fetzer (2012). On the other hand, it is nevertheless noticeable that nearly 40% of the analyzed tasks with initiation involve an analytic warrant after an initiation process took place. Further, only in 10.5%, still no warrant is mentioned after initiation. The focus on initiation emphasizes the hypothesis that a large group of the students is able to formulate (analytic) warrants after being forced to. Nevertheless, only the minority of the students formulates (analytic) warrants on an independent level.

With special regard to the research questions, one can formulate the hypothesis that mathematical giftedness might not influence the need for argumentations. Nevertheless, most of the gifted students are able to formulate warrants after initiation, some of them even analytic. Mathematical giftedness therefore might have an impact on the mathematical basis for the formulation of analytic warrants in order to support (creative) detections and findings. So, incomplete arguments without initiation do not seem to be caused by a lack of ability, but by the low significance of arguments' needs or the missing of structural knowledge of arguments. This finding is further supported by the fact that the students were not taught on arguments in advance. Hereby, former studies of mathematically gifted students' intuition (e.g. Käpnick, 2010) might be relevant in order to explain the low need of giving warrants. In the interpretation of these findings, one has to take some limitations of the study into consideration. The interviews were analyzed on a qualitative level without a control group as it was not possible to exclude many different influencing factors (e.g. differences in school, teacher, language skills and mother tongue). Therefore, the comparison was built on former research findings and studies by different researchers, which mostly show consent in the analyzed categories and therefore allow a certain generalization of the findings for different settings. The comparison nevertheless has to be seen under varying task formats and different settings.

We take up the findings as a basis for a longitudinal study on the changes of the arguments of the students in terms of the structure and content, as well as the need for arguments. During this, the focus will be laid on the individual changes in arguments of the children with special regards to their environmental background in terms of language and family. Moreover, the study focuses on the question whether mathematical giftedness as a potential for outstanding mathematical performance can further be a potential for arguments.

## **“Using geometry, justify (...)”. Readiness of 14-year-old students to show formal operational thinking**

Edyta Juskowiak

Adam Mickiewicz University in Poznań, Poland; [edyta@amu.edu.pl](mailto:edyta@amu.edu.pl)

*The article contains information about the preliminary results of pilot studies carried out by the author on 127 students aged 14 years in the period 2017-2018. The aim of the research was to check students' readiness to use formal operations while solving mathematical problems, as well as to check the correctness of the tool construction by means of which the author attempted to search for answers to the questions posed.*

*Keywords: Piaget's theory, Formal operations, Argumentation, Geometry, Geometric reasoning.*

### **Introduction and theoretical framework**

The development of mathematical concepts in school students is inseparable from their intellectual development. The order and methodology of their learning by a young person is organized in advance because learners at school work in accordance with curriculum programs planned by the authors of the textbooks which set the basis for development and cognition in each of the school subjects.

Development is a constant struggle with what we know and with new information on the path of adaptation, by balancing two processes of assimilation and accommodation. The first one is adapting new information of external origin to what the person already knows and is acquainted with, the second is adapting his knowledge to new information. Man builds new patterns, his intelligence develops. There is a kind of competition between accommodation and assimilation based on comparison, a process which is an important basis for the development of mental operations. According to Piaget, the child's development depends primarily on itself, on the actions it undertakes, which underlie thinking, or the continuous cognitive process. It consists of intellectual operations, mental operations as an action which is interiorized and, therefore, runs in the mind (Piaget, 1952; Piaget, 1973, 2005a, 2005b).

As claimed by Piaget, this internalization takes place in four separate stages of the development of intelligence, linearly following one after another: sensorimotor stage, preoperative stage, concrete operations and formal operations. Everyone, regardless of their place of residence and the environment in which they grow up, goes through all the above-mentioned stages of development, in which reasoning changes from simple forms, strongly related to perception and performed activities, to forms implemented in the mind, abstract and hypothetical. These are qualitative changes, not quantitative changes, new behaviors are built on previous ones without eliminating the old forms but complementing and correcting them.

Piaget's research shows that not all people, regardless of where they live and what they do, reach the level of formal operations; it is also true that many of us do not use formal operations for many aspects of their lives (Przetacznik-Gierowska&Tyszkowa, 2000).

A person who thinks at the level of formal operations is characterized by:

- abstract thinking, i.e. the ability to logically use symbols in relation to abstract concepts (without the need to link them with reality), hypothetical-deductive reasoning, and the development of thinking about abstract objects,
- metacognition, or the skill of parallel reasoning and its monitoring; it is the ability to constantly reflect on one's own cognitive process,
- the ability to logically and methodically solve problems, in particular those of mathematics.

In summary, the process of changing the way of solving problems, starting from specific-operational thinking and ending with formal-operational thinking, is long and tedious, begins at the age of 12 and lasts until 16-17. The manifestations of these changes are connected with the students using a different method of tackling tasks and problems (not only mathematical ones), adopting a different, new attitude open to hypothetical-deductive thinking. A student who solves a mathematical task becomes open to correct inference based on mathematical facts and theories with detachment from the specifics, is able to put forward hypotheses and tries to verify them, attempts to generalize his judgments. In his statements, he uses phrases such as "maybe" and "if", he is characterized by the ability to think logically and critically, displays the tendency to conduct discussions and disputes and to make inquiries.

The pace of changes in the process of cognitive maturation as well as the final effect of these changes are closely related to the natural and school environment in which the student was matured. The moment, the type and the strength of the stimulus which becomes provocation and motivation for development is important. Geometry is a perfect area for the observation of changes in the cognitive development process of a student. Being one of the oldest disciplines of mathematics, due to which the concept of proof and formal thinking developed, it is the foundation of many activities characteristic for mathematical formal thinking. Freudenthal wrote: "Greek geometry was the first proper embodiment of the idea of mathematics. Although mathematical activity, both in algebra and geometry, began two or three thousand years before Euclid, words such as *theorem*, *assumption*, *proof*, *analysis*, *theory*, *axiom postulate*, *definition*, and concepts that they signify are an invention of Greek mathematics" (Freudenthal, 1966, p. 83).

Today geometry still plays a secondary role in Poland, especially in the process of mathematics education. Its presence is more frequent than in 1964 but is still insufficient in the programs of mathematical studies and studies for teachers and corresponds with merely 120 hours during the whole 5 years of study (<https://cutt.ly/MITprog>). In elementary schools the geometry issues account for 30% of the content of textbooks. It is mentioned in the comments to the current curriculum that: "The second branch of mathematics which supports learner's mathematical development is geometry. Although it was indispensable to limit the teaching content in geometry (due to time constraints) the main its part, namely mathematical proofs, was kept in the elementary school curriculum" (Brodzik & Pruszyńska, n.d.).

Geometry requires many competences: imagination, ability to draw logical and rational inference, to reason, to form hypotheses, and to read the content of mathematical tasks with comprehension, as well as being acquainted with all representations of mathematical language - words, symbols and graphics. There is always a fear that illustrations will overshadow the awareness of rational, logical

and deductive reasoning, based on the consciously used definition of the concept under examination, and not on the perception of its features based on a picture – ready-made or drawn on one's own.

In every mathematical discipline, but here in particular, each of three types of mathematical reasoning can be used when solving a mathematical problem. Full formal-operational reasoning is characteristic only for the formal reasoning, but the formal operations also occur in the intuitive reasoning, and their manifestations - in the empirical reasoning. Krygowska defines these types of reasoning as follows: empirical inference at the level of school education is the formulation of a mathematical hypothesis based on observation and experience in a specific physical space or on inductive tests already in the field of mathematics itself; student's reasoning is treated as intuitive in the field of mathematics if in the course of solving a certain problem he uses, above all, imagination, i.e. images of concepts which he considers, regardless of their formal definitions and carries out brief reasoning based on obvious premises, regardless of their correspondence within the given system; finally, we consider a student's reasoning as formal if in the course of solving the problem he realizes the accepted basis of deduction and tries to consciously derive any subsequent conclusions as precisely as possible from previously made claims and given definitions within a given system; uses definitions and theorems properly (Krygowska, 1977, pp. 441-45).

In his theory of intellectual development, Piaget determined that most students over the age of 12 apply formal operational thinking in a form specific for its early stage. However, research carried out in the 1970s in a sample of 10,000 British 14-year-old children revealed that the overwhelming majority of them, namely 80%, do not reach this stage (Shayer, Küchemann, & Wylam, 1976).

It is necessary to check the present situation and determine the level at which Polish 14-year-old students currently reason, particularly now when we are in the course of implementing curriculum and organizational reforms which aim at strengthening the development of application of reasoning and critical thinking. Professor Edyta Gruszczyk-Kolczyńska, who has been observing children demonstrating exceptional mathematical abilities and those who struggle with difficulties when learning mathematics for many years, writes in her books that one of the possible impediments in creative development of mathematics in case of Polish children can be a delay in developing formal thinking. The author has not come across any research containing discussion on these matters in Poland in recent years (Gruszczyk-Kolczyńska, 1992; Gruszczyk-Kolczyńska, 2012). She undertook to study the manifestations of formal thinking characteristic of Polish students.

Some research and articles in world literature attach crucial importance to the choice of concepts of teaching geometrical terms at every educational level which aim at the activation of reasoning and, later, providing correct and formal justification. Proofs and formal reasoning applied on the grounds of geometry are treated as a tool supporting the assessment of students' knowledge (Swoboda & Vighi, 2016; Koleza, Metaxas, & Poli, 2017; Pericleous & Pratt, 2017; Soldano & Arzarello, 2017; Mączka, 2016). Training in teaching geometry is also emphasized as teachers, applying particular teaching techniques and organizational skills used to create active educational

environment, are responsible for provoking appropriate attitudes of students (Mata-Pereira & Ponte, 2017).

## Goals, organization, methodology and tools

The article will present the results of some pilot studies. They were conducted in two rounds: in 2017 on a group of 100 students from one junior high school in Poznań (these studies were part of the research carried out for the diploma thesis of Mrs. Monika Drgas, prepared under the supervision of the author of the article). The second part of the research was carried out in 2018 on a group of 27 pupils at the 7th grade from one primary school in Poznań.

Both pupils from elementary schools and students from junior high schools were surveyed at the same age, being 14 years old, and in the same period of the school year, i.e. in the second part of summer semester. In Poland an educational reform is currently implemented and it influences both the organization of the teaching process and the content of the curriculum. The foregoing 6-grade elementary school was transformed into 8-grade elementary school and existing junior high schools are being phased out. In 2017 14-year-old children were in the first year of junior high schools and, one year later, in the seventh year of elementary schools. The main criterion for the sample groups selection was age, then it was the textbook ensuring knowledge required to tackle the tasks and, obviously, the agreement of school directors, teachers and parents or legal guardians for children's participation in the survey. The research tool in the first round of tests consisted of three tasks, all of them come from a textbook for class 1, Gdańsk Educational Publishing. The goal of each of these tasks was to provoke students' reasoning to check or justify a certain mathematical regularity or fact.

The aim of the study, apart from checking the correctness of the tool's construction in order to develop a proper research tool, was to check the readiness of Polish students at the age of 14 to use formal operations during their mathematical reasoning provoked by geometry tasks requiring students to justify some statements. The tool used in the second stage of the study consisted of 6 tasks, all geometrical ones, two of the tasks from the first stage were used in the second study and one of them will be analyzed in this article. In each of the stages participants had exactly 45 minutes to solve the problems.

### Task

*Check what is the ratio of the area of shaded figures to the area of the rectangle.*

This task checked the ability to carry out a full and correct analysis of the conditions of the task where all data was provided in the figure attached thereto, and then the way of following the instruction through the adopted reasoning and with the use of acquired knowledge. None of the variables needed to carry out the reasoning was given or named. Viewing the figure suggests the same length of certain segments but this fact is not stated in an obvious way (i.e. by using the same color, describing the length with the same variable). Therefore, the task enforces applying the formal operational thinking with reference to known facts, definitions and theorems, dependencies regarding the areas of flat figures, and test it.

As one can see in the task, the use of symbolic language of mathematics as well as of prior knowledge, and applying hypothetical-deductive reasoning, were indispensable to achieve a full, correct and formal solution. But was the formal-operational reasoning applied by the students?

Here there is a proposition (there are obviously more possibilities; they will not be all presented due to article length constraints) of a correct task solution reflecting capabilities of students at the 7<sup>th</sup> grade (at the age of 14) and containing some manifestations of formal operations, such as logical usage of symbols, deductive reasoning, reflection and usage of abstract objects. This solution has been proposed by a student - future teacher of mathematics.

**Figure 1: The example of the correct solution**

The article presents brief description of the results and more detailed analysis of the selected students' solutions which represent different types of reasoning used by students. Due to the aim of the research, attention will be focused on the description of manifestations of formal operations.

### Stage 1

Junior high school students mostly provided correct answers. More than half of the students wrote that the area of the shaded figure is half of the area of the rectangle, but they could not justify it.

Among 100 students participating in the survey, only 12 described the course of their reasoning in the answer sheet; hence only 12 cases were included in the table.

	Feature		
	logically use symbols	reason hypothetically and deductively	think about abstract objects / perceive / perform activities
Number of students	5 - yes 7 - no	4 - no 6 - manifestations 2 - yes	3 - abstraction 9 - perceive
Number of pupils	9 - yes 2 - no	7 - no 4 - manifestations	1 - abstraction 1 - perceive 10 - perform activities

**Table 1: Features of formal reasoning - junior high school students and pupils of grade 7**

### Stage 2

Out of 27 participating in the study, only 11 pupils attempted to solve the task, not every one of them answered the question posed in the task, and those who did it, answered correctly. Most of the pupils did not carry out correct and full reasoning, certainly it was not the formal reasoning, students were not able to use symbolic language, the conclusions were based on intuition - often

infallible but not supported by knowledge - and on specific activities, i.e. measuring the length of segments and indicating certain facts or approximate values.

## Analysis of selected student works

### Example 1

Figure 2: Student's solution – example 1

The student introduces his own indications corresponding to the areas; however, it is unclear why it is done. The student makes certain assumptions and does not explain this step. In addition, his observations are completely false, do not justify the equality of areas which do not look similar. The student combines a symbolic record with the text, equating them. He puts forward a hypothesis or a thesis on the basis of false premises. He does not attempt to prove the observed regularities and uses phrases - "when combined". In the process of reasoning one can notice some manifestations of formal operations and unsuccessful attempts to use them.

### Example 2

Figure 3: Student's solution – example 2

Reasoning fully based on the perception of the figure treated as a specific object to be measured and explored. The student calculated the areas of shaded triangles, calculated the area of the rectangle and subtracted from it the sum of the areas of previously calculated triangles. The calculations do not confirm the fact which was to be proved. There is no reflection or comment, no other attempt to solve the task that could confirm or refute the results.

Exemplar solutions, the correct ones proposed by students and those provided by pupils, are available at [https://drive.google.com/drive/folders/1HFo22kdJeG0SnhkwM7eM\\_IMCIqt9wDrZ](https://drive.google.com/drive/folders/1HFo22kdJeG0SnhkwM7eM_IMCIqt9wDrZ). Due to article length constraints they could not have all been included in the paper.

## Conclusions

The conclusions presented below are related to manifestations of formal operations in the process of solving the problem selected by two groups of children participating in two stages of pilot studies.

The author refers to the type of reasoning applied by students and to manifestations of formal operations, i.e. logical usage of mathematical symbols, deductions, reflection and the types of actions performed in order to find a solution of the problem.

After the analysis of given responses, it appears that students:

- mostly gave the correct answer,
- sometimes worked out solutions based on formal operations, but nevertheless
- answers in the vast majority were not a result of formal / abstract reasoning,
- answers were due to the perception of certain regularities which students perceived in the figure,
- answers were often a consequence of specific actions performed with the use of a ruler, the segments were measured and although the results were often different, the correct answer was given,
- pupils apparently saw no need to justify their statements,
- students applied faulty reasoning,
- students did not apply the rules of deductive reasoning,
- pupils could not separate their reasoning from the specifics given in the figure,
- pupils' intuition was often infallible but they were not able to give it up and apply formal reasoning.

## Summary

The article presents the results of the pilot studies and conclusions drawn on their basis. It describes the readiness of students at the age of 14 to go through the process of solving a selected geometrical problem applying reasoning with the use of formal operations. To make it possible, students must know the properties of the figures as well as be sufficiently mature to conduct theoretical research and reflect upon it. Students should be able to use logical arguments, definitions and statements. Initial conclusions are unambiguous, the vast majority of students are not ready to reason deductively detaching from specifics, imaginary operations and specific activities, although according to Jean Piaget's theory of intellectual development after the age of 12 it should take place in mathematical thinking of students.

The analysis of the material collected during the proper research and an answer to the question whether the hypothesis formulated here will be strengthened or refuted is still ahead of the author. The proper tests were carried out on a sample of 1200 students.

*The research presented in this paper is about the question, if and how the phrasing of a proving task influences students' proof productions. In our study, 381 first-year preservice teachers were asked to work on a proof questionnaire involving two proving tasks, where the phrasings "prove that", "show that", "reason", and "explain" were used alternatively. Students' proof productions were analyzed concerning the kind of reasoning, the use of algebraic variables and the number of words used. While we found statistically significant differences in the proof productions for the easier first task, there were no remarkable differences in the case of the harder second task.*

*Keywords: Proof, argumentation, socio-mathematical norms, semiotic norms.*

## Introduction

The learning about proof and proving is considered to be a main hurdle for beginning university students. Several studies have been conducted to describe and to analyze the low proving competences of freshmen (see Gueudet (2008) for a good overview). Despite these results, only little effort has been made to investigate the relationship between research results, the teaching of proving and the proving tasks used in research. Dreyfus (1999) gives a description of several aspects that have to be considered in the teaching of proving. Dreyfus concludes (p. 103):

The examples in Section 2 provide ample room for questioning what is expected by the different formulations used, including 'explain' [...], 'justify' [...], 'prove' [...], and 'show that' [...]. Does 'show that' mean 'formally prove' or 'use an example to demonstrate that' (or something intermediate between these two)? Does 'explain' mean explain to a fellow student or explain in such a way as to convince the teacher that you understand the reasoning behind the claim?

It was this idea of Dreyfus that made us conduct a study on how students' proof constructions vary due to the phrasing of the proving tasks. We chose the four phrasings "prove that", "show that", "reason" and "explain" to investigate possible systematic differences concerning students' proof productions. While "prove that" and "show that" are genuine phrasings in proving tasks, "reason" and "explain" are also phrasings that are used in studies to investigate students' proof competencies. In this paper, we will describe our research project and outline the main results of this study.

## Theoretical background

There are various phrasings that can be used to formulate a mathematical proving task. In the German school system for example, the concrete phrasings are meant as follows (KMK, 2012; our translation; the added words in quotation marks are the German translation of the former phrasing):

- *to prove* [“beweisen”]: to verify statements mathematically by using known facts and deduction, starting from the assumptions given
- *to show* [“zeigen”]: to verify statements by using valid forms of reasoning, calculations, derivations or logical connections
- *to reason* [“begründen”]: to trace data back to principles or to causal connections by using rules and mathematical relationships
- *to explain* [“erklären”]: to clarify and to make comprehensible data by using personal knowledge and to arrange it reasonably into mathematical relationships

So, there are some definitions or specific requirements combined with these phrasings. Following this differentiation, the mathematical solutions could vary in some detail due to the phrasing used to formulate a mathematical task.

In the mathematical classroom, the meaning of the different phrasing of a mathematical proving task can be considered to be an aspect of sociomathematical norms in the sense of Yackel and Cobb (1996). In the concrete learning contexts, the teacher and the students negotiate what is accepted, when a reasoning, an explanation, or a proof is asked for. Accordingly, the students learn in their daily mathematical class, what they have to do, when dealing with a task starting with “prove”, “show”, “reason”, and “explain”. In this sense, the way students are responding to a specific mathematical (proving) task is a result of a socialization process. This perspective offers the very possibility of existing effects concerning students’ proof productions when using different phrasings in proving tasks and also makes it possible to give an explanation for them.

In line with the theory of sociomathematical norms, semiotic norms have to be considered. The concept of semiotic norms covers the idea that people may develop preferences concerning communicating ideas (e.g. with mathematical symbols, using representations or giving concrete examples) when being confronted with a given and known formulation of a task. Kempen and Biehler (2015) transferred the idea of Dimmel and Herbst (2014) to explain students’ preference of using algebraic variables when being asked “to prove” a mathematical statement. There are some suggestions in the literature that the phrasing of a mathematical task influences students’ solutions. Schupp (1986) discusses the ‘problem of points’ and gives several examples how students’ solutions may vary in reference to a specific phrasing of the task. Knipping et al. (2015) adopt this idea and compare several phrasings of the same task to discuss different solutions obtained in different studies. The authors also consider the influence of sociological factors: students’ solutions in different school contexts (grammar school class and comprehensive or mixed school [“Oberschule”]) differed clearly from each other. Finally, it seems reasonable to link the phrasing of a mathematical task with emotions on students’ side. Hemmi (2006, p. 145) showed that while most of the students felt positive when being asked to solve a task starting with “Show that...”, about 40% of them stated a negative feeling. One might conclude that a negative feeling concerning a given task may lead to the result that a student might not seriously try to answer the task.

## Research questions

The theoretical considerations above led us to consider several hypotheses. Students may link different phrasings of proving tasks with different mathematical activities. According to the meaning of the phrasing “show that” in common speech (in German it is “Zeigen Sie”), this phrasing may lead to an answer of a proving task, where a student is justifying a given claim by only testing one or more examples. Whereas this phrasing might lead to an empirical-inductive answer, a phrasing like “reason” is considered to evoke the formulation of arguments (compare research question 1). In line with the idea of semiotic norms, the different phrasings of proving tasks may lead to the use of different notational systems. One might assume that “prove that” may lead to the use of algebraic variables, whereas “explain” might be combined with the use of (verbal) language (compare research questions 2 and 3). For a deeper analysis of the data we also considered social factors (like gender, age, former math courses at school, ...) and also investigated the data concerning the use of word variables, the use of representations, the use of concrete examples, quality of deductive approach and the structure of the proof. But due to the length of this paper, we will only report on the aspects “kind of reasoning”, “use of algebraic variables” and “number of words used”.

We finally came up with the following research questions:

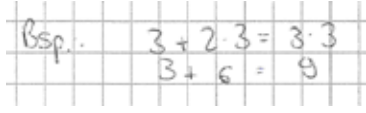

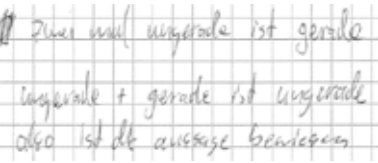

1. In how far do students’ proof attempts vary significantly concerning the kind of reasoning used (empirical-inductive or deductive) with respect to the phrasing of the task?
2. In how far does the occurrence of (algebraic) variables vary significantly with respect to the phrasing of the task?
3. In how far does the number of words students used vary significantly with respect to the phrasing of the task?

## Methodology

Following the winter term in October 2015 in Germany, 381 mathematical freshmen, who took part in a degree program leading to different teacher accreditations at the Universities of Gießen, Münster and Paderborn, participated in this study. These students were asked to work voluntarily on an anonymous entrance test. All students were told, that their results would not affect their marks in any ways.

The mathematical statements used in this survey arise from the field of elementary number theory. Both tasks were chosen due to their manageable amount of mathematic operations as well as their contiguousness to topics dealt with in German grammar schools and are as follows: (1) The sum of an odd natural number and its double is always odd and (2) The product of three consecutive natural numbers is always divisible by 6. Each proving task allows for different approaches, e.g. generic or formal solutions. The first statement can easily be proven by making use of generic examples, by using figurate numbers, or by using algebraic variables (see for example Kempen and Biehler (2015)). We felt the need to include a task that is as easy to understand as the first one, but harder to prove, because in the case of the second task, the mere use of algebraic variables and respective computations does not automatically lead to a proof of the statement  $(n \cdot (n + 1) \cdot (n + 2) = n^3 + 3n^2 + 2n)$ . Here, some additional arguments are necessary to prove the given claim. In this case, a narrative justification seems to be the simplest way of proof. One possible narrative proof for this task might be: If you have three consecutive numbers, one will be a multiple of 3 as every third number is in the

three times table. Furthermore, at least one number will be even and all even numbers are multiples of 2. If you multiply the three consecutive numbers together, the answer must have at least one factor of 3 and one factor of 2. Accordingly, the result will always be divisible by 6 (compare with Healy & Hoyles, 2000). Each statement was introduced with one of the phrasings “Proof”, “Show”, “Justify”, and “Explain”. This allowed for twelve different questionnaire versions in total, as identical operators were excluded. Furthermore, in order to prevent cheating, different colored sheets of paper were assigned to the twelve versions of the questionnaire. Having developed an initial questionnaire, this prototype was piloted in mathematical courses for teacher education at the Justus Liebig University Giessen and the Westphalian Wilhelms-University Münster in May 2015 (N=48). We used the following set of categories to identify the kind of reasoning (see research question 1). Here, the category “empirical-inductive” comprises two aspects. Any mere testing of one or more concrete examples without further arguments or ideas is located in this category. Furthermore, inductive approaches, where the truth of the given statement is asserted on the basis of purely empirical considerations, belong to this category. We combined these two aspects to one category to stress the overall difference to deductive approaches. It has to be mentioned that this distinction of empirical-inductive and deductive reasoning is independent from the correctness respectively the completeness of the argument given; an incorrect deductive argument still counts as deductive.

name	explanation	example (taken from students' answers)
empirical-inductive	The answer is just a verification by one or more examples. No more arguments or ideas are mentioned.	 <p>(Example: <math>3 + 2 \cdot 3 = 3 \cdot 3</math> <math>3 + 6 = 9</math>)</p>
deductive	<p>The student mentions ideas or further arguments that could be used to prove the statement.</p> <p>Moreover, the mere use of algebraic symbols is considered to be a kind of deductive reasoning.</p>	 <p>(two times odd equals even odd + even equals odd accordingly, the claim is proved)</p>

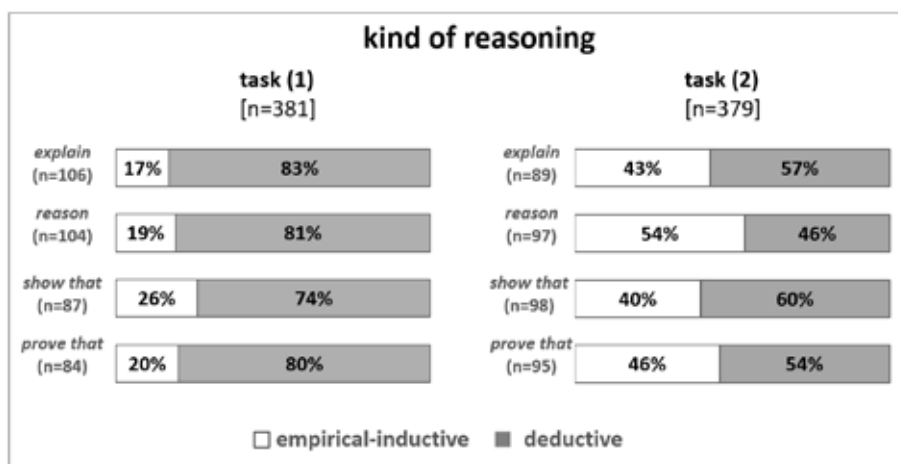

**Table 1: Set of categories to investigate the "kind of reasoning"**

Concerning the use of algebraic variables, we applied this code if any algebraic variable had been presented in the answer to a proving task or not. While the use of algebraic variables is measured as a category to code its appearance, we also counted the number of words used in students' proving attempts. In this case, we were not only interested in the appearance of words, because more or less any proof attempt will make use of some words somehow. Accordingly, we had to count the words to investigate a special kind of shift in students' proof attempts leading to more narrative approaches. When counting the number of words used in an answer of the proving tasks, we did not count the words for structuring the proof production (like “example:”, “proof:” or “q.e.d”) or symbols (like “+”

or “...”). Following this categorization, the first example given above in table 1 is considered to be an empirical-deductive answer, with no use of variables and zero words. The second example is a deductive answer without variables containing 14 words.

## Results

The following results are based on the answers of 381 first-year preservice teachers at the University of Gießen, Münster and Paderborn. The results concerning the kind of reasoning in accordance to the given phrasings are shown in Figure 1.

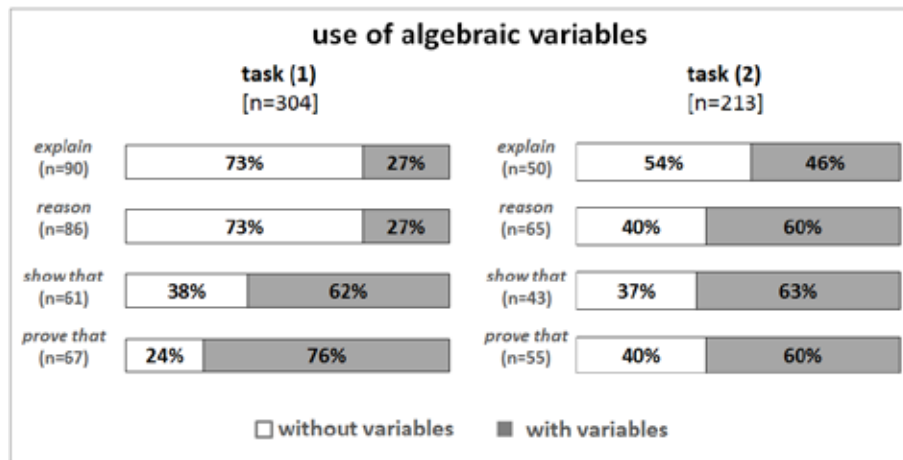

**Figure 1: Results concerning the “kind of reasoning”**

Concerning proving task (1), the percentage of empirical-inductive answers is the highest for the phrasing “show that” (26%) and the lowest for “explain” (17%). This difference is statistically significant with small effect size [Chi<sup>2</sup>-test,  $p=.021$  with Cramer’s  $V=.167$ ]. In the second task, the results are quite different. Around half of the students give empirical-inductive answers. In this case, there is no statistically significant difference between the kind of reasoning in accordance to the different phrasings of the task. This might be due to the fact that the second task is harder to prove (see above). Accordingly, students might have only given examples because they did not know how to proceed otherwise.

When analyzing the data concerning the use of variables and the number of words used, we only referred to the answers making use of a deductive approach, as the ‘empirical-inductive’ proof attempts will obviously include no variables and contain fewer words. The results concerning the use of algebraic variables with regard to the deductive attempts in accordance to the given phrasings are shown in figure 2. Having a look at the answers to the first proving task, the phrasing “prove that” leads to the highest percentage of the use of algebraic variables (76%), followed by “show that” with 62%. Concerning students’ proof productions for task (1), there are several statistically significant differences considering the use of algebraic variables with small and medium effect size (see table 2). One might assume that something like an implicit semiotic norm would lead to these differences. In task (2), the minor differences concerning the use of algebraic variables in accordance to the given phrasings are not statistically significant (Chi<sup>2</sup>-test). Here again, the students’ problem in dealing with the second proving task can be considered as an explanation why no differences concerning the use of algebraic variables in accordance to the given phrasings could be observed. However, the results

concerning task (1) hint that a construct like semiotic norms should be considered, because there, the use of algebraic variables differs in accordance to the given phrasings.

**Figure 2: Results concerning the “use of algebraic variables”**

	P value (Chi <sup>2</sup> -test)	effect size (Cramer's V)
“prove that” vs. “show that”	.021	.158
“prove that” vs. “reason”	<.001	.391
“prove that” vs. “explain”	<.001	.376
“show that” vs. “reason”	<.001	.241
“show that” vs. “explain”	.003	.225

**Table 2: Statistical data concerning the differences about the “use of algebraic variables” in accordance to the given phrasings. P value (Chi<sup>2</sup>-test) and effect size (Cramer's V)**

Students used 25.68 words on average to answer task (1) and 18.83 to answer task (2) (see table 3). Having a look at the arithmetic means of number of words used in accordance to the given phrasings in task (1), there are remarkable and statistically significant differences (see table 4). Whereas the phrasings “reason” and “explain” lead to an increased use of words (27.35 respectively 27.52 on average), “prove that” and “show that” lead to a minor use of words (14.83 respectively 13.11 on average). In this case, we consider the phenomenon of an increased use of words due to the phrasing of a proving task as a matter of semiotic norms.

	task (1) [arithmetic mean]	task (2) [arithmetic mean]
“prove that”	17.91	16.46
“show that”	17.11	21.93
“reason”	32.63	17.16
“explain”	31.60	20.91
<b>overall arithmetic mean</b>	<b>25.68</b>	<b>18.83</b>

**Table 3: Arithmetic means concerning the number of words used in students proof productions in accordance to the given phrasings**

	<b>P value (t-test)</b>	<b>effect size (Cohen's d)</b>
“prove that” vs. “reason”	<.001	1.02
“prove that” vs. “explain”	<.001	.83
“show that” vs. “reason”	<.001	1.05
“show that” vs. “explain”	<.001	.85

**Table 4: Statistical data concerning the differences about the “number of words used” in proving task (1) in accordance to the given phrasings. P value (t-test) and effect size (Cohen's d)**

## Summary and final remarks

The focus of this paper is on if and how the phrasing of a proving task might influence students' proof productions. In the case of the easier proving task (1) about the claim that the sum of an odd number and its double is always odd, remarkable differences could be observed. Here, the phrasing “show that” led to statistically significant more answers consisting only of empirical evidence compared to the phrasing “explain”. While “show that” and “prove that” evoked the use of algebraic variables, “reason” and “explain” led to an increased use of words. While these differences could be observed in the case of the first task, there were no such results in the case of the second task. One explanation might be that the second task (about the divisibility by six of the product of three consecutive natural numbers) was too hard for the students. If the students do not know how to solve a problem in any way, they cannot vary concerning the way they prove the claim. This possible explanation is supported by the fact that much more students only gave empirical-inductive arguments to answer the second proving task (44% vs. 18% in the case of the first task).

Following our theoretical considerations, the differences in students' proof attempts in the context of task (1) can be explained by the framework of sociomathematical norms (in the sense of Yackel and Cobb, 1996). Students had acquired throughout their daily (school) life and their mathematics classes what they are expected to do when being asked “to prove” a statement, “to show” that something is true, “to reason” or “to explain” a given fact. The emergence of respective sociomathematical norms evolves from the (implicit and explicit) discourse taking part in the classroom, where students and teachers negotiate their expectations and requirements. In the case of task (1), the phrasing “show that” led to statistically significant more empirical-inductive approaches than the phrasing “explain”. As a result of sociomathematical norms, semiotic norms can be developed. Students might link a task or the phrasing of a task with the use of certain semiotic resources. In this study, the phrasings “prove that” and “show that” led to an increased use of algebraic variables, whereas “explain that” led to an increased use of words. While we claim, that certain sociomathematical norms have been developed concerning the area of proof and reasoning, we can only guess, which experiences have led to respective phenomena. Here, classmates and (mathematics) teachers will have played a decisive role when negotiating norms. However, other influences from real life might also have affected students' attitude and behavior.

To sum up, the phrasing of a proving task can influence students' proof productions. In this study we could identify differences concerning the kind of reasoning, the use of algebraic variables and the number of words used. This result should be considered in the teaching of proof and in the research in this domain. The teachers at school and at university should be aware of the fact that students seem

to combine different (implicit) norms for phrasings of a proving task when designing tasks for their students. Researcher should consider the fact that the phrasing of a proving task might affect their research results when analyzing the data. But more research has to be done to get deeper into the effects different phrasings may evoke. Beside the formulation of task, also other aspects have to be considered, like social and sociological factors, individual preferences or mathematical thinking styles. These considerations have to be investigated by future research. Finally, as was shown above, the findings of this study seem to be closely related to the two tasks used in this study. More research is needed to confirm or to specify the results obtained in the context of different proving tasks in different domains.

*Mathematics education researchers have highlighted the importance of assumptions in school mathematics given their vital roles in mathematical practice. However, there is scarcity of research aiming at enhancing students' recognition of different roles that assumptions play in mathematical activity. In this paper, we begin to address this issue by formulating two task design principles and reporting on the implementation of a classroom intervention where lower secondary school students in two classes worked, with the same teacher, on a task designed following the proposed principles. Our analysis shows how the task, together with the purposeful teacher's actions in implementing it, led to students' developing appreciation of two roles that assumptions play in mathematical activity.*

*Keywords: Assumptions, Task design principles, Classroom intervention, Teacher's role.*

### Introduction

*Assumptions* refer to statements that doers of mathematics use or accept (often implicitly) and on which their claims are based (Stylianides & Stylianides, 2017). Several researchers in mathematics education have highlighted the importance of helping students be more aware of the roles that assumptions play in mathematics, especially in relation to the notion of *proof*. For example, Fawcett (1938), who treated proof as a key notion in school mathematics, listed four criteria for checking students' understanding of the nature of proof, among which two are closely related to assumptions: students understand "[t]he necessity for assumptions or unproved propositions" and "[t]hat no demonstration proves anything that is not implied by assumptions" (p. 10).

Despite the importance of assumptions in school mathematics, assumptions have received little research and pedagogic attention in school mathematics. Furthermore, existing studies (e.g., Fawcett, 1938; Jahnke & Wambach, 2013; Komatsu, 2017) have mainly focused on geometry at the secondary school level. Research in other mathematical domains is needed that will build on and widen the scope of application of prior research in geometry, given also the recent calls for curriculum reform (see, e.g., NGA & CCSSO, 2010, in the United States) to introduce proof-related mathematical activity across content areas as well as in primary school (e.g., Stylianides, 2016).

To develop students' recognition of the roles of assumptions in mathematical activity, we focus on the design of mathematical tasks, which have potential to affect significantly students' experiences with and understanding of the subject. Specifically, in this paper we propose two principles that can be used to support task design in the area of assumptions, we report on an intervention implemented in two classes where lower secondary school students worked on a task designed following the proposed principles, and we discuss the influence on students' understanding of the roles of assumptions in mathematical activity.

## Task design principles for the roles of assumptions

### Types of assumptions

Assumptions often refer to statements that are accepted as true without proofs, and their typical examples are axioms like the fifth postulate in Euclidean geometry whose modification led to the formation of non-Euclidean geometries. To expand the opportunity for students to experience the relativity of truth in mathematics, we extend the mainstream notion of assumptions to include two additional types of assumptions, both related to mathematical tasks and their formulation: (1) *conditions* of tasks (including premises of statements mentioned in tasks), and (2) *definitions* of terms mentioned in tasks. This paper reports on an intervention concerning the former type in the context of a function task. We are in the process of designing another intervention addressing the latter type.

### Roles of assumptions

Assumptions play multiple roles in the discipline of mathematics. Their primary role has been to introduce the relativity of truth, i.e., whether a proposition is true or false cannot be absolutely determined, but hinges on assumptions (Fawcett, 1938). For example, Euclidean geometry was originally accepted as the standard form of geometry that was deemed to be true in an absolute sense. However, following mathematicians' unsuccessful attempts to deduce the fifth postulate from other postulates, mathematicians created new geometries, the non-Euclidean geometries, by adopting axioms different from the fifth postulate. It was thus recognised that some propositions in Euclidean geometry are true only under the set of Euclidean axioms, and that the conclusions are different under different sets of axioms.

A second role is to mediate disputes that occur concerning the truth of conjectures; mathematicians have managed to resolve such disputes and reach consensus by delving into the assumptions underlying the conjectures. Consider, for example, the conjecture that the limit of any convergent series of continuous functions is itself continuous. According to Lakatos (1976), while Cauchy provided a proof for this conjecture in the 19th century, a counterexample to the conjecture was found in Fourier's work. Mathematicians attempted various explanations for this puzzling situation where the proof for and counterexamples against the conjecture coexisted. Eventually, Seidel analysed Cauchy's proof and discovered a hidden lemma, which once incorporated into the conjecture as a condition (related to the concept of uniform convergence), validated the conjecture.

### Learning goals

Considering the importance of promoting authentic mathematical practice in school mathematics (Lampert, 1992), our study aims to help cultivate students' sense of the two roles of assumptions we discussed earlier. Specifically, we set up the following two learning goals for the intervention in our study (similar to the goals discussed in Stylianides & Stylianides, 2017, for prospective teachers):

Learning Goal 1: To recognise that a conclusion is dependent on the assumptions on which the argument that led to it was based.

Learning Goal 2: To recognise that making the underlying assumptions explicit is crucial for reaching a consensus on the conclusion.

## Task design principles

Based on our previous studies (Komatsu, 2017; Komatsu & Jones, 2019; Stylianides, 2016, chapter 4; Stylianides & Stylianides, 2017), we formulated the task design principles below in order to address the above learning goals:

Principle 1: Designing tasks that are subject to different legitimate assumptions by leaving purposefully some of the assumptions of tasks implicit or unspecified.

Principle 2: Allowing tasks to have different legitimate answers based on different legitimate assumptions about the tasks.

At the centre of these principles is the deliberate act of keeping some of the assumptions of the tasks implicit or unspecified. The typical way of showing a task to students and promptly clarifying its assumptions eliminates the possibility of multiple interpretations of these assumptions and reinforces the intuitive connection between the clarified assumptions and the expected answer. In our on going research (part of which we report here), we intend to break this norm by creating a situation where an assumption of a task is purposefully unstated by the teacher so that the students can work on the task under their own (implicit and potentially varied) assumptions. We anticipate that the disagreement in the proposed answers likely to emerge in the whole-class discussion will prompt the students to explore the reasons for the inconsistency. This discussion, purposefully orchestrated by the classroom teacher, is expected to help students realise that their answers depend on their respective assumptions and that an explicit assumption is needed to justify each answer.

## Method

### Task design

Based on the principles stated above, we designed a task shown in Figure 1, which we adapted from a task implemented in the 2016 National Assessment of Academic Ability in Japan (NIEPR, 2016). With respect to Principle 1, the functional relationship between  $x$  and  $y$  is not specified in the task so that students can work on the task under different assumptions about functional relationships. With respect to Principle 2, the answer to the task is, for example,  $y = 6$  if  $y$  is inversely proportional to  $x$ , and  $y = -6$  if  $y$  is a linear function of  $x$ . Despite the divergence between these answers (as well as an infinite number of other legitimate answers not discussed here), both of them are, or can be, correct as long as the respective functional relationship is assumed.

The table below represents $y$ -values corresponding to the given $x$ -values. Find the $y$ -value when $x = 6$ .						
$x$	...	2	3	...	6	...
$y$	...	18	12	...		...

**Figure 1: The designed task, which we adapted from a task derived from NIEPR (2016)**

### Participants

We conducted an intervention study using the task in Figure 1 in two ninth-grade classes (approximately 40 students in each class, aged 14–15 years) in a Japanese lower secondary school

affiliated with a national university. The intervention consisted of one lesson (50 minutes) and was implemented in the two classes by the same teacher who had five years of teaching experience.

We worked together with the teacher in planning the intervention. Specifically, the first author showed to the teacher the task in its original form from the national assessment, and also discussed the intended learning goals and task design principles we presented in the previous section. The teacher then created a lesson plan and discussed it with the first author. Based on the discussion, we decided to use the task as in Figure 1 that was modified from the original form. The teacher then implemented the task following closely the lesson plan as outlined below. The participating students were not introduced to the notion of assumptions before, but they were familiar with the definition of functions and several kinds of functions: proportion ( $y = ax$ ), inverse proportion ( $y = a/x$ ), linear function ( $y = ax + b$ ), a special case of quadratic function ( $y = ax^2$ ), and step function.

### Data collection and analysis

The data include the transcripts of the videotaped lessons, the students' worksheets, and the field notes taken by the first author during the lessons. The data analysis aimed to determine whether the learning goals described earlier were achieved in each class. We focused our analysis on the whole-class discussions to examine the learning trajectory of each class as a whole, rather than attempting to trace individual students' thinking. Due to space limitations, results from analysis of students' worksheets are referred to only for triangulation, complementing the results pertaining to the whole-class activity. Because the two classes followed nearly identical paths, we report only the results from one class (38 students) in this paper. All student names are pseudonyms.

## Classroom intervention

### The relative correctness of answers

The teacher began the lesson by presenting the task in Figure 1; the students individually worked on it for about five minutes. During this work, some students provided the answer  $y = 6$ , while others the answer  $y = -6$ . This disagreement surfaced during the subsequent whole-class discussion. Misaki first said, "I think  $y$  is 6", but a student objected to her answer, "That's wrong". Aoi then said, " $y = -6$ ", but Shun questioned her answer saying "What?" After that, the teacher posed to the students the pre-planned question of which answer,  $y = 6$  or  $y = -6$ , was actually correct:

- 31 Teacher: Well, now there are two answers. Which is a correct answer?
- 32 Students: Both are correct answers.
- 33 Teacher: Really? Are both correct answers? Please think everyone. [...] [The students start to discuss with their neighbours.]
- 34 Nanami: What? What is the conclusion?
- 35 Takumi: I don't know.

As seen in this interaction, an anticipated sense of confusion emerged among students. While some of them considered both answers to be correct (line 32), others had no idea about which the correct answer was (lines 34, 35). To address this confusion, the teacher then asked students to think more about whether both answers were correct and to write their thoughts on their worksheets. The students then shared their thoughts in the whole-class discussion:

- 39 Ren: Um, I think both [answers] are correct. These two. Since we don't know what the function of this graph is, since we can interpret it as both an inverse proportion and a linear function, I think both are correct.
- 40 Teacher: You've described your opinion that both are correct. Well, let's listen to another student. Riko, can you share [your opinion]? What do you think?
- 41 Riko: Um, I also think both are correct. If we change how we read the table, it becomes an inverse proportion and also a linear function.

Ren and Riko's responses (lines 39, 41) are representative of students' responses and are relevant to Learning Goal 1: recognising that a conclusion is dependent on the assumptions on which the respective argument that led to it was based. That is, these students understood that the correctness of their answers was relative to their assumptions, implying that  $y$  is 6 if  $y$  is inversely proportional to  $x$ , and  $y$  is  $-6$  if  $y$  is a linear function of  $x$ . All students in the class agreed that both answers could be correct and most students shared or wrote similar thoughts. For example, Mizuki wrote on her worksheet, "the answer is 6 if we interpret it as an inverse proportion, but  $-6$  if it is a linear function". Similarly, Nanami wrote, "The graph becomes a curve where the  $y$ -value becomes 6, and also becomes a line where the  $y$ -value becomes  $-6$ , so I think both values are correct depending on how we think about it". These students' responses show that the task has afforded them the opportunity to recognise the connection between different answers and respective assumptions.

### Two ways for pinning down the answer

While the students recognised the relativity of their answers, they started to feel dissatisfied with the task they worked on: Nanami said, "That's not good. I don't know what I am solving". The teacher responded to the students' feeling of dissatisfaction by posing two pre-planned questions (written on the blackboard): "(1) What are the reasons for the answer to be ambiguous? (2) What can we do to address the ambiguity?" The students were given approximately ten minutes to tackle these questions, before sharing their thoughts in the whole-class discussion. The students' responses can be divided into two groups, of which Kenta's and Shun's contributions are representative:

- 75 Kenta: Um, um, [regarding question] number 1, [this] is because there is no explanation about whether  $y$  is proportional to  $x$  or inversely proportional. Um, if there are only points (2, 18) and (3, 12), equations are possible both for  $y = 6$  and  $-6$ . Um, if we interpret it as the graph of the inverse proportion of  $y = 36/x$ , um, we have 6. If we interpret it as the graph of the proportion of  $-6x + 30$ , we have  $-6$ , I think. Well, [regarding question] number 2, I think, we should add an explanation, like when  $y$  is proportional to  $x$  or when  $y$  is inversely proportional to  $x$ . [Kenta misspoke here. He meant linear functions when he talked about proportions.]
- 88 Shun: Um, because there are only two given points, the answer changes depending on whether we connect two points with a line or connect [them] with a curve. [Regarding question] Number 2, I think, if we determine the values of more than two points, the answer will be [uniquely] determined.

According to first group of students (illustrated by Kenta's comment), the reason for the answer to the task to be ambiguous was the absence from the task description a specification of the functional relationship between  $x$  and  $y$ ; the way this group suggested to address the ambiguity was to clarify the

relationship in the task. According to the second group of students (illustrated by Shun's comment), the ambiguity was because only two pairs of values were given in the task; the way this group suggested to address the ambiguity was to provide in the task more points with given values.

### Recognition of the necessity of assumptions

The teacher had anticipated these two kinds of student responses and made a planned move to address them, beginning with the second group's suggestion to increase the number of points with given  $x$ - and  $y$ -values. He plotted the points (2, 18) and (3, 12) on the coordinate plane on the blackboard and said: "Suppose that in the case of [...] 4, we have 6 [meaning  $y = 6$  for  $x = 4$ ]. Is this a linear function? We know three points." Here the teacher selected (4, 6), because the  $y$ -value is 6 when  $x = 4$ , if the function is assumed to be linear.

The alternative possibility of step functions was then proposed by Shota. Shota's suggestion greatly surprised other students, who later began to agree with him and acknowledged that, even if three pairs of  $x$ - and  $y$ -values were given, the function in the task could not be uniquely determined. Below is the whole-class discussion after Shota drew the graph shown in Figure 2.

**Figure 2: Step function drew by Shota (the dotted vertical line was added later by the teacher)**

- 138 Teacher: Well, in this case, what happens? This, this, well, what did you draw?
- 139 Shota: A step function.
- 140 Teacher: Oh, yes, thank you. Is this a linear function?
- 141 Students: No.
- 142 Teacher: Yeah. [...] In the case of 6, this 5, 6, the point in this case... [The teacher added the dotted vertical line in Figure 2, and suggested a question asking the  $y$ -value when  $x = 6$ .]
- 143 Nanami: Anything [would be] okay [meaning that the  $y$ -value can be any values].
- 144 Teacher: Can you predict [the value of  $y$ ]?
- 145 Nanami: Anything [would be] okay.
- 146 Moe: Like quite suddenly [it is] changing.
- 147 Nanami: It could change suddenly, it is changing.

In the above interaction, the students stated that even if another point (4, 6) was added to the table (Figure 1), the function could be a step function rather than linear, and that in this case, the  $y$ -value when  $x = 6$  could not be uniquely determined (lines 143, 145–147). The class thus realised that increasing the number of points was not a viable option to address the ambiguity in the task. The consideration of step functions motivated the class to seek another way to pin down the answer, returning to the way that was represented earlier by Kenta (line 75), i.e., specifying the functional relationship between  $x$  and  $y$  in the task. At the end, the teacher summarised the lesson as follows:

- 194 Teacher: Making this clear [meaning to specify the functional relationship] is good. I introduce this [pointing “in the case of a linear function” and “in the case of an inverse proportion” written on the blackboard], this, the one shown at the beginning is, [...] this is called an *assumption*, *assumption*. So, I believe you see that the answer becomes definite by this assumption.

In this comment, the teacher introduced the term *assumption* and clarified that the conditions, such as “ $y$  is a linear function of  $x$ ”, were assumptions one could make based on the task’s phrasing. He also mentioned that making the assumptions explicit was crucial for reaching a consensus answer. This is relevant to Learning Goal 2, which was reached by the class as illustrated by students’ comments at the end of the lesson when they summarised their learning. For example, Takumi said, “If there is no assumption [made explicit], even if we know many points, the graph cannot be fixed into one function’s graph”. Similarly, Yuka said, “If there is no assumption, different functions can be considered. So, when we want to make the answer definite, we write the assumption”.

## Discussion

In this paper, we described a classroom intervention involving ninth-grade students with a particular mathematical task (Figure 1), designed based on two principles (Principles 1 and 2). Our analysis showed that the task and its purposeful implementation were useful for stimulating the students to recognise that the correctness of their answers was relative to their respective assumptions (Learning Goal 1), and that it was necessary to make the assumption of the task explicit to reach a consensus answer (Learning Goal 2). Hence, the principles can be regarded as helpful for designing tasks that aim to help students appreciate the roles of assumptions in mathematical activity.

Although in this paper we focused on the role of task design in promoting particular learning goals, the results of our intervention highlight also the important role that the teacher played for achieving these goals. Prior to the intervention, we held meetings with the teacher to discuss the task, the two design principles, and to explain the task’s intended purpose. The teacher well appreciated the learning goals of the task and was able to devise a detailed lesson plan where he anticipated students’ responses to the task and planned some questions strategically, preparing himself to capitalise on these responses during the lesson so as to effectively manage students’ contributions and steer class progression towards the learning goals. The intervention played out in both classrooms as expected, thereby limiting the need for teacher to improvise and make in-the-moment decisions; the lesson naturally progressed towards the learning goals, while the students’ contributions were respected and were integrated into the discussions (Sherin, 2002).

A significant aspect of the teacher’s role was asking probing questions. For example, in response to students’ different answers ( $y = 6$  and  $-6$ ), the teacher asked, “What are the reasons for the answer to be ambiguous? What can we do to address the ambiguity?” These questions triggered students’ interest in exploring ways to obtain a consensus answer, and created an “intellectual need” (Harel, 1998) for the class to be introduced to the notion of assumptions. Another important aspect of the teacher’s role was orchestrating whole-class discussions (Stein, Engle, Smith, & Hughes, 2008). When planning the intervention, the teacher had predicted that some students would come up with responses similar to Kenta’s (line 75) and Shun’s (line 88). When implementing the intervention, the teacher ‘filtered’ and ‘sequenced’ the students’ responses (Sherin, 2002; Stein et al., 2008) so that

Shun's and Kenta's ideas were examined, one at a time, in the whole-class discussion. When the students understood that Shun's idea was not viable, he helped students recognize the advantage of Kenta's idea (line 75) to make explicit the functional relationship in the task.

# Primary students' reasoning and argumentation based on statistical data

Jens Krummenauer<sup>1</sup> and Sebastian Kuntze<sup>1</sup>

<sup>1</sup>Ludwigsburg University of Education, Germany; [krummenauer@ph-ludwigsburg.de](mailto:krummenauer@ph-ludwigsburg.de)

*Fostering students' competencies of reasoning and argumentation is an overarching goal of the mathematics classroom with relevance also for statistical contents. However, students' argumentation based on statistical data appears to have received less attention so far. In particular primary students' abilities concerning evaluating and generating their own data-based arguments have hardly been investigated. Our analysis of N=167 answers of primary students addresses this need for research and gives insights into students' abilities in generating data-based arguments and students' possible difficulties. The results, therefore, provide an evidence base that can inform subsequent intervention studies.*

*Keywords: Argumentation, statistics, primary school, scientific reasoning.*

## Introduction

Statistical data are often used as evidence for decision making in various domains of modern societies so that data plays a key role in decision-related argumentation. It thus can be seen as an important goal for the mathematics classroom to encourage primary students to enter into data-based argumentation. With the term *data-based argumentation* we refer to the process by which students critically evaluate data-related statements, and develop arguments, based on statistical data. In a prior study with N=385 fourth-graders (Krummenauer & Kuntze, 2018) we found that about one-third of the sample was able to develop at least one data-based argument. Consequently, as there is evidence that primary students can be able to develop data-based arguments, our earlier findings opened up the way to investigating now more closely students' abilities and the obstacles students encounter when they develop data-based arguments in different task-related contexts. For this reason, we newly designed a set of tasks adapted to the target group in order to further explore primary students' data-based argumentation. In this paper, we report on our analysis of an exemplary task of our newly developed test. In the following section, we first describe the theoretical background on key aspects of data-based argumentation and requirements students have to deal with when they develop data-based arguments. After having specified the research interest, we will report on sample and methods for a coding that afforded the analysis of students' answers. Finally, we present the results which will be discussed in a concluding section.

## Theoretical Background

One of the core aims of argumentation in general is 'to convince others that a statement is true or false' (Stylianides, Bieda, & Morselli, 2016, p. 316). Data-based argumentation can be seen as a specific case of argumentation in which statistical data is used to convince someone that a statement is true or false. In comparison to other argumentation situations such as mathematical proving (e.g. Boero, 1999; Hanna, 2000), data-based argumentation differs in nature, mainly due to the empirical methods used in the data gathering process. Moreover, dealing with phenomena related to statistical

variation (e.g. Watson & Callingham, 2003) leads to specific forms of data-based reasoning and argumentation; even seemingly contradictory statistical interpretations of data can be justified on the base of the same data set. A well-known example for this is the Simpson's paradox (e.g. Blyth, 1972).

However, there are also commonalities of data-based argumentation with generating mathematical proofs. In Toulmin's (2003) approach of analysing arguments, two basic elements of an argument are distinguished: the *datum* and the *conclusion*. The conclusion is a statement that should be substantiated by the argument. The datum is a set of facts which are taken to be true (p. 89–92). So, a core-structure characteristic of arguments is the distinction between available evidence on the one side and the statement that is being supported by the argument on the other side. Inspired by Toulmin's approach, we can structure data-based arguments in a similar way. In data-based arguments, the statement being supported by the argument is often an interpretation of data, or an evaluation of a given statement. The statement then is supported by statistical data, which takes the function of Toulmin's datum. Thus, a consistent connection of a statement with supporting statistical data is the core element of a data-based argument. Additional elements in Toulmin's framework, such as the *warrant* and the *backing*, which can be used to clarify why the conclusion results from the datum, can be assigned to analogous structures of data-based arguments.

These thoughts about the structure of arguments already point to a set of requirements for generating data-based arguments, which can be developed further. As laid out in Krummenauer & Kuntze (2018), requirements of data-based argumentation can be described under a scientific reasoning perspective (e.g. Bullock & Ziegler, 1999; Klahr & Dunbar, 1989; Kuhn, Amsel & O'Loughlin, 1988; Zimmermann, 2007). When students have to generate a data-based argument for evaluating a given statement (as is required in the task in Figure 1, for example), they have to consider the statement as separate from the statistical evidence contained in the available data. According to scientific reasoning, the statement has to be treated as a hypothesis which has to be rejected in case of contradiction with the data. For evaluating the statement on the basis of the statistical evidence the students also have to find out whether the evidence is confirming, contradicting, or irrelevant to the statement (cf. Sodian, Zaitchik & Carey, 1991). In case of relevance, if the data provide evidence contradicting the statement, the statement has to be rejected.

At first sight, these requirements appear as very complex. In particular, it might be expected that younger children lack the necessary skills for mastering such requirements. However, prior empirical research has shown that even primary students already have prerequisites for scientific reasoning and that fostering such skills is possible in primary school (cf. Bullock & Ziegler, 1999; Kuhn, 1989; Sodian et al., 2006; Zimmerman, 2007). On the other hand, these and other studies also show that children often use deficient strategies, such as a positive test strategy, which means that they may seek only for evidence which confirms their prior assumptions. It also has been observed that children tend to accept hypotheses too hastily (e.g. Kuhn et al., 1988; Bullock & Ziegler, 1999; Klahr & Dunbar, 1989) and that they are influenced by their prior views, knowledge and preferences when they evaluate a statement. In contrast, an important strategy for dealing with data-based statements is to challenge them actively by searching for aspects in the data which contradict the statement (Kuntze et al., 2013).

Against the background of such findings it appears as a feasible endeavour to foster primary students in their data-based argumentation, so that the above-mentioned goals can be considered as realistic. Still, the successful development of learning environments requires a fundamentally sound empirical knowledge base about students' abilities and their answering patterns when having to develop data-based arguments.

## Research aim

Our analysis consequently addresses this research need. The core aim is to investigate primary students' abilities with respect to data-based argumentation and the obstacles that might prevent them from developing consistent data-based arguments. This leads to the following research questions:

- (1) To what extent do primary students generate consistent data-based arguments?
- (2) Is it possible to assign those answers, which do not fulfil the requirements, to categories which represent different types of answers?

## Design and Sample

The analysed task, shown in Figure 1, is part of a newly designed test instrument used in a test with  $N=167$  students from southern Germany at the end of the fourth grade (91 female, 76 male; average age  $M=10.4$ ,  $SD=0.57$ ). The task requires to evaluate whether the headline matches the diagram. As a justification is asked ('Justify your answer'), the students have to develop at least one consistent argument based on the data, as these are the only appropriate source of evidence for the required

**Figure 1: Analysed task (translated)**

evaluation. The meaning of the word 'justify' was explained in a standardised instruction before the test.

The analysis of the students' answers to the task combines a top-down coding (double coded, inter-rater reliability:  $\kappa=.91$ ), which is derived from a coding we had already successfully applied in a prior study (cf. Krummenauer & Kuntze, 2018), with a bottom-up analysis for exploring possible difficulties of the participants. To answer the first research question, we analysed in a first step whether the students' answers comply with the requirements of the task. Therefore, we analysed the structure of the arguments in the answers with a scheme inspired by Toulmin's (2003) approach. A successful answer was expected to contain, at a minimum, one data-based argument consisting of a conclusion expressing a negative evaluation (e.g. 'no', or 'the headline does not match the diagram') as well as a datum in the form of a consistent reference to aspects of the data which are appropriate to substantiate the conclusion. Additional elements like a warrant or a backing are not required if a consistent connection between the datum and the conclusion can be clearly reconstructed in the context of the task. In a second step, all answers which did not fulfill these requirements were subjected to an interpretive bottom-up analysis to provide answers to the second research question. For developing a set of distinct categories we followed

Mayring's (2015) approach of inductive category formation; again, taking into account the key elements of Toulmin's (2003) approach.

## Results

The top-down coding shows that 40% of the participants gave an answer which completely met the requirements of a successful answer described in the prior section. Figure 2 shows an answer from this category:

**Figure 2: Example of a successful answer (1)**

The answer starts with the statement 'no' which is to be taken as a direct response to the question in the task. Following the key elements of Toulmin's terminology, the statement 'no' functions as a conclusion and signalizes that the headline in the task has to be rejected. The second part of the answer ('from 1948 until 1957 the gasoline price was the same') contains a statement which refers to aspects of the given diagram. With the conjunction 'because' the student connects the conclusion with the reference to the datum and indicates that the reference substantiates the student's conclusion. Therefore, the reference to the data functions as a datum to substantiate the conclusion.

Figure 3 shows another example of an answer rated as successful. It also starts with a conclusion 'no' and also gives a reference to the given data set ('the prices also decreased from time to time'). In spite of the fact that there are no concrete points of data mentioned, in consideration of the given diagram the analysis yields that the student refers to several points of the data set where the trend line decreases. In contrast to the answer in Figure 2, there is no conjunction which links the conclusion with the reference to the data, but the function of the reference as a datum appears as it was asked for a justification in the task.

**Figure 3: Example of a successful answer (2)**

In both cases shown above, the reason why the datum substantiates the conclusion remains partly implicit. For example, to understand the argument in Figure 3, the contradiction between the statement ('gasoline prices *always* have been rising') and the temporary decline of the prices found in the data has to be considered.

In this context, we would like to note that it is not always necessary to give a warrant or a backing for all connections with data, and that in cases of an evident contradiction between given statement and data the justification required for an argument can be rated as successful. Following Jahnke & Ufer (2015) it is neither helpful nor even possible to refer to all single necessary steps of inference within an argument (cf. p. 332–333). Therefore, the appropriateness of an argument is not only a question of consistency of the argument, but also a question of social convention on what level of justification an argument can be accepted as evident (ibid.). As stated in the previous section, an

argument was rated as successful if it contains at least: 1) a conclusion; 2) a consistent reference to the data; and, 3) if the logical connection of conclusion and datum in the context of the task can be reconstructed.

Besides such answers rated as successful we were able to identify several sub-categories within the answers which did not fulfil the requirements of the task. 5.4% of the sample gave no answer at all; 9.0% were assigned to the category of non-codable answers, which means that the answer was unreadable or the content of the student's answer could not be reconstructed in the context of the task. Further, 9.6% gave an evaluation whether the statement in the headline matches the diagram, but without any justification of their answer; 5.4% gave a context-based answer which means that their answers are based on considerations concerning the context without a reference to the given data. Further, 0.6% developed a mixed data-based and context-based argumentation; 22.8% of the analysed answers were assigned to the category *confirmatory argumentation with selective use of data*. This category includes all answers in which selective aspects of the data are used to generate a confirmatory argument supporting the statement in the headline. In a further 3.6% of the answers, aspects of the data were mentioned in a consistent way, but an inconsistent conclusion is drawn. Another 1.2% of the answers also contained a consistent mentioning of the data, but no clear implication for the evaluation of the statement in the headline is provided. 2.4% of the students' based their argumentation on an inconsistent interpretation of the data set. For example, one of the students who committed this error interpreted the scale on the ordinate axis as the development of the prices. Figure 4 gives an overview of the composition of all analysed answers. In the following we give more detailed insights into examples of students' answers for the most frequent categories developed in the bottom-up analysis.

**Figure 4: Combined results of the top-down coding and bottom-up coding (N=167)**

Figure 5 shows an example of the category 'Evaluation without justification'. In Toulmin's terminology, the answer only contains a conclusion ('Yes the headline is ok') but no other element of an argument. The student does not justify his evaluation of the given headline in any way.

**Figure 5: Evaluation of the statement without substantiating by argumentation**

Figure 6 shows an example of a category of answers in which correct data is mentioned but a false conclusion regarding the evaluation of the statement is drawn. In the first part of the answer ('sometimes, they went down but they also went up often') a reference to the data is given. The conjunction 'so' indicates that the student draws a conclusion ('the headline is correct') based on the mentioned data. However, this conclusion is not consistent with the given reference to the data as the observation that the prices sometimes 'went down' contradicts the statement that the gasoline prices *always* have been raising. Thus, the criterion of a consistent connection of the data and the evaluation of the statement in the headline is not met.

*Manchmal sind sie tiefer gegangen aber auch oft hoch gegangen also ja die ist so Schrift ist richtig*

Translation:

,Sometimes, they went down but they also went up often, so yes, the headline is correct.'

**Figure 6: Correct mentioning of data, but wrong**

Figure 7 shows an answer, in which a student connects her conclusion with particular aspects of the data-set, providing confirming evidence for the conclusion given by the student. How-

ever, the student's analysis of the data remains incomplete, as the word "always" in the given statement shown in the headline implies that all the data in the diagram needs to be considered. This student mentions two values of the data set which support the statement of the headline. The fact that the mentioned data is correct (30ct and 1.70€) suggests that the student was able to read data from the diagram and to understand this data in the context. At the same time, the student appears to neglect other data which would have been necessary to consider in order to generate a consistent argumentation. In this case, the argumentation attempt does not fit to the meaning of the statement presented in the headline ("always"), which makes it inconsistent with what had to be justified. The student might not fully have understood the statement given in the headline. Other possible interpretations are that the student has not searched for counter-evidence in the data but for confirming evidence only or that she might have ignored the counter-evidence as it contradicted her own view.

*Ja sie passt weil die Preise sind ja gestiegen von 30ct bis 1,70€*

Translation:

,Yes it [the headline] fits because the prices increased from 30ct to 1.70€'

**Figure 7: Selective use of aspects of data to confirm the statement**

An important aspect in (data-based) argumentation is the choice of a source of evidence. Figure 8 shows an example of a category of answers in which the students do not use the given data as evidence but their own considerations about the context. The answer in Figure 8 starts with a conclusion ('yes') which is connected by the word 'because' with a context related statement 'today cars consume more fuel than in the past'. The conjunction 'because' indicates that the statement may be intended to function as a datum. However, the task is designed in such a way that the given data needs to be used as the source of evidence: The task does not require the student to evaluate the statement in the headline in general, but to evaluate whether the statement matches the diagram. Therefore, the given context-related explanation is not an appropriate datum to substantiate the required evaluation. However, the student apparently had the opinion that his context-based explanation is relevant to justify his evaluation. It is to assume that the given conclusion might not refer to the asked question, but to an evaluation of the statement in the headline in general. The given context-based explanation, from a scientific reasoning perspective, also can be seen as a hypothesis which was too hastily accepted.

Translation:

,Yes, because today cars consume more fuel than in the past'

**Figure 8: Context-based argumentation**

## Discussion and Conclusions

The results show that 40% of the sample were able to evaluate a statement by generating a data-based argument. This shows that these students were not only able to apply basic activities such as reading data from a diagram but that they were able to use statistical evidence for evaluating a statement by developing a data-based argument. Against the background that the data of this study were gathered without a preceding intervention, it appears as a feasible endeavour to further foster primary students in their data-based argumentation. For this, the results from the bottom-up analysis provide a starting point to inform prospective interventions for fostering primary students with this concern.

The analysis revealed that about a quarter of the sample used selective aspects of the data to confirm the statement given in the headline despite the fact that there is pertinent counter-evidence against the statement. The answers of these students show that they are principally able to understand the given statement, to read data from the diagram, and to draw the logical conclusion that the aspects of data they quote confirm the statement. The difficulty of these students might be located on a meta-knowledge level: We assume that they did not challenge the given statement actively and did not search for counter-evidence in the given data. Answers containing context-based argumentation and those with an inadequate conclusion drawn on the basis of adequately mentioned data also indicate difficulties which can be explained from the scientific reasoning perspective as described in the theoretical background section. As we found indications for similar answering patterns already in our prior study (Krummenauer & Kuntze, 2018), fostering students' meta-knowledge related to scientific reasoning appears to be a promising approach which will be investigated in an intervention study.

As the participants of our study were tested at the end of year four of primary school, the question arises how their abilities might differ from those of students from lower grades. To this, we already started a follow-up study with a sample of 42 third-graders which solved the same task as the fourth-graders. A first top-down coding of the answers shows that a similar percentage of the sample were able to develop data-based arguments as required in the task. Further in-depth analysis of the students' answers is in progress. Beyond this, an interview study with first graders at the time of their entry in school is in preparation to investigate to what extent students at the beginning of their first year in primary school are already able to develop arguments based on statistical data.

<sup>2</sup>University College Copenhagen, Denmark; [choe@kp.dk](mailto:choe@kp.dk)

*Statistical reasoning has often been used synonymously with statistical thinking. In this paper, we focus on the reasoning part and we analyse mathematic lessons about statistics in a primary school class, using a construct from the Anthropological Theory of Didactics approach, called Study and Research Paths. By comparing the a priori tree-diagram of the course with the a posteriori tree-diagram of the observed teaching, it becomes clear that the teacher's questions never make the students engage in statistical reasoning and the students' questions are more concerned with practical and organizational issues than with obtaining a greater understanding of statistical reasoning.*

*Keywords: Mathematical reasoning, statistical reasoning, study and research path.*

### Introduction

Teaching reasoning and justification requires more than just asking students to explain their answers or to pose open problems (Ball & Bass, 2003). Teachers' and students' questions and answers are crucial. This paper contributes further insight into teaching reasoning in elementary mathematics classrooms by analysing a teacher and students' questions and answers during a statistics course. We aim to contribute to a more systematic methodology to study what actually takes place in the classroom and to determine if it is possible to do this by looking at the questions and answers of students and teachers during their lessons.

To analyse the students' reasoning processes in the classroom, we will use a tool from the Anthropological Theory of Didactics (ATD), namely, Study and Research Paths (SRP). SRP provides to model mathematical knowledge from a didactical perspective (Chevallard, 2006). The analysis needs detailed information about context, contents, order of questions and answers. In the last decade several studies has focused on the potentials of SRP; Winsløw, Matheron, and Mercier (2013) examine how SRP and a new diagrammatic representations can be used to analyse didactic processes; Barquero, Bosch, and Romo (2015) illustrate how SRP can be used in professional programs for teachers; and (Jessen, 2017) studies how SRP can support the development of knowledge in bidisciplinary settings.

We investigate whether the teacher and the students ask questions and answer questions in a way that allows the students to engage in mathematical reasoning related to statistics; we also reflect on the potentials and limitations we found when using SRP as an analytical tool. More precisely, we ask the following research question: What is the content of the students' and teachers' questions and answers in the "Youngsters and ICTs" intervention, and does it support the students' opportunities to produce statistical reasoning?

## **Theoretical considerations: mathematical and statistical reasoning**

Researchers and educators around the world have advocated that a primary goal of mathematics education for all grades should be the development of mathematical reasoning (Ball & Bass, 2003). Nevertheless, there is no consensus about the definition of mathematical reasoning in the research literature (Jeannotte & Kieran, 2017; Mariotti, Durand-Guerrier, & Stylianides, 2018). Reasoning in statistics can be seen as a particular form of reasoning in mathematics. del Mas (2004) argues that mathematical and statistical reasoning should place similar demands on a student and should display similar characteristics when the students are asked to reason with highly abstract concepts. At first, mathematical and statistical reasoning appear to be similar, but the nature of the tasks in statistics and mathematics are somewhat different. In mathematical reasoning, context may not play a large role, but in the practice of statistics, the inquiry will always be dependent on data and typically grounded within a context (del Mas, 2004). Statistical reasoning is often used to define the same capabilities as statistical thinking, but Ben-Zvi and Garfield (2004) try to separate the two concepts. They define statistical reasoning as “understanding and being able to explain statistical processes and being able to fully interpret statistical results” (p. 7). Statistical thinking, on the other hand, involves an understanding of why and how statistical investigations are conducted, and also when to use appropriate methods of data and analysis. Both statistical thinking and reasoning can be involved when working on the same task, so the two types of activities cannot necessarily be separated. del Mas (2004), however, writes that it is possible to distinguish them through the nature of the task: “For example, a person who knows when and how to apply statistical knowledge and procedures demonstrates statistical thinking. By contrast, a person who can explain, why a conclusion is justified demonstrates statistical reasoning.” (p. 85). Brousseau and Gibel (2005) argue that the teaching of reasoning used to be conceived as a presentation of model proofs, which then had to be faithfully reproduced by the students. Teachers today see reasoning as an activity, which cannot be learned as a simple recitation of a memorized proof; instead, it is necessary to confront students with problems, where they naturally engage in reasoning. If students are presented with model-proofs today, they are meant to serve as a model of others’ reasoning, which students then can use to produce their own original or creative forms of reasoning. However, as Brousseau and Gibel (2005, p. 14) noted, “There is always the risk of reducing problem solving to an application of recipes and algorithms, which eliminates the possibility of actual reasoning”. When it comes to statistical reasoning, most teachers tend to teach concepts and procedures and hope that reasoning will develop as a result (Cobb & McClain, 2004). Cobb and McClain (2004) argue that, in statistical reasoning, students must reason about data rather than attempt to recall procedures for manipulating numerical values.

## **Study and Research Paths**

Study and Research Paths (SRP) is a recent construct in the Anthropological Theory of Didactics (ATD) (Chevallard, 2006). Within ATD SRP were introduced as a design tool for teaching within the paradigm of “Questioning the world” (Chevallard, 2006). The aim is to focus on important and meaningful “big” questions and not just “visit monuments”, meaning a set of rules prescribing, what is to be studied with no place to raise “What for?” or “So What?” questions (Chevallard, 2006).

The fundamental dialectics between questions and answers are at the root of the idea of SRP (Winsløw, 2011). A group or an individual develops knowledge as a result of working with an overall question, Q. Students identify the “official” knowledge that can help them answer Q; the students use this “studying” to justify their answers to Q by engaging in reasoning, which is the “research” about Q. Elaborating on Q generates the “path” (Winsløw et al., 2013). SRP is normally used to design lesson plans but Winsløw et al. (2013) introduce SRP as a modelling tool to analyse didactic processes. Jessen (2014) argues that a tree-diagram of the SRP is a strong tool for analysing didactical processes. We will use a tree-diagram (an example can be seen in figure 1) to make a SRP analysis in an elementary mathematics classroom. Conducting a SRP a priori analysis entails exploring what questions and answers could occur from one particular overall question (the generating question, called Q0). The tree-diagram refers to the possible path the students could follow after generating Q0. The Q0 must be so strong that students can derive new questions, Qi, from it. The answers to the derived questions add up to an answer to the original question, Q0. The Q0 must be of real interest to the students. This continues with more questions and more answers and

**Figure 1: An example of a SRP tree-diagram**

could leads to a tree-diagram of pairs of questions and answers (Jessen, 2014). The questions in black are ask by the teachers, and the questions in white are made by the students. The grey-coloured questions are those that are created in collaboration between the teacher and the students. The numbers next to the questions and answers indicate the order of the questions. In the SRP-process the media-milieus dialectics must be taken seriously: the information the teacher brings into the class; the answers available through different books, articles, videos or online resources; and the classroom milieu where the teacher and students manage to establish meaningful actions.

### “Youngsters and ICTs”

“Youngsters and ITCs” is a 15-lesson statistics course, which is taught over 3 weeks and intended for grade 6 students; it was designed by C. K. Skott and the second author of this paper, (Skott & Østergaard, 2016)<sup>1</sup>. Before teaching the course, the teacher participated in a professional development workshop (6 lessons) that focused on statistical reasoning and digital technologies. The purpose of the course is to improve students’ reasoning in statistics. The course frames and proposes ways that teachers can engage students in statistical investigations; formulate statistical problems; generate, analyse, and reason about data; interpret results; and disseminate them both inside and outside of a school context. The emphasis of the course is to create new habits of classrooms interactions, in which the students raise questions and explore the context with their teacher, who challenges them to come up with new questions and reflect further on possible answers. This approach breaks away from teaching a succession of more or less independent “chapters” where only “small” questions are raised.

<sup>1</sup> The lesson plan (in Danish) is available at:

<http://auuc.demonstrationsskoler.dk/materialer/innovation/forloeb3/faser/hvordan-bruges-statistik-i-hverdagen>.

## Methodological approach

We employ a micro ethnographic design; this kind of approach is well-suited for describing, analysing, and interpreting a specific aspect of a group's shared behaviour (Garcez, 1997). We use a case study research design to obtain a thick description of the observed teaching and to understand, how all the questions and answers in the classroom operate together in this context, which is part of a complex system (Stake, 1995).

Within a two-year period, we observed a teacher in 31 classroom lessons; 16 observations from the course and 15 from before or after the course. All the observed lessons were video-recorded. Four audio-recorded semi-structured interviews with the teacher were conducted. The choice of semi-structured interviews was chosen to get a deep understanding of the background of the classroom context. All the interviews were transcribed, and 15 lessons selected from the observations were transcribed.

### "Children and young people spend too much time on media ... or?"

"Youngsters and ITCs" was not originally designed as an SRP project. The course was designed by the five design principles by Cobb and McClain (2004) including using technology to support students development of statistical reasoning, establishing norms for students statistical argumentation and the importance of making students explore realistic data - in this case questioning the students media habits, which can be compared with "Questioning the World". The overall question that "Youngsters and ITCs" asks is: "Children and young people spend too much time on media ... or?" (Q0). To answer the overall question, the students must explore the TV patterns and the media habits of each student in their class through a circular working process, which entails collecting data, analysing data, and making conjectures about habits to discuss whether or not the students spend too much time on media. A really important part of the work is to justify how and why the students' conjectures are accurate or true.

The institutional framework for the lessons analysed and presented in this paper is a small elementary school in Denmark. The teacher, Ea, is an experienced mathematics teacher. Her normal teaching is dominated by working with skills framed by a textbook or by iPad exercises. Ea characterizes herself as "a bit old-fashioned. I think it is most important they have skills". When describing dialogs in the classroom, Ea explains, "I fail to tell them anything in twenty minutes ... I do not think they listen when I stand at the blackboard".

In the present article we analyse two lessons (2x45 minutes) of the course (Q3). In this section, the students investigate a set of data that includes 49 students' TV-consumption. They analyse and interpret the data, and make a conclusion, based on that background, about whether the students watch too much TV. The idea is, that the students can use their experiences from the smaller dataset in (Q3), when they work with the authentic and more motivational question Q0. The students are explicitly asked to explain and justify their conclusions.

### Presentation of the a priori and a posteriori diagrams

A comparison between the a priori and a posteriori diagrams illustrates (respectively, Figure 2 and Figure 3) how the intended teaching goals and the actual enacted lessons are different:

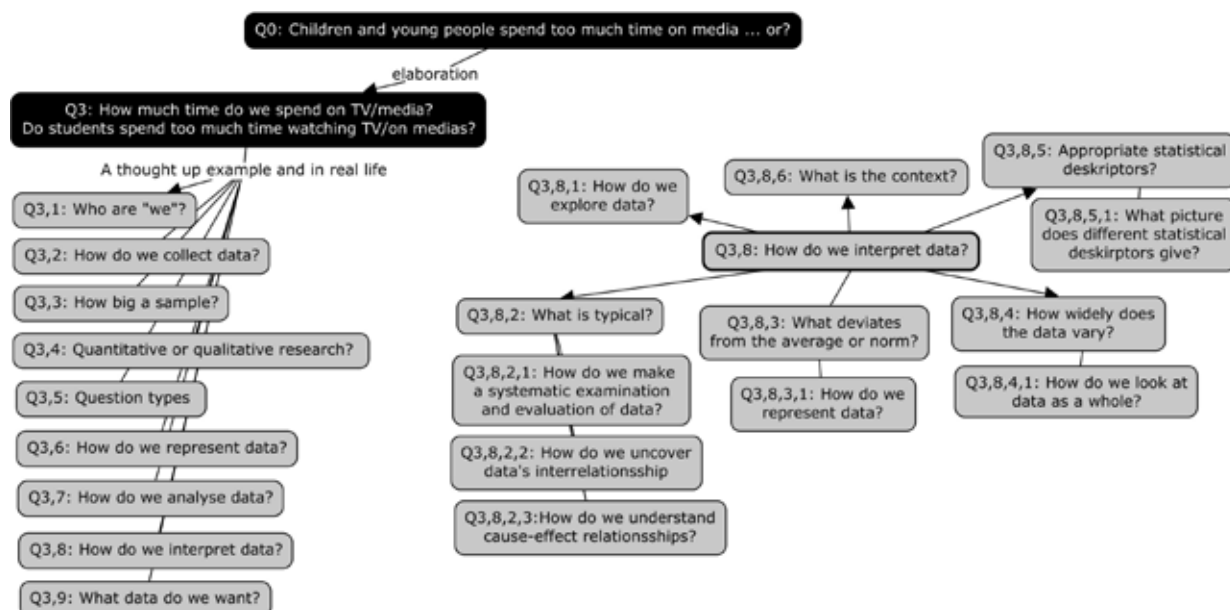

Figure 2: The a priori tree-diagram of the course, Youngsters and ICTs, for Q3

In Figure 2, it is evident that we expect the students to consider and ask many questions in collaboration with the teacher. All the questions from Q3,1 to Q3,9 have extensions like the one shown for Q3,8 to the right. The expectation is that the students' answers will include an explanation of their results and of their choices of models/representations, and that students will use statistical arguments to justify their claims when they generalise about conjectures.

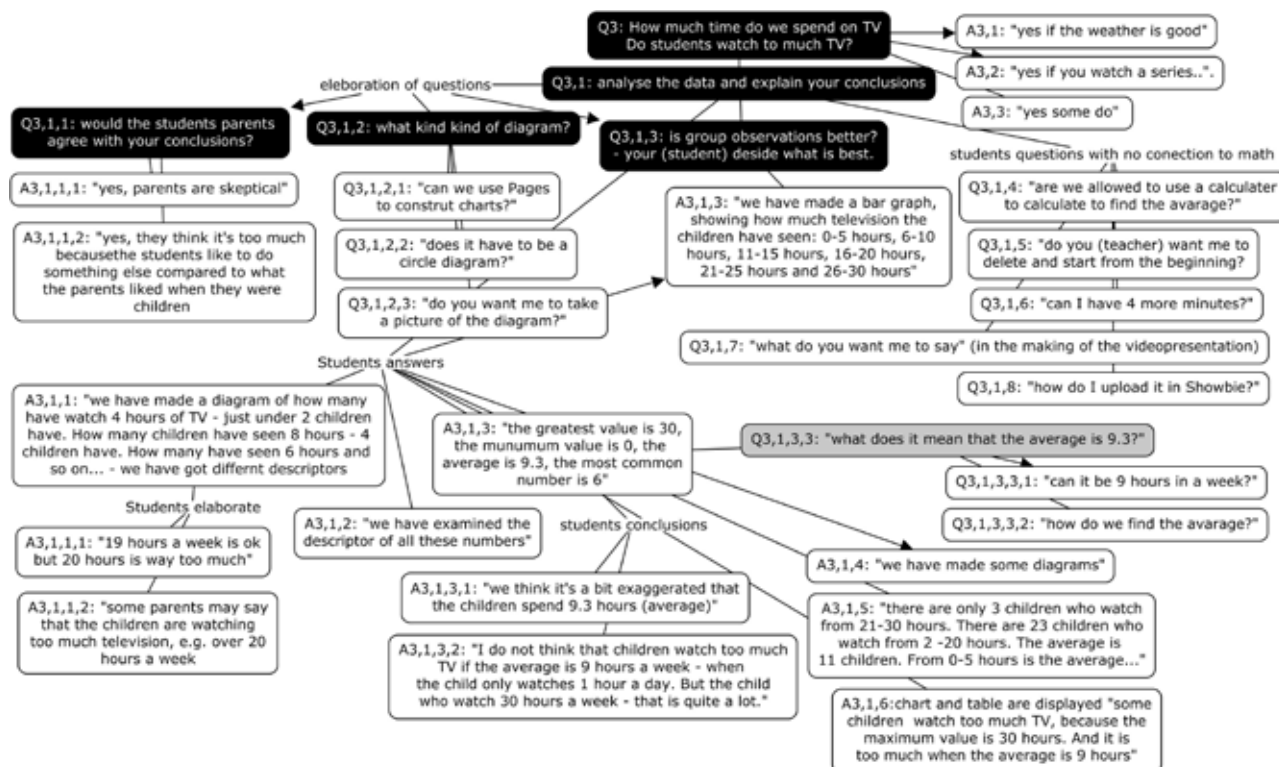

Figure 3: The a posteriori tree-diagram for Q3 in the observed classroom

The posteriori tree-diagram of the observed classroom is constructed by analysing the collected observations from the classroom. Q3 is a question from the teacher Ea, which give rise to three quick answers from the students (A3,1, A3,2, & A3,3) and one new question from Ea (Q3,1). Q3,1 produces six answers (A3,1,1- A3,1,6), and six new questions (Q3,1,1 – Q3,1,8), all with no connection to mathematics. We only see a few questions from the students that focus on specific solutions and procedures (e.g. Q3,1,3,3,1 – Q3,1,3,3,2).

### **Comparing the a priori tree-diagram with the posteriori tree-diagram**

In comparing the two tree-diagrams we do not see any of the expected questions (Q3,1-3,9) from the a priori tree-diagram. Ea does not ask many questions in this lesson, although she does ask a interpretative questions such as Q3,1.1: “Would the students’ parents agree with your conclusions?” The questions Ea asks, do not enable the students to elaborate, explain, or justify their choices. Instead the students answer Ea’s questions with examples from their everyday life and their beliefs about what parents think. In the posteriori tree-diagrams, it also becomes clear that the students ask many questions that are organizational and procedural, including Q3,1,8 (“How do we upload in Showbie?”) and Q3,1,7 (“What do you want me to say [in the presentation]?”). Studying the students’ answers in the posteriori tree-diagram, it is possible to see that there are not any answers that include statistical argumentation like the questions in the a priori tree-diagram Q3,8. Mostly, the students use their own rationale as argumentation: “19 hours a week is ok, but 20 hours is way too much” (A3,1,1,1). However, some answers include calculations of different descriptors, like A3,1,3: “The greatest value is 30, the minimum value is 0, the average is 9,3 and the most common number is 6.”

### **Discussion**

The tree-diagrams reveal a lot of answers that indicate that the students may be unaware of the purpose of the generating question, how to ask questions, and how to answer those questions. The students answer the question, Q3, immediately without any inquiry and without any mathematical argumentations. For example, they say, “yes, [children watch too much TV] if the weather is good” (A3,1), or “yes, [children watch too much TV] if they watch a series” (A3,2). These quick answers could indicate that the students have not understood the premise about “inquiry” that is crucial to this type of investigative work, and the SRP does not contribute to establish a milieu with new norms for working with statistical argumentation. The tree-diagram indicates that the students do not discuss appropriate statistical descriptors. The students simply repeat an approach to analyse data that they have made in earlier lessons by calculating descriptors. Most of the students found the average number of hours spent on media without using any argumentation whatsoever for why it makes sense to calculate the average number of hours or what the average actually says about the dataset. The interpretation of what actually happens in this class may be characterized as ‘model reasoning’ (Brousseau & Gibel, 2005). Overall, the a posteriori tree-diagram does not indicate any joint dialogue in which the students raise questions and explore the context in collaboration with their teacher, who challenges them to create and reflect further on their statistical reasoning. However, we do see that the students apply statistical knowledge and procedures and demonstrate statistical thinking, e.g. when the students draw up charts (A3,1,6), fill tables (A3,1,4), and calculate descriptors (A3,1,3,2). Therefore, this approach can be seen more as “visiting monument” than “questioning the world”

(Chevallard, 2006). To understand the students' development of statistical reasoning, it was rewarding to use SRP as an analytical tool. It helped us to distinguish different strategies for raising and answering questions and to interpret the content in the questions and answers. However, the SRP model has not helped us to clarify the amount of time spent on the different questions and answers and to know if certain areas received a greater focus. The teacher's treatment of students' answers and the possible feedback of students' answers are not visible. Finally, in the model we do not explicitly focus on medias and the lack of integrating new medias, and we do not include the teacher's explanations and introductions; e.g. Ea explicitly explained how to make a frequency-table: "So you start counting how many one hours there are in the survey, and then you type the number here...[points at the Excel sheet]." Ea also explicitly explains how to calculate the average: "... to figure out how much the average is in this week per day - you just sum it together and divide it by seven." To make the diagrams, the teacher explains: "Just get Excel to make the diagrams for you by plotting the numbers in the sheet." These instructions can possibly be seen as a basis for 'model reasoning' and are therefore very important for the interpretation of the students' reasoning processes.

The gap between the a priori and the a posteriori tree-diagrams is in many ways not surprising. Ea participated in the 6-lesson professional development workshop and she worked collaboratively with her colleague during this program, but the intended statistical course is very different compared to Ea's normal teaching method and the milieu established in the classroom, which mostly focuses on mathematical skills. It is also important to notice, that the students also experience a very different way of learning mathematics; an approach, which no matter what, stresses some adaptation. The statistical course challenged Ea's view of classroom dialogs and it was difficult for her to establish new practices: "We'll take the arguments afterwards, because we'll first see all the presentations." However, in the end of the lesson Ea did not prioritize to hear the argumentation from the students.

## Conclusion

The comparison of the two SRP tree-diagrams displaying the teacher and the students' questions and answers show that the content was focused more on 'model reasoning' and statistical thinking and that the course in many ways did not support the students' opportunities for production of statistical reasoning. The SRP tree-diagram has been found to be a convincing tool for analysing classroom practice. A comparison of the two diagrams provides a rich view of the questions and answers in the classroom, which is closely connected to the students' development of statistical reasoning; however, the use of the model had limitations, in the sense that we did not directly include media aspects as feedback, explanations, and introductions. It could nevertheless be interesting to design a "tree diagram" including not only question and answers, but which also include feedback, explanations and introductions and study if this model in any way gives a deeper understanding. Furthermore, it could be interesting also to focus on the processes and relations between the questions and the answers – to explore why the students respond as they do?

# Factors influencing teachers' decision making on reasoning-and-proving in Hong Kong

Chun Yeung Lee

University of Oxford; [chun.lee@education.ox.ac.uk](mailto:chun.lee@education.ox.ac.uk)

*A project is ongoing to develop an intervention that promotes the teaching and learning of reasoning-and-proving in teacher education in Hong Kong. Since the area of reasoning-and-proving in Hong Kong has not been widely studied, this paper reports the first research cycle of the project: to investigate the potential factors that limited reasoning-and-proving activities in Hong Kong classrooms. In this cycle, seven secondary mathematics teachers were interviewed. The participating teachers' perceptions of reasoning-and-proving, students and learning cultures in Hong Kong were examined, and the results indicate factors that may contribute to the marginal situation of reasoning-and-proving in Hong Kong school mathematics.*

*Keywords: decision making, Hong Kong, reasoning-and-proving, teachers' perceptions*

## Introduction

Proof can verify the truth of a mathematical statement and may also promote students' sense making and conceptual understanding in mathematics by providing epistemological justifications (Harel, 2018; Knuth, 2002). Consequently, many mathematics educators suggest that teaching and learning proof and proof-related reasoning activities should spread through school mathematics at different levels and in different content areas. Noting that teachers are the key decision makers of what the students will experience in the classrooms, many studies have been conducted to examine teachers' knowledge and perceptions of proofs (e.g. Knuth, 2002). Yet, reasoning-and-proving (RP, see Stylianides, 2008) tends to have a marginal place in school mathematics. Whilst Western mathematics educators attribute this situation to teachers' counterproductive mathematical knowledge and beliefs about RP, and established mathematical cultures of the schools (e.g. Stylianides, Stylianides, & Shilling-Traina, 2013), studies on factors that influence teachers' decisions around RP activities are scarce in East-Asian countries (e.g. Hong Kong, Singapore, South Korea). The author has begun a project aimed at developing an intervention that promotes teaching and learning RP in teacher education in Hong Kong. Since the area of RP in Hong Kong has not been widely studied, the first research cycle focused on the context, Hong Kong. This paper intends to report the findings of this cycle. This cycle aimed at investigating the factors that limited the teachers' decisions on teaching and learning RP in the situation of Hong Kong classrooms.

## The context: Hong Kong

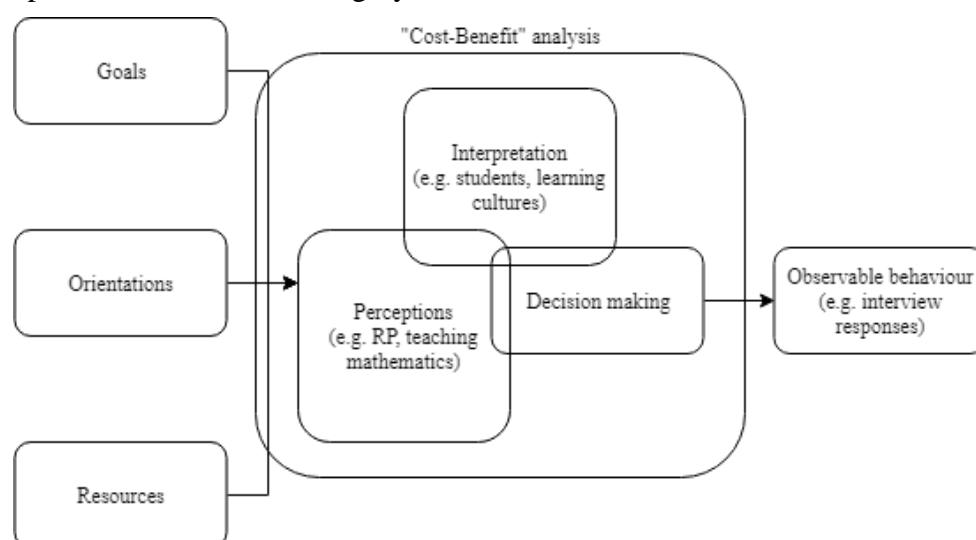

According to the official documents of the Education Bureau, the mathematics education curriculum in Hong Kong aims to develop students' "(a) ability to think critically and creatively, to conceptualise, inquire and reason mathematically, [...]; (b) ability to communicate with others and express their views clearly and logically in mathematical language; [...]" (CDC & HKEAA, 2015, p. 2). Despite the lack of an explicit statement, readers may find some implicit indications of teaching RP among these curricular aims.

Like other East-Asian countries, teachers in Hong Kong are often the primary decision makers of what students would experience in mathematics class through lesson preparation and in-the-moment teaching approaches. Teachers' decisions can be influenced by their perceptions and interpretation of the situation, for example, mathematics and RP, students, and the learning culture (Stylianides et al., 2013). Whilst learning culture in Hong Kong is said to be examination-oriented, which may have influenced decisions on school curriculum and assessments (Brown, Kennedy, Fok, Chan, & Yu, 2009; Choi, Lam, & Wong, 2012), studies have not been widely conducted in Hong Kong to investigate how a teacher's lesson preparation and in-the-moment teaching approaches are influenced by this culture. This study aims at examining the factors limiting or promoting teachers' decisions around teaching and learning RP, with respect to their perceptions of teaching RP, students and the learning culture. As a research cycle of a design-research project, the findings in this study will inform the development of an intervention.

## Theoretical backgrounds

To investigate teachers' decision making around teaching, researchers often examined the relationship between teacher's beliefs, knowledge and practice. Conner (2017) examined the differences in argumentation between two U.S. classes, and suggested these differences might be attributed to the teachers' intentions regarding the components of rationality. Kempen and Biehler (2015) investigated 12 pre-service teachers' perceptions of the generic proof, and reported that participants' preference for formal proof over generic proof in a task might be attributed to the situations that they adopted the construction of a formal proof as a norm for solving the task during their time in school, or they (mis)interpreted that construction of a formal proof was asked in the task. These results indicated that teachers' belief constructs could be complex and influenced teachers' teaching practices. However, the process of decision making and transition from teachers' belief constructs to practices were not thoroughly discussed.

**Figure 1: Model of teacher's decision adopted from Blömeke et al (2012) and Schoenfeld (2011)**

Blömeke, Gustafsson, and Shavelson (2012) and Schoenfeld (2011) attempted to model teachers' decision making. In the model of Blömeke et al. (2012), when teachers' perceptions are affected by their belief and knowledge constructs, their interpretation of the context may mediate between their

perceptions and decision making (and practices). Schoenfeld (2011) further elaborated the process of transition and decision making using the conceptualisation of goals, orientations and resources; he defines resources (with a focus on knowledge) as “the set of intellectual, material, and contextual [information] available to the teacher” (p. 10) and orientations as “an inclusive term encompassing a group of related terms such as *dispositions, beliefs, values, tastes, and preferences*” (p. 29, italics added). I adopted the models of Blömeke et al. (2012) and Schoenfeld (2011): if teaching RP is a routine practice of a teacher, the teacher will continue this routine practice; otherwise, if teaching RP is an unfamiliar practice of the teacher, the teacher will perform a *cost–benefit* analysis on different options using the variables (perceptions and interpretation), and the decision will be based upon the outcomes of the *calculation of expected values* on the options. Figure 1 depicts a model of a teacher’s decision adopted from Blömeke et al. (2012) and Schoenfeld (2011).

## Methods

Seven secondary mathematics teachers participated in this study. These teachers were selected because: (a) they obtained related undergraduate degrees and gained their teacher qualification through postgraduate teacher training programmes; (b) they have been serving local schools differed on locations, school cultures and students’ academic achievements: in Hong Kong, secondary public/government-aided schools and students are divided into three school bands regarding their academic achievement. One participant was serving high-achieving schools, two in mid-achieving schools, two in low-achieving schools, and two were serving private schools that do not belong to any school band; (c) they had worked at schools for at least three years; and (d) they had served at least two schools. Their diverse backgrounds resulted in responses that covered a range of concerns of teachers when considering teaching and learning RP in the situation of Hong Kong classrooms.

The teachers participated in task-based interviews. The tasks and questionnaire items were adopted from the studies of Almeida (2000), Keceli-Bozdog, Ugurel and Bukova-Guzel (2014), Kotelawala (2007), and Yoo (2008) to capture teacher’s knowledge, attitudes and beliefs about RP and their instructional practices. Table 1 lists some sample items. Each interview lasted about an hour, and was conducted and audio-recorded in Cantonese, the teachers’ mother tongue to enable them to express their opinions easily and effectively. The teachers were asked to complete the questionnaire and tasks using think-aloud strategy and then respond to follow-up queries.

Origins of the items	Sample items
Almeida, 2000	<p>Decide which ‘proofs’ you find (a) convincing, (b) not convincing, or (c) incorrect.</p> <p>Proposition: <math>(1 + 1/2 + 1/2^2 + 1/2^3 + \dots + 1/2^n) \rightarrow 2</math> as <math>n \rightarrow \infty</math>.</p> <p>Assumptions/assertions that may be used in the proofs:</p> <p>A1. If <math> a  &lt; 1</math>, then <math>an \rightarrow 0</math> as <math>n \rightarrow \infty</math>.</p> <p>‘Proof’ 1</p> <p>Let <math>S_n = 1 + 1/2 + 1/2^2 + 1/2^3 + \dots + 1/2^n</math>.</p> <p><math>S_5</math> can be represented in the figure as a portion of 2 squares. <math>S_5</math> is 2 less a remainder <math>R_5</math> as shown:</p>  <p>Clearly, the figure shows that <math>R_5</math> becomes smaller as <math>n</math> increases. That is, <math>R_n \rightarrow 0</math> as <math>n \rightarrow \infty</math>. It now follows that <math>S_n \rightarrow 2</math> as <math>n \rightarrow \infty</math>.</p> <p>This proves the proposition.</p>

Table 1(con’t): Sample items of the tasks

The audio-recorded data were transcribed into written Chinese. The transcripts were then analysed using the model of the teacher’s decision (Figure 1) regarding two themes: (a) teachers’ perceptions of RP and teaching and (b) their interpretation of the contexts. Based on the teachers’ responses, their interpretations of the contexts were further divided into (i) interpretation of students as learners and (ii) interpretation of learning cultures. To report the findings, selected excerpts were further translated into English using word-to-word strategy (that is, English grammatical rules are not strictly followed) assisted with appropriate interpretation.

## Results

### Perceptions of RP and teaching

All participants related proofs to logical reasoning and its promotion. For example, when asked which items of learning activities are related to proof, Participant 2 stated, “if the activities enable to develop [students’] logical reasoning, I think the options are [formulating conjecture], [explaining why answers or steps make sense] and [working on one’s own methods for solving unfamiliar problem].” He also added that making a conjecture may be a precursor of a proof.

Participant 2: Like Pythagoras’ theorem, he (the prover) makes a conjecture. If he did not have a conjecture, he would not have tried to prove [it]. Therefore, [we] must first have conjectures.

Participant 4 perceived that, through teaching and learning proofs, students may be provided with epistemological justification of a mathematical statement for promoting conceptual understanding in

mathematical facts and ideas. When discussing ‘proofs’ of “square root of 6 is an irrational number”, Participant 4 expressed his intention and motivation of teaching the proof: to foster students’ conceptual understanding of irrationality of a number:

Participant 4: ... because learning a proof like this means to understand what “irrational” [an irrational number] is... because something is true... like this then [we] can dig out the meaning of “irrational”. Therefore, I will teach [the proof].

The realisation of educational values of proofs may *initiate* teachers’ motivation, like Participant 4, of teaching RP: the teachers initiated the process of *benefit–cost* analysis on teaching RP, but their interpretation of students and learning cultures may mediate between their perceptions, and decisions.

### **Interpretation of students as learners**

Most participants perceived that their students were not capable of nor interested in learning any proof of a mathematical proposition in general.

Participant 1: ... because [in] my school, not many people “accept” (prefer) proofs. They often [prefer], for example Pythagoras’ theorem... it is enough for them to use [the theorem]. Yes, they barely care or think about how this formula was derived. Since they do not want to know, I am not urged to explain. Also, their capability is weak; it will be a trouble if I finish explaining [it] but they still do not understand. Therefore, proofs are relatively limited.

Participant 7: ... Let me say it this way, in my views, [the] ideal [RP lessons] should train (develop) their (students’) that (RP-related) reasoning. Training their logical [reasoning] But in actual lessons, this [training], however, was not emphasised... I think students’ attitudes [towards learning mathematics] are important. In fact, many students are not... enthusiastic [over learning mathematics]. So, I think [if I] keep on asking them (students) to make a conjecture, in fact they are not really making any conjecture. Yes... but if ideally they really can... that is, [if] I ask them to do... use [their] brains to think (make a conjecture)..., then they think. Then, I think [this] is fine. But, in real life, then... in fact, perhaps, not the whole class [would] do (make a conjecture). [I] sometimes, perhaps, find some smarties, and then ask them to do this conjecturing. Therefore, the proportion [of making conjectures] would be far less... in the real life (my actual teaching practices).

To facilitate some RP activities in classroom, the teachers tended to select proofs that they found easy to understand, but there were no systematic selection criteria; instead, the teachers selected a proof by their feelings of its length and complexity.

Participant 5: [I prefer proofs that are] easy to “see”. [The students] all can “see”; that is, easy to explain and understand.

Participant 1: [I choose to teach proofs which are] simple and easy to follow. [Interviewer: What do you mean by simple and easy to follow?] This depends on [my] feelings... This is sometimes my feelings... If, if I am a teacher and have a judgement, if I see this [proof] and I think this can be understood by the majority, from my gut feeling...

Of course, I have to know the characters of my class, then I will evaluate if they can understand what I say... evaluate if they will “accept” (be convinced by and/or understand) this proof. If, after I complete the evaluation, I think [it is] worth saying (teaching) [it], then I will try to say (teach) [it]. If, after evaluation, I think [it is] not worth saying (teaching) [it], then I won’t.

Whilst teachers’ realisation of the educational values of teaching RP (perceptions) may promote their use of RP when teaching (decisions), the participants demonstrated how teachers’ counterproductive interpretation of students’ learning capabilities and attitudes may mediate between their perceptions and practices of teaching RP. Participant 1 demonstrated that his counterproductive interpretation interacted with his perception of what students needed to learn/master and teacher-centred disposition. The choice of a “simple and easy” proof (decision) may refer to his interpretation that (a) the length and complexity of the selected proof were aligned with students’ capabilities, and/or (b) the main purpose of the selected proof was to convince students of the truth of a proposition with less effort. Participant 7 demonstrated that he developed a positive perception of teaching RP and an ideal practice, but his counterproductive interpretation contributed to investing less in involving students in RP activities (e.g. making a conjecture). As a result, teaching RP was limited in their classes.

### **Interpretation of learning cultures**

Apart from their interpretation of students, teachers’ interpretation of the learning cultures where they are situated may also mediate between their perceptions of RP and teaching, and decision making. Like other East-Asian countries, examination-oriented culture is well established in Hong Kong (Brown et al., 2009; Choi et al., 2012). The participating teachers’ responses revealed that this examination-oriented culture greatly influenced their decisions on teaching RP and mathematics.

Participant 4: [My lessons tend to be] exam-oriented! Even if I do not want to be like this, students’ expectation and parents’ expectation are like this... because [we] have examination; [so, we] have drilling exercises... The tasks in examination are not proof-related, so [we] cannot spend much time [on proofs]. If [students] can understand, then understand; if not, then keep on drilling, or solve problems...

Participant 4’s responses suggested a connection between his interpretation of students’ expectation (attitudes) and that of the examination-oriented learning culture. Participant 7 added that the examination-oriented culture has also contributed to the discrepancy between his ideal RP lesson (perceptions of RP and teaching) and his actual implementation.

Participant 7: ... But [the actual lessons focused] more on whether they could “do the maths” (solve the problem tasks), which is more about examination. Of course, I am not completely saying [that my lessons are] examination-oriented; my lessons are really not so examination-oriented. However, [my lessons] in fact tend more to be the side of calculation. Yes, therefore, when having the term “ideally” here, my... my [ideal] practice will be a bit different [from the actual practice].

The participating teachers perceived that preparing students for public examinations is a main role of being a teacher in Hong Kong (a goal); they also held an interpretation that the public examination in

Hong Kong was calculation-oriented. Any decision that may strengthen students' accurate calculation and problem-solving skills was prioritised over the teachers' ideal practices if the decision and the ideal practices were different. For example, Participant 4 perceived that the examination-oriented culture was deeply rooted in his teaching environments, and, as a result, students expected mathematics class to be oriented towards examination preparation. He prioritised the goal of preparing his students for examination highly over the goal of fostering students' conceptual understanding of mathematics. Since teaching RP was not his routine practice, according to Schoenfeld's (2011) model, a "cost–benefit" calculation was performed by Participant 4. His cost of practising RP in his mathematics class outweighed the benefits that he perceived when teaching RP. Therefore, he found it difficult to practise any RP activity in his mathematics class. Therefore, they invested more in involving students in calculation and problem-solving activities, rather than RP.

## Discussion

This study examined the three *interrelated* factors that may influence Hong Kong secondary mathematics teachers' decisions around RP: teacher's perceptions of teaching RP, interpretation of their students as learners, and interpretation of the learning cultures. Whilst the teachers' productive perceptions of teaching RP, for example, recognising that teaching proofs may foster students' conceptual understanding of mathematical ideas and logical reasoning, may promote and develop their ideal practices, their counterproductive interpretation of students' learning needs: in particular, they did not think proofs are needed or suitable for all students (cf. Frasier & Panasuk, 2013; Varghese, 2009), and the learning cultures (examination-oriented culture) may interact with each other and mediate between their perceptions (of students' learning needs) and actual practices.

The teachers perceived examination-oriented culture to be a main factor that limited their decisions on teaching RP; this culture influenced the teachers' interpretation of students' attitudes and their learning needs. Examination-oriented culture is deeply embedded in Hong Kong school mathematics and teachers' interpretation, and the public examination in Hong Kong is interpreted as calculation-oriented. As a result, the teachers deviated from researchers' expectation of making RP spread through school mathematics, and prioritised calculation-oriented teaching materials over RP. If teachers avoid RP in their teaching because they perceive that proofs are less important and/or not suitable for all students in understanding mathematics and preparing for examination, professional development should address teachers' interpretation of students' learning needs and the social contexts (school and learning cultures) and be focused on fostering teachers' reflection on their teaching philosophy and broadening their horizons for learning other trends and visions. Educational reforms including frameworks of public examination and teacher education may also be considered when RP activities should be central of mathematics education in Hong Kong, and worldwide.

# On teachers' experiences with argumentation and proving activities in lower secondary mathematics classrooms

Silke Lekaas

Western Norway University of Applied Sciences, Bergen, Norway; [slek@hvl.no](mailto:slek@hvl.no)

*This article presents an analysis of reports about developmental work written by 23 lower-secondary school teachers from Norway who planned, implemented and reflected upon a lesson involving elements of exploration, argumentation, and proving. An analysis of the tasks that the teachers designed for their students and the scaffolding that they provided during the classroom implementation, revealed that there was little variation in the choice of task and that opportunities for investigation were reduced by providing subtasks and hints. Some teachers also experienced that the unpredictability of the students' contributions and the mathematical content, time constraints and large classes were challenging when leaving traditional teaching practice.*

*Keywords: Proof, proving, argumentation.*

## Introduction

The functions that proofs have for mathematicians and within mathematics as a discipline are important to bear in mind when teaching proof (de Villiers, 1990). In addition to the verification of the validity of a statement, de Villiers suggested to consider other functions of proof like explanation, systematization, discovery and communication. In the same spirit, Hanna (2000, p. 6) stated that “in the classroom the key role of proof is the promotion of mathematical understanding, and thus our most important challenge is to find more effective ways of using proof for this purpose”. Following Stylianides (2016), in this article proving is understood in a wide sense, including auxiliary activities such as exploration, pattern identification, making and testing conjectures, and reasoning by analogy.

Teachers' own knowledge about proof seems not to guarantee meaningful proving activities in the classroom. Schwarz et al. (2008) investigated the pedagogical knowledge about proof of three groups of preservice teachers' from Germany, Hong Kong and Australia. The preservice teachers from Hong Kong and Australia tended to consider preformal proving an atypical part of mathematics teaching and did not fully appreciate its potential in the classroom. Schwarz et al. (2008, p. 808) concluded that “even future teachers with strong mathematical backgrounds are not necessarily experiencing proof in such a manner that they can convey a complete image of proving at the lower secondary level”. Similarly, Knuth (2002a, p. 404) stated: “Future research needs to explore more fully the conceptions of proof that teachers must have as they help students learn to reason mathematically”. More knowledge is thus needed about how to prepare future teachers to create meaningful opportunities for students to engage in exploration, generalization, argumentation and proving.

Despite long reform efforts and studies confirming successful changing efforts, traditional models of mathematics education seem to be persistent in many classrooms (Jacobs et al., 2006). As for the topic of reasoning and proving, it was found that none of the US lessons from the 1999 TIMSS video study showed evidence of developing a rationale, making generalizations, or using counter examples. Similar findings about discrepancies between an intended reform curriculum and persistent traditional

classroom practice were made in earlier studies (Spillane & Zeuli, 1999). A number of studies focused on the already established patterns of teacher practice in collaborative inquiry classroom communities (Walshaw & Anthony, 2008). Less research seems to be done that tries to reveal the challenges that teachers face when trying to transform existing traditional practices characterized by brief demonstrations of procedures and computational tasks.

This article looks at reform efforts in a Norwegian context. Following criticism about focus on routine exercises and rote learning (Mellin-Olsen, 1996), communicative skills, conceptual understanding, reasoning and argumentation have become important goals in the Norwegian curriculum that has been valid without major changes since 2006: All students are supposed to take part in explorative activities, pattern exploration in both geometry and arithmetic, and to acquire so called basic skills, among them oral skills and mathematical writing, which include the ability to “forming opinions, asking questions and using argumentation with help from informal language, precise terminology and the use of concepts” and the ability to build up “comprehensive argumentation concerning complex relationships” (Ministry of education and research, 2013). These are proving activities in the sense of Stylianides (2016).

While other studies were based on interviews with teachers or preservice teachers (Furinghetti & Morselli, 2011; Knuth, 2002a, 2002b; Schwarz et al., 2008), this article is based on reports about developmental work written by 23 teachers who participated in a reform oriented teacher development program during which they planned and implemented a lesson involving elements of exploration, argumentation, and proving. The main research questions addressed in this article are: What were the mathematical properties of the tasks designed by the teachers? How were the tasks structured and implemented in the classroom and which impact did this have on the opportunities for exploration, argumentation and proving? What were the teachers’ reflections about challenges that arose during the implementation of the proving tasks in the classroom?

## **Theoretical perspectives**

In this section, three different models for the classification of tasks are introduced that allow to analyze both mathematical properties of tasks and aspects of their implementation with respect to the creation of opportunities to engage in exploration, argumentation and proving.

### **Classification of tasks**

Stylianides (2016) classified proving tasks based on mathematical criteria namely the number of cases to be considered in the task (single, finite, infinite) and the purpose of the task that can either require to verify or to refute a statement. This gives a classification into six cases that can be helpful in order to make teachers aware of different types of proving problems that will require different proving techniques and can potentially result in different types of proving activities in the classroom. The number of cases and the purpose of the task need not necessarily be made explicit to the student.

The same mathematical problem or topic can be implemented in different ways in the classroom, and the model by Stylianides (2016) does not capture this aspect. For example, statements can be given by the teacher or textbook or students can develop their own conjectures, for instance through pattern identification (Stylianides, 2008). Skovsmose (2001) classified tasks according to their openness,

ranging from the traditional exercise paradigm to landscapes of investigation, and whether they are purely mathematical, giving a pseudo-application or are real-world problems. The property of being a landscape of investigation exceeds the initial formulation of the task. It depends on the students to accept the invitation to explore and on the communication between teachers and students during the working process: the teacher should provide questions, hints and suggestions rather than solutions and explanations. Yeo (2007) distinguished the following five dimensions of openness of a task:

- *Goal*: A standard computational task has a closed goal: finding the one correct answer. An exploratory task has a more open goal since different properties of a notion can be discovered.
- *Answer*: A standard computational task is closed with respect to the answer since it has one correct answer. A modelling task, for example, can result in several different, but meaningful models.
- *Solution method*: Most tasks can be solved in different ways, but it is not unusual that textbooks or teachers close tasks by prescribing the method to be used.
- *Scaffolding*: Many textbook tasks provide subtasks guiding to a solution. A task can be more or less open based on the density of subtasks that lead the students to the final solution.
- *Extensions*: All tasks can be extended, but students are not necessarily aware of this, for example because the extension of tasks is not a usual thing to do within the classroom norms.

## Method

The data collected for this article consisted of 26 reports about developmental work written by teachers enrolled in a teacher development program who planned and carried out a lesson including elements of exploration, argumentation, and proving in lower secondary school, i.e. years 5 – 10. These teachers were not mathematics specialists, but taught several different subjects in lower secondary school. Three reports had to be removed from the data material because the teachers did not give the permission to use them. The teachers were encouraged to run the lesson in a group work setting in order to facilitate active student communication. The reports contained a description of the designed task, observations made during the implementation in class, and reflections about the support provided to the students and any challenges that the teachers experienced.

When starting the analysis of the reports, the mathematical properties of the proving tasks were examined: three categories were generated from Stylianides' (2016) framework about the mathematical properties of the tasks (proving finitely/infinitely many cases, disproving); in addition, it was analyzed whether the students got an opportunity to make their own conjectures or whether the statements to be proved were provided by the teacher. After a first reading of the data material, it became clear that mathematically similar tasks had been formulated and implemented in different ways, such that the original coding was refined using the model of Yeo (2007) in order to analyze different dimensions of openness.

During the final coding, four additional aspects of the material were investigated: the goal of the tasks, the scaffolding provided to the students, the role assigned to argumentation and proving in the classroom, and potential benefits, challenges and obstacles that teachers experienced during the classroom practice. Only the first two aspects are addressed in this article. Examples of codes characterizing the goal of the tasks were *generalize pattern*, *find a proof*, *make conjectures*,

*investigate*, and *justify special case*. Examples of codes characterizing the scaffolding were *division into subtasks*, *teaching proving technique* (with subcategories *creating additional examples*, *systematize results*), *visually aided proving*.

## Results and discussion

Half of the teachers wrote that their usual teaching was characterized by the exercise paradigm (Skovsmose, 2001), i.e. that they usually demonstrated a method and that their students worked with exercises afterwards. The following comment by a teacher is representative: “I do know that I often use tasks that have a clear solution method and one correct answer (T12).” Although the Norwegian curriculum, in action since 2006, requires that “argumentation”, “sharing ideas with others”, “problem solving” are to be both methods in classroom and competence aims (Ministry of education and research, 2013), the exercise paradigm seems to be persistent in many classrooms. This is consistent with research done after reform efforts in other countries (Spillane & Zeuli, 1999).

### Properties of the proving tasks and their implementation in the classroom

**Goals:** Two goals were predominant, pattern generalization and proof or proving as a topic. Almost half of the proving tasks asked the students to find generalizations based on examples revealing a pattern. Task 1 and Task 3 in Figure 1 are typical examples. Four teachers designed tasks about the interior angles sum of polygons guiding the students to note a pattern starting from triangles, quadrilaterals and pentagons. The generalized formula was not provided a priori such that the students got the opportunity to make conjectures about it. Five teachers designed tasks about number sequences and figurative numbers for students in 8<sup>th</sup>, 9<sup>th</sup> and 10<sup>th</sup> grade that required to continue sequences when the first few elements were given, as in Task 3 in Figure 1. None of the teachers discussed the fact that the number sequences could possibly be continued in different ways since only (pictures of) few elements were given and no rule was stated. Thus, the most obvious rule was applied without any discussion, called the plausible pattern by Stylianides (2008). Several of the number sequences were quite simple and already known to students of these grades, for instance the sequence of natural numbers, even and odd numbers, quadratic numbers and figures composed of these. The general formulas were easy to see from the defining properties such that no need to prove naturally arose from these tasks. Stylianides (2016) gave examples of elementary arithmetic problems that can make students aware of the distinction between empirical and mathematically valid arguments such as generic arguments. Several of the given tasks about number sequences lacked the potential of revealing such distinctions to the students. Only in one case, the relationship between quadratic numbers and the sequence of odd numbers was elaborated during the classroom activity and explained by a visually aided proof.

Several teachers made the learning of proving an explicit goal of the task. Four teachers introduced the proving task as an imaginary dialogue between two fictive characters wondering about a problem (Wille, 2017), in order to stimulate oral argumentation and to exemplify the type of activity that was expected from the students. Task 2 in Figure 1 is an example of this. Only the problem is introduced in the imaginary dialogue while no hints to the solution method are given. The teacher’s report about the implementation in the classroom confirmed that the goal of the task was to learn about exploration and proving techniques: she encouraged the students to systematize results and to formulate and test

preliminary conjectures. A genuine need to investigate seemed to be a requirement for the students' engagement in proving: A teacher in 9<sup>th</sup> grade, who had similar intentions to give the students the "possibility to train to think mathematically and explore proving" (T09), chose the already well-known statement that the sum of two odd numbers is even for designing a proving task. She consciously lowered the mathematical demands since the students were "not used to working with mathematics in this way". But, lacking the need for investigation, the students found it difficult to understand why they should "prove something that was already known and true".

<p><u>Task 1:</u> (9<sup>th</sup> grade)</p> <p>1) Knowing that the sum of angles in a triangle is <math>180^\circ</math>, can you find the sum of angles in a hexagon?</p> <p>Hint: Divide the hexagon into triangles. Make drawings and explain your thinking.</p> <p>2) Using the same method as in 1), find the sum of angles in a pentagon and a heptagon.</p> <p>3) Knowing the sum of angles in a triangle, quadrilateral, pentagon, hexagon and heptagon, can you find a pattern?</p> <p>Can you then make a formula for the sum of angles in an n-sided polygon?</p>	<p><u>Task 3:</u> (8<sup>th</sup> grade)</p> <p>You have to lay quadratic tables with enough space for one person on each side. Tables for more persons are put together as shown in the drawing.</p>  <p>a) How many persons can sit around the tables? Fill inn:</p> <table border="1" data-bbox="911 958 1254 1400"> <thead> <tr> <th>Number of tables</th><th>Number of persons</th></tr> </thead> <tbody> <tr><td>1</td><td></td></tr> <tr><td>2</td><td></td></tr> <tr><td>3</td><td></td></tr> <tr><td>4</td><td></td></tr> <tr><td>5</td><td></td></tr> <tr><td>20</td><td></td></tr> <tr><td>100</td><td></td></tr> <tr><td>n</td><td></td></tr> </tbody> </table> <p>b) Do you see a pattern how the number of persons is changing? Explain.</p> <p>c) Explain how you calculated the number of persons when using 20 tables.</p> <p>d) Explain how you can find the number of persons when you use n tables.</p> <p>e) Can you make a formula for table nr. n?</p>	Number of tables	Number of persons	1		2		3		4		5		20		100		n	
Number of tables	Number of persons

<p><u>Task 2:</u> (7<sup>th</sup> grade)</p> <p>Lisa and Per have learned about some properties of numbers (...).</p> <p>Lisa: We've learned that all numbers that finish with an even number, are divisible by 2. Like 12, 14 and 16 that are divisible by 2, because they finish with 2, 4 and 6.</p> <p>Per: Yes, that's easy when we can just look at the last digit.</p> <p>Lisa: How can we know if a number is divisible by four?</p> <p>Per: Well, that's worse. But there must be a rule. Let's find out.</p> <p>Help Lisa and Per. Continue to write the dialogue.</p>																			

**Figure 1: Examples of proving tasks**

Some teachers experienced that the amount of time needed to do investigative activities was in conflict with requirements to cover curricular content: "This implies also that one uses time to investigate, one can't make plans as with other teaching methods that one will use one hour and then be finished with the topic (T01)." Time constraints and "large classes" (T07) were challenges when teachers had to evaluate students' understanding in order to adapt mathematical content to the

individual student: “It is challenging with respect to the available resources to manage to talk to all student pairs and to adapt the tasks to the level they are on and moving towards (T03).”

**Scaffolding:** Many teachers provided a lot of scaffolding in the written text, dividing the task into subtasks that led the students to the discovery of patterns or an appropriate argumentation, see Task 1 and 3 in Figure 1. For example, all tasks designed about the interior angles sum of polygons started by guiding the students to note a pattern starting from triangles, quadrilaterals and pentagons. After hints to use visual representations, they resulted in visually aided proofs that showed a division of polygons into triangles. Similarly, a teacher who designed a task about the area formulas of quadrilaterals consciously chose the order of the quadrilaterals to be considered such that the proofs could build on each other. In 14 of 23 reports, at least part of the scaffolding described by the teachers was coded as “guiding the students through an argumentation”, i.e. students’ occasions to do their own explorations were limited. Teaching practices related to proof differ widely and can be divided roughly into two groups, either focusing on the proving process or on the final product, the proof (Furinghetti & Morselli, 2011). One teacher who had designed a task leading the students step by step through an argumentation became aware of the fact that this deprived the task of its explorative character and hindered the students from working like a mathematician: “(...) by designing the task like this, I guided the students in the ‘right’ direction. I took away the possibility of making mistakes, which is an important part of working like a mathematician (T15).” Other teachers reflected about their support during group work having been too leading, depriving the given task of its investigative character, by funneling or by imposing their own argumentation on the students.

About a third of the teachers started the implementation of their activities with a repetition of definitions and properties of the relevant notions in a whole-class setting. These teachers seemed to consider a lack of knowledge about related notions an obstacle for proving that had to be avoided, rather than to look at proving as an opportunity to explore these notions: “It is important to ensure a common understanding of the notions we are using and some of their properties before we start (T01).” Similarly, the following teacher provided precise definitions in order to prevent misunderstandings in the students’ communication: “Whenever I have to explain a notion to students, I make sure that the definitions are such that everyone understands them in the same way. Only then they are useful for communication.” Though precise definitions are important in mathematics, it can be of great value for students’ understanding of concepts to use tasks with ambiguous conditions and let students explore the consequences of different assumptions or definitions. The learning opportunities that can arise from such proving tasks in the elementary classroom are discussed by Stylianides (2016), while Zaslavsky (2005) investigated the learning opportunities evoked by uncertainty in mathematical tasks on secondary level.

**Extension:** Several of the teachers claimed to have designed landscapes of investigation (Skovsmose, 2001), but none of the activities strictly speaking fulfilled the criteria, since many hints about proof ideas were provided and there was little opportunity for students to extend tasks or to explore their own questions or conjectures.

**Underlying mathematical properties of the tasks:** There was little variety in the proving tasks when compared to the model by Stylianides (2016). The major part of the proving tasks required

justification in infinitely many cases. Only two proving tasks treated a finite number of cases, for example a task about the probability to get certain sums of points when throwing two or three dice. None of the tasks required to disprove a statement. As the nature of the proving task influences the nature of the proving activity (Stylianides, 2016), this might have restricted the diversity of activities that were developed in the classrooms. Of course, each teacher designed only one task such that we have no information about the variety of tasks in a single teacher's classroom. It might however reveal a general tendency that proving tasks might mostly be associated with infinitely many cases.

Despite the fact that proving tasks with infinitely many cases were predominant and a number of proving tasks used geometric representations, none of the teachers made ICT tools available to the students during their investigation. Hanna (2000) wrote that “dynamic geometry software can be used to enhance the role of heuristics, exploration and visualization in the classroom”. Given that the ability to use digital tools, also for purposes of exploration, is among the competence aims of the Norwegian curriculum and considering their potential with respect to exploration and conjecturing, it was surprising that none of the teachers based their classroom activity on digital tools.

## **Final remarks**

Most teachers provided a lot of scaffolding, both in the task formulation and during group work. This might be related to the teachers' conceptions of the role of proof in school mathematics (Knuth, 2002b), apparently emphasizing systematization and explanation as the functions of proof. Many teachers provided definitions and properties of notions beforehand in order to avoid misunderstandings. Proving tasks with ambiguous conditions were not designed by any teacher. ICT tools were not used either which can strengthen the impression that there was some more focus on systematization, explanation of concepts, and support to build arguments than on exploration and conjecturing. There was little variation in the proving tasks when compared to the model of Stylianides (2016), and this might have restricted the diversity of proving activities that arose in the classrooms. In our teacher education courses, we might therefore have to pay special attention to the variation of tasks, and to discussing the value of exploration and the learning opportunities provided by ambiguous proving tasks for students' understanding of mathematical concepts and notions.

All teachers reported that their experience with the implementation of the proving activity was mainly positive. Benefits that were mentioned, included the acquisition of relational understanding, communicative skills, student autonomy, and higher student motivation than usual. Despite of that, several teachers expressed that it would be challenging to work with argumentation and proving in the everyday school reality. They had concerns about the unpredictability of students' contributions and the mathematical content, making it difficult to follow up students' contributions and being in conflict with obligations to cover a specific curricular content, time constraints and large classes that restrict the possibilities to support students individually. In addition to the fact that half of the teachers were still mainly used to the traditional exercise paradigm, the teachers' choices about scaffolding might be related to such concerns. These are important factors that deserve further investigation.

# An epistemological study of recursion and mathematical induction in mathematics and computer science<sup>1\*</sup>

Nicolás León<sup>1</sup>

<sup>1</sup>IMAG, Univ Montpellier, CNRS, Montpellier, France;

[nicolas.leon@umontpellier.fr](mailto:nicolas.leon@umontpellier.fr)

*Keywords: Recursion, mathematical induction, epistemology, computer science.*

The recent introduction of computer science contents in the mathematics programs for French high schools raises several questions about the means and objectives of such a curricular shift: which concepts are relevant for mathematics and computer science? Are these concepts viewed in the same way by both disciplines? What are the didactical consequences of the potential similarities and differences? These questions are studied within the scope of the ANR DEMaIn research project (Didactics and Epistemology of interactions between Mathematics and Computer Science).

In our thesis, taking place as a part of this project, we concentrate on the notions of mathematical induction (MI) and recursion. We choose them as they are (i) pervasive both in mathematics and computer science, (ii) usually present in high school or first-year undergraduate curricula, and (iii) problematic from a didactical point of view, as abundant literature shows (Michaelson, 2008; Rinderknecht, 2014).

We conjecture that recursion and MI are closely related to each other and that their joint study might help solve some of these didactical problems, an idea that is supported by the existing literature (see, for example, Drysdale, 2011). Methodologically, we adopt the approach of didactic engineering (Artigue, 2014), which prompts us to initially perform an epistemological analysis of both notions. In particular, we would like to pinpoint the different conceptions of recursion and MI that mathematicians and computer scientists have. Therefore, we pose the following research questions:

1. What meanings can be found for recursion and MI in the fields of mathematics and computer science?
2. What relations exist between these two notions?

## Methodology

To address these questions, we proceed in three steps:

1. We consult various academic books, either exemplifying or discussing the points of view of mathematics, computer science or logic on recursion and MI. We intend to identify the contexts in which the words “recursion” and “mathematical induction” are used and the links between them that are implicitly or explicitly assumed.
2. We complement these findings with the information obtained from interviews with mathematicians and computer scientists, in order to gain insight on practices related to recursion and MI that are less visible in the books.

---

<sup>1</sup> Communication supported by the French National Research Agency <ANR-16-CE38-0006-01>.

3. We develop a characterization of recursion and MI that is in accordance with the academic literature and expert usage, and appropriate for subsequent didactical analysis.

The books for step 1 have been selected considering that they should be exemplary of a specific look at recursion and MI, that the study of these concepts should take place on an important portion of the book, and that it is desirable for them to have been cited repeatedly in the academic literature. It was not a pre-requisite for them to address undergraduate students, as the epistemological study aimed at characterizing advanced usage.

The choice of experts for step 2 has been made according to availability criteria, and also trying to cover a broad spectrum of research areas. The format of the interview is semi-directed, based on a flexible questionnaire, so as to be able to deepen in specific aspects of the use of the concepts that could appear spontaneously during the conversations.

## Results

We discuss preliminary results from the analysis of the first five books and four interviews. New books and interviews will be incorporated into the study before tackling step 3, whose results we also expect to present at CERME.

While the concept of MI seems relatively stable, recursion appears as a weave of fuzzy meanings. Interviewed researchers find it difficult to specify a definition of recursion. Books addressing computability theory will usually put forward the precise mathematical definition of recursive functions, relations, and sets, but even here one can find some ambiguity: “recursive” might also mean, more generally, that something is being defined in terms of (a simpler version of) itself. Computer science books present yet another aspect of the concept, by highlighting its connection with the notions of nested loops or structures: recursion is here viewed as a convenient way to organize procedures or data when certain regularities are observed.

Additionally, the close link between recursion and MI is also noticeable both in the discourse of researchers and book authors, as words like “inductive”, “recurrent” and “recursive” are sometimes used interchangeably, depending on the context.

# Explanatoriness as a value in mathematics and mathematics teaching

Eva Müller-Hill

University of Rostock, Germany; eva.mueller-hill@uni-rostock.de

*In this foremost philosophical paper, I propose a rather holistic idea of (re)establishing mathematical proof in school mathematics by explicating and enacting the particular merits of mathematical proof with respect to a variety of mathematical activities, e.g.: observation, systematic variation of example cases, informal argumentation, defining, hypothesising, inductive and abductive reasoning. Such activities are connected naturally to proving in practices of mathematics, with “practice” referring both to mathematics as a human endeavor in general, and to mathematics a (scientific) discipline. To this end, a concept of “mathematical value” from the philosophy of mathematical practice is employed. I focus exemplarily on the value of explanatoriness, which is both a core merit of good proof in scientific mathematical practice, and an important didactical goal of teaching proof.*

*Keywords: explanation, mathematical value, proof, philosophy, mathematical practice.*

## Introduction

From the perspectives of mathematics education research and curriculum development, it is widely agreed to date that mathematical proving shall be encouraged and fostered in school mathematics throughout all content areas and grade levels. At the same time, at least in Germany, standards of rigor and formalization in classroom proving changed rapidly in comparison to, e.g., the traditional Euclidean paradigm of proof in elementary geometry, or to algebraic proving in the  $\varepsilon - \delta$  - calculus, and developed into content-oriented, depictive, or intuitive ways of argumentation. In spite of the efforts to make mathematical proving an integrated core element throughout the curriculum, the demand for more proving in German mathematics classrooms frequently produces teachers' complaints: the curriculum is too dense, time is too short, and after all, proof is not that relevant for the final exams; pupils don't like proof, they are afraid they cannot handle it and fall into blockade, and after all, proof is not that relevant for students' future lives. This phenomenon can, probably and partly, be explained as an enduring symptom of a perceived “false dichotomy” (Sierpinska, 2005) of mathematical proving on the one hand, and other kinds of mathematical activities on the other. Such a dichotomy may have been over-emphasized by both the traditional university part of mathematics teacher education (at least in Germany), and by the former, strong curricular focus on proofs in the context of elementary geometry, with a sustainable effect on teaching attitudes and beliefs that cannot be simply suppressed by declarations of curricular intent (compare also Knuth, 2002) for similar aspects of teachers' proof conceptions and attitudes towards teaching proof in the U.S.). Hence, there appears to be an ongoing need for clarification of a reasonable interpretation of the call for more proving in mathematics classrooms. This need was already expressed by Stylianides (2007), together with the proposal of defining a framing core concept of mathematical proof to be explicated and enacted in classroom (pp. 291f.), which can be coherently specified both with regard to different loops of the curricular spiral, and to different fields of mathematical content, and which allows for a clear distinction from inductive, “empirical” (p. 298) arguments. In recent years, the awareness of this need has also led to a deep discussion in mathematics education about diverging and common aspects of

mathematical proof and argumentation (Mariotti et al. 2018). A substantial part of this debate is devoted to logical or cognitive aspects, including the role of deductive vs. other forms of inferential reasoning, of argumentation base, of language, symbolism, or other semiotic elements (ibid.), e.g., the analysis of structural and referential aspects of argumentations and proofs that provide cognitive unity in conjecturing-and-proving learning settings (Fiallo & Gutierrez 2017), or the examination of the coordination of different registers in the transition from argumentation to proving (Duval, 2007; with a different reading of “epistemic value” than I will use in the following).

## Focus and rationale of this paper

The approach I want to propose here is, in a way, a complementary one. One main difference is that it does not aim at a closed definition of what mathematical proof is, nor at an emphasis of a clear-cut distinction of proving vs. non-deductive forms of mathematical activities, e.g., inductive or abductive argumentation based on variation of example cases. A second main difference is the idea that an investigation of mathematical proving and related activities that sticks to the logical and cognitive aspects, might not suffice to grasp all epistemologically relevant facets, which may partially conform to approaches employing Habermas’ model of rational behavior (reported in Mariotti et al. 2018). The term “false dichotomy” cited above refers to Michael Otte’s view of *complementary* facets of proving in mathematics (Otte, 1990, p. 59ff.), and emphasizes intuitive, social, and metaphorical facets of proof which cannot be properly modeled with regard to the logic and cognitive functioning of proof or argumentation. Several much more recent studies from different fields suggest that, in a similar vein, issues of epistemic values essentially connected to mathematical proving, like explanatoriness, transcend the scope of logical and cognitive matters, due to a discursive character, to non-reducible pragmatic and affective aspects, and also to the metaphysics of mathematical proving; compare, e.g., (Müller-Hill, 2011) on the epistemic role(s) of formalizability as a feature of discursive proving actions, (Novaes, 2018) on explanatoriness within a dialogical conceptualization of mathematical proof, (Andersen, 2018) on a socio-empirically informed view on acceptable gaps in proofs, (Johansen & Misfeldt, 2016) on argumentation and problem choice as mathematical values, or (Dawkins & Weber, 2017) on the integral role of values like “increasing mathematical understanding” for the “apprenticeship of students into proving practice” (p. 123). Thus, a focus on explanatoriness as an *epistemic* value does not mean to exclude other perspectives than the epistemological one, but is inclusive to, e.g., sociological, communicative, and pragmatic perspectives. The following sections aim at *indicating first steps into the direction* of a program which consists of (1) explicating the particular epistemic merits of the idea of proof that become manifest in the activity of proving in mathematical practice, (2) understanding these coherently in view of the whole process of hypothesizing, generating and communicating proof, (3) emphasizing aspects and features of what counts as proof in mathematical practice that play a particular role in achieving these merits, and (4) indicating elements of a variety of mathematical activities, particularly the generation, operation with, and variation of examples, that already correspond to these aspects and features of proof. In the next two sections, a number of useful concepts, conceptions and results have to be introduced in quite curtate descriptions. First, I provide conceptual considerations as well as exemplary socio-empirical evidence for an understanding of explanatoriness as a core epistemic value of *scientific* mathematical practice in the sense described above. This goes hand in hand with the

stance that the epistemic nature of the scientific discipline of mathematics, understood as a human practice and endeavor which generates, communicates and imparts mathematical knowledge and skills, is relevant to the teaching and learning of mathematics for principal reasons. I then sketch a philosophically informed didactical model of mathematical explanation, developed in (Müller-Hill, 2017), and a model of the interplay of deduction, induction, and abduction in explanation processes. I shortly review the socio-empirical insights on the background of these models, and finish with a glimpse on future work in enacting explanatoriness as a value in school mathematics.

### **Explanatoriness as an epistemic value in scientific mathematical practice**

I employ a concept of *value* here that emerged in recent discussions within philosophy of mathematics (see Larvor, 2016). I follow Ernest's understanding of value as something that is "expressed through the action of valuing", and "manifested in both the prizing of certain characteristics and in the making of fundamental choices" (Ernest, 2016, p. 190), including besides ontic, aesthetic, and ethical values also *epistemic* values (p. 191). Ernest discusses the epistemic values of truth, provability, universalism, objectivism, and rationalism (pp. 193ff.). *Explanation* is a well-known and frequently discussed *function* of mathematical proof, both from the point of view of philosophy and of mathematics education. Frequently proposed features of explanatory proofs are, e.g., surveyability (Müller-Hill, 2013), reference to characteristic features of the involved mathematical entities and structures (Steiner, 1978), or width (Hanna, 2014). These are more or less intrinsic features of mathematical proofs as objects. Understanding explanatoriness as a fundamental *value*, which manifests itself particularly in activities related to mathematical proving, somehow changes the perspective: Explanatoriness is conceptualized rather dialectically by looking for *traces of valuing actions* (like prizing and choice-making) directed at proving in mathematical practice that may *indicate* this value. The issue of (epistemic) *values* in mathematics has, with exceptions like (Lorenzen, 1974, pp. 152ff.), rather been neglected by philosophy of mathematics until recently (Ernest 2016, p. 191) due to the methodological paradigm of classical analytical philosophy, which also dominated philosophy of mathematics for quite a long time. Accordingly, philosophy can contribute to an epistemology of mathematics by conceptually grasping epistemic features of proof through semantic analysis of, e.g., knowledge attributions, resulting in truth-conditions. Concerning the question of epistemic *values* in actual mathematical practice, a different approach is needed that can take concrete valuing actions like prizing and choice-making of practicing mathematicians into account. Valuing actions directed to mathematical proving may include the way in which examples are chosen and exploited during a proving process, the prizing of alternative hypotheses, the choice of definitions and methods, the degree of formalization and abstraction, the representations used, or the fine-grainedness of the argumentation. Philosophy of mathematical practice, a transdisciplinary endeavor at the intersection of philosophy and sociology of mathematics, has developed conceptual and methodological frameworks that allow appropriate investigation of such issues.

### **Results from a socio-empirically informed epistemological study**

In this paragraph, I will review exemplary empirical results from an interview study (Müller-Hill, 2011) conducted with mathematicians of high standing, from various fields of professional specialization areas, under the lenses of explanatoriness as an epistemic value in mathematical

practice (for further methodological details and results of this study, see also (Müller-Hill, 2013)). In general, the interviewees thoroughly point to a strong relation between explanatory proofs and understanding why the proven theorem holds (ibid.; particularly aspects (2)-(4)). This is in line with the close relationship of explanation and understanding which is widely agreed upon in philosophical as well as in didactical discussions (see, e.g., the still prominent, well-differentiated discussion in (Sierpinska, 1994), or the very recent (Dawkins & Weber 2017)). Furthermore, selected quotes from (Müller-Hill, 2011) display that prizing and choice-making within processes of generating, communicating and assessing proofs in mathematical practice happens with respect to the *robustness* of hypotheses and arguments *under local and global attacks*, e.g., when “try[ing] to shoot holes in it” and “ask questions why it is true, why it works this way, not that way” (Interview 4, p. 246). This appears to be particularly relevant in review processes, as “the right way of understanding the contribution that [a] new proof brings” is to ask “what is really the new idea” that “makes something work that previously did not work”, and to find “the key argument that made the proof work”, or instead, “where it breaks”. If the proof is “non breaking” under attacks, one “would see the spark of [a] new idea that finally makes it work” (Int. 5, p. 246). It also includes *variation of perspective or context*, to look at a hypothesis or an argument “from different directions, through different angles” (Int. 4, p. 246). Also, “in the process of understanding it happens that you have a definition, and that you think you understand it, and that you come back to it for one reason, or somebody tells you something about it, and that you realize that you never understood it at all” (Int. 6, p. 246). In prizing and choice-making actions, the *balance between establishing a “big picture” and “the details”* is also valued. The “big picture” conveys “the real understanding of why it is true” (Int. 5, S. 199), a “global idea” of “why it works like that”, an “overview of the proof” (Int. 4, S. 179), which also affects the consistency with already established results. On the other hand, there are “the details, to follow the proof from step to step, the logical consequences” (Int. 4, S. 179), and “the process of writing down these details”, which are sometimes not valued as equally important to the global picture because “not all people are good in this” though they “really know mathematical truths” (Int. 5, pp. 171, 199). A well-balanced proof, in this sense, also makes it easier to “be able to look at it at a later time, and still be able to reproduce the arguments” (Int. 4, p. 179), which is taken as an indicator for understanding (see also (Hanna, 2014)). The different aspects have a *context-dependent impact* on concrete valuing actions: “So one thing: maths is in a sense something personal. [...] When do I think I understand something?” (Int. 4, p. 246), which can be influenced by “deep personal involvement with [a] proof” (Int. 2, p. 313).

### **Explanatoriness within a didactical model of nomic mathematical explanation**

Insights gained from the interview study appear to be in line with the concept of so-called *nomic mathematical explanation* (Müller-Hill, 2017). In this view, an explanation provides a general pattern, expressed by a general conditional sentence, from which a phenomenon can be inferred as a regular consequence under certain conditions. Moreover, an explanatory, nomic pattern has to fulfill certain conditions on form (ibid., p. 181) and content.

#### **Conditions on form: Basic structure of an explanatory pattern**

Whenever manifestation condition(s)  $\mathcal{M} = \{M_1, M_2, \dots, M_n\}$  would be fulfilled, the event  $E$  would take place (as a manifestation of certain properties of the involved objects) **and** whenever manifestation condition(s)  $\mathcal{M} = \{M_1, M_2, \dots, M_n\}$  would not be fulfilled (but condition(s)  $\mathcal{M}'$  instead), the event  $E$  would not take place (but the event  $E'$ ).

The second part of the pattern is usually not formulated explicitly. An example pattern discussed in (ibid., p. 202) was reconstructed from a student's explanation of why the sum of three consecutive natural numbers is divisible by three: *Whenever we would take three consecutive numbers  $a$ ,  $b$ ,  $c$ , and move 1 from the biggest number  $c$  to  $a$ , we would get three times  $b$ .*

### Conditions on content: Basic invariance criteria for an explanatory pattern

Some philosophical contributions on the *concept* of *mathematical* explanation (see Hanna, 2018) provide ontic conditions, like reference to “a characterizing property” or “salient feature“ of the involved mathematical entities, for an argument to qualify as explanatory. Such conditions serve to explicate the conceptual meaning of „explanation“. The account of nomic mathematical explanation developed in (Müller-Hill, 2017) complements the ontic conditions by spelling out *epistemic* invariance conditions as *search keys*, *test* and *quality conditions* for explanatory patterns. It is to a good extent compatible with ideas of explanatory unification and causal explanation that are at the heart of well-established views of scientific explanation (Kitcher 1989). Table 1 reports and illustrates conditions that are relevant to grasp the aspects of explanatoriness resulting from the interview study.

<b>Functional invariance</b>		Invariance under intervention at the manifestation conditions: pattern gives correct information, if $\mathcal{M}$ is fulfilled or not (e.g., regarding the example pattern above: <i>What if I intervene at <math>M_i</math> by taking non-consecutive numbers <math>a</math>, <math>b</math>, <math>c</math>.</i>
<b>Scope invariance</b>	<i>Object invariance</i>	Pattern also gives correct information when the involved objects are varied (e.g., by varying the chosen triplet $(a, b, c)$ ).
	<i>Contextual &amp; representational invariance</i>	Pattern also gives correct information when the used contexts and/or employed representations are varied (e.g., by changing from symbolic to figurative representations of $a, b, c$ ).
	<i>Embedding invariance</i>	Pattern is consistent with corresponding patterns for an embedded or expanded pool of related phenomena (e.g., with the transition from natural numbers $a, b, c$ to integers).

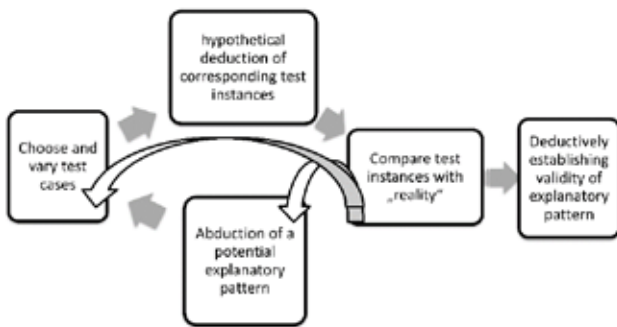

**Table 1: Invariance criteria for explanatory patterns (Müller-Hill 2017)**

Functional invariance is *necessary* for an explanatory pattern. However, there can be explanatory patterns with different degrees of functional invariance, which affects the pattern's *informativity*: the more differentiated the intervention relation, the more informative the pattern. Scope invariance has different specificities (object, contextual/representational, embedding), each of which can also occur with different degrees. The degrees of scope invariance affect a pattern's *systematization power*.

### The process of explanation generation

The *process* of generating a nomic explanation can be described as an iterative cycle of phases of abduction, deduction and induction (Figure 1), starting with *abducting* a potential explanatory pattern.

The abduction may be creative, that is, on the basis of experience gained by working with and varying test cases, the subject identifies a (by her) formerly unknown pattern to explain the phenomenon (e.g., *by exploring  $1 + 2 + 3, 2 + 3 + 4, \dots$* ). But it may also be rather selective, that is, the subject already knows one or several alternative patterns that are explanatory for a class of somehow related, familiar phenomena, and identifies (*by partial analogy, e.g., to familiar opposite-change task formats on addition*) one of these that could potentially also explain the phenomenon in question (Magnani, 2001).

**Figure 1: Interplay of abduction, induction and deduction**

The cycle continues with choosing and varying test cases for the pattern (e.g., for “Whenever we would take three consecutive natural numbers  $a, b, c$ , and take 1 from the biggest number  $c$  and pass it to  $a$ , we would get three times  $b$ ”). Via *hypothetical deduction*, instances of the proposed pattern are produced for each test case (e.g.,  $(1 + 1) + 2 + (3 - 1)$  should be equal to  $3 \cdot 2, \dots$ ). These test instances are then compared with “reality”, thereby *inductively backing* or weakening the pattern (e.g.,  $(1 + 1) + 2 + (3 - 1) = 2 + 2 + 2 = 3 \cdot 2, \dots$ ). If the pattern appears to be sufficiently backed up by inductive evidence, one can exploit the experiences already made to collect ideas for a *deductive justification* of the pattern’s general validity (e.g., by replacing concrete test values for  $a, b$ , and  $c$  by generic figurative or general symbolic representations), or enter the cycle again with a variation of the former test cases to find a more general or more informative pattern (e.g., by trying out equidistant instead of consecutive number tripels). If not, one may iterate the whole cycle.

### Reviewing the results from the interview study

We can now distinguish between explanatoriness in a situated sense, and explanatoriness in a systematic sense (see Table 2), which are complementary.

	Abduction	Quality of invariance	Informativity/systematization
<i>Explanatoriness in a situated sense</i>	creative	Emphasis on functional invariance, detailed and detailed differentiated manifestation conditions	More informative, less systematizing power
<i>Explanatoriness in a systematic sense</i>	selective	Emphasis on scope invariance, generalized manifestation conditions	Less informative, more systematizing power

**Table 2: Situated and systematic sense of explanatoriness**

Employing this distinction, the interview study results reported above suggest that prizing and decision making within mathematical activities related to proving in scientific mathematical practice happens with regard to explanatoriness *both* in the situated and in the systematic sense, with context dependent weighting. This includes, particularly, the balancing of informativity and systematization power, as two complementing aspects of explanatoriness.

## Outlook and future work: Enacting explanatoriness in class

Regarding educational issues, the framework presented in this paper is meant both as a model and tool for researchers to reconstruct, analyze and understand explanation and valuing processes in mathematics and mathematics teaching, and as a basis for task design, and for initiating such processes in classroom. In this sense, the program formulated at the beginning of this paper entails at least two core messages: under an epistemic reading, „mathematical proof” in any strong sense is an ideal construct that is paradigmatic regarding the virtues and validity claims of the discipline of mathematics (that is one reason why we should still teach about it). However, various kinds of actual mathematical activities directed to providing proofs can and should already be driven and regulated with respect to these virtues and validity claims (that is why they work effectively in mathematical practice, and that is how we should teach them). The paper provides a rough impression of how these programmatic aims can be pursued, regarding exploratoriness as an epistemic value connected to proving. Though tersely presented, the reported results already indicate some opportunities and types of activities related to mathematical proving that can be appropriate to enact explanatoriness as a value in class. As a simple example, think of tasks like the following that could be tackled when introducing the concept of mean value (in German Gymnasium, e.g., in grade six): *Starting with a given data set of natural numbers, think of ways to vary the set in order to increase, lower, or leave invariant its mean value. Justify your answers.* Pilot runs with corresponding learning environments in the form of written tasks produced data that we actually evaluate to revise the learning environment design. However, it needs well-trained teachers to exploit such opportunities properly (compare, e.g., Lesseig, 2016a; 2016b). The next step in our work is to gain and analyse video-data from implementations of the revised learning environments. The results will also be used for developing a video-vignette based teacher training for secondary in-service teachers.

*After analyzing the relation between mathematics and computer science and the place given to proof, logic and reasoning, we propose and discuss a framework for the study of their interactions based on the ckç model. Then, we exemplify this model in the analysis of a problem, making explicit a mathematical solution and an algorithmic solution.*

*Keywords: Mathematics, computer science, proof, reasoning, problem solving.*

The research presented in this paper is part of a research project funded by the French National Research Agency, called DEMaIn (Didactics and Epistemology of the interactions between Mathematics and Informatics). This project, started in 2017, aims at better understanding the relations between mathematics and computer science, from an epistemological view, in order to tackle didactical issues (Modeste, 2016). It follows from two observations. On the institutional side, computer science enters many curricula at different levels and in many countries (for France, see Gueudet, Bueno-Ravel, Modeste, & Trouche, 2017). On the epistemological side, computer science and mathematics share many concepts and methods (Modeste, 2016) and their frontier is rather blurry. One of the main topics of the project deals with logic, language, proof and reasoning in mathematics, computer science and their interactions. In this paper, we provide epistemological insights regarding this topic and a framework for analyzing proof and reasoning in problem-solving situations in mathematics and computer science, suited to analyze students activities in these fields, including computer-assisted situations.

## Proof, reasoning and logic in mathematics and computer science

Mathematics and computer science share common foundations, based on logic. Logic makes explicit the language and the validation rules in both disciplines. This directly relates to the nature of proof and reasoning in mathematics and computer science. In previous works we have shown that the role of proof and reasoning is rather similar in mathematics and computer science, but with an emphasis on different kinds of properties (Meyer & Modeste, 2018; Ouvrier-Bufferet, Meyer, & Modeste, 2018). Some specific types of proofs are particularly important at the interface of the two disciplines, like mathematical induction, and its variations.

---

<sup>1</sup> Communication supported by the French National Research Agency <ANR-16-CE38-0006-01>.

We consider that the activities in mathematics and computer science share common aspects, in particular the central role of problem solving. Various models in logic can be used to describe and structure the activities in mathematics or computer science. Following Durand-Guerrier (2008), we consider that First-order logic (namely Predicate Calculus) is a relevant epistemological reference for analyzing mathematical activity in a didactic perspective, allowing to take in consideration the articulations between syntax and semantics. We have provided evidence in (Durand-Guerrier, Meyer, & Modeste, to appear) that it is also the case for computer science.

In this paper, we will focus on four concepts and their relations: proof, formal proof, algorithm and program.

**Proof.** We call *proof* (in mathematics or computer science) a finite sequence of statements organized according to some determined rules (explicitly or implicitly) in order to convince someone of the truth of a statement (Balacheff, 1987). The level of details of the proof generally depends on the source and the recipient of the proof.

**Formal proof.** A *formal proof* is a text consisting of a finite sequence of statements, expressed in a well defined formal language, where the statements are deduced from the previous ones or from axioms following predefined deduction rules. Most of the proofs could be expressed as formal proofs (if the axioms and deduction rules were made explicit). Nowadays, formal proofs are often produced by or for software called *proof checkers* which can automatically validate a proof.

**Algorithm.** An *algorithm* is a finite sequence of organized instructions, that describes how to solve a problem, that is, how to obtain a defined goal starting from given data. The steps must be considered as elementary by the recipient of the algorithm, and the algorithm must not be ambiguous. In other words, the producer of the algorithm and its recipient must agree on the granularity of the details of the algorithm.

**Program.** A *program* is a text consisting of a finite sequence of instructions, written in a well defined (programming) language, that is, having a precise syntax (structure of the language) and semantics (effect of each instruction). An algorithm can be described with a program.

These definitions make clear the fact that the relations between proof and formal proof and between algorithm and program are pretty similar, with, on one side, an informal description, more suitable to human interactions (but also driven by some rationality) and on the other side, a formal language with a precise syntax and semantic, that can be interpreted and checked by computer.

In previous work about algorithmics (Modeste, 2012; Modeste & Ouvrier-Buffet, 2011), we have made explicit the links between algorithm and proof. In particular, any (constructive) proof can be interpreted as an algorithm. In a more formal context, the *Curry–Howard isomorphism* states there is a strict correspondence between programs and formal proofs.

We hypothesize that it is valuable taking into consideration these four concepts for questioning the place of proof and reasoning in mathematics, computer science and their interactions.

Finally, let us precise what we will consider as *reasoning*. We enclose in reasoning, in mathematics and computer science, all the human activities that permit to solve problems and increase the epistemic value of properties or problem solutions. Reasoning is clearly at the origin of the building of proofs, formal proofs, algorithms and programs, and is strongly related to logic. Indeed, logic is

built in order to model the way of reasoning and reasoning is based on a (not completely explicit) set of logical rules (e.g. Mesnil, 2017).

This leads us to formulate the following research questions: What place and role do proof, formal proof, algorithm and program have in the teaching and learning of mathematics, computer science and their interactions? What is the nature of reasoning in computer science in comparison to mathematics and how can we analyze this reasoning in problem-solving and proving activities?

To answer these questions, we are currently developing a framework that permits to analyze problems, problem-solving and proving activities in mathematics and computer science. We will first introduce our framework and then illustrate its possible use by an example. Finally, we will briefly discuss the future development of this framework, in relation with our project's goals.

## **A framework for analyzing reasoning and proving in problem-solving activity**

Our framework is based on a specific definition of *problem*, on a framework called *concept-problem* and on the *ckç* model.

### **The central notion of problem**

The notion of problem and problem solving is central in mathematics and computer science. In the literature, problems attest of the questions of the two fields and, in practice, they structure the research activity. The notion of problem also carries the issue of generality, important in mathematics and computer science. For our purpose, we will use a definition of problem, based on theoretical computer science and computability and complexity theory (see, for instance, Garey & Johnson, 1979). We consider a problem as a pair  $(I, Q)$  where  $I$  is a set of instances and  $Q$  a question that can be instantiated on any of the element of  $I$  (Modeste, 2013). Solving a problem  $P=(I,Q)$  is finding the answer to the question  $Q$  for any element  $i$  of  $I$ . This answer can be given by a formula depending on  $i$ , any characterizations of the subsets of  $I$  for which the answer is a given value, an algorithm that permits to construct the answer for any  $i$ , etc. In all cases, a proof can be given that the proposed solution to  $P$  is correct, that is, for all  $i$  in  $I$ , the answer given to  $Q(i)$  is correct. This definition is general enough to describe any problem.

In Modeste (2012, 2013) we have shown that this definition allows to conveniently analyze curricula, textbooks and activities in algorithmics, in particular concerning the place given to proof. Giroud (2011), has used a similar definition to develop what he called the “concept-problem”, in order to study the problem-solving activities of students, mainly based on the Theory of Conceptual Fields (Vergnaud, 2009). We will rely on Giroud's idea that different problems can be related to the main problem  $p$  studied (called by Giroud the situations “giving meaning to  $p$ ”) and follow his idea of representing problem solving with flowcharts between related problems.

### **The *ckç* model to analyze proof and reasoning**

The *ckç* model (Balacheff, 2013) is an enrichment of Vergnaud's Theory of Conceptual Fields. It considers a concept as composed of four elements: a set  $P$  of the problems that give meaning to the concept and a representation system  $L$  (the *signifier*), similarly to the model of Vergnaud; but it separates the invariants in two types: a set  $R$  of operators that permit to transform a problem in another one; and a set  $\Sigma$  of controls that permit to decide whether an operator  $r$  applies to a given problem  $p$ , and to determine whether or not a problem is solved.

The  $ck\phi$  model has been designed to study proof and reasoning (this motivated the separation between operators and controls) and to be appropriate for analyzing computer-assisted learning situations. This leads us to use it in our research project for describing concepts and conceptions.

### Description of the framework for analyzing problems

We use the  $ck\phi$  model, to describe concept-problems. For us, a concept-problem on a given problem  $p$  will be described with:

- a set  $P$  of the problems that give meaning to the problem  $p$ , that is having a link with  $p$ ,
- a set  $R$  of operators that transform a problem in another problem, we will denote  $p_2=r(p_1)$  if the operator  $r$  transforms  $p_1$  in  $p_2$  or  $p_1 \rightarrow_r p_2$ ,
- a set  $\Sigma$  of controls that describe if an operator  $r$  is relevant to apply on a problem or if a problem is solved;
- a representation system  $L$ , that permits to describe elements of  $P$ ,  $R$  and  $\Sigma$ .

In (Durand-Guerrier et al., to appear; Modeste, 2012) we have used such a framework to analyze the concept “algorithm” and its relation to proof. We proposed to distinguish two levels of problems, to bring to light a tool-object dialectic, and to differentiate the situations where proof concerns the controls level (elements of  $\Sigma$ ) and the situations where the studied problem  $p$  consists in proving something. In this second case, the operators concern proving strategies and the controls of  $\Sigma$  concern logic rules ( $\Sigma$  can remain mostly implicit while controlling the use of the operators).

In this paper, we extend this framework to any situation in mathematics and computer science, including problem-solving and proving situations, assisted or not with a computer. The framework will allow us to focus on proof and reasoning in these activities.

Finally, we consider that the operators and controls occur at two (intertwined) levels: syntactic and semantic. It is clear that the presence of a computer (programming tool, proof assistant or many other tools<sup>2</sup>), brings some new controls (including feedback) that have a strong syntactic dimension. For example, a very basic control can come from what is called *syntactical analysis* which checks if an expression (formula, program, logic statement...) is well-formed with respect to the grammar of the language. This kind of feedback from the computer can be considered as a purely syntactic control. On the other hand, any interpretation (by the user) of the expression in terms of the objects represented or for specific values of the variables would be considered as a semantic control.

### Example of problem analysis

In this section, we illustrate the use of our framework for problem analysis, focusing on analyzing the problem itself, the *a priori* analysis (analysis of students’ solving of the problem is one of our next perspectives). We have selected a problem from a well-known website called Project Euler: “Project Euler is a series of challenging mathematical/computer programming problems that will require more than just mathematical insights to solve. Although mathematics will help you arrive at elegant and efficient methods, the use of a computer and programming skills will be required to solve most problems.” (<https://projecteuler.net/>). These problems, at the interface between

---

<sup>2</sup> For example CAS or softwares like Aplusix: [www.aplusix.com/](http://www.aplusix.com/)

mathematics and computer science, seem interesting to us to confront our framework. We will consider the following problem:

**Problem 1.** If we list all the natural numbers below 10 that are multiples of 3 or 5, we get 3, 5, 6 and 9. The sum of these multiples is 23. Find the sum of all the multiples of 3 or 5 below 1000.

In our framework, the problem can be described as an instance of the general problem  $P_{3-5}(I, Q)$  with  $I$  the set of all natural numbers and  $Q(i)$  the question “What is the sum of all the multiples of 3 or 5 below  $i$ ?”. Although the problem consists in solving  $P_{3-5}(1000)$ , the value 1000 is large enough to require to think about the general problem while solving it.

Here, we will describe with flowcharts two ways of solving the problem<sup>3</sup>, one considered as more “mathematical” and the other considered as more “algorithmic”. In the flowcharts, problems are represented in blue and arrows between them represent the transformations under the action of an operator (in green) selected according to a control in red (controls on operators and on the status of problems). Sometimes, an operator can generate several problems. We will not give details about the representation system  $L$  in this paper.

### A “mathematical” solution

This solution is based on the observation that if we want to sum all the multiples of 3 and 5 under 1000, we can count the multiples of 3 and the multiples of 5, and only multiples of 15 will be counted twice. Since we can derive from the formula of the sum of the first integers a formula for the sum of the first multiples of any  $n$ , we can solve  $P_{3-5}(1000)$ . In the end, we can write:

$$\sum_{\substack{k=1 \\ 3|k \text{ or } 5|k}}^{999} k = \sum_{\substack{k=1 \\ 3|k}}^{999} k + \sum_{\substack{k=1 \\ 5|k}}^{999} k - \sum_{\substack{k=1 \\ 15|k}}^{999} k = 3 \sum_{k=1}^{333} k + 5 \sum_{k=1}^{199} k - 15 \sum_{k=1}^{66} k = 233168$$

### An “algorithmic” solution

This solution is based on an enumeration of the numbers below  $n$ , a test of the property “being a multiple of 3 or 5” and an accumulation of the values satisfying the property. This can lead to this algorithm (in a pseudo-code, close to the programming language Python):

<b>Function Sum_3-5 (n)</b>  $S = 0$ <b>for</b> $k$ <b>from</b> 1 <b>to</b> $n-1$ : <b>if</b> $k \bmod 3 == 0$ <b>or</b> $k \bmod 5 = 0$ <b>then</b> $S = S + k$ <b>return</b> ( $S$ )	% We define a function returning the sum % of the multiples of 3 or 5 below n % S will contain the sum of the multiples % We enumerate the integers below n % if they are multiples of 3 or 5 % we add them to S
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<sup>3</sup>

Due to space constraints, we cannot show all the solutions that we have identified in our *a priori* analysis.

The solving process is described more precisely by the flowchart in figure 2.

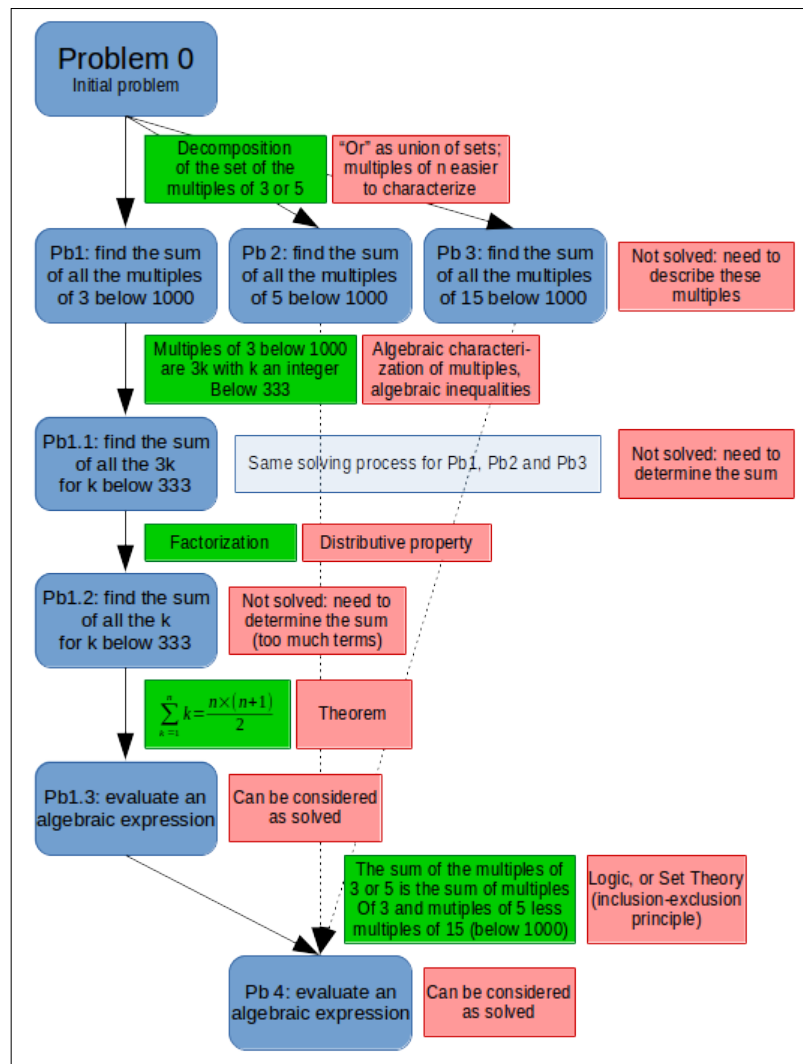

Figure 1: A mathematical solving

### Discussion and comparison of the 2 solutions

The two solving processes analyzed show two very different (correct) strategies. We can clearly distinguish the types of operators and controls that take part in the solutions. In the mathematical solving process, we can notice how the use of algebraic operators (factorization, formula...) are controlled and chosen regarding the sub-problem studied. In the algorithmic solving process, we can notice operators and controls that make clearer the way decisions can be taken about choosing algorithmic tools ("for" loop, "if" structure). Although operators and controls are different between the two solving processes, we can notice that the framework allows to describe finely both of them. This supports our claim that there are many common aspects of the problem-solving process in mathematics and computer science.

### Conclusion and perspectives

Our framework permits to analyze problem-solving strategies in mathematics and computer science, with an emphasis on proof and reasoning. On the epistemological side, it puts light on the controls in mathematics and computer science and will permit to discuss their differences and common

points, which can be taken into account in a didactical perspective. The framework should also permit to describe and analyze problem-solving strategies developed by students, in particular faced with problems that can be solved with mathematics and computer science. Another goal is to be able to use this framework for situations that integrate formal tools (computer-assisted situations) – by detailing syntactic controls and their use, which needs to detail the role of the system of representations L – and for situations of proof and proving (by taking into account different levels of control, as aforementioned). In the next step of the DEMaIn project, we will use this framework in the design, analysis and experimentation of didactical situations at the interface of mathematics

and computer science.

# A systemic investigation of students' views about proof in high school geometry: the official and shadow education systems in a school unit

Andreas Moutsios-Rentzos<sup>1</sup> and Eleni Plyta<sup>2</sup>

<sup>1</sup> University of the Aegean, Greece; [amoutsiosrentzos@aegean.gr](mailto:amoutsiosrentzos@aegean.gr)

<sup>2</sup> University of Athens, Greece; [lnemath4@hotmail.com](mailto:lnemath4@hotmail.com)

*In this paper, we discuss the views that the high school students of a school unit hold about proof in geometry. We consider the school unit as an open system that in Greece functions at the interaction of the official and the shadow education system. We mapped aspects of the institutional discourse that are visible to the students: the school teachers, the geometry textbook and the shadow education teachers. We focused on five different types of reasoning that may appear as a proving argument (acceptable or not): empirical, narrative, abductive, reductio ad absurdum, formal. The results of the mixed methods data collection and analysis revealed complex interactions of the two systems on the students' views and on their mathematical identity construction.*

*Keywords: Proof, geometry, complexity, high school, shadow education.*

## Proof in high school geometry: official and shadow education systems

Though proof and proving lies at the heart of modern mathematics, research findings suggest that the high school students experience limited opportunities to be engaged in rich proving practices (Otten, Gilbertson, Males, & Clark, 2014). The geometry course may potentially give the high school students opportunities to deal with different types of proof (Hanna & de Bruyn, 1999), but this feature seems not to be exploited in the geometry classroom, where the vast majority of the experienced proofs seem to be of the form: a deductive argument written in formal mathematical language (Battista & Clements, 1995). Furthermore, though abductive reasoning is at the crux of the proving process (Arzarello, Andriano, Olivero, & Robutti, 1998), the students seem to struggle using an abductive argument in the formulation of a deductive proof (Pedemonte & Reid, 2010). Considering the language of proof, Weber (2010) differentiated the deductive arguments expressed in a *narrative form* (using everyday language) from the *formal* ones (using necessary mathematical relationships for the proof theorem and linking words without explanation steps or texts). Moreover, the students seem to mainly choose an argument that is expressed in a mathematically acceptable way (valid or not), in order to satisfy a teacher, rather than themselves (Hoyles & Healy, 2007).

Drawing upon the fact that a significant number of high school students in Greece attend private tutoring lessons (Bray, 2011; which increases as the students approach the national exams to enter university), our study attempted to map the perceived effect to the students' views about proof in geometry, with respect to *both* the *official education system* and the *shadow education system*. 'Shadow education' refers to the private tutoring, which complements the official school teaching and is focussed on improving the students' performance in the official education system (Bray, 2011; Mazawi, Sultana, & Bray, 2013; Mori & Baker, 2010). In this study, we employ the term *institutional discourse* to refer to all the sources of mathematical authority that are visible to the students, which may communicate to the students what a high school acceptable proof in geometry

should be. The school teachers and the textbook communicate what the students perceive as an officially acceptable proof (Bieda, 2010), but the effect that an un-official source authority (such as the teachers of the shadow education system) would have on their views about an acceptable proof in geometry remains an open question.

In line with our previous studies (Moutsios-Rentzos & Pitsili-Chatzi, 2014; Moutsios-Rentzos & Korda, 2018), we focus on the school unit as an open system interacting with the broader educational system: official and shadow. Considering that the elements and the subsystems of a system are in a reciprocal relationship, constantly changing themselves and the system, we posit that the students in a school classroom who attend private tutoring lessons constitute a sub-system of the school unit, affecting and being affected by the official and the shadow institutional discourse, thus affecting the whole school unit. A similar role is played by the school textbook, which constitutes a seemingly common reference point for both official and shadow teaching. Nevertheless, the teachers' personal views and practices are mediators of the textbook knowledge to the students (Hanna & de Bruyn, 1999). This is a complex situation, since teachers (official or shadow) may choose to differentiate their teaching content from official textbooks (Tarr, Chavez, Reys, & Reys, 2006), whilst at the same time they are influenced by their own views or beliefs about geometry when it comes to teaching practices (Stipek, Givvin, Salmon, & MacGyvers, 2001).

Following these, we adopted a systemic approach to investigate the high school students' views about what constitutes an acceptable proof in high school geometry. We focussed on what is *visibly* communicated to the students as the *institutional discourse* about proof in geometry, in a three-faceted model: the *school teacher practices* and the *textbook* (representing the official education system discourse), as well as the *private tutoring school teacher practices* (representing the shadow education system discourse). In this study, our conceptualisation of the institutional discourse about proof includes the different proving methods and argument types employed in the proving argument, as well as the language employed in expressing the argument. In order to gain deeper understanding about the wholistic impact that the official and shadow education institutional discourses may have on the students' relationship with mathematics, we investigated the students' *mathematical identity*, contrasting their *self-identification* with their *being identified by the others* (Abreu & Cline, 2003; Kafoussi, Moutsios-Rentzos, & Chaviaris, 2017). In this case, the significant 'others' were the school and private tutoring school teachers. The construct of mathematical identity allows us to obtain a measure of the qualitative relationship that the student has with mathematics, as well as of its links with the authority figures of the official and the shadow education system. Consequently, we address the following questions: a) What aspects of proof and proving practices are identified in the three-faceted institutional discourse (the school geometry textbook, the school teachers' practices and the shadow education teachers' practices)? b) How do the students relate these aspects of proof with the three-faceted institutional discourse? c) How do the students identify themselves with respect to mathematics and the three-faceted institutional discourses?

## Methods and procedures

The study was conducted with the students attending the first grade (16 years old) of a public Greek "Lykeio" (high school). We included in the study only the students who took private tutoring

lessons (N=47; out of 76), their geometry teachers (with the pseudonyms Petros, Katia and Michalis) and the private tutoring school teachers (with the pseudonyms Thaleia, Nikolas, Dionysis) of a private tutoring school that is chosen by the vast majority of the students. Finally, we considered the official geometry textbook (Argyropoulos, Vlamos, Katsoulis, Markatis, & Sideris, 2010). The data collection was conducted close to the end of the first high school year, including:

- 1) *School textbook analysis* with the task (of both theory and applications) being the unit of the content analysis. We drew upon Otten et al. (2014) and Weber (2010) to investigate the following: a) *proving methods* including: *direct* proof, the Euclidean-type of proving in geometry *analysis and synthesis* (drawing from Pappus; see, for example, Heath, 1956, p. 442), and *reductio ad absurdum*; b) *argument type* including: *deductive*, *empirical*, an *outline* of the proof, explicit indication that is already proven elsewhere or that it will be proved later (*past or future*), no argument but explicitly *left to be proven by the students*, and *no argument*; c) *deductive proof language* (see Weber 2010): *formal* (containing mainly symbolic language) or *narrative* (containing mainly natural language).
- 2) *Structured observations* of the school teachers' teachings (the private tutoring school did not give us permission to conduct any observations), in order to obtain a mapping of the proving practices communicated in the school class by the teachers. We focused on the teachers' practices about proof reasoning and proof language in the school class.
- 3) *Semi-structured interviews* with the school and the shadow education teachers to investigate their proof teaching practices; based on Almeida (2000), Bieda (2010), Moutsios-Rentzos and Korda (2018).
- 4) *Students' views about proof in geometry questionnaire*, to identify their views about which proving argument is more likely to appear in the school textbook, the school class or the shadow education. We chose a theorem from the school textbook (with no proof included) and five arguments (Balacheff, 1988; Weber, 2010): deductive-narrative, deductive-formal, abductive, reductio ad absurdum, empirical (see Figure 1).
- 5) *Being good at maths questionnaire*, investigating the way that the students' identity is constructed, contrasting self-identification ("I am ... at maths") and being identified by the teachers of the two systems ("My school teacher considers me to be ... at maths", "My shadow education teacher considers me to be ... at maths") on a five-point Likert scale (with "3"= "average").

## Mapping the official and shadow education systems in a school unit

### The geometry textbook

The geometry school textbook includes mainly deductive arguments (see Table 1), which appear in the form of direct proof, with reductio ad absurdum and analysis-synthesis proofs having fewer appearances. Concerning language, students encounter deductive arguments in narrative form in the theory part of the book, while the applications are both in narrative and formal form. Thus, proof in the Greek Geometry textbook is communicated mainly as a direct proof, containing deductive-narrative arguments, which accords with the findings of the analysis of the Greek Algebra textbook of the same Lykeio grade (Moutsios-Rentzos & Pitsili-Chantzi, 2014).

Appearances of proof and proving	Theory	Applications	Total
<i>Argument type</i>			
Deductive	73	32	105
Empirical	6	0	6
Outline	3	0	3
None - Past or future	1	0	1
None - Left for students	4	0	4
None	35	0	35

Direct	63	27	90
Analysis-Synthesis	2	3	5
Reductio ad absurdum	10	0	10
<i>Deductive proof language</i>			
Narrative	45	18	63
Formal	28	14	42

**Table 1: Appearances of proof and proving in the school geometry textbook.**

### **The school teachers' proof teaching practices**

Considering their teaching practices, as well as the type of arguments and expected students' activity, deductive reasoning came up with the highest appearance in the school classroom. The teachers were mainly asking students about deductive, yet isolated, arguments rather than a complete proof, which later were collected and written by the teacher to constitute the proof. In case of the students' having difficulties in finding arguments or synthesising the proof, the teachers asked additional questions, feeding the students' abductive argumentation. In general, abductive arguments were quite common, but they were not present in the written proof, as they did not include reasoned conjectures (Herbst & Arbor, 2004). No reductio ad absurdum or empirical arguments were included in the teachings we observed: neither by the teachers, nor in the students' responses. Considering the language of the arguments, we noticed a divergence between verbal and written arguments: the teachers constructed the proof in a more narrative form, while the arguments written were closer to formal. The teachers justified this choice, as a result of the limited instruction time within the classroom. Moreover, considering types of reasoning, all three teachers stressed the importance of abductive reasoning in their teaching, as abductive arguments help students to focus, think and find the "right solution". Nevertheless, their reluctance to include them in the written proof is evident, as, for example, Katia stated that she prefers to use the "formal way", indicating the type of arguments used in the official textbook. Commenting about the rest of deductive forms

used in the school textbook, the school teachers noted that *reductio ad absurdum* alienates students, as it is not commonly found in the textbook and the teachers themselves don't use it in the classroom. Finally, all teachers agreed that empirical arguments are employed in the school classroom, but they all said that they emphasise to the students the fact that the idea "it's right because it looks like so" is not acceptable in geometry.

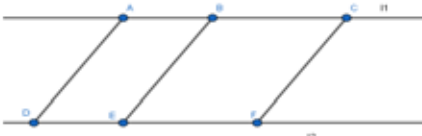

<p><b>Prove that parallel segments who have their extremes in two parallels lines are congruent.</b></p>  <p><b>Abductive argument</b> We notice that in order to prove that segments AD, BE and CF are congruent, we only have to prove that quadrilaterals ABED and BCFE are parallelograms, because afterwards using parallelogram properties we will be able to assume that the opposite sides are equals. But the latter statement is applicable since <math>AB \parallel DE</math> and <math>AD \parallel BE</math> (using the assumptions given) which means ABED is a parallelogram, and also <math>BC \parallel EF</math> and <math>BE \parallel CF</math> which means that BCFE is a parallelogram.</p> <p><b>Empirical argument</b> We can notice using the diagram that quadrilaterals ABED and BCFE are parallelograms. Thus they have their opposite sides equals, so <math>AD = BE = CF</math>.</p>		<p><b>Deductive-formal argument</b> <math>l1 \parallel l2</math> thus <math>AB \parallel DE</math>. Also <math>AD \parallel BE</math>. Using the definition, ABED is a parallelogram, thus <math>AD = BE</math>. Working similarly for BCFE. So: <math>AD = BE = CF</math></p> <p><b>Deductive narrative argument</b> We know that quadrilateral ABED has two pairs of parallel sides: <math>AB \parallel ED</math> since <math>l1 \parallel l2</math> and <math>AD \parallel BE</math> (given as an assumption). So, we can conclude using parallelogram definition that ABED is a parallelogram, thus it has its opposite sides equals, meaning <math>AD = BE</math> (1). Working similarly, the quadrilateral BCFE is a parallelogram, since <math>BC \parallel EF</math> (<math>l1 \parallel l2</math>) and <math>CF \parallel BE</math>, so we can conclude that <math>BE = CF</math> (2). From (1), (2) we conclude: <math>AD = BE = CF</math>.</p> <p><b>Reductio ad absurdum</b> Let segments AD, BE, CF be parallel but not congruent. The quadrilaterals ABED and BCFE are parallelograms (since they have two pairs of parallel sides) but they don't have their sides equals (from our assumption). The latter statement is invalid, considering parallelograms properties, thus the segments AD, BE, CF are congruent.</p>	
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

Figure 1: One statement, five arguments

### The shadow education teachers' proof teaching practices

Considering the shadow education system, the private tutoring school teachers also chose to talk especially about abductive reasoning and the abductive arguments they use in the classroom. Referring to deductive proofs, they made a special reference to *reductio ad absurdum* and the difficulties the students face, because of their lack of knowledge of mathematical logic. All three agreed that they use this proof type only when it's absolutely necessary in a school textbook case and nowhere else. Finally, they also agreed with the school teachers that they make absolutely clear in their students that they must reject empirical arguments in geometry, because "it says prove that they are parallels, not see that they are parallels" (Nikolas). Considering the argumentation form, the teachers stated that while they accept all argumentation forms that their students would produce, they prefer to use more narrative and less formal arguments. They also expressed their preference for narrative arguments, commenting about textbook's proofs: "I write it the way I think of it at that time or the way my student uses...I want to keep close to the textbook's proof, but I think the language used is very formal and students don't understand it written this way" (Dionysis).

### The students' views: the school teacher, the shadow education teacher, the textbook

Considering the students' evaluations about the five argument types, it seems that when focussed on the official discourse (school textbook and teaching), the students evaluate the presented arguments as not to statistically significantly differ from the theoretical neutral, with only the empirical argument getting a statistically significant lower evaluation ( $Mdn=2.0$ ,  $P=0.005$ ; One-sample Wilcoxon Signed Rank Test). Considering the unofficial institutional discourse, three arguments (Narrative, Abductive, *Reductio ad absurdum*) were evaluated as looking statistically significantly

closer to what the students encounter in the private tutoring school teachings (respectively,  $Mdn=4.0$ ,  $P=0.001$ ,  $Mdn=4.0$ ,  $P=0.006$ ,  $Mdn=4.0$ ,  $P=0.001$ ; One-sample Wilcoxon Signed Rank Test). When considering both official and shadow education, the Friedman's ANOVAs (followed by Wilcoxon Signed Ranks Tests with Bonferroni correction applied) revealed that the students considered three argument types (Abductive, Reductio ad absurdum, Empirical) to be statistically significant more like the ones they encounter in the shadow education teaching in comparison with the official system: Abductive (teaching and textbook; respectively,  $P=0.024$ ,  $P=0.001$ ), Reductio ad absurdum (only textbook;  $P=0.001$ ), Empirical (teaching and textbook; respectively,  $P=0.497$ ,  $P=0.003$ ). No statistical differences were identified in the Deductive and Narrative arguments.

Concerning the students' mathematical identity about their 'being good at maths', the students thought that their school teacher's identifying them as being good at maths, would not statistically differ from "Average" (see Table 2). In contrast, their self-identification and their being identified by the shadow education teacher is statistically significantly higher than the "Average". When considering both systems, it is revealed that the students' self-identification does not statistically significantly differ from their school teacher's identification, but it is statistically significantly lower than their shadow school teacher's identification.

<i>Being identified by the ...</i>	<i>M</i>	<i>Mdn</i>	<i>P<sup>a</sup></i>	<i>P<sup>b</sup></i>	school class <sup>c</sup>	shadow education
school class teacher	3.15	3.00	0.340	<0.001		
shadow education teacher	4.17	4.00	<0.001		<0.001	
<i>Self-identification</i>	3.38	4.00	0.028		0.312	<0.001
<i>Notes.</i> <sup>a</sup> One-sample Wilcoxon Signed Rank Test (Median = '3': "Average"). <sup>b</sup> Friedman's ANOVA. <sup>c</sup> Wilcoxon Signed Ranks Test (with Bonferroni correction applied).						

**Table 2: Student's identification about their "being good at math"**

### **Re-visiting the complexity in the school unit: concluding remarks**

Considering the institutional discourse, the school teachers and the textbook seem to converge. The textbook analysis revealed the dominance of deductive, narrative arguments, in the type of direct proof, with few appearances of proof by analysis-synthesis or reductio ad absurdum. The same argument types are evident in the observed proving practices of the school teachers, though they state the importance of abductive arguments in the conjecturing phase of proving. Considering the shadow education teachers' *reported* practices (since no observations were conducted), we identified a bigger variety of the type of arguments and the language used. While they uphold the view of geometry proof as a deductive argument, they explicitly stated that most of the times the teacher has to add more ideas and to differentiate the argument or the language used, in order for the solution to be more transparent and accessible to the students. Furthermore, they agreed with the school teachers about the importance of abductive reasoning and argumentation in teaching, as well as about their stressing to the students that empirical arguments are not acceptable in geometry.

The students' views seem to converge with the institutional discourse, as the empirical and the reductio ad absurdum argument are the least likely to be chosen by the students. Furthermore, the

fact that the institutional discourse favours the narrative form is evident in the students' views. The students' views also support the private tutoring schools claims for a richer proof repertoire, as three arguments types (Narrative, Abductive, Reductio ad absurdum) were evaluated as being statistically significantly looking closer to what they encounter in the private tutoring school teachings than the school class teaching. Though the empirical argument was not evident in our observations and the teachers strongly argued against its being a valid argument, the students' views revealed that for them it is an argument that was missing only in the school textbook.

The students' self-identification about their being good at math converges with their school teacher, even though they think that their private tutoring school teacher would think higher of them. Thus, though both teachers are sources of mathematical authority, the students' self-identification seems to be aligned with the teacher of the official system. The importance of this alignment lies on the general nature of the phrase "being good at math", which embodies the students' positioning about mathematics. Hence, the students identify themselves as being good at mathematics or not, in line with the school teachers' sociomathematical norms.

Consequently, the complex relationship of the two systems is evident on their links with the students' views about proof. The shadow education system seems to offer a richer proof experience, which remains essentially unofficial, in meaning it does not significantly affect the students' mathematics identity construction. Further research should be conducted to map these relationships, as they develop through the three Lykeio grades; especially in the last grade of Lykeio, where the national exams (required to enter university) are a third pole of authority that transcends all school units, thus affecting the authority of both the shadow education teacher and the school teacher.

# Meta-knowledge about definition: The case of special quadrilaterals

Shogo Murata

University of Tsukuba, Graduate School of Comprehensive Human Sciences, Japan;

[smurata@human.tsukuba.ac.jp](mailto:smurata@human.tsukuba.ac.jp)

*Keywords: Defining, meta-knowledge, special quadrilaterals*

## Introduction

In proving processes, it would be important for us to focus not only on proofs but also on definitions. For example, if the same mathematical object can be defined differently, the chosen definition plays a crucial role in proving different results on properties of the object. The previous studies related to definition and defining focus on interactions between concept images and concept definitions (Vinner, 1991; Zandieh & Rasmussen, 2010), or interactions between examples and definitions (Zaslavsky & Shir, 2005; Zazkis & Leikin, 2008). While it is important for us to focus on the role of the example, it is also important to notice the Meta-Knowledge about Definition (MKD). MKD would be characterized as a controller of constructing definitions. Therefore, it is necessary to answer the question: How can Meta-Knowledge about Definition foster students' defining activities?

## Method

The method is theoretical exemplification for prospective empirical investigation, which is the construction a framework and the use it through some examples. When we define mathematical objects, the definitions would be controlled by some criteria. Here, the definitions themselves are described by object-language and the criteria of definitions are described by meta-language. Van Dormolen & Zaslavsky (2003) proposed the seven criteria of definition: hierarchy, existence, equivalence, axiomatization, minimality, elegance, and degenerations. Table1 is proposed by reorganizing these criteria as MKD. It is expected to characterize students' defining activities from the perspectives of definitions, examples, and MKD.

Purpose:	Define it relatively according to the purpose or the context.
Existence:	Confirm the object to define exists in a system.
Equivalence:	Construct equivalent statements about the object to define.
Arbitrariness:	Define it by selecting a statement from the equivalent statements.
Coherence:	Define it by using undefined terms and defined terms.
Non-circularity:	Define it not to make definitions circular reasoning.
Non-contradiction:	Define it not to be a contradiction to other definitions.
Minimality:	Define it by minimal conditions for the existence.
Elegance:	Define it more nicely, more simply, or more applicably.
Exactness:	Define it exactly to exclude examples not to expect.

**Table1: The components of Meta-Knowledge about Definition**

## Result and Conclusion

By using the components of meta-definition, we defined ten special quadrilaterals: (1) Square, (2) Rectangle, (3) Rhombus, (4) Parallelogram, (5) Isosceles trapezoid, (6) Kite, (7) Cyclic quadrilateral, (8) Trapezoid, (9) Ellipse quadrilateral, (10) Tangential quadrilateral (See Figure 1). The *purpose* of defining was to construct a hierarchical classification focusing on sides and angles. According to the *elegance*, we defined these quadrilaterals focusing on duality between sides and angles. The quadrilaterals of (3), (6), (9), and (10) were defined by focusing on equality of sides, while the quadrilaterals of (2), (5), (7), and (8) were defined by focusing on equality of angles. Furthermore, according to the *exactness*, the definition that “A kite is a quadrilateral in which two pairs of adjacent sides are equal” was not accurate. It was necessary to correct “two pairs” to “*distinct* two pairs” for exact definition. As a result, we constructed the hierarchical classification focusing on sides and angles, and discovered the ellipse quadrilateral which is an unfamiliar figure but should exist certainly.

It is concluded that students’ mathematical defining activities could be fostered through some processes in which mathematical definitions are controlled by MKD. We could use the components of MKD as a framework for analyzing students’ mathematical defining activities. The implication for mathematical practice is to pay attention not only to the interactions between example and definition but also to the role of MKD. It is important for teachers to prepare teaching materials that will facilitate students’ activities of examining definitions at a meta-level.

*In tertiary education, proof comprehension, that means reading and understanding written proofs, is an important activity in learning processes. However, to our knowledge there are no (empirical) studies analyzing the influence of reading strategies and the students' individual characteristics on proof comprehension, yet. We developed a proof comprehension test in analysis based on an assessment model of Mejia-Ramos et al. (2012) to test the relation of students' individual characteristics to proof comprehension. To get a first in-depth look which factors influence proof comprehension we analyzed the data of 64 students in their second semester in university. Additionally, we asked the students about their use of reading strategies. The results show that proof comprehension correlates with prior knowledge and with the use of single reading strategies. Possible consequences for mathematical higher education are discussed.*

*Keywords: Proof comprehension, reading strategies, individual characteristics.*

## Introduction

Learning how to prove is one of the main components students have to encounter in tertiary mathematics programs. In order to understand, what a proof is and how to construct proofs, students read many proofs for example in their lectures or in their text books. Those proofs are given to the students by their lecturers, not only to show them, that an assumption is true, but also to teach proof methods and general ideas of mathematics that are used in the proof (Mejia-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012; Weber 2012). In many papers, understanding proof covers and is measured by different aspects like comprehending the written text, validating if a given argument can be categorized as a proof, evaluating of given arguments or even constructing a new proof. Stylianides (2015) questioned the validity and comparability of those different research findings:

“Take, for example, a study that draws conclusions about students' understanding of proof based on students' argument constructions in response to a number of proving tasks. This study is likely to report a poorer picture of students' understanding of proof than another study that considered also students' evaluations of their own constructions (...)” (Stylianides, 2015, p. 213)

Selden and Selden (2015) mention four concepts related to proof or proving in mathematics education research literature: proof construction, proof validation, proof evaluation, and proof comprehension. Proof construction is about doing proofs of given statements. Distinguishing if a written argument is a (correct) proof is defined as proof validation, and assessing if a given proof is nicely written is meant by proof evaluation. Lastly proof comprehension means to understand a written and correct proof. In this contribution, we focus on proof comprehension in the field of “analysis”, concrete which individual characteristics and reading strategies may influence proof comprehension.

## Theoretical Framework and related literature

The definition of proof comprehension has to cover many different aspects and is connected to the question of how to measure proof comprehension. A first approach in this direction was done by Mejia-Ramos et al. (2012) by developing an assessment model for proof comprehension. Their model consists of seven dimensions, divided into two categories without a hierarchical order. Understanding a proof on a local basis includes to understand the *meaning of the proof's terms and statements*, the *logical status of statements and proof framework* and the *justifications of claims*. To understand the proof on a holistic basis, one has to *summarize the proof via the high-level ideas*, identify the *proof's modular structure*, *transfer the general ideas or methods to another context* and *illustrate the proof with examples*. Based on this assessment model, Mejia-Ramos and colleagues constructed proof comprehension tests and also gave an instruction manual on how to develop and validate such proof comprehension tests (Mejia-Ramos, Lew, La Torre, & Weber, 2017; Mejia-Ramos et al., 2012). Likewise, Hodds, Alcock, & Inglis (2014) developed proof comprehension tests and measured a positive influence of their self-explanation training on the proof comprehension of undergraduate students. To solve items of a proof comprehension test correctly, learners have to read the proof and sometimes to combine the content of the proof with prior knowledge. Items should be avoided that can be solved by referring to the prior knowledge only and not to the proof. These items would only assess prior knowledge and not proof comprehension.

In order to analyze students' behavior while trying to comprehend written proofs, Weber (2015) videotaped and analyzed four excellent students in their senior year while reading proofs. He identified five strategies which the students used to foster proof comprehension: “(i) trying to prove a theorem before reading its proof, (ii) identifying the proof framework being used in the proof, (iii) breaking the proof into parts or sub-proofs, (iv) illustrating difficult assertions in the proof with an example, and (v) comparing the method used in the proof with one's own approach” (Weber, 2015, p. 289). In a follow-up study reported in the same paper, Weber asked 83 mathematicians, whether they desired their students to implement those strategies, and most mathematicians did. In a separated study, Weber & Mejia-Ramos (2013) found similar strategies while watching major students read proofs and also present results indicating that a majority of students claimed not to use these strategies. In contrast to this Weber & Mejia-Ramos (2011, 2014) interviewed mathematicians why and in which way they read proofs. One reason to read proofs was to discover the proofs' methods which may be useful for the mathematicians own research. To get the main ideas, the mathematicians zoom in on a proof's problematic parts and zoom out and look at the high-level structure.

As far as we are aware, there is no (empirical) study analyzing whether the use of those strategies has indeed an influence on proof comprehension and whereas students benefit from the strategies mathematicians use. Psycho-linguistic studies showed that general reading comprehension correlates with prior knowledge and the use of reading strategies (e.g. Carell, 1983; Crowley & Azevedo, 2007; Pearson, Hansen, & Gordon, 1979;). We find similar results in mathematics education research referring to other concepts of proving. For example, Sommerhoff et al. (2016) analyzed the influence of domain specific and domain general cognitive student prerequisites on proof validation and showed, that conceptual mathematical knowledge influences the students' proof validation skills. Those results suggest a possible relation between prior knowledge and the use of reading strategies

on proof comprehension. Additionally, psycho linguistic researchers looked at the relation between individual characteristics and reading or text comprehension. For example, individual interest has a positive influence on text comprehension (see e.g. the overview of Schiefele, 1992). Despite this, we have not yet found an analysis concerning the relation between individual characteristics like interest or self-concept and proof comprehension.

All in all, we assume that the analysis of the relationship between reading strategies, individual characteristics and proof comprehension provide a deeper insight into the role of proof comprehension in undergraduate learning processes. Besides, such an analysis probably contributes to develop interventions supporting undergraduate students improving their proof comprehension.

## Research questions

In this study we analyze the relation between proof comprehension, the use of reading strategies, and individual characteristics like interest in proof. Therefore, we focus on the following research questions:

1. Are proof reading strategies correlated with proof comprehension?

*According to the results of Weber (2015) and Weber & Mejia-Ramos (2013) we expected the above mentioned five reading strategies to influence proof comprehension. In addition, we expected some influence of the reading strategies based on the self-explanation training of Hodds et al. (2014).*

2. Do individual characteristics (like self-concept, interest or prior knowledge) correlate with proof comprehension?

*General reading comprehension research showed relations between reading comprehension, prior knowledge and some individual characteristics, especially interest. We expected prior knowledge to influence significantly proof comprehension and we assumed at least a little relation between proof comprehension and interest in proof or interest in university mathematics.*

## Method

### Sample

Our sample consist of 64 students (21 students in a bachelors' program, 34 students in a teacher education program, to 9 students we have no information concerning their study program) in their second semester at a German university. Both types of students heard the same lectures till now. The mean value theorem, which was used in the proof comprehension test, was part of their Analysis I lecture, but with a slightly different proof.

### Measuring proof comprehension

Based on the assessment model of Mejia-Ramos et al. (2012), we developed a proof comprehension test to the mean value theorem, which states that if  $f$  is a continuous function on a closed interval  $[a, b] \subset \mathbb{R}$  and differentiable on the open interval  $(a, b)$ , then there exists a point  $c \in (a, b)$ , such that the tangent in the point  $c$  equals the secant through the endpoints  $a$  and  $b$  of the interval. The proof of the theorem uses a helper function  $h$ , and distinguishes two cases,  $h$  constant and  $h$  not constant, to show the assertion.

As the proof is not written in detail, for example not all justifications are explained, we could develop items based on the assessment model of Mejia-Ramos et al. (2012). First, we constructed open-ended items for every dimension of the assessment model. Then we wanted to change most of the items to multiple-choice items because the objectivity of the test is raised in this way. Still, most of the items remained as open items, because it was not possible to create good distractors. The first version of the test was given to experts of the *khdm* (Kompetenzzentrum für Hochschuldidaktik in Mathematik, in english: Centre for Higher Mathematics Education) for a review. We improved the test based on their answers and comments. Afterwards the new version was given to 52 students at the end of their first semester in an analysis lecture. Their answers were analyzed, and the test again revised. The final test had 10 items, 5 items referring to a more local comprehension and 5 to holistic comprehension. Four of them were multiple-choice Items. This is an example of a multiple-choice item referring to holistic comprehension:

We prove $h(a) = h(b)$ . Why is this useful in the proof?	
<input type="checkbox"/>	$h(a) = h(b)$ shows that $h$ is differentiable in $(a, b)$ . (13.0%)
<input type="checkbox"/>	If $h(a) \neq h(b)$ , then the maximum or minimum of $h$ could be on the endpoints of $[a, b]$ . (right answer, 53.7%)
<input type="checkbox"/>	If $h(a) \neq h(b)$ , then we could exclude the case „ $h$ constant“. (24.1%)
<input type="checkbox"/>	$h(a) = h(b)$ shows $f(a) = f(b)$ and therefore $f$ could be constant. (9.3%)

**Figure 1: Item in the proof comprehension test (percentage of chosen answers,  $N = 62$ )**

We took care, that the items could not be answered by prior knowledge only. Each item was scored dichotomously, i.e. one point for a solution which was accepted as correct and zero points for other solutions. Concerning the multiple-choice items only one answer was correct (1 point). The open items were coded separately by two people given 1 point for a correct answer with only small mistakes (for example a missing declaration of variables used in the answer) and zero points for wrong answers. A missing answer was coded zero points if the student still answered items afterwards so that we assumed that the student had have enough time for answering the question.

### Measuring the use of proof-reading strategies

In addition to the proof comprehension test, we developed different scales to assess students' use of proof-reading strategies on a four-point Likert scale from 1 (disagree) to 4 (agree). In total we developed 22 items covering different kinds of reading strategies, using ideas from a German reading comprehension test (Schlagmüller & Schneider, 2007), the self-explanation training from Hodds et al. (2014), and the expected effective reading strategies (i) – (iii) from the study of Weber (2015) mentioned above. We assigned the proof-reading strategies to 5 different scales, which are listed in table 1.

Scale	Example
Before reading (4 items)	“I think about the assertion before I read the proof.”

While reading (4 items)	“While reading the text, I highlight important propositions.”
Elaborated reading (5 items)	“I build connections between the different ideas of the proof.”
Reproductive reading (4 items)	“I sum up each line of the proof in my own words.”
After reading (5 items)	“I discuss the proof with my learning group.”

**Table 1: Learning strategies sorted in scales**

### Measuring individual characteristics

Afterwards the students got a test to examine their prior knowledge in analysis (Rach & Heinze, 2017). The eight test items were coded dichotomously and students could gain up to 8 points in this test. The sum of their answers was computed to a test score for further analysis. Moreover, we asked the students to state their German and mathematics school grades and their grade of their analysis I course. At last we asked the students to estimate statements about other individual characteristics. They rated statements covering their *interest* in school and university mathematics (Ufer, Rach, & Kosiol, 2017), their interest in proof (Ufer, Rach, & Kosiol, 2017), their *self-concept* referring to proof (Ufer, Rach, & Kosiol, 2017) and to school respectively university mathematics in general (Ufer, Rach, & Kosiol, 2017) and their *satisfaction* referring to their university career (Schiefele & Jacob-Ebbinghaus, 2006). Because of practical constraints, some characteristics were only covered by one item. The scales of the individual characteristics (interest and self-concept) had good till very good reliabilities, so the individual mean value of a single student on a scale was computed if the student answered half of the items of the scale at least. In contrast, the reliabilities of the predicted scales for the proof-reading strategies were not good, so we only inserted single items in the analysis.

### Results

The reliability of the proof comprehension test ( $M = 3.59$ ,  $SD = 1.83$ ,  $Max = 10$  points,  $\alpha = .57$ ) was medium. The single items' mean value was  $M = .15 - .76$  ( $SD = 0.36 - 0.50$ ,  $Max = 1$ ). An explorative factor analysis did not show any empirical evidence for different factors of proof comprehension, a local or a holistic understanding, so we measured proof comprehension by the sum of the whole test items as a test score. The following correlations were analyzed with Pearson correlation coefficient.

#### RQ 1: Are proof reading strategies correlated with proof comprehension?

Analyses show that there were only two correlations between proof comprehension and the use of single proof-reading strategies (negative correlation: “I skim read the proof and concentrate on important aspects” ( $r = -.28$ ,  $p < .05$ ), positive: “I divide the proof into coherent parts” ( $r = .27$ ,  $p < .05$ )). The positive correlation refers to Weber's (2015) third suggested useful proof-reading strategy. The correlation between Weber's (ii) proof reading strategy and proof comprehension is nearly significant ( $r = .21$ ,  $p < .1$ ). As there are not many correlations, we looked at the mean values of the proof-reading strategies for further analysis. The absolute interpretation of mean values is dangerous but carefully interpreting, it can give us a first insight into students reading strategies. Some of the proof-reading strategy items have high mean values, meaning that nearly all students said they do this while reading the proof, for example “I think about the assertion, before I read the proof” or “I read the proof several times”. Whereas the use of other strategies was only mentioned by

a few people, for example “I prove the assertion on my own before reading the proof” which is the first of Weber’s (2015) assumed, useful reading strategies.

## **RQ 2: Do individual characteristics (like interest, self-concept or prior knowledge) correlate with proof comprehension?**

As expected, proof comprehension correlates positively with the grade in the last analysis lecture ( $r = .39, p < .01$ ) and with the prior knowledge in analysis ( $r = .46, p < .01$ ). There is no correlation of the students’ final school grade or their last mathematics school grade. The proof comprehension only correlates negatively with the students’ interest in school mathematics ( $r = -.27, p < .05$ ), there were no other significant correlations.

## **Discussion**

Proof comprehension is an important activity in university mathematics, however students struggle a lot by performing this activity. To get a better insight into proof comprehension, we developed a proof comprehension test in the field of analysis to analyze the relation between proof comprehension and students’ individual characteristics, based on the assessment model of Mejia-Ramos et al. (2012). Our results show no empirical evidence for a separated local or global comprehension of proof. This supports the results of our first study (Neuhaus & Rach, 2018) we made with students at the beginning of their university career. We cannot see any differences between local or holistic items concerning the students’ answers. Mejia-Ramos et al. (2012) also don’t view the different types of their assessment model as part of a hierarchy. So while an empirical distinction between local and holistic proof comprehension might be difficult, we think that a theoretical separation is still helpful to get the whole picture of proof comprehension and to develop items for proof comprehension tests.

The correlation of the proof comprehension with prior knowledge was expected and shows that undoubtedly, for understanding proofs, a solid basis of concept understanding in the field is needed. However, there were no positive correlations between proof comprehension and the students’ interest in university mathematics or their mathematical self-confidence, which is somewhat surprising. We assumed that at least interest in proofs would predict proof comprehension with a small influence. Instead of this, a negative correlation between interest in school mathematics and proof comprehension suggests that interest in school mathematics and interest in university mathematics have to be analyzed separately.

Only one of Weber’s (2015) expected useful proof-reading strategies and none of the reading strategies based on Hodds et al.’s self-explanation training (2014) correlate with proof comprehension, but as only single items were included in the analysis, further studies need to be done. Another difference is, that Weber (2015) looked at good students reading proofs and predicted the used reading strategies to be useful to generate proof comprehension, but maybe only better students can benefit from those strategies. Thus, for the practical context, one should be aware that not for every student every strategy is helpful. In addition, only few students declared to use one of Weber’s suggested helpful strategies and some other strategies, fitting the results of Weber & Mejia-Ramos (2013). Maybe the strategies need to be given to and practiced by the students in advance so they could benefit more from proofs given to them in their lectures.

Our proof comprehension test only refers to one proof in one mathematical topic (in this case analysis). For a broader view, proof comprehension has to be measured by different proofs in different topics. Additionally, we only assessed a partial part of the students' proof comprehension as they were allowed to look at the proof while answering the proof comprehension test and maybe the questions indicated them to look to the proof in more detail. Furthermore, the sample is rather small and the students only report a self-estimation for their individual characteristics and their use of the proof reading strategies. There is no real evidence in which way and how often they really use the strategies. That's why we want to reproduce the presented results with a bigger sample. Additionally, research is needed on the effectiveness of proof-reading strategies, the correlations between proof comprehension and other concepts of proving, like proof validation, and proof comprehension in different topics. With our study, we did a first step to get a deeper look into the concept of proof comprehension that may help us in the future to support students in this activity.

## Abduction in argumentation: Two representations that reveal its different functions

Chrysi Papadaki, [David Reid](mailto:dreid@uni-bremen.de) and Christine Knipping

University of Bremen, Germany

[chrysi@uni-bremen.de](mailto:chrysi@uni-bremen.de), [dreid@uni-bremen.de](mailto:dreid@uni-bremen.de), [knipping@math.uni-bremen.de](mailto:knipping@math.uni-bremen.de)

*Abduction can function in argumentation and proving processes in different ways. In this paper we focus on the ways in which abductive arguments, taking place in argumentation and proving processes, can be reconstructed in the frame of a Global Argumentation Structure (GAS). We propose two different ways to model abductive arguments within a GAS, with a forward or a backward flow, depending on the function of these arguments in the whole argumentation.*

*Keywords: Abduction, argumentation, proof, Toulmin-model, Global Argumentation Structure.*

### Introduction

Researchers in mathematics education have seen abduction either as process of reasoning backwards (a kind of reversed deduction) (Pedemonte, 2002; Knipping, 2003) or as a process for creating hypotheses (Peirce, 1878; Pease & Aberdein, 2011). The purpose of this paper is to examine the ways in which abductive arguments have been modelled up to now and to propose two different ways of modelling them, depending on their function in the argumentation. We are interested in modelling abductive arguments in the frame of the whole Global Argumentation Structure (Knipping, 2003) of the argumentation or proving process taking place, rather than in isolation from the other arguments taking place (as done for example by Pedemonte, 2002).

### Abduction in argumentation and proof

Abduction is an area of research that has received increasing emphasis in mathematics education, in reference to a number of different processes. Here we discuss abduction in mathematical argumentation. As we consider mathematical proof to be a kind of argumentation, our discussion includes also abduction in mathematical proof.

A simple way to distinguish between abduction and deduction is to consider how they connect a case to a result via a rule. An example often cited in the mathematics education literature comes from an article Charles Saunders Peirce published in *Popular Science Monthly* in 1878. At this time he referred to abduction as “hypothesis”, and characterised the two processes as shown in Table 1 below. From this example it is evident that abduction can be thought of as a reversed deduction, reasoning from a Result via a Rule to a Case, rather than from a Case via a Rule to a Result.

Deduction.	Hypothesis. [Abduction.]
<i>Rule.</i> —All the beans from this bag are white. <i>Case.</i> —These beans are from this bag. $\therefore$ <i>Result.</i> —These beans are white.	<i>Rule.</i> —All the beans from this bag are white. <i>Result.</i> —These beans are white. $\therefore$ <i>Case.</i> —These beans are from this bag.

**Table 1: Peirce’s syllogisms for deduction and abduction (1878, p. 472; CP 2.623)**

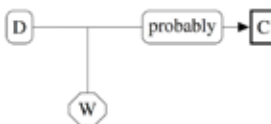

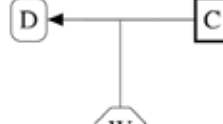

Toulmin (1958) provides a model that can be used to analyse arguments in general, not only deductive arguments. In his model (see Figure 1), an argument includes the following elements:

C (claim or conclusion) the statement of the speaker, D (data) are data justifying C, W (warrant) the inference rule that allows data to be connected to the claim, B (backing) is reason to believe W, Q (qualifier) expresses *how much* to believe C, R (rebuttal) tells you *when* belief in C is *not* supported

**Figure 1: The Toulmin model of an argument (1958)**

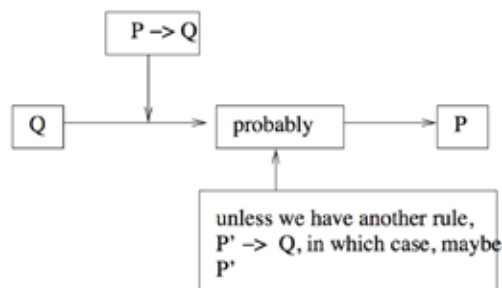

Toulmin considered only two types of reasoning when he created his model, namely deduction and induction. There are however, several cases in the literature of researchers modelling abduction using Toulmin's model in different ways. In Table 2 we use Peirce's example and terminology as a common reference in order to describe and depict the different ways in which abduction has been modelled using Toulmin's terminology.

Peirce	Pease & Aberdein (2011)	Pedemonte (2002)	Knipping (2003)
Rule	W 	W 	W 
Result	D	C	C
Case	C	D?	D
Function of abduction	Generating hypothesis	Reasoning backwards	Reasoning backwards
Structure of abduction (Flow)	Forward	Forward	Backwards

**Table 2: Peirce's abduction modelled with Toulmin's terminology**

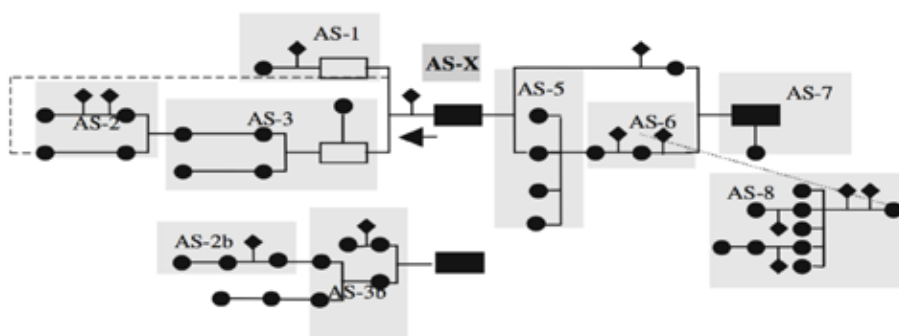

Pease and Aberdein (2011) keep the forward flow (arrows pointing from left to right) of Toulmin's model but they characterise as a datum the Result that is known and needs no justification, and the claim as the Case that is inferred. They express the uncertainty of the claim by employing a qualifier (the word "probably") before the claim (see Figure 2). Pedemonte (2002) was the first researcher in mathematics education to use Toulmin's model to describe abduction. She too models an abductive argument with a forward flow but reverses Pease and Aberdein's (2011) placement of data and claim. She considers a claim to be the known target of the inference (Result) and the datum to be the unknown fact (Case), which must hold in order for the claim to stand. She denotes the

status of the unknown datum with a question mark next to the letter D representing the datum. The difference between Pease and Aberdein's, and Pedemonte's modelling of abduction may arise because of the different functions they attribute to it. Pease and Aberdein see abduction as a process of generating a hypothesis, whereas Pedemonte sees it as a reversed deductive process, as "reasoning backwards". It is also important to note that these researchers model individual arguments, in isolation from other arguments.

**Figure 2: Structure of an abductive argument, Pease and Aberdein (2011, p.12)**

In contrast Knipping (2003, 2008) describes a way of linking together arguments analysed using the Toulmin model to describe larger structures of argumentation. She reconstructs the whole argumentation of students, building a Global Argumentation Structure (GAS), which reveals a complete overview of the argumentation that took place. For example, Figure 3 shows her analysis of the argumentation in a lesson in which the Pythagorean theorem was proven. Knipping (2003), like Pedemonte, sees the function of abduction as "reasoning backwards". She reconstructs complex deductive argumentation processes, which may contain some abductive arguments. The flow of the overall GAS is a forward one, but the flow of the abductive arguments is a backward one (see Figures 3 and 4). Like Pedemonte (2002) she considers the claim to be the Result of the inference and the datum to be the Case, which must hold in order for the claim to stand. But she marks the abduction differently, by reversing the arrow to indicate the backward flow, and she does not use a question mark next to the letter D to indicate the unknown fact.

**Figure 3: GAS of discussion on the Pythagorean theorem, Knipping (2008, p. 437)**

The arrow in AS-X in Figure 3 marks the abduction. The students know they want to conclude that ABCD is a square, and they use abduction to go from this desired conclusion to the datum ( $BCD=90^\circ$ ) needed. The dotted line marks the shift in focus to finding an argument for the conclusion ( $BCD=90^\circ$ ). Through AS-2 and AS-3 they establish  $BCD=90^\circ$  and combining this

datum with the previous established statement ABCD is a rhombus, they deduce the desired conclusion, ABCD is a square.

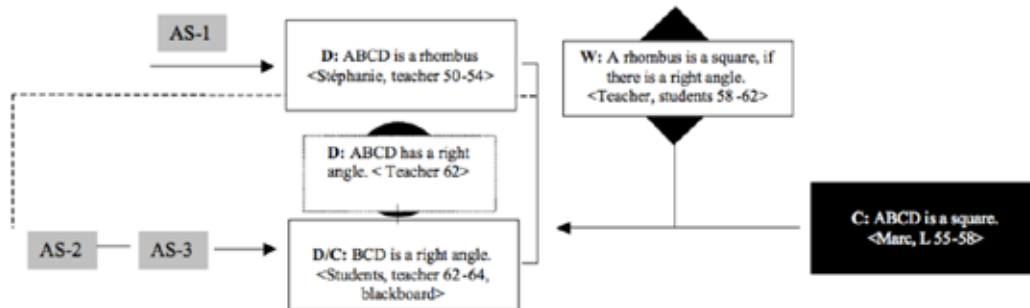

Figure 4: Abductive argument reconstructed with a backward flow, Knipping (2003, p.8)

## Methodology of the data analysis

In the following we compare two Global Argumentation Structures developed following the procedures outlined in Knipping and Reid (2013). They describe a three-stage process: reconstructing the sequencing and meaning of classroom talk; analyzing arguments and argumentation structures; and comparing argumentations to reveal their rationale.

Here we are chiefly interested in comparing two Global Argumentation Structures that emerged in two mathematics classrooms and which have some interesting differences regarding the abductive arguments taking place in them. We will describe each context and the abductions that occurred before comparing the two.

### Ms James' classroom

The abduction described here occurred in Ms James' grade 9 (age 14-15 years) classroom in Canada. The class was trying to explain why two diagonals that are perpendicular and bisect each other define a rhombus. The students had discovered and verified this property while working in a Dynamic Geometry Environment (DGE).

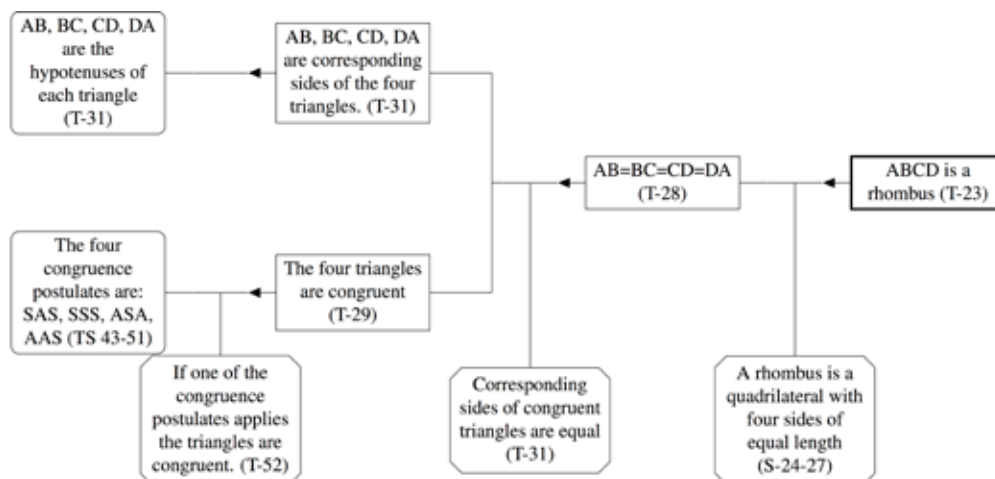

Figure 5 shows the reconstructed argumentation stream that occurred after the class had identified the given information in the situation and had recorded it in the diagram Ms James was drawing on the board. She then asked the class what information was needed to show that a shape is a rhombus, given the definition. This stream is interesting because the statements that were made first chronologically, appear last, on the right hand side, and vice versa. This is similar to the abductive stream described by Knipping (2003) in that the argument goes backwards from the intended conclusions to the data needed to deduce that conclusion. It differs, however, as it involves several abductive steps connected in a stream.

There are linguistic markers of what is going on in the transcript. For example, Ms James says:

Ms James: If I can prove that that is the same length as that, is the same length as that, is the same length as that [draws in the segments AB, BC, CD, and DA]. If I can prove that, I'm done. Rhombus. [Statement T-28 in Figure 5]

The phrase “If I can” marks this as an abduction. In a classroom proving process, where the main flow of the argument is deductive, it makes sense to diagram such abductions in this way, as if they were deductions, but marking them with arrows showing the flow of the argument in the opposite direction. This is shown in the GAS in Figure 6.

**Figure 5: The abductive argumentation stream from Ms James' class (the parenthetical comments after each statement indicate speaker and transcript line)**

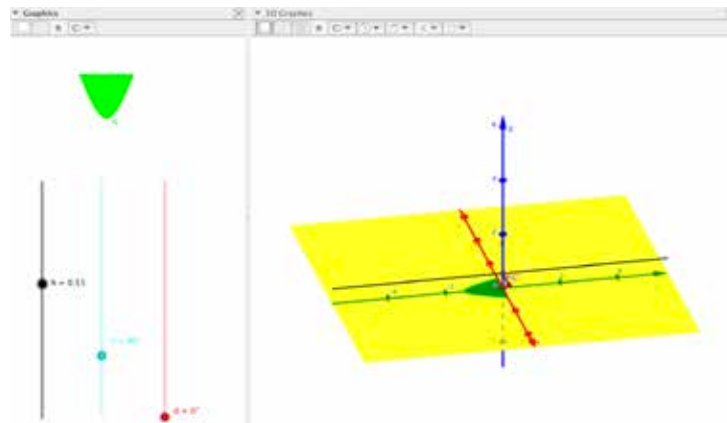

**Figure 6: The GAS from Ms James' class. The shaded area is the abductive stream shown in Figure 5**

## Axel and Dave

In the case presented here two 10<sup>th</sup> grade students (Axel and Dave) in a German classroom worked together on a geometry task designed in a DGE. All the students in the classroom worked on the geometrical tasks in pairs and at the end all the tasks were discussed in a whole-class discussion with the focus being the argumentation the students provided to justify their answers. In the task the DGE window was divided into two sub-windows (see Figure 7). On the right sub-window (3D Graphics) there was a 3D coordinate system in which a solid had been constructed and hidden, and the plane  $xOy$ . On the left sub-window there were three sliders ( $h$  for height,  $n$  for tilt and  $d$  for spin) that the students could manipulate in order to move the invisible solid, and a two-dimensional

depiction of the intersection of the solid with the  $xOy$  plane. The main question set to the students was: “What solid do you think this could be, judging from its cross-sections?”. The students were provided with a worksheet, which included an Exploration Matrix with specific  $(h, n, d)$  slider-positions they could use if they wanted. They were asked to justify their answers in writing. The students were not told how to justify their conclusions, only that they should attempt to explain the validity of their conclusions and to be as complete (leaving no doubts) as possible. There was no requirement that they follow a deductive structure, or that they produce a formal proof.

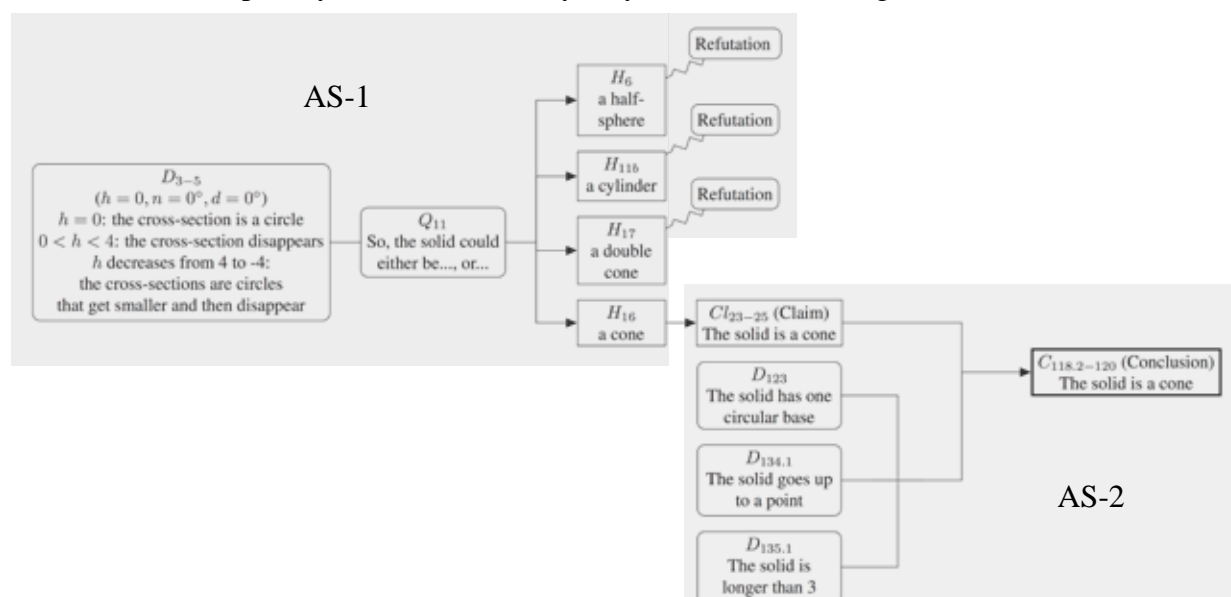

**Figure 7: Task in DGE – Position ( $h=0,55$ ,  $n=90^\circ$ ,  $d=0^\circ$ ) of hidden solid**

The GAS presented here (Figure 8) represents Axel and Dave's argumentation that took place in their discussion during their pair work alone, before the classroom discussion. Axel and Dave used the positions in the Exploration Matrix for their explorations. They started by generating four hypotheses and during their exploration they refuted step-by-step three out of the four hypotheses. The remaining hypothesis ( $H_{16}$ ) became then a claim ( $Cl_{23-25}$ ), which they would later provide an argument for, in order to verify it. After the verification the epistemic value (Duval, 2007) of the statement "The solid is a cone" changes and from a claim it becomes a conclusion ( $C_{118.2-120}$ ). This GAS has two phases (Argumentation Streams). In the first phase (AS-1) belongs the process of generating hypotheses, during which the students suggest possible solutions to the problem, basing their decisions on the data they gather. This is then followed by the second phase (AS-2), during which more data are provided to support the claim ( $Cl_{23-25}$ ). With the support of these new data, the claim is then treated by the students as a conclusion ( $C_{118.2-120}$ ).

The abduction here (AS-1) is not represented as reasoning backwards, rather a process of suggesting multiple possible solutions to a problem all of which, at least initially, seem plausible. Here the chronological flow of the statements made corresponds to their logical function in the argumentation. For example, the conclusion  $C_{118.2-120}$  (which is usually the last inference drawn in an argumentation) comes last both chronologically (in the argumentation) as well as structurally (in the GAS). In such cases, in which speculation is required and the students engage in hypothetical reasoning, it makes sense to diagram abduction with a forward flow.

In the case of Axel and Dave, unlike in that of Ms James' classroom, there are no warrants in the GAS. This should not be interpreted as that the students had no warrants in mind when creating hypotheses or drawing conclusions. The absence of warrants is merely the result of our

methodology according to which, what is depicted in the reconstructed argumentation is only what the students state explicitly, and not what they may have been thinking but have not said.

**Figure 8: The GAS in Axel and Dave's discussion**

## Conclusions

Abduction has two different functions, *explaining* and *exploring*, and depending on the function that it has in argumentation, the reconstructed Global Argumentation Structure is also different.

In Ms James' classroom abduction was used to reason backwards from a desired conclusion to the data needed to deduce it. The students know that the shape is a rhombus and they are seeking data that can connect that conclusion to what they know about the diagonals. They are using abduction in order to *explain* the known conclusion. Most of the arguments in the GAS are deductive, and it is important to note that the final 'official' proof omits the abductive steps. Having abducted the necessary data, they then establish it deductively from other data they already know, and then use it to deduce their desired conclusion. In the case of Axel and Dave, abduction is used to generate hypotheses. They are *exploring* to discover something new. Their hypotheses are then tested in the second phase of their argumentation, through comparison with data generated in the DGE.

The differences in the GASs in these two situations reveal an important difference in the way abduction functions in them. This shows how such an analysis can reveal not only the presence of an abduction but also the role it plays in the overall argumentation. The ways in which the abductions in Ms James' classroom and Axel and Dave's pair work were represented, as flowing backwards or forwards, reflect the functions of the abductions. When abductions are used to explain, the flow is backwards to the facts that explain the conclusion. When abductions are used to explore, the flow is forwards, from data that has been collected to possible results, and includes qualifiers to mark the epistemic value of the inference. The role of qualifiers is vital in order to keep a forward flow for the abduction in an overall abductive GAS.

These differences in function, in turn, depend on the nature of the mathematical tasks. In the case of Axel and Dave the geometrical object the students are asked to work with is unknown and they are not told that they need to prove anything. The focus of their argumentation is the generation and justification of hypotheses, rather than proof production. It is not even possible for them to deductively prove a hypothesis is correct; they can only disprove false hypotheses. In Ms James' case the task was explicitly to find a proof of a given statement. The status of the statement as a conclusion is already established, by the students empirical explorations earlier and by the teacher's authority. In such a proof production task it is clear that the overall structure must be deductive, and abductive argument is incidental, not essential to the argumentation. The final proof could have been produced without using abduction.

We have shown in this paper how Pease and Aberdein's (2011) way of modelling abduction (forward flow of the abductive argument) can be embedded into GASs reconstructed using Knipping's (2003, 2008) methodology, when the function of the abduction is exploring. We are not claiming that the two ways that abduction has been modelled in the GASs we described are all the possibilities. Research in other contexts will no doubt reveal other ways in which abduction is embedded in argumentation structures. However, our describing and distinguishing these two ways, along with the associated functions of the abductions in the argumentation, is a contribution to research in this area.

### Introduction

Proof-related words such as “proof” and “argumentation” are used by different people in different ways. According to recent publications within mathematics education research, the meaning of “proof” is still a subject of debate among researchers (e.g. Balacheff, 2008; Cabassut et al., 2012; Mariotti, Durand-Guerrier, & Stylianides, 2018; Reid, 2015; Reid & Knipping, 2010; Stylianides, Bieda, & Morselli, 2016). In an international context, it is especially important for researchers to consider cultural dimensions that may affect the use of such words in different countries (e.g. Reid, 2015; Sekiguchi & Miyazaki, 2000). As discussed by Shinno et al. (2018), there are two words for “proof” used in Japan: *shōmei* and *ronshō*, as follows.

Some Japanese works distinguish the word *ronshō* from *shōmei* by referring to their relationship with the system of mathematics. [...], such that *shōmei* is related to deriving consequences from premises for establishing the truth of a proposition, while *ronshō* is related to the (axiomatic) system in which logical relations between propositions take place. (Shinno et al., 2018, p. 26)

Sometimes, *ronshō* is used as a special type of *shōmei* (Shinno et al., 2018). This distinction is similar but not identical to the distinction between the French words: *preuve* and *démonstration*, as Balacheff (1987) discussed. According to this distinction by Balacheff, *preuve* and *démonstration* are translated as the English words “proof” and “mathematical proof”, respectively. As a commentary on Shinno et al. (2018), Koichu (2018) also discusses two proof-related words in Hebrew: *hohaha* and *hanmaka*.

Two Hebrew words are frequently used in the official Israeli mathematics curricula: *hohaha* (translates as proof) and *hanmaka* (translates as both argumentation and reasoning). Similarly to Japan, Israeli curricula treat *hohaha* as a particular case of *hanmaka* where the former notion

presumes mathematical rigor and the latter one is somewhat vague and alludes to providing an argument without strictly prescribing what type of argument may be used. (Koichu, 2018, p. 26)

Identifying such proof-related terminologies and their differences and similarities across languages might reveal underlying cultural issues in the educational system or curricula of different countries. For Japan, the word *ronshō* indicates an emphasis on a systematic approach to mathematics, and the word *shōmei* is reserved for validating a general statement (Shinno et al., 2018). This is likely due to the quasi-axiomatic nature of the content and sequencing of the Japanese geometry curriculum and to the fact that all statements required to be proven in the textbook relate to general objects (Miyakawa, 2017). In the case of Hebrew, “the *hohaha* and *hanmaka* notions are complementary in Israeli middle school textbooks, as well as in the intermediate-level high school curriculum” (Koichu, 2018, p. 26). Koichu also mentions that in Miyakawa’s (2017) finding, it “sounds as if the idea of *shōmei* was put forward in Israeli textbooks, but *ronshō* was in the minds of the textbook writers as part of their horizon knowledge” (p. 26). Thus, a linguistic or terminological comparison of the teaching of proof in different countries might be possible. In doing so, it behooves researchers to investigate how such linguistic differences may affect curricula and textbooks (or classroom teaching) in each country.

The meaning of proof-related words differs from culture to culture, depending on the language used in a specific country. Nevertheless, it is possible for researchers to identify similar connotations across different languages. In order to further discuss cultural and linguistic dimensions of proof, the present study attempts to reveal issues concerning the relationship between natural and mathematical language on the teaching of mathematical proof.

## Theoretical background and methodology

Mariotti (2006) states, “it is not possible to grasp the sense of a mathematical proof without linking it to the other two elements: statement and theory” (p. 184). Within this triad (statement, proof, and theory), the first two elements, statement and proof, can be subjected to investigation in terms of their different linguistic formulations; the third element, theory, is of a more epistemological nature. A model (a reference epistemological model) proposed by Shinno et al. (2018) consists of three layers—“real-world logic”, “local theory”, and “axiomatic theory”—which are characterized in terms of the epistemological nature of theory, wherein the statement is formulated, and the proof is carried out. For the purposes of international discourse, it is important for researchers to make a distinction and/or connection between the linguistic formulation (representation) of the statement/proof and its epistemological nature (Balacheff, 2008). For example, the linguistic distinction between *shōmei* and *ronshō* can be understood through the epistemological distinction between local and axiomatic theory (Shinno et al., 2018).

This paper pays special attention to linguistic formulations of the statement to be proven in Japanese textbooks. Concerning the linguistic aspects of proof, it is important to take into account the relationship between natural and mathematical language, because word usage in natural language may influence how statements and proofs are formulated and understood by students in mathematical discourse. This topic has been discussed in various ways (e.g. Barton & Neville-Barton, 2004; Cousin & Miyakawa, 2017; Duval, 2017; Mejia-Ramos & Inglis, 2011; Pimm, 1987; Planas, Morgan,

& Schütte, 2018). In this paper, we analyse some typical statements from Japanese textbooks to clarify how ordinary Japanese language is used in mathematical discourse. We also present a pilot study which allowed us to investigate Japanese undergraduate students' difficulties with linguistics issues related to statement with quantifications.

## The relation between natural and mathematical language in Japanese textbooks

### The grammatical characteristics of the Japanese language

Mathematics sentences such as  $5 + 3 = 8$  are introduced at the beginning of the first grade (6- to 7-year-old students) in Japan. As seen in Figure 1, the textbook (both Japanese and English versions) shows how to read the sentence (“5 plus 3 equals 8”), alongside other representations such as blocks.

Figure 1: Math sentence in a Japanese textbook (Shimizu & Funakoshi, 2011, p. 39)

The sentence “5 plus 3 equals 8” is seen as mathematical discourse in English, which translates as “5 *tasu* (たす) 3 *wa* (は) 8” in Japanese. Here “*tasu*” refers to “plus”, and “*wa*” refers to “equals”. From a grammatical point of view, however, this Japanese sentence is not proper. In ordinary Japanese, it should be “5 *ni* 3 *wo tasu to* 8 *ni naru*” (please focus on only the bold words in this sentence, since others are particles which have no counterparts in the English sentence). Here, “*tasu*” means “plus (or add)”, but “*naru*” means “makes (or becomes)” which can be the same as “equals”. This is because, in Japanese grammar, the verb generally appears at the end of the sentence. If the sentence “5 *ni* 3 *wo tasu to* 8 *ni naru*” above is translated literally into mathematical symbols, it would be like “5 3 + 8 =” which contradicts the syntax of mathematics (Hirabayashi, 1994). This fact can be seen as a linguistic peculiarity of Japanese grammatical characteristics. This may cause an obstacle in the understanding of mathematical sentences on the basis of Japanese language, because grammatical order of some statements, which appears at a more advanced level such as AE and EA statements, is crucial for interpreting what a given statement mean in mathematical discourse.

### Difficulties related to the linguistic and logical aspects from an international perspective

One characteristic of statements in Japanese textbooks for lower secondary schools is that the statement to be proven is considered a universal proposition (Miyakawa, 2017). However, universal quantification using ordinary language and words such as “any” and “all” is rarely encountered in lower secondary textbooks across domains; that is to say, universality is rarely formulated in written form. Therefore, Japanese students and teachers are required to interpret a universal proposition without any quantification. This is probably because the Japanese language does not use articles (Shinno et al., 2018). As Pimm (1987) comments, the situation is similar in Russian, in which

there is no article marker distinguishing *a* from *the*, the definite from the indefinite. Yet this language contains a sophisticated mathematics register fully capable of distinguishing the meaning ‘there exists’ from ‘there exists a unique’. (Pimm, 1987, p. 81)

Japanese does not have such “a sophisticated mathematics register”, at least in secondary school textbooks. Additionally, according to Durand-Guerrier et al. (2016), it is difficult even for people who speak English (and many European languages) to distinguish an implicit universal quantifier from other meanings of an indefinite article:

A well-known difficulty is related to the meaning of ‘a’ that can either refer to an individual, a generic element, or an implicit universal quantifier. (Durand-Guerrier et al., 2016, p. 89)

Beyond the grammatical aspects of a given language, this issue is related to students’ interpretations of universal quantifications. We will develop this issue when introducing the pilot study.

Most Japanese students have few opportunities to consider quantification in their own language. Most do not encounter quantifiers formulated in mathematical terms or symbols such as “ $\forall$ ” or “ $\exists$ ”, based on predicate logic, until they reach university. To this point, and as a reply to Shinno et al. (2018), Czoher, Dawkins, and Weber (2018) argue that “universal statements in American classrooms are often not explicitly quantified, either” (p. 25). Further, Czoher et al. (2018) introduce an excerpt from a textbook used in the United States:

In a popular undergraduate textbook, Hammack (2013) directly addressed this point:

Now we come to the very important point. In mathematics, whenever  $P(x)$  and  $Q(x)$  are open sentences concerning elements  $x$  in some set  $S$  (depending on context), an expression of form  $P(x) \rightarrow Q(x)$  is understood to be the statement  $\forall x \in S (P(x) \rightarrow Q(x))$ . In other words, if a conditional statement is not explicitly quantified then there is an implied universal quantifier in front of it. This is done because statements of the form  $\forall x \in S, P(x) \rightarrow Q(x)$  are so common in mathematics that we would get tired of putting the  $\forall x \in S$  in front of them. (Hammack, 2013, p. 46).

We interpret this excerpt to mean that a focus on universal statements is an invariant part of mathematical practice. (Czoher et al., 2018, p. 25)

While we agree with both Hammack’s assertion, “if a conditional statement is not explicitly quantified then there is an implied universal quantifier in front of it”, and Czoher et al. (2018)’s commentary, it seems to us that this book is intended to introduce undergraduate students to predicate logic. At the undergraduate level, Japanese students also need to pay attention to the similar point made in the excerpt. We wonder if this phrase still holds true for general statements taught at lower grades in the United States. It might be difficult to examine, however, because “proving opportunities are limited or non-existent in the curriculum as enacted in many American classrooms” (Czoher et al., 2018, p. 24), even though, as they also mention, it is important to make empirical comparisons of the usage of universal quantifications across different countries.

As described above, most students do not encounter quantifiers formulated in mathematical terms or symbols until they reach the undergraduate level. It is worth investigating whether language influences students’ understanding in the transition from secondary school to university. Here, we focus on the linguistic aspects of universal and existential quantifications to be formulated in a given statement, so-called AE and EA statements, as below (e.g. Dubinsky & Yiparaki, 2000)).

- AE statement: *For every  $x$ , there exists a  $y$  such that  $f(x, y)$ .*
- EA statement: *There exists an  $x$  such that for every  $y$ ,  $f(x, y)$*

Previous studies, conducted in English-speaking countries, reported that students faced difficulties in distinguishing the two kinds of statements (e.g. Dubinsky & Yiparaki, 2000). Difficulties related to AE/EA statements are also prevalent in the Japanese mathematics (education) community, and there is an assumption that these difficulties are affected by ordinary language (e.g. Hosoi, 1981). These difficulties are related to what Selden and Selden (1995) call “unpacking (logical structure of) informal statements”. Let us briefly explain the linguistic issues of the universal and existential quantifiers of AE/EA statements. In terms of English, they can be explained as follows.

In everyday language, statements where the words ‘there is’ precede the words ‘for every’ are almost always interpreted as if the words ‘for every’ precede the words ‘there is’. (Durand-Guerrier et al., 2012, p. 376)

Unlike in ordinary English sentences, it is difficult to interpret this exchange between the words “there is” and “for every” in Japanese. In English, both phrases precede the *variables* such as “for every  $X$ ” and “there is  $Y$ ”. In Japanese, the words “for every” precede the variable, but the phrase “there is” does not precede. Thus, the grammatical order of the English phrase, “there is  $Y$ ”, is not preserved in Japanese (cf. Hosoi, 1981), because “is” or “exist” cannot precede the object “ $Y$ ”. Rather, the phrase “ $x$  exists” is more natural than “there exists  $x$ ”. Due to this linguistic issue, it is unusual for Japanese speakers to read and write the words according to the order of EA statements, as in English. In Japanese, when we intend to write two kinds of statements in a distinct way, different formulations or representations by ordinary Japanese are possible, but all of them contain vague words or additional notations (like brackets) to preserve the order.

### **A pilot study: Japanese students’ interpretations of AE and EA statements**

To investigate Japanese undergraduate students’ difficulties or gaps associated with their interpretations of statements involving multiple quantifiers, we conducted a pilot study targeting 47 undergraduate students (as native Japanese speakers) who had already learnt mathematical statements with multiple quantifiers. The questionnaire included both AE and EA statements formulated in two ways: mathematical and English. The participants were asked to translate each statement into Japanese and to judge whether a given statement was true or false. Figure 2 indicates the two types of questions. Different formulations of the same statement are found in 1A and 2A and 1B and 2B; 1A and 2A are AE statements (true), while 1B and 2B are EA statements (false).

The participants were divided into two groups. Twenty-four participants were asked to translate 1A and 1B into the Japanese form, while 23 participants were asked to translate 2A and 2B into the Japanese form. Both groups were then asked to judge whether a given statement was true or false and to write down their justifications. The results are shown in Table 1.

- Type 1: Mathematical form  $\rightarrow$  Japanese form (N=24)
  - 1A:  $\forall n \in \mathbb{N}, \exists K \in \mathbb{N}, 2n < K$
  - 1B:  $\exists x \in \mathbb{R}, \forall y \in \mathbb{R}, x + y = 0$
- Type 2: English form  $\rightarrow$  Japanese form (N=23)
  - 2A: For every natural number  $n$ , there exists a natural number  $K$  such that  $2n < K$
  - 2B: Let  $x$  and  $y$  be real numbers. There exists an  $x$  such that for every  $y$ ,  $x + y = 0$

**Figure 2: Two types of questions**

	1A (true)	1B (false)	2A (true)	2B (false)
True	23	2	21	20
False	1	22	2	3

**Table 1: Result of participants' true/false judgments**

These results show that most participants could adequately interpret AE statements (both 1A and 2A). However, there are considerable variations in their interpretations of EA statements. Although many participants could judge that statement 1B (in mathematical form) was false, most of them (20/23) failed to interpret statement 2B (in English form) in their own language. It is worth noting how ordinary language influenced their discrepant interpretations. Figure 3 shows a typical example of this confusion, wherein the participant interpreted the false EA statement (2B) as a true AE statement in Japanese. The box on the right in Figure 3 provides our back-translation. It is important to note that this translation is not “correct” in terms of the English language, because the order of Japanese phrases is preserved, and the term “*tonaru* (となる)” which corresponds to “such that” is not translated. The point here is that the condition which comes after “such that” in English precedes “*tonaru*” in ordinary Japanese language, and Japanese people may not clearly know from this sentence whether the first phrase “For every  $y$ ” is included in the condition of the existential proposition (EA statement) or not (AE statement). The meaning of the sentence would be clearer if we put the two first phrases into brackets or quotations, but this is not common.

<p>和訳:</p> <p><math>x, y</math> を実数とする。</p> <p>すべての <math>y</math> に対して、<math>x + y = 0</math> となる <math>x</math> が存在する。</p> <p>真偽: 真</p> <p>理由:</p> <p><math>x = -y</math> とおけば、命題は成り立つ。</p>	<p>(Japanese translation):</p> <p><i>Let <math>x</math> and <math>y</math> be real numbers.</i></p> <p><i>For every <math>y</math>, <math>x + y = 0</math>, <math>x</math> exists.</i></p> <p>(True/False): <i>True</i></p> <p>(Justification): <i>Set <math>x = -y</math>, the statement holds.</i></p>
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 3: A typical example of incorrect interpretation**

## Conclusion

The logical difference between AE and EA statements may not always be preserved when the two statements are written in everyday Japanese sentences. The pilot study shows that many students are not very conscious of this linguistic characteristic; therefore, most of them failed to interpret EA statements (English) in the Japanese language. To create an opportunity for further international comparative study, it is important to elaborate a meta theoretical language (e.g., a reference epistemological model) for research from international perspectives, since a researcher may need to use different languages for different purposes (Chellougui, Thu, & Winsløw, 2016). Without such a common ground, it would be more challenging for international readers to share “invariant aspects of mathematical reasoning” (Czocher et al., 2018) which we initially associated with a Japanese context.

# Planning for mathematical reasoning – Surprising challenges in a design process

Helén Sterner

Dalarna University and the University of Linnaeus, Sweden; [hse@du.se](mailto:hse@du.se)

*Keywords: Design Principles, Mathematical reasoning, Patterns*

## Introduction

Generalizing is a key element in mathematical reasoning as well in early algebra and algebraic thinking (Kaput, 2008). However, students find it difficult to understand the meaning of generalized arguments, which means that teachers need to support students to develop their generalized argument (Stylianides & Stylianides, 2017). A way to increase teachers' possibilities to support students' reasoning may be through intervention studies. Stylianides and Stylianides (2013) write about the importance of research-based interventions of proof and proving in teaching. Since generalized arguments can be seen as a part of proof and proving (Stylianides & Silver, 2009), intervention studies also about generalized arguments should be important. Similar reflections have emerged in the Argumentation and proof group at CERME where a lack of design-based studies promoting investigation in the classroom and a need to shift research focus from the learners to the teacher is emphasized (Mariotti, Durand-Guerrier, & Stylianides, 2018). This poster will exemplify a part of a cyclically recurring intervention process by answering the question: What challenges do teachers meet when trying to understand a given Design Principle (DP) (McKenney & Reeves, 2012) and design and implement teaching based on it?

## Mathematical reasoning and algebraic thinking

One part of mathematical reasoning and early algebra as well as of algebraic thinking is the structure and the understanding of relationships in quantities (Kaput, 2008); these relationships could be embedded in figural repeating patterns. Patterns and pattern identification could be seen as essential components in elementary school when working with the activity of reasoning-and-proving (Stylianides & Silver, 2009). Teaching patterns can provide students' understanding and support their arguments why things work the way it do. Mulligan, Mitchelmore, English and Crevensten (2013) make similar assumptions, pointing out that teaching and learning mathematics through patterns and structure as well as generalized approaches may provide students with a deep understanding of mathematics.

## Methodology

The frame of this study is based on educational design research, as well as an intervention inspired by classroom design research (Stephan, 2015). In the implementation of the intervention, DPs will be used to address the specific foci in this case, strategies for mathematical reasoning and proving in algebra. Three mathematics teachers (grade 1 and 6) and the author are part of this intervention. DPs are used to guide the content of the interventions and the DPs are used as a framework in the initial analyses. The DPs will guide and give the intervention a theoretical foundation in the ongoing process (three recurring cyclical phases):

first designing the intervention and the teaching, second the three teachers implementing the intervention and the third, the reflection after the implemented intervention. To stimulate mathematical reasoning, and proving in teaching and learning of pattern, six DPs have been created from previous research, and one of them is presented in this poster.

DP1           The students will have possibilities to *identify* a pattern, to *structure* the pattern and to *generalize* the pattern (Mulligan et al., 2013; Stylianides & Silver 2009).

### **Preliminary results from a part of the design research process**

Preliminary results show the complexity involved in teachers' understanding of teaching and learning patterns relating to DP1. The complexity becomes visible when teachers discuss and try to understand the concepts; identify, structure, and generalize patterns in relation to their own practice. Teachers try to exemplify what it means to identify, structure and generalize, and thereby become aware that the concepts overlap. Results also show that teachers' understanding of generalization develops during the discussion; from equalizing generalization with general formulas to generalizations as something possible to show with different representations such as describing with words or showing with concrete material and pictures. In the classroom, teachers meet challenges when trying to challenge students' understanding of a generalized pattern, for example by asking them to explain what is behind a general formula.

# Metacognitive activities of pre-service teachers in proving processes

Nele Stubbemann<sup>1</sup> and Christine Knipping<sup>2</sup>

<sup>1</sup>University of Bremen, Germany; nele.stubbemann@uni-bremen.de

<sup>2</sup>University of Bremen, Germany; knipping@math.uni-bremen.de

*Proving processes are often complex and difficult. Problems during the phase of proof finding are not unheard of. The ability to find out which knowledge and strategies we need to prove a given statement and how to use knowledge and strategies in proving is called metacognition. A study with pairs of pre-service teachers shows that content knowledge is an important factor whether or not metacognitive activities like monitoring can help handling problems in the proving process.*

*Keywords: Metacognition, monitoring, proving processes, pre-service teachers.*

## Introduction

To be able to successfully prove a geometrical statement, one needs more than just subject-specific knowledge and methodological knowledge of proving procedures (Heinze & Reiss, 2003). It is important to know if what one is doing makes sense, is promising and productive. This ability to reflect on one's own knowledge is called metacognition, which is important in general life as well as in mathematics and allows one to find out what knowledge and strategies are needed to solve a problem and how to use knowledge and strategies in proving.

In mathematics education a lot of research exists about metacognition in problem-solving (e.g. Kuzle, 2013; Schoenfeld, 1987, 1992). But there is little research about the significance of metacognitive activities for proving processes, in particular there is nearly no research on pre-service primary school teachers' metacognitive activities, even though they will later in their classrooms be responsible to establish the basis for argumentation. Our research project addresses the need of future teachers to be able to understand and perform proving processes, as well as to perceive their argumentation basis. Metacognitive competences can in our view be useful and fruitful, if taken care of in a sensible way.

The metacognitive activity of monitoring is the focus of this paper. How monitoring is in play during the proving process of students, particularly in what we call loops, elongations, circular reasoning and wanderings is of interest to us. We look specifically at what role content knowledge plays in this and what impact content knowledge has on monitoring.

## Theoretical background

The colloquial meaning of metacognition is approximately "reflections on cognition or thinking about your own thinking" (Schoenfeld, 1987, p. 189). Schraw (1998) divides metacognition into two big fields. *Knowledge of cognition* is the knowledge about one's own cognition or about cognition in general. The *regulation of cognition* is an accumulation of activities that help to control one's own learning. It includes *monitoring*, which is the activity of controlling and evaluating one's understanding and one's own performance during a process, in our case the proving process. According to Heinze and Reiss (2003) the ability to prove a statement includes metacognition. Wittmann (2014) focusses on two things that are important for proving statements, factual knowledge and metaknowledge about proofs. According to Wittmann students often do not have sufficient

metaknowledge about proof, which includes knowledge of the functions of proof, characteristics of proving as well as knowledge of how to prove.

The difference between proving as a process and proof as a product is important as well. Wittmann (2014) sees the process of proving as the activity of finding a proof. The process is complex, needs creativity and problem solving competencies. It can go in leaps and bounds and includes sudden success as well as phases where one does not know what to do. The proof product on the other hand is the final product of the proving process. It is succinctly verbalised and neatly written down. Looking at the written proof one cannot see the efforts of the proving process.

## **Empirical methods**

The base of this research project are case studies of four pairs of pre-service primary school teachers. These students participated in a lecture course on elementary geometry in the third semester of their Master Studies. Participation in the study was voluntary and took place in the spring of 2018. Video recorded interviews are the basis of the case studies. The students worked in pairs on proof tasks so that discussions between them provided insight into their metacognitive activities. In the first part of the semi-structured interview, questions about their own proving experiences and proving in general were asked. Then the students were given two statements from plane geometry, one after the other, which could be proven with knowledge from the lecture. Afterwards the process of finding the proof was discussed with the students.

The transcripts of the interviews were looked through for obstacles that can occur in the proving process. In a second step these obstacles were scanned for monitoring activities, which were then coded with a system for categorizing metacognitive abilities developed by Cohors-Fresenborg and Kaune (2007a), that divides monitoring into eight subcategories, e.g. the controlling of calculations and the controlling of argumentation. This allowed us a differentiated view on monitoring activities. After coding the data, the effect of monitoring in the identified phases with obstacles were analysed. Particularly the influence of content knowledge was focused on in order to clarify the impact of the assumed relationship between monitoring and content knowledge for the proving processes and specifically their successful performance.

## **Prototypes for obstacles in proving processes**

Proving processes are rarely linear. Having difficulties, getting stuck or trying something that is not constructive is normal. After looking through the data we can distinguish four specific obstacles that the students encountered in their proving processes: *loops*, *elongations*, *circular reasoning* and *wanderings*. In the following we are going to characterise these obstacles with data from all four groups. With these examples we explain to what extent monitoring influences these obstacles and show the important role of content knowledge.

### **Loops**

*Loops* are one type of obstacle in proving processes. In a discussion one might have a kind of side discussion that is still part of one's proof idea and attempt, but that is not really constructive for the proof. To resolve a *loop* situation one must rein in this discussion and pursue the original proof idea instead.

A typical example for a *loop* is the following discussion of Pia and Charlotte (Group 3). The two students attempt to prove the second statement: “A parallelogram is a rectangle if and only if its diagonals have the same length.” During their discussion they draw a rectangle and a parallelogram and argue whether or not they should use the drawing of the parallelogram to prove the statement or if they should use the drawing of the rectangle instead. While Pia is arguing that in a parallelogram the diagonals cannot have the same length, Charlotte suddenly has a new idea; here a *loop* starts. Charlotte wants to change the statement they have to prove to the following: “A parallelogram is a square if and only if its diagonals have the same length”. She describes her thinking.

At that moment Pia uses the definitions of a square and a parallelogram and the connections and differences between the two (every square is a parallelogram, but not every parallelogram is a square). She intends to make clear to Charlotte why her idea, to substitute the rectangle in the statement with a square, is not helpful for the proof of the original statement. Pia’s behaviour is a reaction to a monitoring activity, which is the examination of her partner Charlotte’s understanding of mathematical objects and their role for their argumentation. According to the system of Cohors-Fresenborg and Kaune (2007b) this can be categorized as the monitoring activity M4c: “Controlling of Argumentation – uncovering mistakes in the argumentation” or M2b: “Controlling of an assessment of (assumed) mistakes – uncovering one’s own false ideas or those of others”. Charlotte then applies this knowledge to squares and rectangles and understands why her idea will not work out as a proof. Both students are back at the “starting point” (arguing about which drawing to use for their argumentation), the *loop* is closed. Their side discussion ends, they do not lose themselves in it. They are back on to their original path.

In this example of a *loop*, Pia’s monitoring activities match the “problem” Charlotte has (Why can we not use a square in our argumentation?) and helps them to end their side discussion. They go back to their original proof idea. Their monitoring was quite precise regarding the comprehension of the geometrical objects square, rectangle and parallelogram. Pia showed that she possessed the content knowledge necessary to make use of the monitoring activity and improve their work.

## Elongations

An *elongation* in a proving process occurs when one does not pursue the shortest possible way, but instead substitutes several steps for one step.

**Figure 1: Drawing for the first statement (Group 4)**

*Elongation* simply means to lengthen an action or a process. Often these are hard to determine in data, as a shortest possible way needs to be defined first, in order to be able to find variations of it. To define this, one has to consider (theoretically) available knowledge which may differ between people and in time. The shortest way of a grade 5 student may differ from that of a university professor; the shortest way in a first proof of a new theorem may be an elongation later on, when shorter ways have evolved.

The first statement our students had to prove was: “Given is an angle with arms  $g$  and  $h$ . If you draw a line  $k$  parallel to arm  $g$  that crosses arm  $h$ , then  $h$  and  $k$  together with the angle bisector form an isosceles triangle”. The shortest way to prove the statement that one might

follow is using the Alternate Interior Angles Theorem with the angle  $\frac{\alpha}{2}$  to show that the base angles have the same size, then the Isosceles Triangle Theorem can be used. Nina and Maja (Group 1), as well as Daria and Leonie (Group 4), proved the statement using the Corresponding Angles Postulate with the angle  $\alpha$  (see Figure 1). Then supplementary angles and the Triangle Postulate are used to be able to show that the base angles are equal. This is an example of an *elongation*, as the students had the same basic idea, but for the elongated proof more steps are used than needed.

Neither in the proving process of Group 1 nor in the process of Group 4 a monitoring activity could be found that triggered an *elongation*. The cause of the observed *elongation* seems instead to be the angle the students focussed on ( $\alpha$  instead of the angle  $\frac{\alpha}{2}$ ) and therefore more steps were needed to show that the base angles of the triangle are equal. No indication was found why a group decided to focus on  $\alpha$  instead of  $\frac{\alpha}{2}$ . Sufficient content knowledge seems to be the reason that the groups were still able to prove the statement. The students applied all necessary theorems and did not get to a point where they did not know how to proceed.

### Circular reasoning

While involved in the proving process *circular reasoning* is hard to see for the students engaged in proving. *Circular reasoning* makes it impossible to produce a correct proof, because one falsely assumes what is meant to be proven by the proof.

Dennis and Julius (Group 2) showed *circular reasoning* in their ‘proof’ for the first statement. After the exploration and discussion of the statement, Dennis and Julius began to write down their ‘proof’. In the first part of their text the students attempted to show that two of the angles in the triangle had the same size. Julius had noted that the angle bisector divided the angle  $\alpha$  into two angles of the same size, labelled as base angles of the triangle in his drawing (see the two “ $\frac{1}{2}\alpha$ ” written in red, Figure 2), instead of labelling them as two halves of  $\alpha$  (two equal parts of an angle bisector). His argumentation was questioned by Dennis: “Then the question is, whether we can assume that they [Dennis is pointing more at the base angles than at the sides h and k] have the same length”.

**Figure 2: Drawing for the first statement with “red angles” (Group 2)**

His question shows a monitoring activity, as Dennis is checking what they are doing while they are still in the proving process. Both students have just started writing down the proof. With his question Dennis controls the effectiveness of their approach and if they are still on target. According to the system of Cohors-Fresenborg and Kaune (2007b) this is the monitoring activity M4a: “Controlling of Argumentation – local examination”. As a reaction to the monitoring question Julius writes a second explanation about why the base angles have the same size. As a reason he mentions the equality of the two sides of the triangle. This explanation is unfortunately circular as he assumes that the length of the two sides of the triangle are equal, which still needs to be proven.

In *circular reasoning* monitoring affects the proving process differently than in the loop. Dennis and Julius end up with a circular argument in their proof of the first statement because of a monitoring

activity. While in the loop the monitoring brings the students back to a reasonable way. Dennis' monitoring activity is also rather imprecise, more like a bad feeling instead of a well-founded suspicion, and the reason for the *circular reasoning*. Both students lack the necessary content knowledge and cannot not use monitoring activities to their advantage. Their monitoring activity did not improve the quality of their proof, but instead guided the students into *circular reasoning*, which also demonstrates their lack of knowledge about logic and the structure of a proof.

### **Wanderings**

The abandoning of a good proof idea in favour of ideas that are not constructive is what we call *wandering*. An example of *wandering* is shown by Pia and Charlotte (Group 3). During their discussions Pia and Charlotte have a productive idea to prove the first statement. They use the Alternate Interior Angles Theorem to show that the base angles of the triangle are equal. For the next step in their proof they need to show that a triangle with two equal base angles has two sides of the same length. For this they have the idea to use the Isosceles Triangle Theorem. But Pia is not sure, if the theorem can be used in both directions and asks: "Can you say that?", which is actually a monitoring question. According to the system of Cohors-Fresenborg and Kaune (2007b) this would be the monitoring activity M5a: "Determination of position: naming of Deficiency of Understanding – defined step". This labelling of a deficiency in her understanding is an important monitoring activity as Pia can only follow and support their argumentation if she understands the concepts and the connections between them.

In this case the monitoring question is the starting point for the *wandering*. Because of Pia's monitoring question her partner Charlotte is now insecure in her belief and understanding of the Isosceles Triangle Theorem. Even though Pia affirms that she believes that they are allowed to use it, Charlotte abandons this proof idea in favour of another idea. Their new idea does not work out; their written proof is more a construction protocol with a proof idea but not a proof. For this statement, both first have a good idea how to prove it, but then they discard their idea and start with new ideas which in the end do not work out. They end in a *wandering*.

Like in the loop, and in contrast to the circular reasoning, Pia's monitoring here is quite precise. She questions the use of one specific theorem, the Isosceles Triangle Theorem, which is important for their proof. Unfortunately, both students lack the necessary content knowledge, in this case the content of the theorem, to make use of their monitoring.

### **Preliminary results**

One can raise the question whether or not metacognitive activities, especially monitoring activities, can help students to prevent problems in their proving processes. In theory, monitoring one's work and progress should help students to prevent or find problems and mistakes.

Our prototypes can be systematized in a fourfold table along the dimension "monitoring" and "content knowledge" (see Table 1). Loops are in the field of monitoring and content knowledge, elongations in the field of content knowledge without monitoring. Circular reasoning and wanderings are in the area of monitoring, but with no content knowledge. In the area without monitoring or content knowledge we suspect another prototype, *dry spells*. A dry spell is a part of one's proving process

where one hits a barrier and does not know how to go on for quite some time. Not actively working at the proof anymore can be a sign for a dry spell, as well as remaking drawings, calculating something or recapping what one already knows in the hope of getting a new idea. Looking at the success that is (or not) shown in the proving process, it is possible to group the observed obstacles (loops, elongations, circular reasoning and wanderings). Both loops and elongations are parts of a proving process where one still reaches the proof in the end, but not in the shortest or easiest way as one's ideas would have allowed. These two are *detours* in the proving process. Circular reasoning and wanderings are parts of one's proving process where one follows an idea that does not end in a proof. These are *drifts* in the proving process. *Dry spells* can be seen as a third group where the proving process pauses, but this still remains to be looked at in our data.

		Content knowledge	
		yes	no
Monitoring	yes	<p><i>loops:</i> side discussion that gets back to the original discussion and proof idea</p> 	<p><b>drifts</b></p> <p><i>circular reasoning:</i> using things that are yet to be proven</p>  <p><i>wanderings:</i> abandoning good ideas in favour of proof ideas that do not work out</p> 
	no	<p><i>elongations:</i> using several steps when one step would have been possible.</p>  <p><b>detours</b></p>	<p><i>dry spells:</i> parts of a proving process where one does not know how to go on or what to do for a longer period</p>  <p><b>dry spells</b></p>

**Table 1: Overview of the obstacles and the relation to monitoring and content knowledge**

Whether or not one follows detours or drifts in a proving process seems to depend on one's *monitoring activities*. Looking at the monitoring activities described above, one can see that monitoring has many different facets, for example controlling an argument, naming problems in the comprehension of arguments and their connection or uncovering deficiencies in understanding. But our examples show that the mere existence of monitoring activities is not enough to indicate the success of a proving process. There seem to be differences in the way that monitoring activities are expressed. Monitoring formulated in a general way like "Is that possible? Is that right?" like the example of a circular

reasoning by Dennis and Julius (Group 2) seem to be about a gut feeling that something is not quite right, without knowing exactly what. This type of monitoring activities we shall call *lower-level monitoring*. It is not specific enough to help pinpoint a concrete mistake and correct it. Dennis' question "Then the question is, whether we can assume that they have the same length" is one example for this. What we call *higher-level monitoring* is a metacognitive activity that is more precise and aims at specific parts of an explanation or argumentation. For example, if one can use a specific theorem the way it is used in the argumentation or if the comprehension of a specific geometric object is correct. Pia and Charlotte (Group 3) showed higher-level monitoring in both cases, in the loop and in the wandering. In one case Pia questioned the use of a specific theorem, the Isosceles Triangle Theorem, at a specific point of their argumentation. In the other case Pia monitored and corrected Charlottes' understanding of the definition of and the connection between squares, rectangles and parallelograms. These interventions were precise and specific and therefore higher-level monitoring.

The level of monitoring does not seem to be the only factor influencing the quality of a proof as one reason for ending up in drifts can be monitoring activities. In cases where the monitoring could not be used profitably, monitoring activities seem to have a negative effect on the proving process. Looking at the two examples of drifts, in one case, Dennis and Julius (Group 2) show lower-level monitoring, the other students, Pia and Charlotte (Group 3) demonstrate higher-level monitoring. Nevertheless, both groups ended up in a drift. *Content knowledge* is the other factor that influences the success of the proving process. The circular reasoning in Dennis and Julius' proof of the first statement happens because they do not know how to prove the equality of the base angle in the triangle (and lack the logical and methodological awareness that you cannot use what you want to prove). Pia and Charlotte end up in a drift after Pia's monitoring activity, because both cannot remember all of the content of the Isosceles Triangle Theorem, which led them to abandoning their proof idea. Looking at detours, monitoring activities can also show a positive effect, for example ending detours by closing loops. Here the monitoring and the content knowledge used afterwards ended the side discussion and brought the students back to their original proof idea, thereby helping them not to end in a drift. Thinking about these examples, content knowledge seems to be what enables one to find a solution to the obstacles that monitoring activities reveal. One can only benefit from monitoring activities if one has the content knowledge necessary to "fix the problems", for example to discern the problematic parts, to recognise what is wrong or missing or to see possible corrections. Without content knowledge one is less likely to find and correct mistakes, misunderstandings or errors through monitoring.

Monitoring is important in mathematics and especially in proving. It allows to control and evaluate one's own performance and understanding during the process. In the proving process three different categories of obstacles can appear: detours, drifts and dry spells. The interviews with the pre-service primary school teachers show that monitoring activities have a relevant influence. But not every monitoring activity has the same influence on proving processes. One can differentiate between monitoring of a lower and a higher level. Whether monitoring activities support or inhibit the success of the proving process is also highly dependent on one's content knowledge.

*We present a case study whose aim is to describe argumentation's features of a high school mathematics' teacher. The data was collected in a geometry class, while the teacher and her students discussed the straight line. In this paper we describe features of class discourse, associated with a conception of argumentation linked to both argumentation and speech acts. Among the findings we point out both the educational purpose of the teacher in promoting argumentation in her class and the uses of argumentation by the teacher.*

*Keywords: Argumentation, teacher's knowledge, class speech*

## Introduction

Current research in Mathematics Education recognizes the importance of favoring argumentation in class (Ayalon & Hershkowitz, 2018; Staples & Newton, 2016). It also recognizes the teacher's role, the task's design, opportunities for participation, or the analysis of arguments. However, few studies consider argumentative features of the mathematics teacher while teaching. In this paper, we present some results of a research that we are developing where we are interested in both identifying features of mathematics' argumentation in class and analyzing the influence of the teacher's knowledge on the characteristics argumentation.

## Theoretical background

Like different authors in educational research (e.g. Asterhan & Schwarz, 2016), we assume the definition of the argumentation theory presented by Eemeren and his colleagues (1996):

Argumentation is a verbal and social activity of reason aimed at increasing (or decreasing) the acceptability of a controversial standpoint for the listener or reader, by putting forward a constellation of propositions intended to justify (or refute) the standpoint before a rational judge (p. 5).

Even though this definition was not developed in the context of mathematics education, we find it very useful for us to study argumentation in mathematics class. This definition, concerning argumentation, recognizes 'complex interactions' in mathematics class, where teacher and students discuss tasks' solutions. It also implies that we try to move away from the traditional stance, where argumentation is assumed as a set of premises and conclusions formulated with the help of formal symbols whose meaning is established beforehand.

The definition of Eemeren and colleagues suggests that in a math class one can construct claims, provide evidence to support claims, and evaluate this evidence to judge the validity of the claims. This definition puts the argumentation in a social environment. Argumentation not only is part of the class discourse, but also offers opportunities for the articulation of alternative ideas, reflection and reasoning, favoring learning (Ayalon & Hershkowitz, 2018).

## Methodology

In order to observe the argumentation in a class context we carry out a case study with a high-school mathematics teacher. The data were obtained in a 9th grade course (15-year-old students), in a public school in Medellin (Colombia), where the teacher and her students discuss the properties of straight lines. The teacher has 8 years of experience in high school mathematics teaching, is a mathematics graduate and holds a master's degree in Mathematics Education. She voluntarily agreed to participate in the study. We observed two classes in September 2017, which were recorded in audio and video. The researchers were just listeners and without intervening during or after the class. The teacher was informed of the purpose of the research; she selected the group and the classes to be observed.

## Result and implications

We have discussed two class segments to support the case study. We emphasize the features of the argumentation of mathematics' teacher, on one hand, related to the conception or definition of the argumentation and on the other hand, to the uses of the argumentation on the part of the teacher.

We can identify argumentative features that respond to the verbal, social, rational and educational intentions that the mathematics' teacher spontaneously expresses in the natural environment of the classroom when teaching mathematics. Although we describe a particular case, it is important to describe and analyze other cases of mathematics teachers at different school levels, which could enrich our definition of argumentation, show us other features and possible uses, and generate concepts that could contribute to the study of argumentation in mathematics class.

The description of argumentation' features have allowed us to identify possible links of the teacher's argumentation to mathematics knowledge. We also express the limitations of our study, which seems only descriptive, but which attempts to expand and adapt it to his use in the complex environments of the mathematics class. It seems that more tests and a longitudinal study are needed to validate the findings.

## Beyond direct proof in the approach to the culture of theorems: a case study on 10-th grade students' difficulties and potential

Fiorenza Turiano<sup>1</sup> and Paolo Boero<sup>2</sup>

<sup>1</sup>I. I. S. Arimondi – Eula, Savigliano, Italy; fiorenza.turiano@gmail.com

<sup>2</sup>University of Genoa, Italy; boero@dima.unige.it

*In this paper, we aim to contribute to the discussion on the students' cognitive processes inherent in proof by contradiction in geometry, particularly as concerns the role played by images. We will present an episode from a one-year experimental pathway in Euclidean geometry designed to develop the culture of theorems in 10<sup>th</sup> grade: in crucial moments of proof by contradiction, we observed some students' gestures and reasoning aimed to restore the harmony between visual and conceptual aspects, which had been broken by conflicts due to specific features of that proof in geometry. The students' need of keeping such harmony poses didactical questions, which, if conveniently taken in charge by the teacher, might contribute to design smoother pathways to the indirect proofs.*

*Keywords: Culture of theorems, euclidean geometry, indirect proofs, figural concepts, meta-knowledge of proof*

### Introduction

The development of students' competencies concerning theorems is one of the most important goals in the high school. Its relevance is stressed by the Italian national guidelines for curricula in the high school (MIUR, 2010), according to the current definitions of competency (European Community, 2018), in particular, its requirements of autonomy and awareness. In this perspective, developing Culture of Theorems (CoT; Bartolini Bussi et al., 2007) means to acquire, not only knowledge, but also meta-knowledge about theorems: the kind of statements (declarative or hypothetical); the role of hypothesis and thesis; the different methods of proving; the role of previously validated statements and axioms; the distinction between the construction of a conjecture (based on different processes: induction, abduction, analogy, etc.) and the construction of a proof (within a theory). Therefore, autonomy and awareness are two co-present basic requirements in the activities inherent in CoT: exploring to get conjectures; tackling construction problems and their theoretical validation; constructing proofs. We chose the Euclidean geometry as a domain to set up a learning environment suitable for the development of the CoT in two 10<sup>th</sup> grade scientific oriented classes. In Italian school, the passage from intuitive to deductive geometry takes place in the 9<sup>th</sup> grade: the students must be educated to justify geometrical facts and to prove theorems. These goals require an evolution in the students' ways of looking at geometrical figures and their awareness of links between a proof of the statement and the theory within which the proof makes sense. Thus, we chose the construct of figural concepts (Fischbein, 1993) and the definition of mathematical theorem (Mariotti, 2001) to frame our experimental pathway. In agreement with the literature, in our pathway the indirect proofs (by contraposition and by contradiction) posed specific cognitive and didactical problems that had been absent in situation of direct proof. We tried to deal with them by using the model for indirect proof elaborated by Antonini and Mariotti (2008). In particular, in this paper we consider a classroom episode concerning proof by contradiction, in which the analysis of students' behaviors, performed

according to that model, allowed us to identify specific instances of the obstacles deriving from the drawings that should support the reasoning in its different phases, and some spontaneous students' ways to escape them. The discussion will concern the choice of suitable tasks for smoother approaches to proof by contradiction, and some aspects of the potential and limitations of Euclidean Geometry, as the privileged field to approach the culture of theorems in high school and, in particular, the issues related to indirect proofs.

### **Theoretical background**

The Theory of Figural Concepts (TFC; Fischbein, 1993) highlights that geometrical figures possess simultaneously conceptual qualities (controlled by constraints within the realm of an axiomatic system) and image features (based on the perceptive-sensorial experience). The interplay between image component of a drawing and theoretical knowledge may (and should) implement a harmonious fusion between concept and image: the theoretical knowledge transforms the image into a geometrical figure. Fischbein calls Figural Concept this complete harmonious fusion. TFC is a suitable construct for our study for at least three reasons: to investigate how and if the students manage to deal with the relationships between different components in the geometrical figures; to interpret the difficulties deriving from a missing or incomplete fusion; to explain different students' behaviors concerning proof by contradiction, when they deal with it in two different domains: elementary number theory (e.g. when proving the irrationality of  $\sqrt{2}$ ), Euclidean geometry.

Mariotti (2001) defines a theorem as the triad (S-P-T) statement-proof-theory: a statement, its proof, and a theory (as a system of shared principles and deduction rules) within which this proof makes sense. Antonini and Mariotti (2008) refine this triad in order to better describe and explain the process involved in an indirect proof, due to its logical structure. According to them, proving by indirect method requires two phases: 1) a shift from a statement  $S$  (called principal) toward a statement  $S^*$  (called secondary, which is proved by a direct method) obtained assuming as hypothesis the negation of the thesis of the principal one (in proof by contradiction) or of its thesis (in proof by contraposition), and as thesis, respectively, a contradiction or the negation of the hypothesis of the principal one; 2) the validity of the implication  $S^* \Rightarrow S$  depends on the logical theory, that is external to the theory in which the principal and secondary statements are formulated. The two authors call meta-statement  $S^* \Rightarrow S$ , meta-proof the proof of  $S^* \Rightarrow S$ , meta-theory the logical theory into which the meta-proof makes sense. Then, any theorem with indirect proof consists of a couple of subtheorems belonging to two different levels: the level of the mathematical theory and the level of the logical theory. Unfortunately, usually teaching practice takes for granted the meta-theorem.

### **Method**

#### **Euclidean geometry as a suitable domain for a teaching-learning pathway to the CoT**

We chose Euclid's plane geometry to make 10<sup>th</sup> grade students approach the CoT for at least three reasons: 1) in Italy, since the end of the XIX century, Euclidean geometry has been considered to be the most suitable domain to allow high school students to tackle theorems, proofs, proving; 2) Euclidean geometry offers the possibility to deal with different kinds of proof; 3) the validation task of a geometric construction provides the teacher with the opportunity of making the students aware of the nature and relevance of theoretical thinking in mathematics.

## **The structure and tasks of the pathway**

In the schoolyear 2016-17 our project was designed and implemented for the first time in a 10<sup>th</sup> class scientific-oriented. It took about 46 hours. In the same school, in the next year, the experiment involved two 10<sup>th</sup> classes (named 2A and 2D, respectively of 31 and 20 students). It was 7 months long, 2 school-hours (100 minutes) per week, summing up to about 56 hours. All the lessons were held by the same teacher (the first author), in the same day: first in 2A, then in 2D; a researcher (the second author) played the role of participant observer. The pathway was divided into 3 modules: 1) from the construction of a tangent circle to the two sides of a given angle, to the construction of the tangent circle inside a given triangle; 2) from conjecturing about sufficient conditions that create different kinds of triangles inscribed in a circle, to the proof of the relation between inscribed angle and central angle that subtends the same arc; 3) given a circle, from exploring and proving the relationships between its tangent and intersecting straight lines, to solving some problems concerning inscribed and circumscribed quadrilaterals. The classroom activities alternated individual tasks (presented on worksheets to be filled by the students – enough time was allocated to them, in order to develop specific linguistic skills) and collective discussions orchestrated by the teacher. They were addressed to identify gaps, mistakes, linguistic issues and elements of meta-knowledge of proof; and to reflect on different strategies of proof and on the organization of the proof text according to its specific structural constraints. In some cases, the discussion concerned also the comparison and the analysis of a few students' individual productions, selected and made anonymous by the teacher. The individual activities concerned different kinds of tasks: construction problems and related theoretical justifications; proving of produced conjectures (after having been shared and refined under the guide of the teacher in collective discussions); analysing and refining some mates' productions; cloze activities on proof texts; identifying salient meta-mathematical aspects of produced texts. At the end of each module, the summative assessment was made up of two parts: 1) a homework including: a) the written revision of all the personal worksheets, with careful identification of gaps or mistakes, comments on their specific causes of difficulties, with correction or reconstruction; b) a written report on her own experience: if she met difficulties during the work of the module, and when and how (and if) she overcame them; 2) a classroom work: the students were asked to correct and refine 3 worksheets, chosen by the teacher: one produced by a schoolmate, two produced by herself.

The collected data consist of all the individual productions (including home-works and self-reflective reports) and audio-recordings and field notes taken by the teacher and the participant observer.

## **The student's specific background on proof**

The pathway followed a curricular 9<sup>th</sup> grade geometric course (triangles and quadrilaterals), approaching the basic notions of CoT, included construction problems and theorems with direct proofs. The teacher estimated that more than 65% of the students were at ease with this kind of proof.

## **The episode: a construction problem for the approach to proof by contradiction**

From the first module of 2017/18 pathway we focus on an episode, which concerns the validation of the construction of a circle tangent to the sides of a given angle; it consists of 5 steps carried out in parallel in the two classes. The related Euclid's proof by contradiction consists of a few steps, and most students already knew all the theorems and definitions used in this proof, including Euclid's

definition of tangent to a circle (only one point of intersection). They were also familiar with the construction of the bisector of a given angle. Therefore, in our a priori analysis, we judged that proof suitable for beginners' first approach to proof by contradiction in geometry, and we predicted that at least some students would have been able to perform such mathematical reasoning. Here, we report only that part of Euclid's proof which proves by contradiction that if we assume EA perpendicular to diameter BA (see Figure 1) then it meets the circle in only one point. We didn't show it to the students.

Euclid' Statement (proposition 16 in Book 3): The straight line drawn at right angles to the diameter of a circle from its extremity will fall outside the circle. (Heath's translation)

Figure 1

(Proof) For suppose it does not, but, if possible, let it fall within as CA, and let DC be joined. Since DA is equal to DC, the angle DAC is also equal to the angle ACD (prop. I.5). But the angle DAC is a right angle; therefore, the angle ACD is also right: thus, in the triangle ACD, the two angles DAC, ACD are equal to two right angles; which is impossible (prop. I-17). Therefore, the straight line drawn from the point A at right angles to BA will not fall within the circle.

### First step: construction of the tangent circle to both sides of a given angle

Lesson 1 (50'). We didn't propose any method of construction and let the students propose it. We collected their worksheets.

Lesson 2 (100'). By collective discussion, we analyzed all their methods (be they right or wrong) and, among them, we chose the following one, because it was aligned with the classroom background:

Figure 2

- 1) Take a point C on the bisector of the angle aVb.
- 2) From C draw the perpendicular line to side a and name T<sub>1</sub> the intersection point.
- 3) From C draw the perpendicular line to side b and name T<sub>2</sub> the intersection point.
- 4) Draw the circle of center C and radius CT<sub>1</sub>: it is tangent to both the sides of the angle given.

### Second step: theoretical justification of the construction

Lesson 3 (100'). Here is the text of the proof task; two hints are added:

By using definitions and theorems that you know, explain why (i.e. prove that) the obtained circle is tangent to both sides of the angle.

Hints: 1) In the 3<sup>rd</sup> step of the construction we took for granted that also T<sub>2</sub> belongs to the constructed circle. Now you must prove that CT<sub>1</sub> = CT<sub>2</sub>. 2) Given the definition of tangent line, in order to prove that each side of the angle is tangent to the circle, you must prove that each side of the angle has only one point in common with the circle: the side a has, in common with the circle, only T<sub>1</sub>, the side b has, in common with the circle, only T<sub>2</sub>. Try to find a reasoning by contradiction about only one side; for the second one you can re-use it.

Lesson 3) in the 2A class: we observed that almost all students proved that  $CT_1 = CT_2$ , but no one was able to continue. The difficulty was to find the starting point of proving by contradiction, so, we decided to offer it: “Let us suppose that the circle has two points,  $T_1$  and  $T_1^*$ , in common with side  $a$ . What consequence can you derive from this new figure?”. While we were waiting for some contributions, we observed gestures simulating reciprocal position of triangle and line, and listened fragments of speech left open. But, the situation reached a stalemate. Thus, the teacher drew the Figure 2 on the blackboard, added the segment  $CT_1^*$  (like in figure 3 – see later), and said: “Let’s look at the angles: in  $T_1$  and in  $T_1^*$ . Which kind of angles do you think they are?”. Her goal was to hint an isosceles triangle, due to two equal angles (opposite to equal sides). She suggested the students to think about the kind of the resulting triangle, based on the reasoning, in spite of how it looked. But most students saw a scalene one. They looked very uncomfortable, because of the conflict (cf. TFC) between the drawing and the reasoning guided by the teacher. She observed that Fed was slowly moving his index and medium fingers, a scissors-like movement; she interpreted it as a representation of  $CT_1^*$  that was collapsing on  $CT_1$ . She asked him the meaning of his gesture. He said: “I see an isosceles triangle, then it has two right angles, (...), I must refuse it; (...)?”. Thus, the teacher mirrored that gesture and asked: “In which case, could the angle in  $C$  be the zero angle? Look at your fingers moving”. Fed: “If the two sides collapse in one... and  $T_1^*$  in  $T_1$ ”. Fed smiled. This interpretation spread quickly in the classroom and revitalized the atmosphere: almost all the students restarted to work. But, the lesson-time ended: we had to stop and collect their worksheets.

Lesson 3) in 2D: we decided not to distribute the hints sheet, because it had interfered in an ineffective way with the students’ reasoning, and to guide in interaction with students the construction of the proof by contradiction in a smooth way, drawing the side  $CT_1^*$ . We proposed to consider the triangle  $CT_1T_1^*$  as isosceles. Suddenly, Bea said: “ $CT_1^*$  can’t be a radius of the circle. It’s the hypotenuse!”. By collective interaction, the teacher replied the same gesture made in 2A: several students saw in it the zero angle and carried on their work. Meanwhile, Fra showed his worksheet to the teacher, where he had written: “if there were two points of intersection, then  $CT_1$  would have not been perpendicular to side  $a$  (the negation of the hypothesis)”. The teacher told him that his reasoning was the incipit of another kind of proof and encouraged him to complete it. However, the teacher did not share it with the class, in order to not interfere with another way of reasoning, especially because, in that moment, her goal was the proof by contradiction. The discussion was oriented in that direction.

Analysis of the texts: only 6 students out of 51 produced a rather complete proof by contradiction. Students’ difficulties to deal with the impossible figure at the beginning of the proving process were well represented by three students who, when they had to draw the  $CT_1T_1^*$  triangle, wrote that they choose  $T_1^*$  “very near” to  $T_1$ . Concerning the subsequent phase of proving, in some cases, students’ words resonated with the gesture of closing the two sides of the angle: “The triangle must become the radius  $CT_1$ ”; “The angle goes to 0 and the triangle does not exist anymore”. Some students wrote that the triangle was impossible, because the width of one angle was 0; other students transformed the “impossible” triangle by making it collapse on the segment  $CT_1$ , because “the measure of the angle  $T_1CT_1^*$  must be 0”.

**Third step: reviewing some proofs produced by mates.**

Lesson 4) (100'). In both classes, students were provided with the photocopies of proofs produced by some of them: 2 for the first part of the task, and 5 proofs for the part that concerned proof by contradiction. They were asked to review, correct and improve their mates' proof texts. Most students worked in a rather exhaustive way on the first group of productions (direct proofs), while they had difficulties with the other five productions. A collective discussion followed, still oriented in the direction of putting proving by contradiction into evidence.

#### Fourth step: individual written refining the proof

Lesson 5) (50'). Task: "Taking into account the discussion, write down in an accurate and complete way the theoretical justification that the circle is tangent to both sides of the angle."

First part:

The circle of center  $C$  and radius  $CT_1$  meets side  $b$  in a point  $T_2$

Second part:

The circle of center  $C$  and radius  $CT_1$  is tangent to the side  $a$  of the angle.

**Figure 3: the two parts of the statement**

This time, more than one third of students produced more or less exhaustive proofs by contradiction, but in some cases the texts looked like mere transcripts of what the teacher had put into evidence.

Lesson 6) (50'). We provided students with a written theoretical justification of the construction; all the steps were reported, but their justifications were lacking. The conclusion after the emergence of the contradiction was already complete. The drawings of Figure 3 were reported on the worksheet. The students were requested to complete the text by writing the justifications of the statements, which they considered lacking. In this case, most productions were exhaustive and satisfactory.

#### Interpreting students' difficulties

According to Antonini and Mariotti's (2008) model of indirect proofs, the students were expected to meet difficulties due to the transition from a direct proof initiated by falsifying the thesis of the theorem, to the management at the meta-level of the resulting contradiction. But another, strong difficulty intervened at the beginning of the reasoning: the existence of an impossible figure  $T_1^*$ , which contrasted with perceptual evidence (hence the choice of two "very near" points  $T_1$  and  $T_1^*$ ). It is like if the choice of very near points might make the existence of a second meeting point between line  $a$  and the circle more reasonable! In this case, a complementary interpretation of students' difficulties might be provided by TFC, particularly when Fischbein (1993, p. 148) says: "There is certainly a conflict here generated by the fact that the two systems, the figural and the conceptual, did not yet blend in genuine figural concepts [...]. The figural effect is too strong and it seems to cancel the conceptual constraints". Accordingly, in our case, we might interpret students' difficulties in accepting the impossible figure by considering the conceptual assumption of the existence of two points of intersection as the starting point of the direct reasoning that brings to the contradiction, and the conflict with its figural representation. Indeed, in the case of the proof of irrationality of  $\sqrt{2}$ , most of the same students had easily accepted to start their reasoning from the assumption that  $\sqrt{2}=m/n$ , with  $m$  and  $n$  coprime integers. The direct proof could be developed up to the conclusion that  $m$  and

n should have had 2 as a common factor. Then, the transition to the logic meta-level inherent in the management of the contradiction made some students hesitant just for a while, without preventing them from reaching a conclusion. On the contrary, in our geometric case the transition to the logic meta-level was problematic: another “impossible figure” worked again as an obstacle, and some students felt the need of collapsing that figure to eliminate the source of the contradiction, instead of accepting the contradiction and coming to the conclusion of refuting the negation of the thesis.

## Discussion

The 2017/18 teaching experiment allowed us to better understand some reasons for the difficulties met by students approaching proof by contradiction through a typical theorem of Euclidean geometry. The difficulties in two different phases of proving depended on the figures of the (necessary) visual support to develop the proof (impossible figures!), intertwined (in the second phase) with the difficulties inherent in the management of the contradiction at the meta-level. In order to deal in the future with the approach to proof by contradiction in Euclidean geometry we are now considering three possibilities:

First, to lessen the difficulty inherent in the impossible figure by changing the geometry theorem at stake. Tall et al. (2012) suggest a proving situation related to the proof that the angular bisector of any angle in any triangle intersects the axis of the opposite side in a point that cannot be internal to the triangle. The proof is based on the assumption of an internal point of intersection, and on the consequent reasoning that brings to the conclusion that all the triangles are isosceles.

Second, to approach indirect proofs in geometry through a different treatment of the same situation considered in this paper: the starting point would be to prove that a secant line meeting the circle in  $T_1$  and  $T_1^*$  cannot be perpendicular to the radius  $CT_1$  (like the student Fra. did). By this way students would learn to move to the meta-level of logic considerations inherent in indirect proofs without the obstacle of impossible figures; then they might move to a proof by contradiction for another theorem.

Third, to take into account some students' tendency to reason dynamically<sup>1</sup>, in order to escape the contradiction related to the impossible figures, and to show how it may result in a valid proof; and then to move either to a proof by contraposition, or to a proof by contradiction as another way of proving the same theorem by reasoning on the impossible figure.

These possibilities are not mutually exclusive. More generally, we may ask ourselves if the domain of Euclidean geometry is suitable for students' approach to indirect proofs. Indeed, in the literature many examples of such approach concern other domains, and even the first encounter of our students happened in the arithmetic field, without any relevant difficulty. For us, two reasons still suggest to privilege Euclidean geometry for a full-fledged approach to indirect proof (in particular, to proof by

---

<sup>1</sup> Students' dynamical reasoning might result (through a suitable mediation by the teacher) in a direct proof: let us consider the distance between C and the secant line, as the segment of perpendicular CH drawn from the center of the circle to the secant line; the identity:  $CH = \sqrt{CT_1^2 - T_1H^2}$  results in the fact that the distance CH approaches the length of the radius of the circle (and thus the radius becomes perpendicular to the straight line) if and only if  $T_1H^2$  goes to 0, i.e. the triangle  $CT_1T_2$  collapse on  $CT_1$ .

contradiction). First, the nature of proof by contradiction: the obstacle of the “impossible figure”, if conveniently dealt with thanks to a suitable preparation, might put into better evidence the nature of the proof by contradiction and the necessity to move to the meta-level (Antonini and Mariotti, 2008). Second, during the process of proving by contradiction, impossible figures do not intervene only in Euclidean geometry, but also in other fields of mathematics (e.g. in Calculus) when students represent the negation of the thesis. Thus, it would be good that students meet impossible figures and deal with them in high school. Moreover, we may add that proof by contradiction entered Western mathematics through Euclid’s elements, while it was absent in other important historical developments of the discipline (like in the case of Chinese mathematics; see Siu, 2012). Thus, it is a cultural product that needs a suitable teacher’s mediation. The field of Euclidean geometry seems to be suitable for it, provided that a smooth approach to indirect proofs is planned.

# Identifying key ideas in proof: the case of the irrationality of $\sqrt{k}$

Xiaoheng (Kitty) Yan<sup>1</sup> and Gila Hanna<sup>2</sup>

<sup>1</sup>Simon Fraser University, Faculty of Education, Burnaby, Canada; [xkyan@sfu.ca](mailto:xkyan@sfu.ca)

*The mathematics education literature reveals an ongoing interest in fostering students' ability to construct and reconstruct proofs. One promising tool is the concept of "key idea". This study examined the relationships between how well students identified and formulated key ideas of the proof the irrationality of  $\sqrt{k}$  for non-square  $k$  and their subsequent ability to reconstruct the proof. The findings show that students' proof reconstructions were closely aligned with key ideas that they identified. Very few students were able to use precise language and point to an idea that helped them both understand the proof and reconstruct it. The findings suggest that mathematics educators, in their desire to see students enhance their understanding of proof and proving by the use of key ideas, need to create opportunities for key idea identification and proof reconstruction with attention to students' differing approaches to reconstructing a proof.*

*Keywords: Key idea, proof reconstruction, undergraduate mathematics.*

## Introduction

Since Hanna (1990) highlighted the distinction between proofs that prove and proofs that explain, it has been widely accepted that the purpose of using proof in the classroom is not merely to convince students that a mathematical statement is true, but also, and more importantly, to provide them with mathematical insights (e.g., Hanna, 1995; Mariotti, Durand-Guerrier, & Stylianides, 2018; Mejia-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012; Stylianides, Stylianides, & Weber, 2017; Thurston, 1995). Closely associated with the notion of "proofs that explain" is that of a *key idea* in a proof. For some scholars this term refers to a central mathematical idea, method, or strategy used in a proof, whereas for others it connotes the outline, overview or architecture of a proof. Despite these different interpretations of *key idea*, this notion has had pedagogical implications that are consistently aligned with the promotion of students' ability to undertake proof construction and reconstruction on the basis of richer understanding (Detlefsen, 2008; Duval, 2007; Gowers, 2007; Hanna & Mason, 2014; Koichu & Zazkis, 2013; Raman, 2003; Robinson, 2000).

Despite the increasing interest among mathematics educators in fostering the ability of students to construct and reconstruct proofs, and in proof reconstructability in particular, there are limited studies that investigated how university mathematics students go about identifying the key idea(s) of a proof, consciously or unconsciously, or how key idea(s) are actually used to help students grasp the overall structure of a proof or the mathematical insights embedded in it. Of those empirical studies that have investigated students' comprehension of proof (e.g., Weber & Mejia-Ramos, 2011), very few have probed the identification of key ideas as a factor that promotes the ability of undergraduate university mathematics students to construct and reconstruct proofs. This paper examines the relationships between the students' ability to identify and formulate key ideas of a proof and their subsequent ability to reconstruct the proof, with specific reference to the use of *key ideas*.

## Theoretical underpinnings

Practicing mathematicians have paid considerable attention to the concepts of understanding, remembering, and reconstructing proofs (Byers, 2010; Manin, 1998; Thurston, 1995). Gowers (2007), a Fields medalist, suggests that focusing on the main idea(s) of a proof would enhance its memorability and reconstructability.

### Key ideas

The notion of *key idea* in proof construction and reconstruction stems from both mathematical and pedagogical considerations. Lai and Weber (2014) reveal that mathematicians value and emphasize the presentation of the main ideas of a proof over that of a completely rigorous proof. Similarly, mathematics educators have discovered that to help students understand and remember proofs it is more beneficial to put an emphasis on the main ideas contained in the proofs than to teach the students how to build valid sequences of logical steps (Durand-Guerrier, Boero, Douek, Epp, & Tanguay, 2012; Hanna & Mason, 2014; Hemmi, 2008; Knipping, 2008; Malek & Movshovitz-Hadar, 2011). Furthermore, Duval (2007) suggests using main ideas to overcome students' mental blocks in proof construction. Such ideas described above are "key ideas" which carry the flow of information in mathematical proof (Detlefsen, 2008) and capture the gist of a proof (Robinson, 2000).

The term *key ideas* may mean different things to different people. Some scholars refer by that term to the most important mathematical ideas, methods, or strategies used in a proof, whereas others have in mind an outline, overview or architecture of a proof. The former maintain that a proof can foster understanding more successfully if it is constructed on the basis of well understood and internalized key mathematical ideas (Gowers, 2007; Hanna & Mason, 2014; Mason, Burton, & Stacey, 1985). The latter, while also focusing on the central constructive idea, propose a general approach in which a proof task is broken into chunks to highlight its overall structure (Leron, 1985; Mejia-Ramos et al., 2012; Robinson, 2000; Selden & Selden, 2015). Robinson (2000) suggests that it is essential to ignore low-level details while highlighting the overall structure of the proof. Selden and Selden (2015) suggest the construction of a proof framework or outline specifically to reduce the burden on the working memory of the mathematician or student. Raman (2003) understands the term *key idea* differently. For her, it refers to a heuristic idea that one can map to a formal proof with an appropriate degree of rigor.

In this study, the term *key idea* in a proof was presented to the students as an idea, such as mathematical fact or concept, a specific proving approach or technique that one actually needs to remember in order to know how to go about re-constructing a proof. One might ask "why reconstruction?" At the undergrad level, students often apply a previously learned proof to reconstruct a proof of that type on a new problem. In this sense, proof reconstruction is an outcome measure of the power of *key idea*.

Here are examples of key ideas. 1) To prove that  $\sqrt{2}$  is irrational, a key idea might be: to start with a minimal fraction  $p/q$  and look for a smaller such fraction. 2) To prove that the sum of the first  $n$  positive integers,  $S(n)$ , is equal to  $n(n+1)/2$ , a key idea might be: to notice that each pair  $(1 + n)$ ,  $(2 + (n-1))$ ,  $(3 + (n-2))$  ... has the same sum; another key idea might be: to represent  $S(n)$  in a triangular

form of dots. 3. To prove Viviani's theorem, a key idea might be: to use the fact that the area of a triangle is half its base times its height.

## Method

Both qualitative and quantitative methods were used in the larger exploratory study on the key ideas of proofs. This paper reports the results based mainly on the qualitative data collected from 17 first year undergraduate mathematics students, who attended a transition-to-proof class in the honours program of mathematics or mathematics education at an urban university in central Canada. The age range of the participants was from 19 to 38.

## Data Collection and Analysis

The purpose of the quantitative survey' was to gather data on the use of key idea(s) in proof construction and reconstruction. For example, students' agreement to some statements about key ideas were as follows: 1) When I read a proof, I try to identify its key ideas (76%); 2) After constructing a proof, I tend to identify the key ideas used in it (59%); 3) When I reconstruct a proof, I am less likely to get lost if I already know the key idea used in the proof (53%). Student work was the major source for investigating how students identify key ideas in a proof and how they use the key ideas to reconstruct it. It included worksheets, individual assignments, group work, mid-term tests, final exams, as well as snapshots of students' proving products on a board or on paper. Five complete proofs were used for students to identify and formulate key ideas. The paper focuses on the proof of irrationality of  $\sqrt{k}$  for non-square  $k$  for investigation and discussion.

The proof of the irrationality of  $\sqrt{k}$  for non-square  $k$  (see Figure 1) was selected from the book *Charming Proofs: A Journey into Elegant Mathematics* (Alsina & Nelsen, 2010).

### The irrationality of $\sqrt{k}$ for non-square $k$

In this proof, we interpret  $\sqrt{k}$  as the slope of a line through the origin, as illustrated below.

**Theorem:** If  $k$  is not the square of an integer, then  $\sqrt{k}$  is irrational.

*Proof.* Assume  $\sqrt{k} = \frac{m}{n}$  in lowest terms. Then the point on the line  $y = \sqrt{k}x = \frac{m}{n}x$  closest to the origin with integer coordinates is  $(n, m)$ . However, if we let  $p$  be the greatest integer less than  $\sqrt{k}$  so that  $p < \sqrt{k} < p + 1$ , then the point with integer coordinates  $(m - pn, kn - pm)$  lies on the line and is closer to the origin since  $\frac{m}{n}(m - pn) = \frac{m^2}{n} - pm = kn - pm$ , and  $p < \frac{m}{n} < p + 1$  implies  $0 < m - pn < n$  and  $0 < kn - pm < m$ . Thus we have a contradiction and  $\sqrt{k}$  is irrational. ■

Figure 1: The proof shown to the students

This proof was given to the students who attended “Problem, Conjectures and Proofs” course as an in-class exercise which consisted of three components: 1) reading the proof, 2) responding to seven prompt questions such as, “What is the method of the proof?”; “Explain how to use  $p < \frac{m}{n} < p + 1$  to prove that  $0 < m - np < n$  and  $0 < kn - pm < m$ . What is the relevance of these inequalities?”; and “What is the idea of the proof? Limit yourself to three or four sentences”, and 3) reconstructing the proof. The instructor gave the students approximately 40 minutes to read the proof and to respond to the prompt questions designed by the instructor. After the students handed in the worksheets, they had approximately 30 minutes to reconstruct the proof. For all the three components of the exercise, the students were asked to work individually.

Fifteen responses were collected. At the end of the course, follow-up question sheets designed to gather more information about students’ perceptions of the notion of key idea were also collected. Email discussions were also conducted with three participants.

## Findings

The findings are based on the work of 15 students for whom there is complete data. The students’ work on this proof is organized by the relationship between how well the students identified and formulated the key ideas of the proof and how well they subsequently used them to reconstruct the proof (see Table 1). Each of four qualified judges (two mathematics educators and two mathematicians) assessed the students’ responses independently and then the four settled on a grouping of the responses into three categories: 1) clear key ideas (well-formulated mathematical ideas useful in the proof), 2) unclear key ideas (imprecisely formulated mathematical ideas with no clear way to use them in the proof), and 3) unhelpful key ideas (well-formulated mathematical ideas irrelevant to the proof). The main criteria used to categorize how well the students identified and formulated the key ideas of the proof were relevance and clarity in stating where the contradiction comes from in the proof.

Proof Reconstruction	Identification of Key Idea			Total
	Clear	Unclear	Unhelpful	
Successful	2		1	3
Unclear		3		3
Problematic			9	9
Total	2	3	10	15

**Table 1: Relationships between key idea identification and proof reconstruction**

Nine out of 15 students identified the key ideas of the proof inappropriately and were unsuccessful in reconstructing the proof. These key ideas, irrelevant to the proof presented, fall into three categories (see Table 2). The first two types reflect students’ misunderstandings of the proof: 5 out

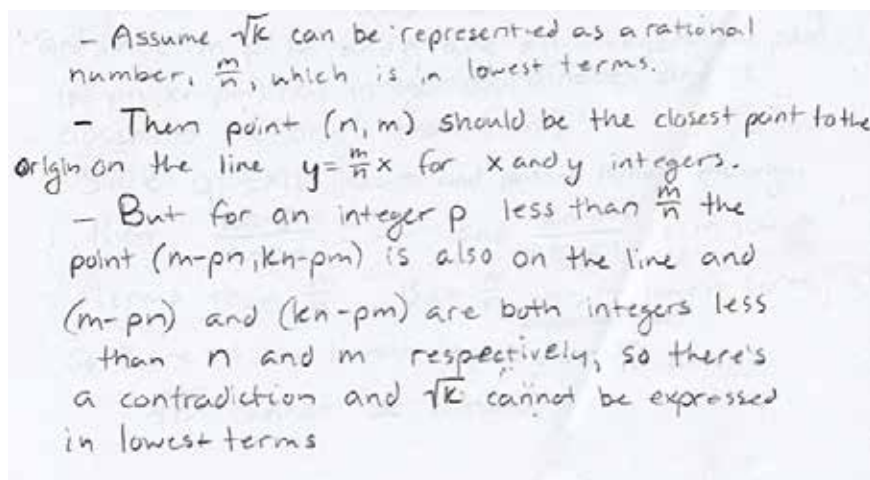

Type	What key ideas focused on	Number of Students
1	Properties of straight lines or linear function	5
2	Well ordering property	3
3	Mechanical procedures	1
Total		9

**Table 2: Types of unhelpful key ideas**

of 9 students improperly considered that the key idea of the proof involved the properties of straight lines or linear functions, while 3 students claimed incorrectly that the Well Ordering Property was used in the proof. The third type “mechanical procedures” shows that the student simply listed the procedures to be followed to complete the proof without addressing the mathematical ideas used.

Student Kathy displayed a clearly identified key idea of the proof followed by a successful reconstruction. As shown in Figure 2, she offered a well-articulated key idea of the proof by breaking down the key idea into three related elements: 1) an assumption being made – “assume  $\sqrt{k}$  can be presented as a rational number  $\frac{m}{n}$  in lowest terms”, 2) the consequence of the assumption – “then point  $(n, m)$  should be the closet point to the origin on the line  $y = \frac{m}{n}x$  for  $x$  and  $y$  integers”, and 3) what contradicts the assumption – “point  $(m-pn, kn-pm)$  is also on the line and that  $(m-pn)$  and  $(kn-pm)$  are both integers less than  $n$  and  $m$  respectively, so there is a contradiction”. The logical progression of the three elements was clearly stated and well presented.

In Kathy’s proof reconstruction (see Figure 3), the same structure and wording of the key ideas appeared. In fact, the reconstruction was an expanded version of the key ideas with adequate details of reasoning and verifying. Notice that, from the instructor’s perspective, the proof could have stopped when Kathy reached the point where “the point  $(m-pn, kn-pm)$  has integer coordinates and is closer to the origin than  $(n, m)$ ”. However, Kathy continued on to explain that “ $y = \frac{m}{n}x$  is linear

**Figure 2: Kathy’s key idea of the proof of the irrationality of  $\sqrt{k}$**

and passes through the origin then  $\frac{kn-pm}{m-np} = \frac{m}{n}$  and  $\frac{kn-pm}{m-np}$  is in lower terms  $\frac{m}{n}$ ”, which did not appear in the original proof presented to the students. It seemed that in order to come to the conclusion, Kathy needed to see the integer coordinates of the two points in the form  $\frac{kn-pm}{m-np} = \frac{m}{n}$  to argue that now a new point was found such that  $\sqrt{k} = \frac{kn-pm}{m-np}$  in lower terms than  $\frac{m}{n}$ . This intention and action to be more explicit and transparent than the original proof shows that the student reconstructed a proof that she understood, and needed to communicate with herself and the instructor about what she considered critical to reach the contradiction.

Assume  $\sqrt{k}$  rational. then  $\sqrt{k} = \frac{m}{n}$  for some integers  $m$  and  $n$ ,  $n \neq 0$ , and  $\frac{m}{n}$  in lowest terms.

Then for the line through the origin with the slope  $\frac{m}{n}$ ,  $(n, m)$  should be the closest integral point on the line to the origin.

But ~~for~~ <sup>there exists</sup> an integer  $p$ , where  $p < \frac{m}{n} < p+1$ , and the point  $(m-pn, kn-pm)$  is also on the line  $y = \frac{m}{n}x$  and from  $p < \frac{m}{n} < p+1$ ,  $0 < m-pn < n$  and  $0 < kn-pm < m$

and since  $m, p, k$ , and  $n$  are all integers, the point  $(m-pn, kn-pm)$  has integer coordinates and is closer to the origin than  $(n, m)$  ✓

Since  $y = \frac{m}{n}x$  is linear and passes through the origin then  $\frac{kn-pm}{m-pn} = \frac{m}{n}$  and  $\frac{kn-pm}{m-pn}$  is in lower terms than  $\frac{m}{n}$ . But  $\frac{m}{n}$  was in lowest terms, <sup>enough that point is closer to origin than  $(n, m)$</sup>  (supposed to be)

So there is no lowest terms for  $\frac{m}{n}$  and  $\sqrt{k}$  cannot be rational!

Figure 3: Kathy's reconstruction of the proof of the irrationality of  $\sqrt{k}$

When asked to reflect on what led to the success in understanding and communicating the key ideas of the proof, Kathy stated that:

I have to break the proof into related steps so that I can understand it when I am reading it, and communicating that is just the process of putting the ideas of those steps back into words. When doing this, I choose phrasing that would help me to understand the proof better. So I think that I did well on those questions because they are similar to my own process of understanding the proofs presented.

There was one case of an incorrect key idea followed by a successful reconstruction. A student stated that, "The main idea of this proof is we won't have a line when the slope of it is irrational. The graph will be a curve." However, his reconstruction of the proof was complete and clear, despite the mis-identified main idea. To probe what was going on in the student's mind, attempts were made to discuss the work with him. Unfortunately, the student was not interested in such discussions.

## Discussion

The findings indicate that compared to the original proof, students' proof reconstructions varied in some ways. These variations deserve some pedagogical attention given the fact that a deep understanding of a proof often leads to a personal interpretation of the proof. In Kathy's case, she deliberately added some details that did not appear in the original proof. The "unnecessary verification" served her as a necessary self-explanation to make a strong argument. Similarly, another student interpreted "a closer point to the origin" presented in the original proof as the

integral coordinates “below  $m$  and  $n$ ” so that he could link the point  $(m-pn, kn-pm)$  back to the straight line.

Three out of 15 participants identified the key ideas and reconstructed of the proof with limited success, while nine students did not manage to state a key idea clearly. Consequently, these nine students’ reconstructions of the proof tended to lack clarity as well. What seems to have thwarted their ability to reconstruct the proof was their lack of success in identifying clearly a key idea of the proof with the intention of re-using it in future reconstruction. The inadequate level of clarity in these students’ work might be due to a lack of full or partial understanding of the proof, or simply due to a struggle with being precise in expressing their ideas.

The findings are somewhat in line with Raman, Sandefur, Birky, Campbell, & Somer (2009) in that a proof should not be thought as having only one particular key idea: “We refer to “a” key idea rather than “the” key idea, because it appears that some proofs have more than one key idea” (p. 2–156). The findings do support Gowers’ (2007) view that a key idea provides not only a clue how to remember a proof but also to write it up. In fact, the findings bring evidence that the students’ proof reconstructions were closely aligned with the key ideas they themselves identified – varied in type as those key ideas may have been. It is therefore important for mathematical educators to be aware of these variations so as to understand students’ work better. In addition, instructors could be attentive to students’ differing approaches to reconstructing a proof and aim at creating more opportunities for students to identify key ideas and engage in proof reconstruction.

### Introduction

Working Group 2 was formed in 2011 and has developed as a forum for discussing theoretical and empirical research on the teaching and learning of arithmetic and number systems. Our common work targets to gain and enhance knowledge about students' understanding and meaningful learning in this content area regarding different age and achievement levels. The scope of the TWG comprises kindergarten to 12<sup>th</sup> grade, and emphasizes research-based specifications of domain specific frameworks, concepts and goals, analysis of learning processes and learning outcomes in different classroom cultures, as well as innovative teaching and diagnostic approaches that balance procedural and conceptual knowledge.

Learning arithmetic and number systems from Kindergarten to High School is a very broad field with a great variety of themes and research approaches. This year, the group intensively discussed twenty papers and four posters that reflected the richness of the field. According to the path we pursued at CERME 10, we had the chance to broaden our discussion by regarding the same topics from different perspectives; cognitive psychologists and mathematics education researchers. In comparison to the TWG work of the last years, there was also a change regarding the research approaches. Whereas the last two CERME conferences were dominated by design based research, this year was characterized by a good balance of qualitative and quantitative approaches.

### Overview on discussed papers and posters

The various presented and discussed papers can be pooled in four groups of themes: The role of manipulatives in learning processes in early arithmetic, learning and teaching numbers and operations in kindergarten to first grade, learning and teaching arithmetic in second to sixth grade, as well as different foci on learning rational numbers. Additionally, there was one paper on metacognition.

#### Role of manipulatives

*Natividad Adamuz-Povedano, Elvira Fernández-Ahumada, Teresa García-Pérez and Rafael Bracho-López* reported on an exploratory study of 25 students using manipulative materials to develop number sense understanding in 6 year olds by presenting two activities, jumping frogs and skip kangaroo. The findings illustrated how effective active behaviors from the students had enhanced.

*Doris Jeannotte and Claudia Corriveau* explored the use of manipulatives by children, in particular based-ten blocks and abacus, for solving arithmetical tasks. Considering the concept of affordance, as related to interactions between an individual and the environment, they analyzed both, the use of manipulatives and the affordance in two grade 3 classes, as inseparable units of teaching and learning.

## Numbers and operations in early arithmetic

*Camila P. Nogues* and *Beatriz V. Dorneles* explored deeper into the skills of number estimation and quantitative reasoning through the discussion of the relationship between these two important concepts of understanding. They found indeed a correlation between grades 3 and 4 students' performance in the quantitative reasoning task and number line estimation tasks.

*Évelin Assis* and *Luciana Vellinho Corso* presented an intervention study in Brazil which involved 136 first-grade students in the teaching and understanding of counting principles. A key product of this experiment was to analyze the efficiency of the intervention in order that it could be used in any first grade classroom.

*Pernille Sunde* and *Peter Sunde* investigated the development of mental strategies in single-digit addition in 83 first grade students. The used strategies were assessed by two interviews that were conducted in a period of five month. Surprisingly, quantitative analysis revealed no influence of instruction for strategy change.

*Michael Gaidoschik* discussed the “structure-genetic didactical analysis” paradigm, which emphasizes the need of children explore and internalize part-whole relations between numbers. He questioned the role of counting in early math classrooms, and offered a didactic alternative in line with the needs of the children as well as the subject matter.

*Luciana V. Corso* and *Évelin Assis* analyzed teacher's perceptions of their first grade students' profiles including students' behavior, attention, interaction and knowledge by area of mathematics writing and reading. The findings presented teachers perceptions related very closely to student achievement in a counting principle test, but only for students with a good performance.

## Learning arithmetic in second to sixth grade

*Joana Brocardo*, *Catarina Delgado*, *Fátima Mendes* and *Jean M. Kraemer* presented a teaching experiment with grade 3 students in the domain of partitive division. It aimed to explore how students adapt personal knowledge to varying task conditions. Data analysis confirmed that variation influences students' strategies, and allowed to designate three critical aspect of the learning process.

*Ems Lord* and *Andreas J. Stylianides* presented results of a mixed methods study that focused on calculation flexibility and written algorithm on Year 6 students. Results revealed that formal algorithms were the most frequently selected strategy, and gender, prior attainment and confidence were all significant predictors of the use of formal algorithms.

*Robert Gunnarson* and *Ioannis Papadopoulos* analyzed written solutions for arithmetic expressions of Swedish and Greece students (grades 5 and 6) focusing on the order of operation (addition, subtraction and multiplication) and the precedence rules. Data showed that paring is as frequently used as sequential calculations. Thereby, three qualitatively different types of pairing were identified.

An analysis of four popular German textbooks (grades 2 and 3) with a focus on developing and consolidation of understanding of multiplication was presented by *Sandra Gleißberg* and *Klaus-Peter Eichler*. Using their own conceptual framework based on the work of Bruner, the analysis showed that the vast majority of tasks require working on the non-verbal-symbolic level alone.

### **Different foci on learning rational numbers**

*Lalina Coulangue* and *Grégory Trains'* study aimed to understand the role of register of numeration units (tenths, hundredths) for teaching and learning decimal numbers at primary level in France. Their findings revealed students' difficulties in unit-conversions and in associating the numeration units with the decimal notation. A new perspective on teaching is suggested to prevent those difficulties.

*Ioannis Papadopoulos*, *Styliani Panagiotopoulou* and *Michail Karakostas* investigated strategies used by primary, secondary and tertiary education students to calculate mentally operations involving rational numbers. The findings revealed the mental form of the written algorithm as dominant strategy across all educational levels.

*Pernille L. Pedersen* and *Peter Sunde* investigated the relationship between 99 fourth-grade students' ability to compare fractions and to solve tasks all four operations. Data analyzes showed that comparative rational number tasks are correlated with division and multiplicative items, and therefore suggested that understanding of fractions is closely connected to multiplicative reasoning.

A summary of four studies on secondary students' conceptual and procedural knowledge of fractions was presented by *Xenia Vamvakoussi*, *Maria Bempeni*, *Stavroula Pouloupoulou* and *Ioanna Tsiplaki*. The researchers developed and evaluated an instrument to measure both knowledge types, and identified students' individual differences in combining procedural and conceptual knowledge.

*Carlos Valenzuela Garcia* and *Olimpia Figueras* designed a teaching model for fractions based on applets aiming to support the development of fraction mental objects in elementary students. The performance of two students, described in the paper, showed that working with the applet lead to an enhanced notion of fractions, e.g., from fractions as fracturer to fractions as number and as measurer.

*Sofia I. Graça*, *João P. Ponte* and *António Guerreiro* developed a study that aimed to identify grade 5 students' knowledge of rational number operations and number sense before and after a teaching experiment. Results indicated that students' performance changed; at the beginning it based on their whole number knowledge, later they exhibited conceptual knowledge, number and operations sense.

*Carvalho, Renata* and *João P. Ponte* surveyed grade 6 students' strategies in mental computation in rational numbers within a qualitative design research approach including three phases. Data analysis allowed to describe typical strategies regarding tasks with different cognitive demands, and revealed that, e.g., memorized rules are mostly applied without meaning.

*Maria T. Sanz Garcia*, *Olimpia Figueras* and *Bernardo Gómez* focused on students' performance (15 and 16 years old) in solving particular fraction word problems, and measured their difficulties by accuracy. Results suggested that the increase of steps in a problem leads to the increase of students' difficulties caused by insufficient basic fraction knowledge.

### **Metacognition in problem solving**

*Aikaterini Vissariou* and *Despina Desli* investigated metacognitive strategies used by sixth graders solving a non-routine mathematics problem. Despite the fact that students reported the use of

metacognition, their demonstration of the used strategies was quite low. Additionally, their successful solution to a problem was not necessarily connected to the employment of metacognitive strategies.

### Discussed posters

*Évelin Assis* and *Luciana V. Corsos*' poster depicted well their analysis of the intervention pilot study discussing the adaptations that needed to occur on route. *Alix Boissière* presented a board game around the notion of fractions for grades 4 to 6. It was developed based on the theory of didactical situations and pretested in several classrooms. *Kazuhiro Kuriharas*' poster introduced a theoretical framework for analyzing the development of students' understanding the algebraic structure. Hereby, the focus is on the extension of number sets. *Charlotte Rechtsteiner* analyzed flexible mental calculation skills of freshmen and graduates. Results indicated that the flexibility scores are not adequate for prospective primary teachers.

### Summary and outcomes

The great variety of papers was challenging, but also the strength of this TWG since it ensured interesting and often animated discussions in a supportive quizzical environment. Thereby, we went far beyond the specific topics of the single papers, worked out differences and commonalities of used terms, concepts, theoretical frameworks and methodological approaches. We realized once more different conventions in different countries of naming numbers and operations, as well as partly conflicting views of quantitative and qualitative approaches. Altogether, we broadened our own culturally influenced perspectives and drew new inspiration for further research. The aspects we discussed reflected the whole spectrum of arithmetic in primary and secondary level and comprised

- the importance of counting in different cultures and curricula, as well as a critical reflection on counting for developing strategies in mental calculation.
- the influence of instruction and the need to design learning environments based on our knowledge of students' strategies, conceptions and misconceptions.
- the importance of supporting students' conceptual knowledge regarding numbers and operations in different number systems.
- the clarification of methodology in terms of what is measured, why is a measure used, what does a result mean, and how does it contribute to better understanding of teaching and learning.
- the meaning of 'number estimation' as positioning natural numbers in a segment, and its connection to relational thinking.
- the challenges of transition between number systems, between representations, and from intervention research to students understanding (long term)

Reflecting our work in a conclusive discussion, we agreed that our various research is driven by a common goal: Supporting all student's understanding and meaningful learning to develop conceptual knowledge, number sense and structure sense in different number systems, as well as flexible and adaptive expertise in calculation strategies in all operations. Our further work is directed towards specifying terms and work on common understanding of number sense, structure sense, flexibility, manipulatives and mental calculation. Furthermore, we want to advance our methodological approaches and bridge the gap between quantitative and qualitative by triangulation.

## Use of conceptual metaphors in the development of number sense in the first years of mathematical learning

*Promoting experiences to develop the so-called number sense since early school years has become a focus of interest in mathematics education research. By number sense we mean a broad concept that refers to a deep understanding of the decimal number system, the relationships between numbers and operations, and the development of capabilities such as flexible mental calculation, numerical estimation and quantitative reasoning. This paper is an exploratory study (25 pupils), part of an on-going research, where a methodological approach, based on the use of manipulative materials for developing in six-year-old students' number sense is explored. Particularly, in this study, we present and analyse two activities, in which a jumping frog and a kangaroo are used as conceptual metaphors for the acquisition of calculation strategies that encourage number sense development.*

**Keywords:** Number sense, Conceptual metaphor, Primary Education, Manipulative resource.

### Introduction.

Expressions such as "number sense", "numerical consciousness" or "numerical thinking" are being imposed with force in the current studies on mathematical knowledge. In general terms it refers to several important abilities that involve mastering a wide range of skills with numbers. For McIntosh, Reys and Reys (1992) numerical thinking is a person's overall understanding of numbers and operations along with the ability and inclination to use this understanding in flexible ways to make mathematical judgments and to develop useful strategies for managing numbers and operations.

In the Curriculum and Evaluation Standards for Mathematics Education of the National Council of Teachers of Mathematics (NCTM, 1989), five components that characterize numerical sense were identified: (1) correctly understand the meaning of numbers; (2) be aware of the multiple relationships that exist between numbers; (3) recognize the relative magnitude of the numbers; (4) know the relative effect of numerical operations; (5) have reference points for measurements of common objects and situations in the environment. In the same line, Sowder (1992) expresses that number sense is developed when students understand the size of numbers, they think about them and represent them in different ways, they use numbers as references and develop accurate insights into the effects of operations with numbers.

Although there is still no general consensus on the concept and operation of numerical thinking, many authors (Berch, 2005; Godino, Font, Konic, & Wilhelmi, 2009) are trying to define it, identify the keys to its development, establish criteria to evaluate it and analyse its repercussions on children's learning.

The school context is a privileged place to work with the possibilities offered by this powerful tool. Teachers must consider the number sense as an essential objective and articulate the resources and activities necessary to develop it.

Manipulative resources provide us with very advantageous visualizations to present, know and materialize both numbers and operations. To the visual properties of the resources must be added their sensory and motor properties, as they invite manipulation and movement. In this sense, another way of teaching and learning mathematics appears, because it is recognized that mathematical cognition is embodied and is intimately linked to our sensorimotor functioning (Gallese & Lakoff, 2005).

The matching of symbolic mathematics, initially quite abstract and apparently less close for students, with insights from the real world, helps to forge links between conceptual and procedural knowledge, which is critical to success in mathematics (Siegler, 2003). Conceptual metaphors are, among others, methodological strategies that facilitate neurological mechanisms that allow us to adapt the activated neuronal systems through the sensory-motor experience, making possible the seemingly complicated journey from the concrete to the abstract (Lakoff & Johnson, 2003). Thus, there arises a new way of conceiving the teaching and learning of mathematics associated with embodied mathematical cognition linked to sensory-motor functioning, departing from Piaget's theory of cognitive development, which separated motor-sensory development from conceptual development, basing the second on the first, but without the parallel development that we defend.

Conceptual metaphors provide a transition from one mode of representation to another or from a concept that is part of our knowledge to a more abstract one. Consequently, they value the three levels of representation of Bruner (1972): enactive, iconic and symbolic, putting into play and relating the four dimensions of mathematical thought (mathematical contents, non-rational processes, strategies and procedures and perception). Of course, this journey between the three types of representation does not have to be unidirectional and without return, from the enactive to the symbolic representation, passing through the iconic, but it can go back or advance through the levels on its way to conceptual consolidation. Conceptual metaphors do not only respond to a final objective of a cognitive nature, but also contribute to a didactic enrichment by providing resources and useful tools to address complex problem situations (Soto-Andrade, 2007), which makes them even more valuable for the construction of mathematical knowledge and the development of the competences associated with it.

This paper is part of an on-going research, where a methodological approach for developing six-year-old students' number sense is explored. The proposal is based on the use of manipulative materials, rigorously structured (García-Pérez & Adamuz-Povedano, 2016), that keep the relationship number-space very present, giving students a numerical support for the learning of the decimal numbering system, as well as an arithmetic support for operations. Here we present two activities, as specific examples of the use of a variety of conceptual metaphors (maps, routes, characters...) that play an important role for number sense development, as motivating and facilitating elements, both in the teaching and learning processes. In the design of these activities we take into account the limits that Cole and Sinclair (2017) show relative to the use of conceptual metaphors.

## Teaching materials

As we mentioned before, this proposal is based on the use of manipulative materials, rigorously structured, which we describe:

- *Number line*: it is a tape in which part of the set of natural numbers is presented. It starts with zero, a number that we will need to represent different situations: starting point, absence of counting elements, total loss, etc., and it ends in 100 example see figure 1.

**Figure 1: Detail of the number line**

With it we can practice progressive and regressive recitation, form the first series and perform simple addition and subtraction operations. We can also compare positions on both sides of the 10 to begin the observation of regularities and changes.

The tape shows, with great consistency, the numerical order, the pattern that generates numbers and distances. The numbers colored in red, in addition to meaning exact tens, are privileged positions, strategic enclaves when planning routes that take us from one number to another.

- *Numerical panel*: it presents the numbers from zero to ninety-nine by families (figures 2 and 3). This format enhances the display of numbers on the tape expanding the possibilities of analysis and relation.

**Figure 2: Collective numerical panel      Figure 3: Individual numerical panel**

As in the case of the tape, the complete tens are highlighted with a red background, facilitating their location and indicating they are essential elements within our numbering system. The number-space association in the panel shows very clearly the patterns and regularities of our decimal number system. On this "precise map of the numbers" it is also possible to perform many addition and subtraction operations by tracing horizontal paths (we move forward or backward through the rows) and vertical (we raise or lower the columns by multiples of ten).

- *Numbering box*: this material facilitates full exploration and manipulation of numbers, favoring a correct understanding of decimal numeration system. It consists of abundant plastic sticks and red and green rubber bands, see figure 4 below. The work with the numbering box produces a qualitative leap in the understanding of the decimal structure of the number and its size, since it provides a concrete and faithful model to the visible reality, which gives meaning to the use of written symbols and concepts. Regarding place value, in addition, we should move from that understanding to much more flexible forms. We can achieve this by removing the tens and units from the box and exploring

other groups with total freedom, leaving or removing the rubber bands of the tens. Regarding the calculation, the numbering box directly connects with breakdown strategies and facilitates the graphic transcription that is derived from the manipulation of quantities.

**Figure 4: Numbering box**

## Selected activities

In this paper we only show two activities focused on the number line resource. However, the methodology implies the implementation of other activities based on the use of the other resources. This provides students with greater flexibility in reasoning about numbers, an aspect directly related to the quality of their numerical sense.

### Activity 1: Saltarina, the frog

The convenient breakdown of numbers is a fundamental skill to give agility and efficiency to thought calculation, so let children show some characteristics of development of their number sense. Young children find it difficult to acquire because they require complex skills such as observation and analysis of the complete operation, reflection and planning of the tactics to be used, and also a good handling of numbers at the mental and written level. To work on this awareness of what may be suitable for the proposed calculation we use the conceptual metaphor of the jumping frog, it is a frog that jumps forward and backwards through the number line. In addition, Saltarina has a fixation with the colour red: whenever she can, she boots in the numbers coloured in red (see figure 5 below).

Teacher: This is Saltarina, a very funny frog that comes and goes on the number tape jumping without stopping. Do you know what her favourite colour is? ... It's red! ... and the numbers that have this colour look like springboards to take energy to jump higher. You can be sure that whenever she has the opportunity she bounces on them. Today, Saltarina jumps eight, do you know how she will do that if she is on thirty-six?

**Figure 5: Saltarina is on 36**

Student 10: She will jump four to land on forty and later she will jump another four.

Teacher: Very good! Let's check it!

The real movement is made, taking the clamp with the frog that bounces onto forty and ends the jump on forty-four.

Teacher: She has reached forty-four! Now let's say in writing what has happened.

Teacher: Say with me, please.

Teacher and students: Saltarina was on thirty-six [she writes 36 on the blackboard figure 6], first she has made a leap forward of four to reach forty [she writes +4] and then she has made another leap of four [she writes +4]. It has reached forty-four.

**Figure 6: Saltarina's jump**

Teacher: She has reached forty- four! ... What if she now adds eight again?

Student 10: Now she has to jump six to fifty and then two.

Teacher: And how do we express it with numbers and signs?

On the board, teacher writes the jump in two movements and the arrival number:  $44 + 8 =$ , and below  $44 + 6 + 2 = 52$

In Figure 7, we have examples of two students' activities, one in which Saltarina adds eight and another which goes back six. In both, the empty number line has been used as a scheme for the representation of forward and backward:

**Figure 7: Saltarina's worksheet**

Next, we analyse some examples showing different strategies that take part of what we have denominated *tactical calculation* (Adamuz-Povedano & Bracho-López, 2017), shows the operation 63-24 see figure 8, the student rewrites the operation explaining the plan he will follow, removing three units, then two tens and finally one unit. Since he is not still self-confident in mental calculation he makes partial annotations.

**Figure 8: Work out 63-24**

**Figure 9: Work out 45+29**

In Figure 9 the student rewrites the followed mental route to get the result, again Saltarina's strategy appears adding 5 to get 50 and then adds 24 in a convenience way.

## Activity 2. Skip Kangaroo!

In this activity we will use the number tape as if it were a numbered track in which a kangaroo makes jumps of different magnitude passing from one family to another. The objective is to reinforce operations in which there is change of tens, i.e. operations of adding and subtracting with taken. The kangaroo should overcome a fence that is placed in an exact ten and can jump progressing in the numerical sequence (we will relate it to the expression "+") or going backwards (expression "-"). The connection between movement in space and numerical operation is being established. This activity places students in front of the control of phenomena and develops their relational thinking. With the tape and the Kangaroo, we configure a "mathematical scenario" in which we can experiment with different possibilities to relate the numbers of two families. Children should determine the starting point, the direction and magnitude of the jump, and the arrival number. They should then insert these data into an arithmetic structure. Very important processes such as estimation, decision making and the translation of each specific situation into the language of numbers and signs, which favour the development of the numerical sense, are involved in all this work.

**Figure 7: Kangaroo on the number tape**

In this episode, see figure 10 above, the kangaroo is at number seventy-eight and it will jump until it reaches some number in the family of the eighties. First, we analyse the situation from a broader perspective, asking the group questions such as: What jumps shall not exceed the fence? It means, how far can he go without going over 80? What will be the minimum jump length? And the maximum?

Student 1: At least he has to jump three, up to eighty-one.

Student 1: And the most you can give is a jump from eleven to eighty-nine.

Then, with the contributions of all, we will be expressing verbally each of the possible solutions and their corresponding written expression.

Student 3: If it takes a jump of five, it reaches eighty-three.

We check on the number tape whether this is a correct solution

Teacher: How will we express this by writing what you have just said? (We write on the board at the same time we relate)

Teacher and Students: it begins at seventy-eight (78), jumps forward five (+5) and reaches eighty-three (= 83).

On the board will be written:  $78 + 5 = 83$ . We will continue exploring other possibilities from the same starting position. So, we will collect all the arithmetic structures on the board:  $78+3=81$ ,  $78+6=84$ ,  $78+9=87$ ,  $78+4=82$ ,  $78+7=85$ ,  $78+10=88$ ,  $78+5=83$ ,  $78+8=86$  and  $78+11=89$ . Then, we will observe them as a whole, becoming aware that with them we have translated each event into the language of numbers and signs. Moving forward with this observation, the teacher can bring the attention to the amounts that remain and to which they change, thus intuitively introducing the concept of a variable:

Teacher: From what number has the kangaroo always jumped? What jumps has it made? With what jumps did it stay close to the start? With which did it get very far? ...

Two sessions were developed with the dynamics showed; the kangaroo was introduced, working only with components in a sensorimotor and verbal level until we were sure that the whole group understood the proposal. In each participation, the student had to decide first the direction of the jump and the magnitude of the jump; then choose the exit number. These decisions inform the teacher about the students' number sense much more than the calculation itself. Then, the movement was actually made on the number tape verifying that it was feasible and, finally, the operation explaining the jump was verbalized. In the third session this activity is made on written level. To ensure the accessibility of all the students, an image of the tape with the corresponding numerical section was included in the worksheet. Below, we show two cases with interesting results. In figure 11 it is appreciated that the student discovers how to control the situation, the control of phenomena that is so present in the relational thinking, so that the number of arrival is always 41. In figure 12, the student ends, according to his own words, with "a jump from end to end"(that it is to say from 49 to 31)

Figure 8: Example of Kangaroo's worksheet

Figure 9: Example of Kangaroo's worksheet

The number tape section showed in this activity is a great help for students with difficulties because it reduces anxiety about the calculations (they can do the count directly) and focuses attention on the reflection and written expression of events. On the other side, there are students that are soon aware of ways to control numerical relationships (i.e. the student who experiments with the arrival at 41 from different positions in Figure 8). The implementation of these activities shows that the sensorimotor experience is very positive since practically the whole group correctly identifies the operation (addition or subtraction) that corresponds to each jump. Although there are students who work more slowly and do not manage to complete the twelve required possibilities, those that do, do it correct.

## Final comments

This work is a first approach to the development of number sense by using conceptual metaphors. Authors are aware that evidences should be tested empirically through wider research, but some interesting aspects already arise from this work. Among others, it may be said that (1) the activities proposed develop the relational thinking. They imply an active behaviour of children, provoking reflection on what they should do, and how they are going to solve it. This way of acting involves the

knowledge that children have of numbers and how numbers relate to each other through operations, fostering relational thinking in flexible contexts that admit more than one solution to the challenge posed. (2) It also promotes transparent algorithms for calculation. Our approach, the tactical calculation, shows the reflection and planning designed by the student. (3) A communicative approach is given to mathematical language. The classroom becomes a place where students can talk, expose their plan and discuss the decisions they are making. This oral language gives shape and meaning to expressions with numbers and signs. Children are building an interactive dictionary full of meanings that all share. (4) Working memory is reinforced. Having the number line and the position of the characters in view gives confidence to the students and helps them to concentrate on the choice of tactics and graphic representation. Then, in the absence of resources, these visualizations (already in the mental plane) will be fundamental to solve problems and calculations.

## **Development of an intervention program in counting principles for first- grade students – Pilot study**

Évelin Assis<sup>1</sup> e Luciana Vellinho Corso<sup>2</sup>

<sup>1</sup> Universidade Federal do Rio Grande do Sul, Brasil; evelin\_assis@hotmail.com

<sup>2</sup> Universidade Federal do Rio Grande do Sul, Brasil; l.corso@terra.com.br

### **Development of the intervention program:**

This study was designed considering the need of developing effective interventions that could help basic education teachers to favor their students' learning process. The objective of this study was to develop and intervention program focused on teaching counting principles for first-grade-children and to evaluate its applicability through a pilot study. The planning of the program was based on the guiding principles established by researchers of the field (Clarke, Doabler, Nelson & Shanley, 2015; Fuchs & Fuchs, 2001) and in intervention studies (Dyson, Jordan & Glutting, 2011; Praet & Desoete, 2013; Toll & Van Luit, 2013).

### **Method of the Pilot Study**

The objective was to evaluate the applicability condition of the intervention program in terms of: the quality of the proposals, duration of the sessions and the functionality of the idealized dynamics through the pilot study. Participated in this study 10 first-grade students from a public school located in Porto Alegre, Brazil. The application of the intervention occurred in 4 sessions of approximately 1h30 (2 sessions of 45 minutes in each meeting). In total, there were 8 sessions, each one with focus on a specific counting principle. All sessions were structured with the same dynamics (previous motivation, contextualization, activity and systematization) and were applied by the researcher. The researcher registered the progress of the intervention using a field dairy.

**Results:** with regard to the quality of the proposals, the researcher's notes indicated that most of them worked properly, but needed some kind of adaptations. This could have occurred for two reasons: first, the sample of 10 children ended up being too large, which was an obstacle to maintain the group attention and to give more individualized attention to the students; second, the participating children had good previous knowledge, completing the tasks faster than expected once they understood the instructions of the researcher. Regarding the duration of the sessions, the 45 minutes idealized weren't fully used because the intervention took place in the children's regular classroom and also because they were fast to complete the activities. Finally, the idealized dynamics for the sessions worked well, with the initial moments (previous motivation and contextualization) acting positively to engage the previous knowledge of the students. The final moment of systematization was repeatedly pointed out as needing to be reorganized. All the researcher's notes helped to reformulate the intervention program, culminating in its second version (presented below) to be tested as an experimental study. A paper presenting the experimental study, with the final intervention program in counting principles, was submitted to the TWG2.

Guiding questions:	Tasks:
Session 1: stable order, one-to-one correspondence and cardinality. - where do we find numbers? - what are their purpose? - how can we count them? - is there a right way to count? Which one? - what can we do to know how many things there are in a set?	- observation of the room to search for numbers and their purposes; - analyses of journals and magazines to search for numbers and then ordering them; - game: “which one is missing?”
Session 2: stable order, one-to-one correspondence, cardinality and order irrelevance. - how can we count without getting lost? - how can we know if we already counted one item? - how can we count a set that is not organized?	- demonstration of counting marbles in figures by the researcher; - demonstration of counting marbles in figures using little papers; - individual practice.
Session 3: stable order, one-to-one correspondence, cardinality, abstraction and order irrelevance. - what can we count? - where do we begin to count?	-game board: “color game”; - game board: “two hands”.
Session 4: stable order, one-to-one correspondence, cardinality, abstraction and order irrelevance. - how can we count in our heads? - how can we organize numbers when we’ll count? - how can we find out what number is without knowing its name?	- bingo of numbers; - closing questions: (can you say one thing you learnt during the intervention? Which task was easy? Which task was difficult?).

**Table 1: Intervention post adjustments**

## Conclusions

The pilot study was important and helpful for testing the initial version of the intervention program. It was possible to analyze the activities, structure and time planned to the intervention program and to make improvements culminating in its second version that was applied as an experimental study.

*Abstract: The objective of this article is to present an experimental study of intervention in counting principles, aiming to investigate its efficacy. The experimental study involved 136 first-grade students, from 3 public schools located in Porto Alegre, Brazil. The students were divided into control group (n=76) and experimental group (n=60). The intervention occurred 2 times per week, during 2 weeks, with the experimental group, while the control group remained with regular instruction. The results point to the efficacy of the intervention program in counting principles, with students in the experimental group showing higher statistically significant advances in the post-test (counting principles evaluation task) than the students in the control group. Some educational implications are addressed.*

*Keywords: Counting principles. Intervention. Experimental study.*

Number sense and counting principles have been evidenced as important predictive factors of posterior mathematical achievement (Jordan, Glutting & Ramineni, 2010; Martin, Cirino, Sharp & Barnes, 2014; Passolunghi, Vercelloni & Schadee, 2007; Stock, Desoete & Roeyers, 2009). Besides, both, when less developed, appear as characteristics of the group of children that presents mathematical learning difficulties - MD (Bull & Johnston, 1997; Cirino, Fuchs, Elias, Powell & Schumacher, 2013; Dorneles, 2006; Vukovic, 2012). In regard to counting, studies show that children with MD use immature counting strategies (fingers or verbal counting) for a longer period (Bull & Johnston, 1997; Dorneles, 2006) and have difficulties to retrieve basic facts from memory (Cirino et al., 2013). Research results such as these emphasize the importance of helping students to consolidate the counting principles in the beginning of the school years, which in turn, will help them develop efficient strategies and procedures to count efficiently and, thereby, prevent the development of arithmetical difficulties.

Counting is an important knowledge that begins to be developed informally by children, through everyday experiences. Nunes & Bryant (1997) point that many teachers recognize their students get to the classroom knowing a lot of things, including counting. Its relevance is highlighted by several authors and Dorneles (2004) synthesizes well this idea by stating that counting is a cognitive tool important not only to comprehend posterior contents, but also to develop more elaborated mathematics skills. Knowing the relevant role of counting, it is necessary to pay attention to the development of this ability. While children learn to count, they need to put in practice some principles that guide this action, as well as comprehend what is the purpose of counting and the way of doing it correctly (Nunes & Bryant, 1997). Gelman & Gallistel (1978) studied this learning process and established five guiding principles of counting, which must be consolidated by children in order to develop other mathematical knowledge. The principles are: stable order, one-to-one correspondence, cardinality, abstraction and order irrelevance. The first three principles are classified as “how to count”, the fourth is denominated as a definer of what is countable and the fifth one consists of a

synthesis of the application of the other ones. Those five principles are the bases of the children's posterior numerical construction (Dorneles, 2004).

### **The current study**

Considering the extreme relevance the counting principles have in relation to mathematical learning and that most children who have difficulties in this area present problems, specifically, with counting strategies and the retrieval of basic facts, justifies the need of the development and implementation of intervention programs focusing on counting principles. Such an approach, put into practice in the beginning of formal schooling, can facilitate the students' learning process. Besides, most intervention studies developed in the mathematical field focused on number sense (Aragón-Mendizabal, Aguilar-Villagrán, Navarro-Guzmán & Howell, 2017; Bryant et al., 2011; Dyson, Jordan & Glutting, 2011; Fuchs et al., 2010; Praet & Desoete, 2013), which points to the lack of intervention instructions in counting principles.

### **Method**

This is an experimental intervention study focusing on teaching the counting principles to first-grade students. It has the objective of evaluating the effectiveness of a short intervention, comparing the achievement of the experimental and the control groups.

### **Participants**

The study included 136 first-grade students (63 girls and 73 boys), aged between 6 and 7 years old, from 10 classes, belonging to 3 public schools located in Porto Alegre, Brazil. They were divided in control group ( $n=76$ ) and experimental group ( $n=60$ ), both groups were statistically equivalent and, through the analysis of students' performance case by case, were formed by children with different levels of performance in a counting principles task. The parents of all participating students gave their authorization through the signing of the Free and Informed Consent Form and the Dissent Form. Approval for this study was obtained from the Research Ethics Committee of Universidade Federal do Rio Grande do Sul. The intervention was offered to the experimental group, by the researcher, while the control group remained with regular instruction. Unfortunately, it wasn't possible to follow teachers' regular instruction during the execution of this study, so we do not have data about the control group's learning, although, we hypothesize that there was less focus on mathematics and more on literacy, because this is the main concern of first year teachers in Brazil.

### **Procedures**

In august 2017, a pilot study was conducted to evaluate the applicability of the intervention program, that culminated in its second version, the one used in this study. From September to December 2017, the pre-test, intervention and post-test procedures were done. The interval between the pre-test and the intervention was one month and between the intervention and the post-test was 20-30 days.

### **Instruments**

Counting principles task (as pre and post-test): this task was administered individually, by the researcher, in an interview format (see Table 1). The instrument was used to evaluate the construction of the counting principles by the students. It is the same task used by Dorneles (2004, 2006). For each

principle, the students were classified into three groups: principle consolidated (Y – yes); in construction (IC); not consolidated (N). Some criteria were established to classify the children in each group because some of the questions (like 2, 3 and 5) are formed by more than one query. In this case, the child's answer was classified as “Y” if he/she answered all the solicitations in each question correctly; “IC” if only one part of the question was correctly answered; “N” if the student did not answer any part of the question correctly.

Principle:	Solicitation:
Stable order	The experimenter asks the child: “until how much can you count?” and tell him or her to count out loud until the number said.
One-to-one correspondence	The experimenter shows 10 chips in a row and asks “how many chips are there?”. Then, shows 10 chips misaligned and asks “how many chips are there?”. This procedure is repeated with 15 chips.
Cardinality	By the end of counting 15 items, the experimenter asks “how many are there in total? Can you give me 10?”
Abstraction	The experimenter asks “if you were counting 15 candies, would you count the same way you counted the chips?”.
Order irrelevance	The experimenter asks the child to count the 15 chips, arranged in a row, in a different order, that is, initiating by another chip. Then, the child is asked to say how many chips would remain if the row was undone. After, the experimenter asks the child to count 8 chips of the set, separating them aside, and then, to count the remaining 7 chips of the row. By the end, the child has to say how many chips there are in the total.

**Table 1: Counting principles task**

### **Intervention in counting principles**

In regard to the intervention, whose development is described in detail in the poster submitted to the TWG2, some guiding principles are on its bases, as the ones presented by Clarke, Doabler, Nelson & Shanley (2015): engaging children's previous knowledge, through “warming up” exercises in the beginning of the sessions to help them establish connections between previously learned contents and the new ones; promoting interactions, through the gradual responsibility of the students with their learning processes by considering their previous knowledge and the knowledge needed to complete the tasks by themselves successfully; and providing mathematical verbalizations, in a way that it was possible for the students to use specific mathematical language and have the opportunity to speak and think mathematically.

Besides those ideas, the principles established by Fuchs & Fuchs (2001) also contributed to the development of the intervention program in counting principles: fast pace, varied activities and engaging, challenge the patterns of achievement, self verbalization and visual and physical

representations (primary level, to be done with whole classes); adaptations easy to adopt so the teacher can incorporate it in the class routine, adaptations that are adequate for the targeted students as well as for other students (secondary level to help children with more difficulties); focus on the student as unity for instruction and decision making, intensive instruction and explicit instruction of basic skills (tertiary level, as an individual and intensive intervention).

The intervention sessions consisted mainly in providing children with opportunities to work with and practice the counting principles, helping them to be aware of how counting works and how to do it correctly. They occurred twice a week, during two weeks, for 20-35 minutes, including the dislocation time of the children. The sessions were made with small groups (5 students maximum), in a room provided by the schools and were conducted by the researcher see table 2 below.

Guiding questions:	Tasks:
Session 1: stable order, one-to-one correspondence and cardinality. - where do we find numbers? - what are their purpose? - how can we count? - is there a right way to count? Which one? - what can we do to know how many things there are in a set?	- observation of the room to search for numbers and their purposes; - analyses of journals and magazines to search for numbers and then ordering them; - game: “which one is missing?”
Session 2: stable order, one-to-one correspondence, cardinality and order irrelevance. - how can we count without getting lost? - how can we know if we already counted one item? - how can we count a set that is not organized?	- demonstration of counting marbles in figures by the researcher; - demonstration of counting marbles in figures using little papers; - individual practice.
Session 3: stable order, one-to-one correspondence, cardinality, abstraction and order irrelevance. - what can we count? - where do we begin to count?	-game board: “color game”; - game board: “two hands”.
Session 4: stable order, one-to-one correspondence, cardinality, abstraction and order irrelevance. - how can we count in our heads? - how can we organize numbers when we’ll count? - how can we find out what number is without knowing its name?	- bingo of numbers; - closing questions: (can you say one thing you learnt during the intervention? Which task was easy? Which task was difficult?).

**Table 2: Intervention in counting principles**

## Results

The data analyses were made through the Z test of proportion comparison. This test was chosen because the objective was to compare two proportions: the proportion of progress of the intervention

group and of the control group. The data related to the intervention result will be presented next Table 3. The stable order were not considered in the analysis because all children had consolidated this principle.

Principle	Group	Progress	(%)	p-value
One to one correspondence	Control	29	35,37	0,0016
	Experimental	39	59,09	
Cardinality	Control	9	11,69	0,0138
	Experimental	17	26,15	
Abstraction	Control	14	17,07	0,1093
	Experimental	17	25,37	
Order irrelevance	Control	38	43,18	0,0001
	Experimental	53	71,62	

**Table 3: Results of the intervention**

It's possible to observe that in activity A (one-to-one correspondence), the improving rate in the principles construction by the experimental group was of 59,09%, being statistically superior (p-value=0,0016) in relation to the control group (35,37%). In activity B (cardinality), again the experimental group demonstrated a bigger improving rate (26,15%) than the control group (11,69%), being statistically significant (p-value=0,0138). In activity C (abstraction), the students in experimental group also got superior improving rate (25,37%) when compared to the control group (17,07%), but this improvement did not show statistical superiority (p-value=0,1093). In activity D (order irrelevance), the experimental group once again evidenced a bigger improving rate (71,62%) than the control group (43,18%), being statistically significant (p-value=0,0001).

## Discussion

Both groups showed advances, which was expected, since even the children that did not participate in the intervention process were having regular instruction, and so, they were learning. The results demonstrated that the improving rates of the experimental group were superior to the rates of the control group in all principles analyzed. Besides that, in three counting principles (one-to-one correspondence, cardinality and order irrelevance) this improvement was statistically superior. This result points to the effectiveness of the intervention program focusing on counting principles with short duration (2 sessions per week during 2 weeks). Besides that, it is important to highlight that the program effectiveness can be attributed not only to the tasks, but also to the type of teaching that was offered and the principles underlying the development of the intervention.

This finding is in agreement with other intervention studies that also compared control and experimental groups. Fuchs et al. (2010) developed an intervention in counting practice and evidenced that the three groups of participants (experimental with practice, experimental without

practice and control) improved their achievement, with the children that received some kind of intervention showing more advances than the ones in the control group.

In the same way, Dyson, Jordan & Glutting (2011) indicated that students with low income participating in a intervention condition in number sense showed more improvements than the subjects of the control group in the post-test. Praet & Desoete (2013) also pointed to similar findings: both experimental groups in their study demonstrated better achievement than the control group after getting intervention. Mononen & Aunio (2016) conducted an intervention research on counting abilities to children with low achievement. Their results indicated that the students in the experimental group improved their counting abilities significantly in comparison to the students in the control group, after the intervention. Other authors evidenced that specific interventions, designed to small children, involving one or more aspects of number sense, are effective and promote improvements in mathematical achievement (Aragon-Mendizábal et al., 2017; Bryant et al., 2010; Dowker & Sigley, 2010; Dyson, Jordan & Glutting, 2011; Fuchs et al., 2010; Mononen & Aunio, 2016; Praet & Desoete, 2013).

### **Implications for education**

Our findings have important implications for teaching and learning. It highlighted a fundamental aspect of mathematical learning (counting principles), how to teach them (intervention) and how to help students to participate actively in their learning processes. It is urgent to help teachers to promote pedagogical actions that support students' learning process in relation to mathematics, area in which a lot of students show difficulties. It is important to act positively in this scenario: helping both students, through the teaching of specific strategies to facilitate learning, and teachers, through encouraging their monitoring of teaching and learning mathematics.

Considering these aspects, we believe the study presented here could reached some teachers' needs. The intervention was developed based on guiding principles that need to be incorporated into regular instruction. Besides that, the intervention program used is brief, being developed in a short period of time, and could be included in the teachers' planning of instruction. The materials used by the researcher to conduct the intervention sessions were given to all teachers participating in the study, making it possible their further use by them. The results demonstrated that even a short investment in counting principles caused improvements in the children's performance, showing that it is possible to promote significant learning through concise and quality interventions dedicated to certain content area in the pedagogical planning.

### **Limitations of the study**

The research results described in this paper should be considered in the context of some limitations. First, the time available to conduct this research was limited due to the fact that this study is part of the masters dissertation work of one of the authors and there was a deadline for its development and conclusion. Second, the counting principles task used was selected because it is a short and practical instrument, however, we believe that a broader task could elucidate more aspects to be analyzed and discussed. Another limitation concerns the choice of statistical analysis that was conducted. It is possible that different findings would have emerged if, besides the Z-test, the study included the

association of different statistical tests, which could have made it possible to reinforce or question some of the results found or even to elucidate other possible outcomes.

## Conclusions

The study demonstrated improvement in the children's performance in the counting principles task, from pre to post-test, with the participants showing good advances rates. This improvement was attributed to the intervention program because the students in the experimental group showed a bigger proportion of progress than the ones in the control group, showing statistical superiority in three of the four principles analyzed. Also, it is important to highlight the duration of the intervention: it was a short investment of time specifically devoted to the work with the counting principles, with carefully planned opportunities for the students to deal with and practice counting using the principles established by Gelman and Gallistel (1978). The results of this study point to the need of continuing to investigate interventions that target counting principles which consist of a fundamental knowledge to be learnt in the beginning of formal schooling.

# Design of a board game around the notion of fractions

Alix Boissière

IMAG, Univ Montpellier, CNRS, France; [alix.boissiere@umontpellier.fr](mailto:alix.boissiere@umontpellier.fr)

*Keywords: Rational numbers, educational game, didactic engineering.*

## Introduction

In 2014, the French ministry of education launched a strategy for teaching mathematics. It favored the use of games to “enhance student motivation and encourage them to be autonomous”<sup>1</sup>. But games can also be used to facilitate learning itself. Pelay (2011) showed that Brousseau’s theory of didactical situations (TDS) has an intrinsic play-based dimension articulated to the didactic one and introduced the crucial concept of the didactic and play-based contract. Our PhD project continues Pelay’s work both on the theoretical aspects and implementation ones.

## The didactic and play-based contract

One of the key concepts of the TDS is the *didactic contract*, the set of behaviors coming from the teacher and expected by the student and vice-versa (Brousseau, 1997). During his PhD, Pelay observed that in some cases the play-based stakes were more important than the didactic ones. He showed that it was impossible to analyze summer camps’ activities using only the concept of the didactic contract. This led him to develop the concept of *didactic and play-based contract*:

The didactic and play-based contract is defined as the set of rules and behaviors, both explicit and implicit, between an activity leader and one or several participants in a project that links explicitly or implicitly playing and learning (Pelay, 2011, p.278).<sup>1</sup>

Pelay studied how the contract is set up and how it evolves when the rules are changed. Furthermore, he introduced the concept of didactic and play-based engineering, grounded on the methodology of didactic engineering (Artigue & Perrin-Glorian, 1991).

## Back to the school context

Our research project originates on the hypothesis that the concepts developed by Pelay in the summer camp context are also relevant in the school context: the play-based dimension of the TDS might offer new perspectives to the study of teacher and student interactions when games are used in the teaching and learning of mathematics. We aim to develop a didactic and play-based engineering that will be implemented both in a laboratory setting and in classrooms, taking into account the articulation between the didactic and play-based dimensions from the start.

## Methodology

In order to develop a didactic and play-based engineering to use in class, we need to take into account the transmission and reproducibility stakes. Perrin-Glorian (2011, p.68) introduced the didactic engineering of the second kind as “an engineering aiming to produce resources for teachers and study

<sup>1</sup> My translation

the impact of research on ordinary teaching”<sup>1</sup>. It consists of planning for two levels of study: a first one, in a laboratory setting, to test the theoretical validity of the situations, and a second one to test the adaptability of the situations to teaching. The preliminary studies, conception and a priori analysis are common to the two levels of study, and they will differ by their experimentations, a posteriori analysis and validation. The first step to our research was the design of a board game to be the core of the didactic engineering.

### **Designing a game on fractions**

Relying on previous research (Pelay, 2011), we hypothesized that board games are likely to favor the active engagement of students in didactic situations build around them. We chose to develop a game that could be used from grades 4 to 6, as it is at the transition between elementary and middle school in France. The notion of fraction was one of the possible topics. The epistemological study has showed different aspects to this notion. We chose to address it from the point of view of size ratio and the composition and decomposition of surfaces. We collaborated with teachers to make sure that the game would be adapted from grades 4 to 6. We ended up creating “L’atelier des potions”, a game in which the students follow recipes for “magical potions”. The game and the choices made in the design will be presented in the poster.

### **Perspectives**

Pretests of the game have been made in a dozen of classes throughout the year and we have developed teaching activities around the game. We are now developing a didactic and play-based engineering around the game and activities.

*Adaptive use of meaningful knowledge is widely adopted as key learning objective in the changing society. This paper presents the results of a teaching experiment in the domain of partitive division. It is designed to explore how grade-3 students do adapt personal knowledge to the variation in task conditions. They can use 52 unifix cubes to model the process directly. The second condition requires that they mentally anticipate the results of sharing the same quantity of carts between respectively two and three children. The study shows that the variation in conditions combined with classroom climate challenge a great part of the students to use adaptively “pieces of knowledge” acquired in different areas of reasoning in equal group situations.*

*Keywords: multiplicative thinking, adaptive expertise.*

### Introduction

By the turn of the century, “Mathematical proficiency” is proposed as basis for a large consensual agreement about the goal of mathematics instructions in the changing society (Kilpatrick, Swafford, & Findell, 2001). Globally said, primary school students should develop and organize domains of meaningful knowledge in such a way that it should be used adaptively to tackle and solve new or less familiar problems.

According to Hatano & Inagaki (1986), it is “domains-specific knowledge” that develops along the accumulation of learning experiences, and what adapts to constraints of new situation are, according to Vergnaud (2009), the “schemes for reasoning”. Considering the crucial role of developing these schemes for reasoning, we explore in our research (i) what grade-3 students know about the quantitative and numerical relationships involved by combining, sharing, and segmenting in equal groups setting, and (ii) how they do adapt meaningful personal knowledge to well-chosen variations of task-conditions.

### Theoretical framework

Our framework connects four aspects of students’ expertise involved in the exploration of the process of partitioning in grade 3 required to analyze the relationship between the conditions of the tasks and the personal way of tackling and solving these tasks (Threlfall, 2002).

### Schemes of reasoning

Combining  $n$  equal groups to obtain an intended quantity of “things” (e.g. 5 bags with 6 cookies each) constitutes children’s earlier encounter with an application for multiplication (Greer, 1992). Children

extract from their activities the notion of number as composite unit and the invariant relationship between the number of groups and the number of units per group that constitute the conceptual base of the arising scheme “multiplicative double counting” (Tzur et al., 2013).

According to Freudenthal’s (2002) phenomenological analysis of division as mental act, division arises in three ways, as (i) continually taking away (by repeated subtractions), (ii) distributing in equal parts (distributing cyclically the same share to several persons), and (iii) inverting a multiplication. The first and second one correspond to the difference made between quotative division (measurement; ratio) and partitive division, and between the two associated schemes of reasoning: segmenting and partitioning (e.g. Tzur et al., 2013; Thompson & Saldanha, 2003). The third variant consists in figuring out the effect of both segmenting (e.g. 52 cookies into bags of 6 cookies each) and partitioning (e.g. distributing 52 cookies between 6 children) by constructing an appropriate arithmetical sequence of repeated addition (or multiples). In this case, the remainder represents the four simple steps left to reach 52 after 8 steps of 6 on the (mental) number line.

Research results show that sharing one-by-one is rarely used, and that students prefer to build-up the quantity (inverting multiplication by repeated additions) instead of subtracting repetitively (e.g. Heirdsfield, Cooper, Mulligan & Calvin, 1999). Taking advantage of this tendency and adopting the idea that students must observe variation in key variables to constitute deep understanding (Lo, 2012), we focus students’ activity on exploring the critical differences among partitioning problems (variation in total number of objects, number of persons/parts, number of objects in each part; remainder) in relation to the invariant multiplicative structure ( $a = q \times d (+ r)$ ) of any partition. We conjecture that this relationship should function as tie between partitioning and combining on the one hand (Greer, 2012), and between partitioning and segmenting on the other hand (Thompson & Saldanha, 2003).

### **Mathematical principles and numerical relations**

Towards the learning process, we conjecture that to reach the highest level of comprehension, students should (1) formulate the numerical equivalence of  $a \times b = c$  and  $c \div a = b$  and (2) use it explicitly to derive unknown quotients from memorized correspondent products (e.g.  $100 \div 25$  via  $4 \times 25 = 100$ ), as well as tackling and solving partitioning problem using appropriate patterns of multiples (e.g.  $13 \times 4 = 52$ ;  $52 \div 4 = 13$ ;  $4 \times 13 = 52$ ;  $52 = 13 \times 4$ ) knowing that each number and consequently each operation can be composed and decomposed in different ways (Gray & Tall, 1994; Tall, 2013). Last but not least, understanding the product ( $mn$ ) as being in multiple reciprocal relationships to  $n$  and to  $m$ , they should derive a lot of quotients from familiar numerical relations (e.g.  $60 \div 15$  via  $15 = \frac{1}{4}$  of 60) (Thompson & Saldanha, 2003). We expected differences in reasoning, computing and symbolization in function of the progression through the well-documented sequence of multiplication procedures: from counting all strategies, through sequences of repeated addition and doubling procedures, to using patterns in numbers and operations, and finally, to deriving unknown products from surrounding memorize facts (e.g. Verschaffel, Greer & de Corte, 2007).

### **Strategic skills**

Adopting Threlfall’s (2002) conception of flexible mental calculation as interaction between noticing and knowledge, we conjecture that an appropriate variation of task conditions should motivate and

foster students to adapt the above domain-specific knowledge to the constraints of situations (Vergnaud, 2009; Hatano & Inagaki, 1986). In this perspective, specific tasks should give students the opportunity to develop particular strategic skills: (i) relating the numbers of problems to other familiar situations, (ii) composing and decomposing numbers multiplicatively, (iii) using patterns of multiples and (iii) transforming multiplication and division.

### **Classroom culture**

It is well known that classroom climate motivates students to reflect about how they should tackle the situation taking advantage of what is met before. This factor is included in the following three conditions proposed by Hatano and Inagaki (1986) for promoting adaptive expertise: (i) variability inherent to the task environment, (ii) variability permitted in the individual's procedural application and (iii) variability of explanation permitted by the culture.

### **Methodology**

This article reports part of a research project that follows a design research methodology, specifically a teaching experience (Gravemeijer & Cobb, 2006) that has the objective to understand how students can develop the ability to tackle and solve problems, adapting personal knowledge to new situations' constraints.

The project team developed two teaching experiences: one focused in addition/subtraction and the other one focused on multiplication/division. Each teaching experience included a set of tasks that was designed and reformulated using a three-step cyclic process: (1) design tasks, (2) analyse what children noticed in the numbers and how they use their knowledge about numbers and operations to solve the task presented in the class or along clinical interviews and (3) reformulate the previous task.

We present part of the teaching experiment on multiplication/division that involved a third grade class (students age 8-9) with 20 students. The underlying "conjectural hypothetical theory" (Gravemeijer & Cobb, 2006) for this experiment concerns a possible learning process between the construction of the products of the multiplication tables and related quotients (start point) and elementary forms of reasoning proportionally (end point).

The first three tasks of this teaching experiment that involved a total of nine tasks, intend to help students to see the multiplicative structure of equal group situations as "some numbers of composed units". This paper focuses the second task: What is sharing? The objective is to observe how these students adapt personal knowledge to the variation in task conditions. The invariant condition is the number of objects distributed (52 stickers). The variant conditions are: (1) possibility to use (part one), or not (part three) concrete material, (2) the number of persons/parts and (3) with or without remainder.

The teacher of the class analysed and discussed with the researchers all the underlying justifications for the tasks, classroom organization and proposed focus for discussion with students. This teacher's practice promotes reflective discussions based on students' proposals to solve the tasks.

Data was collected through video recordings of the classroom work, researchers' field notes and students' written answers. According to the task design, the teacher organized the class into two

groups of 4 and two of 6 students. In the first part of the task students could model the process of distributing 52 stickers<sup>1</sup> using 52 unifix cubes and register their shares in a given table.

The objective of the second part of the task is to register and connect the numbers of the distribution on a given diagram (Figure 1, two left images) and to symbolize the structure of the distribution using the expression  $a = qd + r$  (distributions with rest) or with  $a = qd$  (distributions without rest).

Figure 1 shows four tables for distributing 52 objects among different groups of people. Each table has a title, an illustration of the people, and a list of variables to be recorded. The variables are: Number of objects to distribute, Number of parts (persons), Number of objects for person, Number of distributed objects, and Remainder. A 'Control' section at the bottom of each table shows the equation  $52 =$  followed by a blank box for the result.

The numbers of the distribution by FOUR	
Number of objects to distribute	→ <input type="text"/>
Number of parts (persons)	→ <input type="text"/>
Number of objects for person	→ <input type="text"/>
Number of distributed objects	→ <input type="text"/>
Remainder	→ <input type="text"/>
Control $52 =$ <input type="text"/>	

The numbers of the distribution by SIX	
Number of objects to distribute	→ <input type="text"/>
Number of parts (persons)	→ <input type="text"/>
Number of objects for person	→ <input type="text"/>
Number of distributed objects	→ <input type="text"/>
Remainder	→ <input type="text"/>
Control $52 =$ <input type="text"/>	

The numbers of the distribution by TWO	
Number of objects to distribute	→ <input type="text"/>

Number of parts (persons)	→ <input type="text"/>
Number of objects for person	→ <input type="text"/>
Number of distributed objects	→ <input type="text"/>
Remainder	→ <input type="text"/>
Control $52 =$ <input type="text"/>	

**Figure 1: Distribution numbers**

In the third part (Figure 1, two images on the right), students must envision the result of partitioning connecting the numbers of the new partition with those of the first one (Figure 1, two images on the left).

We formulated the following conjectures: (1) as students know that they can approach and solve the task in their own way and that the work will be discussed in a final phase, we expect them to use what they already know, adapting it to the task conditions (Hatano, 2003); (2) as they have 52 objects, we expect students to distribute them in two different ways: one by one or two by two (an intuitive way of distributing); (3) the second part of the task allows students to discern the meaning of the different numbers of the distribution and to connect them in an appropriate way that represents the underlying structure (multiplicative structure of partitioning); (4) as the number of people is half of the number of people in the part 1 of the task, we expect that most students will deduct the part they each receive using the double / half ratio (idea of proportional relations).

The following categories for analysing data were constructed from the theoretical framework: (1) way of modelling connected to (2) the representation of the distribution, and (3) the numbers relations and operations used to calculate the unknown.

We elaborated a detailed written description of how each group of students solved the task, integrating their written productions with video recordings and transcription of episodes that illustrated students' discussion and approach to solve the task. Those descriptions were used to characterize the variation in reasoning and calculations as defined in the categories of data analysis. The results that we synthesize in the following section reflect the interpretation of the observed variation.

<sup>1</sup> In Portugal children often have collections of Panini stickers

## Results

### Distributing in equal parts

Confirming our conjecture, some groups cyclically distribute the same amount of objects (one or two) to each element of the group. However, some groups did not model the situation as expected and followed a personal way of acting, reasoning and representing.

One of the groups with 4 students organized the cubes in 13 bars with 4 cubes each (see figure 2). They explained:

Student 1: We only need the first round.

Teacher: Why?

Student 2: We formed groups of 4 and we counted.

(...)

Student 1: We formed groups of 4 and we counted them. We have 13.

Teacher: And what does this mean?

Student 2: Each one with 13.

Teacher: Each one has ...

Student 3: 13 stickers.

Teacher: Why did you form groups of 4?

Student 1: Because we had to divide 52 by 4.

The other group with 4 students used the relation “to divide by 4 is the same as half of the half”. One student explained “First of all the number of rounds is 13. It was a quarter of 52. The number of objects distributed in the 13 (points to the thirteenth round) is 52”.

As expected, understanding what happens when some cubes remain, originated some hesitations and discussion within the two groups with six students. For instance, one of the groups understood that there were 4 cards left but still continued to pose other possibilities for the number of cards that each could receive:

Students: We have 4 left.

Teacher: Ok. We have 4 left. And can we have another round?

Student 1: No. We had to rip the card.

Teacher: We do not usually rip cards, do we?

Student 2: And if we give 7 cards to each of us?

Teacher: And if we give 7 cards to each of us? What happens?

Student 3: And if we give 6 cards?

Teacher: And if we give 7 cards to each of us? What happens?

Student 2: There are more left.

The register of the distribution of the 52 objects in the table originated some mistakes. For instance, some of them register the sequence of multiples of 4 instead of the numbers of objects distributed in each round.

Analysed data shows that the table presented in the task was not adequate to register the reasoning used by the groups that modelled the distribution via “one fourth is half of the half” or that related distributing one by one to the final distribution of 8 to each one:

Rodadas	Número de objetos distribuídos
1.ª	12
(...)	

52 - 24 = 28  
4 x 7 = 28

Rodadas	Número de objetos distribuídos
1.ª	8x2=16
(...)	

Figure 2: Adapted registration

### Relating the numbers of the distribution to control the outcome

It was expected that students, in the extension of the modelling, would recognize and register correctly the meaning of the numbers of both distribution on the dispensed diagram. Relating the number of groups to the numbers of objects per group and what remains, they would understand that the outcomes of both “division” can be controlled by symbolizing the multiplicative structure of the distribution with the adequate sequence of repetitive additive and the corresponding decomposition of 52 into  $a = qd (+r)$ .

Os números da distribuição por QUATRO	
Números de objetos a distribuir...	52
Números de partes (pessoas)...	4
Número de objetos por pessoa...	13
Número de objetos distribuídos...	52
Resto...	0
CONTROLO 52 = 4x13	

Os números da distribuição por SEIS	
Números de objetos a distribuir...	52
Números de partes (pessoas)...	6
Número de objetos por pessoa...	8
Número de objetos distribuídos...	48
Resto...	4
CONTROLO 52 = 6x8+4	

Figure 3: Meaning of the numbers

Figure 4: Multiplicative structure

The video recording, registration of the meaning (Figure 3) and representations of the distribution (Figure 3 and Figure 4) on the individual worksheets show that, in open reflection and discussion under direction of the teacher, all the students succeed to control the outcomes as expected.

### Deriving distributing by 2 and 3 from distributing by 4 and 6

The results confirm our conjecture: students do not use cubes and deduce the part that receives each one using the rule that if we have half of the persons each one receives twice as many objects. All students apply the rule by comparing the two distributions without rest:  $52 \div 2$  with  $52 \div 4$ , halving the number of person goes with doubling the number of objects per person.

However, some groups apply this relationship to  $52 \div 6$  without considering the 4 remaining objects and give the incorrect answer of 16 objects per person.

### Discussion

Data analysis confirms the conjecture that varying conditions of the task (whether concrete material is used or not; different number of persons/parts; division with or without remainder) stimulates the adaptive use of the knowledge and procedures that the students already have, which favours the possibility of adapting the acquired knowledge and procedures to the numbers involved in the task. This complex situation of sharing gives students the opportunity to explore ways of thinking that allow them to take advantage of what they already know. Also, it allows the teacher to promote students' reflection on different ways of understanding the multiplicative relationship involved in this task.

Data analysis suggests three critical aspects of the learning process in this domain that we propose for further investigation and discussion:

- *Envisioning the process and the result of dividing instead of directly modelling.* The fact that some groups do not distribute objects cyclically suggests that modelling with objects does not make sense because students already have an idea of the inverse relationship between combining and dividing that allows a more abstract approach. Our new conjecture is to give only 4 (or 6) cubes to envision, and represent numerically the process of sharing 52 by 4 (or 6) persons.

- *Exploring remainder patterns using the inverse relation.* Several divisions without rest and with rest raise the question "what explains this difference?". Using the knowledge of the inverse relationship between combining and sharing/segmenting students could investigate 'from where the remains come' (divisibility).

- *Understanding the ambiguity of symbolization with numerical expressions.* Segmenting/distributing can be represented with different numerical expressions. Giving students the opportunity to think multiplicatively in the context of division to explore numerical patterns can promote the ability to compose and decompose numbers using operations to represent them (12 is  $3 \times 4$ , 12 is a quarter of 48, 4 is 48 to divide by 12).

*Mental computation provides a good environment to develop students' strategies in division of rational numbers. In this paper, we seek to analyze mental computations strategies in rational number division used by grade 6 students, during a teaching experiment. The teaching experiment emphasizes collective discussions and was based on tasks involving number sentences and word problems with the four basic operations. The methodology was design-based research with two experimental cycles involving two teachers and 39 students. All lessons were audio and video recorded. The results show that students mostly use numerical relationships strategies supported by propositional representations in rational number division. Initially, students' strategies are based on applying a procedure and evolve to strategies that relate division and multiplication.*

**Keywords:** *Mental computation, students' strategies, rational numbers, division.*

## Introduction

Learning mathematics is not just about memorizing and replicating a set of procedures. A deep understanding of concepts is needed to learn mathematics with meaning and to develop mathematical proficiency. The development of mathematical proficiency stands on the interrelation between five strands: conceptual understanding, procedural fluency, strategic competence, adaptive reasoning and productive dispositions (Kilpatrick, Swafford, & Findell, 2001). Procedural fluency needs to be built based on conceptual understanding. The development of students' mental computation skills with rational numbers, using word problems and number sentences, can provide a good environment to achieve such conceptual understanding. The discussion of mental computation strategies allows teachers to understand students' thinking about rational numbers, their conceptual understanding. Furthermore, it helps students to construct and reconstruct new knowledge based on what they previously learned. In this paper, we seek to analyze what mental computation strategies grade 6 students use in rational numbers division during a teaching experiment. The teaching experiment emphasizes collective discussions and was based on mental computation tasks involving number sentences and word problems with the four operations

## Division of rational numbers

For students, division is a difficult operation. It begins with whole numbers and becomes more complicated with fractions and decimals. According to Sinicrope, Mick and Kolb (2002), division has different meanings that students need to learn and understand. In fact, division can be used to: (a) determine the number of groups (measurement division – when dividing  $2 \div 1/2$ , we find the number of times  $1/2$  falls within 2); (b) determine the size of each group (partitive division – when dividing  $3/4$  of a pie equally by 3 people, we find the amount of pie for each person); (c) determine the dimension of a rectangle array (inverse of a Cartesian product – we find one dimension, in a problem of area in which the total area and other dimension are known). When working only with fractions, the authors add two more meanings: (d)

to determine a unit rate (a printer can print 100 pages in two and one-half minutes. How many pages does it print in one minute?), and (e) as the inverse of multiplication. A deep understanding of rational number division involves understanding all these meanings, but, Siebert (2002) emphasizes the key importance of measurement and partitive division. Usually, students use the “invert and multiply” rule to divide fractions focusing only in procedures. For this author, this algorithm does not seem to be associated with division, since it has no signs of division and it is not in line with students’ understanding of what division means (finding the number of groups or finding the size of each group). Sinicrope et al. (2002) consider these meanings important, but highlight the importance of connecting the context of a problem with the algorithm to be used, since each context triggers a set of procedures to solve a problem. In line with this perspective, Siebert (2002) stresses that division with fractions must be explored using real-life contexts to help students to create images and make connections between the solutions of these problems and the knowledge they have about division with whole numbers, as this allows students to extend their knowledge. After constructing these images with meaning, they are prepared to understand the “invert and multiply” rule.

### **Mental computation with rational numbers**

In this study, mental computation is seen as an exact computation made mentally in a quick and effective way, using mental representations and involving number facts, memorized rules, and relationships between numbers and operations (Carvalho & Ponte, 2017). In addition, students need to understand the size and value of numbers and the effect of an operation on a number, as well as to be able to make estimates to check the reasonableness of solutions (Heirdsfield, 2011). When computing with rational numbers, notably with fractions, a reconceptualization is needed because, multiplying and dividing fractions not always produces a product bigger than the factors or a quotient smaller than the dividend. As computing with rational numbers involves more complex reasoning than computing with whole numbers, we assume that the use of memorized rules (e.g., application of procedures such as multiplying/dividing by powers of 10) may sometimes support students’ computation and the establishment of numerical relationships. Number facts used by students in mental computation can involve knowledge about results of some operations (sums, differences, products, and quotients) or relationships among numbers and operations that they have stored in their memory throughout school experiences. Using numerical relationships, involves a deep understanding of numbers and operations, the capacity to use fundamental properties of operations and the notion of equality to analyse and solve problems (Empson, Levi, & Carpenter, 2010). Some numerical relationships strategies used by students are related to the change of rational number representations (Carvalho & Ponte, 2017) (e.g., fraction  $\rightarrow$  decimal; decimal  $\rightarrow$  fraction or a rational number to a whole number concerning 10/100), to equivalences between mathematical expressions and to inverse relationship between operations. Number facts and memorized rules can emerge as mental computation strategies, *per se*, but they also arise as a support in establishing relationships between numbers and operations and vice-versa.

In the perspective of Dehaene (1997), memory plays a central role in mental computation, not only for its ability to store number facts, but also for the mental models that it creates, based on previous knowledge, supporting students’ reasoning. In mental computation we use mental representations from the world that surrounds us, in sense making and in making inferences. According to the theory of mental models (Johnson-Laird, 1990), such mental representations may be: (i) mental models, if they are general perceptions of the world (e.g., using a general context of fair sharing to share a given

quantity); (ii) mental images, if they involve a more specific perception of the real world where some characteristics are considered (e.g., relating the symbolic representation  $1/2$  to a pizza divided in two parts taking only one part); and, (iii) propositional representations, if they represent true or false statements that play an important role in the inference process (e.g., to compute  $1/4 \div ? = 1/2$ , we realize that if  $1/2 \times 1/2 = 1/4$  then the missing value is  $1/2$ ).

## Research methodology

This study is qualitative and interpretative with a design research approach (Cobb et al., 2003). As a developmental study, it seeks to solve problems identified from practice, mainly the difficulties in learning rational numbers and near absence of mental computation with this number set. It bases on a teaching experiment with mental computation tasks that provide opportunities for discussing students' strategies. It includes three phases: preparation; experimentation and analysis. In the preparation phase (2010) we undertook a preliminary study in grade 5 (conducted by the first author in her classes) to understand students' strategies when computing mentally with rational numbers, and to figure out practical aspects of students' mental computation strategies, important for planning the teaching experiment. Such planning also considered the research on rational numbers and mental computation with rational numbers. In the second phase (2012-13), cycle 1 (CI) and 2 (CII) were carried out involving two teachers and two grade 6 classes (39 students) from two different schools selected according to teacher's availability to participate in the study, with the first author as a participant observer. During this phase some refinements were made in the teaching experiment (e.g., changing the sequence of tasks). Data were collected through video and audio recordings of the classroom work with mental computation. Finally, in the analysis phase, the dialogues recording students' strategies were transcribed. In this paper we will focus on students' strategies to compute with division of rational numbers with fractions and decimals. To analyze data, we defined three main categories of strategies and several subcategories (Table 1) that we relate with students' mental representations (images, models and propositional representations). These categories emerged from the data informed by the literature review.

Categories			
Numerical relationships		Number facts	Memorized rules
Subcategories	Change representation	Two halves make a unit	Rule to add/subtract fractions
	Part-whole comparison	A half of a half is a quarter	Invert and multiply rule
	Relation between operations		

**Table 1. Categorization of mental computation strategies with rational numbers**

The categorization was made according to the strongest notion involved in students' strategy. For example, if there is a strong use of numerical relationships, as the change of representation, we coded this strategy in the category "numerical relationships" and subcategory "change representation".

## The teaching experiment

The teaching experiment relies on the conjecture that a systematic work with mental computation tasks with rational numbers represented as fractions, decimals and percent, and whole class

discussions may contribute to the development of students' mental computation strategies and understanding of their errors. Before the teaching experiment, the students already had worked with rational numbers in different representations and operations, with emphasis on algorithms. The teaching experiment included ten mental computation tasks with rational numbers (with several number sentences or word problems each) to carry out weekly. All tasks were provided by the first author and discussed in detail with the participating teachers. These tasks were presented at the beginning of a class by using a timed PowerPoint to challenge students to compute mentally in a faster way. The students had 15 seconds to solve each number sentence and 20 seconds to solve each word problem individually. The results were recorded on paper. Each task has two parts, both with 5 number sentences or 4 word problems. Upon finishing each part, there was a collective discussion of students' strategies. These mental computation lessons lasted 30 to 90 minutes. The discussion moments were regarded as very important. They allowed students to show how they think and which strategies they use to compute mentally in tasks with different cognitive demands. These moments were important for students to think, reflect, analyze, make connections, share, and extend mental computation strategies, as well as to identify skills that they should develop about numbers and operations.

The students began to compute mentally with fractions (addition/subtraction in task 1 and multiplication/division in task 2), then with decimals and fractions with the four basic operations (task 3), and then only with decimals (addition/subtraction in task 4 and multiplication/division in task 5). Subsequently, they solved word problems in measurement and comparison contexts involving fractions and decimals (task 6). Percent was used in task 7, as the teacher begun working with statistics. Then, students used decimals, fractions and percent in tasks 8, 9 and 10. In task 10 they solved word problems. The tasks were designed following three principles and considering previous research on mental computation and rational numbers: *Principle 1*. Use contexts to help students to give meaning to numbers. A structured knowledge is associated with the context in which it was learned and, most of the time, it is difficult for a student to bridge this knowledge to new situations. *Principle 2*. Use multiple representations of rational numbers. We used fractions, decimals, and percent representations in the same task and in several tasks along the teaching experiment (e.g.,  $2,4 \div 1/2$ ). We used even numbers and multiples of 5 and 10, benchmarks such as 25% or  $1/2$  to facilitate equivalence between decimals, fractions and percent, and to stress numerical and part-whole relationships. *Principle 3*. Use tasks with different levels of cognitive demand. For example, taking into account mental computation levels (Callingham & Watson, 2004) we designed tasks in which the students have to use the concept of half (e.g. 50% of 20 or  $1/2 + 1/2$ ) or need to use a more complex numerical relationships (e.g., 20% of ? = 8), to do the computation. When planning the lessons, we sought to anticipate students' possible strategies to better prepare the collective discussions. All classroom activities were led by the teachers, with the first author making occasional interventions to ask students to clarify their strategies.

### **Students' mental computation strategies for division of rational numbers**

In this section we analyse students' mental computation strategies in dividing rational numbers with fractions and decimals. The examples selected (Table 2) are representative for the strategies used by students in CI and CII. We begin with questions using division by  $1/2$  because we think this is an essential step to understand the division of rational numbers, especially the relation between dividend, divisor and quotient. We used other benchmarks as  $1/4$  or the division between a fraction and a whole number to support students' extension of knowledge from the division of whole numbers.

	Mental computation question	Mental computation strategies	Mental representation	Students' meaning of division

Task 10	$0.75 \div ? = 3$	<b>Rui (C II):</b> <i>Numerical relationship</i> (change representation decimal → fraction; relation between numbers)	<i>Propositional representation</i>	<i>Inverse relationship between multiplication and division</i>

Table 2: Synthesis of Students strategies in rational numbers division

In task 2, students compute mentally with fractions in number sentences and open number sentences. To solve “ $4/8 \div 1/2 = ?$ ” students could simply identify that dividend and divisor represent equivalent fractions, so the quotient is 1. However, most of the students apply the “invert and multiply” rule as Rita did: “I inverted the 2 with the 1. I did 4 times 2 and get 8 and 8 times 1 and get 8. I get the unit. I wrote 1”. Rita used a *memorized rule* probably supported by *mental images* of procedures that she knows. In the 2<sup>nd</sup> part of task 2, Ana’s strategy to compute “ $1/4 \div ? = 1/2$ ” and António’s strategy to calculate “ $3/4 \div ? = 1/4$ ” led to discuss another way of thinking about dividing rational numbers. Ana explained: “I just know that  $1/2$  times  $1/2$  is  $1/4$ . So, I put immediately  $1/2$ ”. She used a *numerical relationship* strategy (relation between expressions) based on a *propositional representation* (if  $1/2 \times 1/2 = 1/4$  so  $1/4 \div 1/2 = 1/2$ ) supported by a *number fact* (half of a half is a quarter). Her strategy emphasizes the relationship between multiplication and division as inverse

operations. To compute “ $3/4 \div ? = 1/4$ ” António explained: “I thought of 3€ I forgot the 4 [in the denominator]. 3€ dividing by 3 persons is equal 1€ to each person...  $3/4$  dividing by 3 persons is  $1/4$ ... I thought  $1/4 + 1/4 + 1/4$  [is]  $3/4$ ”. António used a *numerical relationship* strategy (relations between expressions). He relates division ( $3/4 \div 3$ ) with multiplication through repeated addition ( $3 \times 1/4 = 1/4 + 1/4 + 1/4$ ). António uses the context of money (*mental model*) to share money between 3 persons, and so, he “forgot the 4” from the denominator to make an extension of what he knows about whole numbers division. He probably searched in his quotients repertoire, one that gives 1 (*number facts*), and validated his strategy using a *propositional representation* (if  $3/4 \div ? = 1/4$  and  $3 \div 3 = 1$ , so,  $? = 1/4$  because  $1/4 + 1/4 + 1/4 = 3/4$ ). António’s strategy shows how a partitive division context that he knows can be a model to think and compute the given mathematical expression.

In task 5, Maria explained her strategy to compute “ $2.1 \div ? = 8.4$ ”, showing flexibility in working with equivalent representations of rational numbers: “I did 2 times 2.1 and then 4 times and I get it [8.4]. But we must divide. The inverse of 4 is  $1/4$  that is 0.25”. She used a *numerical relationship* strategy (relation between numbers and operations) supported by *number facts* and *propositional representations*. To find the missing number, Maria used *number facts* (time table of 2 and 4) to find the multiplicative relationship between the 2.1 and 8.4. The given operation was division and she used multiplication (inverse operation) to think. So, she needs to answer using the “inverse of 4 is  $1/4$  that is 0.25”. Her strategy could be supported by the *propositional representations*: if  $2.1 \div ? = 8.4$  and  $2.1 \times 4 = 8.4$  so  $2.1 \times 4 = 2.1 \div 1/4 = 8.4$ . A sequence of true statements leads to the correct answer.

The word problem presented in Table 2 (task 6) can be solved by using the expression  $22.5 \div 1/2$ . Eva’s strategy was: “It is 45 baskets. I only multiply 22.5 by 2”. Questioned why she multiplied by 2, she answered: “Because of  $1/2$ . To get the unit we must add five tenths twice, so we multiply by 2”. This was used to discuss division sense when using a divisor less than 1, since the quotient gets bigger than the dividend, and not smaller as it happens with whole numbers. Eva used a *numerical relationship* strategy (relations between operations and part-whole relationship). She understood that two halves make a unit and explained it using two equivalent representations ( $1/2$  and 0.5). This gives meaning to the multiplication by 2 instead of the division by  $1/2$ . Understanding this, she supported her strategy in a *propositional representation* (if  $1/2 = 0.5$  and  $0.5 \times 2 = 1$ , so,  $22.5 \div 1/2 = 22.5 \times 2 = 45$ ). The meaning of the “invert and multiply” rule was discussed using Eva’s explanation.

In task 10, the last task of the teaching experiment, Rui computed “ $0.75 \div ? = 3$ ” explaining: “I changed 75 hundredths to  $3/4$  because it’s equivalent. So,  $3/4$  divided by a number that I don’t know to get 3...  $3/4$  dividing by  $1/4$  is equivalent to 3.3 divided by 1 is equivalent to 3 and 4 divided by 4 is equivalent to 1”. He changed representation from decimals to fractions (*numerical relationships*) and this was essential to see that there is a multiplicative relationship between dividend and quotient ( $3/4 \div ? = 3$ ). He was not explicit about this relation, but when he stated “ $3/4$  dividing by  $1/4$ ” he assumed that the result is  $1/4$ , and this could come from  $3 \times 1/4 = 3/4$ . To validate his strategy, Rui solved the operation ( $3/4 \div 1/4$ ) after knowing the result 3. Since the denominators are equal he divided numerators and denominator to get the answer  $1/4$ . His strategy could be supported by a *propositional representation* that gives meaning to his way of thinking (if  $0.75 = 3/4$  so  $0.75 \div ? = 3$  is equivalent to  $3/4 \div ? = 3$ . If  $3 \times 1/4 = 3/4$ , then,  $3/4 \div 1/4 = 3$  because  $3 \div 1/4 \div 4 = 3/1$ ). Interestingly, Rui always used the word “equivalent” to talk about the equal sign. This shows that he understood it as a sign of equivalence and not as a sign that requires a solution.

## Discussion and conclusion

In this paper we share and analyze the most representative mental computation strategies in division of rational numbers, used by students in CI and CII of our study. To develop students mental computation strategies, we designed tasks that include benchmarks, different rational number representations (Kilpatrick et al., 2001), different levels of cognitive demand and contexts to support students to connect number sentences with world problems and vice-versa (e.g., Sinicrope et al., 2002). This allows students to give meaning to number representations and extend previous knowledge about whole numbers.

In the beginning of the study (task 2) most students use memorized rules such as “invert and multiply” two divide two fractions. This is a procedure that most students use, certainly without meaning, because it does not seem to be associated with division (Siebert, 2002). To divide fractions, students multiply most of the time without relating these two operations. When challenged to compute mentally in open number sentences they use numerical relationships strategies, with an emphasis on the change of representation. Decimal division was more difficult for students than fraction division, probably because they learned a rule to divide fractions and not to divide decimals. Therefore, students prefer to change decimals to fractions to use the rule or to relate division and multiplication (as did Maria and Rui). In open number sentences it is not possible to use directly the “invert and multiply” rule. The use of this kind of task in the teaching experiment was an important step in the development of students’ mental computation strategies in division, since they need to relate numbers and operations instead of applying rules, where mental representations play an important role. Mental representations as propositional representations support students’ reasoning while several relationships are made, and mental models can provide real-life contexts with meaning for students, so they can solve mathematical expressions (as did António). During the teaching experiment, several word problems were used and related with number sentences to help students to create mental representations and make connections between real-life contexts and mathematical expressions (Siebert, 2002). For example, in task 5 we used the expression  $12.2 \div 0.5$  to relate later with the problem shown in task 6 (see Table 2). The use of word problems was another important step in the development of students’ strategies as it gives a real-life context where students need to search for an operation to solve it. This search allows students to find mathematical expressions where the contexts facilitate an understanding of relationships previously discussed in the classroom. Eva’s strategy to solve a word problem in a measurement context represented an opportunity to give meaning to the relationship between dividing by  $1/2$  and multiplying by 2 as well to the “invert and multiply” rule, used several times by students.

This study shows whenever students apply a memorized rule they mostly apply a procedure without meaning. They explained a set of procedures (as Rita did) where no meaning of division is shared. When students use numerical relationships strategies they use multiplication to solve a division, stressing the relation between these two operations. The inverse relation between these operations emerged in a strong way in students’ strategies, especially in open number sentences tasks. The missing value was the divisor that can be calculated dividing dividend and quotient, but students solved it by searching for a known relationship (as Ana did) or the relation between dividend and quotient (as Maria and Rui did). On one side, the use of multiplication can be a sign of students’ difficulty in dividing rational numbers, so they search a more familiar operation to solve the problem.

On the other side, the use of multiplication emphasizes multiplicative relationships between numbers and the inverse relation between division and multiplication (e.g., Sinicrope et al., 2002). Partitive division meaning was introduced by António when he used a money context to share equally 3€ by 3 people. He drew his knowledge from division of whole numbers and extended it to rational numbers. He used a known context to model the resolution of a number sentence. António's self-validation of his answer shows a strategy made with understanding. The measurement meaning of division was provided in the basket problem, where Eva's strategy was very useful to give meaning to some relations previously made by students as we already stressed above.

To conclude, this is a singular study in Portugal that provides suggestions to teachers who want to develop students' mental computation strategies in rational numbers division. Sharing and discussing students' strategies with the whole class presents an opportunity for teachers to understand students' reasoning, but also to construct collectively an understanding about the division of rational numbers where several relationships can be explored. Further research focusing mental computation with rational numbers involving different representations is needed, as well as their contributions for the transition between arithmetic and algebra in students learning process.

*Abstract: The research field about teachers' perceptions on students' performance highlights the importance of understanding this approach in order to help students to improve their learning outcomes. This study aims to contribute to this discussion. It involved 136 first-grade students, from 10 classes of 3 Brazilian public schools. The teachers participated by filling out a questionnaire about the students' learning profile, including aspects such as: behavior, attention, social interaction and knowledge by area (mathematics, reading and writing). The teachers' answers were related to the students' achievement in a counting principles task. The results show that teachers have correct perceptions about the students who master the counting principles, but the same is not true for the ones who did not consolidate or were still developing the principles. The educational implication of the study is pointed out.*

*Keywords: Teachers' perceptions. Counting principles. Learning profile.*

Teachers' role in the learning process of the students is often recognized by researchers in the mathematics field, especially when they present the research outcomes and reflect on its educational implications (Hoge & Coladarci, 1989; Südkamp, Kaiser, & Möller, 2012). Studies focusing on this perspective provide important data concerning teachers' perceptions on students' learning which brings implications for the way teachers plan their pedagogical actions (Hoge & Coladarci, 1989; Südkamp, Kaiser, & Möller, 2012). In this sense, the knowledge provided by this field of research allows to better comprehend and favor the teaching and learning processes.

This research involves the investigation of teachers' perceptions about the learning profile of first year students and seeks to verify if there is a relation between the teachers' perceptions and the students' actual performance in a counting principles task. The counting principles, established by Gelman and Gallistel (1978), are the basis for children's learning how to count with success. The principles are: stable order, one to one correspondence, cardinality, abstraction and order irrelevance. As evidenced by Stock, Desoete & Roeyers (2009), children with good achievement in counting by the end of kindergarten presented good performance in arithmetical abilities in the first year, pointing to the predictive value of the counting principles.

In 1989, Hoge and Coladarci conducted a systematic review on teacher judgments about their students' achievement. Initially, the authors contextualized teacher judgments through two perspectives: the cognition of teachers and their assessment. The first one addresses the decision-making of educators (in relation to planning, for example), noting that this process is influenced by their judgment on their students. The second involves thinking about the importance of the accuracy of teacher judgments in the context of assessment: educational decisions are made on the basis of the

educators' assessment and their judgment is an important source of information about the students (Hoge & Coladarci, 1989).

In 2012, 23 years after the review mentioned, Südkamp, Kaiser & Möller also studied the precision of teachers' judgment about the performance of their students, conducting a meta-analysis on this subject. The authors pointed out that teacher judgment is one of the primary sources of information about students' academic performance, as Hoge and Coladarci (1989) highlighted. An accurate assessment of students' performance is a prerequisite for educators to be able to adapt their pedagogical practices, make decisions and support the students' development of an appropriate academic self-concept (Südkamp, Kaiser, & Möller, 2012).

The literature showed studies involving teachers' judgment/perception with different objectives: to verify predictors of performance (Teisl, Mazzocco & Myers, 2001), to identify students with difficulties in mathematics (Nelson, Norman, & Lackner, 2016), and to observe the relationship between teacher perceptions and students' performance in mathematics, specific math skills, student feeling, motivational factors, and activities choices (Eds & Potter, 2013; Martinez, Stecher, & Borko, 2009, Schappe, 2012).

Although these works show divergences in some aspects, they generally point to a positive relation between the teachers' perceptions on students' performance and the students' actual learning outcomes. The authors note the need for research on this relationship, highlighting the importance of teacher judgment for students' evaluation, pedagogical planning and decision making. The present study seeks to contribute to this discussion. The purpose of this study is to investigate the relationship between teachers' perceptions about the learning profile of their 1st year students and the students' actual performance in a counting principles task.

## **Method**

### **Participants**

The study included 136 Brazilian students (63 girls and 73 boys), aged between 6 and 7 years old, from 10 groups of 1st year of Elementary Schools. It involved 3 public schools. This group of children was participating in an intervention research, entitled "Intervention in counting principles for elementary school students", submitted as a paper to TWG2, this year. Students were assessed in a counting principles task and their teacher filled out a questionnaire focusing on their perceptions about the students' academic achievement. Therefore, besides the students, their teachers (n=10) also took part in this study. All of them were graduated in Pedagogy and 9 had post-graduation in the Education area. Regarding the teaching experience with first year of Elementary School: 1 teacher had 6 months, 1 teacher had 2 years, 2 teachers had 3 years, 1 teacher had 5 years, 1 teacher had 9 years, 1 teacher had 18 years, 1 teacher had 28 years, 1 teacher had 31 years and 1 teacher had 36 years. The parents of all participating students gave their authorization through the signing of the Free and Informed Consent Form and the Dissent Form. Approval for this study was obtained from the Research Ethics Committee of Universidade Federal do Rio Grande do Sul.

## Procedures

The researcher administered the counting principles task, between September and December 2017, individually to each child in a room provided by the schools. The teachers received the questionnaire at the beginning of the data collection and returned it according to their availability.

## Instruments

1) Counting principles task: The task is conducted in an interview format. There are specific questions to assess each principle. The questions were asked in the following order: stable order (“Until how much can you count?” “Count out loud up to the number you said, please”); one to one correspondence (The experimenter shows 10 chips in a row and asks “how many chips are there?” After, the researcher shows 10 chips misaligned and asks “how many chips are there?”. The same procedure is repeated with 15 chips. This activity will be called “A”); cardinality (by the end of counting 15 items, the experimenter asks “how many are there in total? Can you give me 10?” This activity will be called “B”); abstraction (the experimenter asks “if you were counting 15 candies, would you count the same way (in the same order) you counted the chips?” This activity will be called “C”); order irrelevance (the experimenter asks the child to count the 15 chips, arranged in a row, in a different order, that is, starting from another chip. Then, the child is asked to say how many chips would remain if the row was undone. After, the experimenter asks the child to count 8 chips of the set, separating them aside, and then, to count the remaining 7 chips of the row. By the end, the child has to say how many chips there are in total. This activity will be called “D”). For each principle, the subjects were classified into three groups: principle consolidated (Y – yes); in construction (IC); not consolidated (N). Some criteria were established to classify the children in each group. Some of the questions (2, 3 and 5) are formed by more than one query. In this case, the child’s answer was classified as “Y” if he/she answered all the solicitations in each question correctly; “IC” if only one part of the question was correctly answered; “N” if the student did not answer any part of the question correctly.

2) Teachers’ questionnaire: The teachers received a questionnaire, adapted by the author, based on the scale of "Strengths and Weaknesses of Attention-Deficit / Hyperactivity-symptoms and Normal-behaviors - SWAN" (Swanson et al., 2005), containing questions about attention, behavior, knowledge by area (mathematics, writing and reading) and social interaction. The objective of the questionnaire, presented in the table below, was to investigate the teachers' perceptions about the general learning profile of their students. For each statement, teachers could select one of four frequency options: often, sometimes, rarely, or never.

1 - Shows interest for the proposals	14 – Shows difficulties in writing
2 - Pays attention to the explanations	15 - Shows difficulties in reading
3 - Keeps the materials organized	16 - Shows difficulties in mathematics
4 - Complies with the teacher's requests	17 - Avoid tasks involving numbers
5 - Interactes well to colleagues	18 –Shows counting knowledge
6 - Manages well the time attributed to accomplish a task	19 – Shows difficulties in socializing

7 - Engages in activities	20 – Shows difficulty in understanding instructions
8 - Knows to take turns: when to speak and when to listen	21 - Plays together with colleagues at playtime
9 - Questions when in doubt	22 - Complaints about the class proposals.
10 - Requires a lot of attention from the teacher	23 - Demonstrates slowness to finish the tasks
11 - Moves a lot during class	24 – Is easily distracted
12 - Forgets about making the homework	25 - Expresses him/herself well
13 – Does not comply with the rules	

**Table 1: Teachers' questionnaire**

## Results

The relationship between the questionnaires of the teachers and the performance of the children in the counting principles task was investigated. In order to do the analyses, it was necessary to make an adjustment in the questions of the questionnaire. Although all of them counted with the same frequency for answers, there were distinct kinds of affirmation, which meant that the same frequency attributed to two different questions resulted in opposite answers. For example: the “often” frequency is a positive answer to question number 1 (“shows interest for the proposals”), but negative for the question number 20 (“shows difficulty in understanding instructions”). Considering this fact, before running the analyses, it was necessary to transform the answers so they kept the same direction of association. They were classified as positives (1 to 9, 18, 21, 21 and 25), which had maintained the frequency (often, sometimes, rarely, never), and negatives (10, 12 to 17, 19, 20, 22 and 24), which suffered the transformation (never, rarely, sometimes, often). In this way, the frequency “often” for the positive question number 7 (“engages in activities”) had the same effect of the frequency “never” for the negative question number 23 (“demonstrate slowness to finish the task”). The box-plots, shown below, were constructed to highlight the frequency of distribution of the teachers' answers in relation to the students' constructs. It can be seen that most of the graphs below shows increasing frequency throughout the answers, with few occurrence in "never" and a gradual increase in the following answers. The only graph that does not follow this pattern is related to the construct "IC" (in construction principle) in activity C: this may be due to the fact that only 6 children presented this construct, making the analysis difficult due to the scarcity of data for this variable.

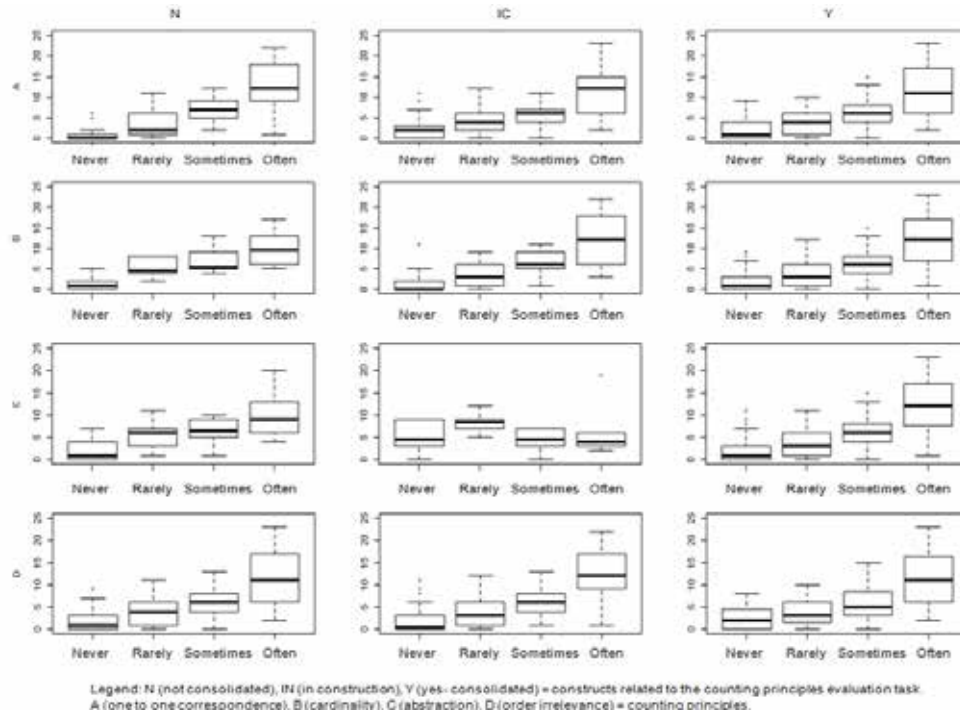

Figure 1: Box-plot graphs

Considering the information presented in the graphs, the Kruskal-Wallis test was applied to verify if the median of performance of the children in the counting principles task, between the four groups of frequencies (never, rarely, sometimes and often), was different, that is, if the oscillations in the graphs were statistically significant ( $p < 0.05$ ). The samples were independent, so if one group has a high median, it does not interfere in the median of another group (high or low).

One to one correspondence						Cardinality					
Construct of the principle	Number of students	Answers of the teachers	Median	p-value	sig	Construct of the principle	Number of students	Answers of the teachers	Median	p-value	sig
N	29	Never	0	0,0843		N	6	Never	1	0,6615	
		Rarely	2					Rarely	4,5		
		Sometimes	7					Sometimes	5,5		
		Often	12					Often	9,5		
IC	50	Never	2	0,0188	a	IC	17	Never	0	0,089	
		Rarely	4					Rarely	3		
		Sometimes	6					Sometimes	6		
		Often	12					Often	12		
Y	57	Never	1	0,0446	a	Y	113	Never	1	0,0003	a
		Rarely	4					Rarely	3		
		Sometimes	6					Sometimes	6		
		Often	11					Often	12		
Abstraction						Order Irrelevance					
Construct of the principle	Number of students	Answers of the teachers	Median	p-value	sig	Construct of the principle	Number of students	Answers of the teachers	Median	p-value	sig
N	14	Never	1	0,3114		N	63	Never	1	0,0061	a
		Rarely	6					Rarely	4		
		Sometimes	6,5					Sometimes	6		
		Often	9					Often	11		
IC	6	Never	4,5	0,2873		IC	46	Never	0,5	0,2982	
		Rarely	8,5					Rarely	3		
		Sometimes	4,5					Sometimes	6		
		Often	4					Often	12		
Y	116	Never	1	0,0001	a	Y	27	Never	2	0,0096	a
		Rarely	3					Rarely	3		
		Sometimes	6					Sometimes	5		
		Often	12					Often	11		

Figure 2: Kruskal-Wallis test results

As observed above in figure 2, in the one to one correspondence principle the medians of the "N" (not consolidated) construct were the same, since their p-value was greater than 0.05. In the "IC" (in construction) and "Y" (consolidated) constructs there was a difference between the medians, indicated by p-value less than 0.05, the medians of each response being different from each other. Although a numerical difference was observed between the medians of "N" construct responses, a statistical significance was not found (at 5% level) due to the low sample size. The number of students with the "IC" and "Y" constructs, which presented a significant difference, was 50 and 57 respectively, while the "N" construct had 29 students.

In the cardinality principle, it was possible to observe difference between the four medians only for the "Y" construct ( $p < 0.05$ ), with the "N" and "IC" constructs not showing statistically significant differences. Again, this can be attributed to the size of the sample of each construct, since 113 children showed mastery of the cardinality principle, while only 17 were constructing it and 6 did not demonstrate its consolidation. In the abstraction principle, the "N" and "IC" constructs, with 14 and 6 subjects, respectively, did not present differences between the medians of the responses. The "Y" construct, with 116 students, showed to be statistically significant ( $p < 0.05$ ) with the four medians differing from each other. In the irrelevance of the order principle, the construct "N", with 63 subjects, was shown to be statistically significant ( $p < 0.05$ ), with the four medians being different. The "Y" construct, although with a small number of students, 27, was also evidenced as statistically significant ( $p < 0.05$ ). The answers "Never" and "Rarely" presented median equality, as indicated by the letters in the table. The construct "IC", in turn, even with a larger sample than the previous one, with 63 subjects, was not statistically significant, showing equal medians.

## Discussion

It was expected that the results of the data analysis, relating the teachers' perceptions about their students' general learning profiles and the constructs presented by the students in the assessment of the counting principles, would show that children who did not consolidate a certain principle would present a very frequent occurrence of "Never" or "Rarely" answers in the questionnaires; students who were constructing the principles would have "Sometimes" answers more frequently; children who demonstrated a "yes" construct for the counting principles, supposedly, would present a large occurrence of "Often" answers in the teaching questionnaires. In general, it is possible to consider that there was little differentiation in the occurrence of responses for almost all constructs: both those who did not consolidate the principles and those who were constructing them, or who already mastered them, obtained the same types of answers in the questionnaires, varying in the number of times they received them.

The results raise some possibilities of analysis. First, the relationship between teachers' perceptions about the students' learning profiles was in agreement with the performance of the students only in the cases of those who showed consolidation of the counting principles. Such a result converges with other studies demonstrating that teachers' judgements, through rating scales, are good predictors of students' academic performance, more specifically, in relation to students who did not develop learning difficulties in mathematics (Teisl, Mazzocco & Myers, 2001). Another possibility concerns how teachers answered the questionnaires: once they received the documents and were able to fill

them out without the presence of the researcher, it is not known exactly how they did it, what criteria they used to choose a response in to the detriment of another, whether they filled out quickly or dedicated time to think about the issues raised there. A third point refers to the number of students per class. The classes involved in this study had a maximum of 25 students. Although it seems a small number, it is complex for a teacher, alone, to have complete knowledge of all his/her students. Even though the questionnaire was delivered in the second half of the year, a period of time when teachers would have had time to get to know their students, it is difficult to know, precisely, how much and what each teacher knew about their pupils.

### **Limitations**

The research results described in this paper should be considered in the context of some limitations. First, the counting principles task used was selected because it is a short and practical instrument, however, we believe that a broader task could elucidate more aspects to be analyzed and discussed. The same must be said in relation to the Swan questionnaire. Another limitation concerns the choice of statistical analysis that was conducted. It is possible that different findings would have emerged if the study included the association of different statistical tests, which could have made it possible to reinforce or question some of the results found or even to elucidate other possible outcomes.

### **Conclusion**

This study showed that the teachers have correct perceptions of their students when it comes to students with good performance, that is, those with "Y" construct in the counting principles. Students who do not present consolidation or who are constructing the principles were perceived by the teachers in a way that did not correspond to the students' performance in the counting task used in this study.

This work points to the need and importance of deepening and expanding the development of teacher studies and their perceptions. More importantly, it is extremely relevant to investigate how teachers form their perceptions, what criteria they consider when evaluating students and how they see their students.

This study shows that there are still many aspects that need to be discussed between researchers and teachers, seeking to establish a significant link between theory and practice. It is imperative that teachers, especially those responsible for the early years of Elementary School, acquire knowledge about the factors involved in learning the initial mathematics: knowing how the learner learns will help them to identify aspects related to not learning and, therefore, perhaps their perceptions are clearer and they can recognize children who are facing problems. It is imperative that the link between researchers and teachers be built and used in favor of student learning, allowing the two sides to dialogue and understand how academic conceptions can contribute to pedagogical practices and vice versa.

*We focus on the teaching and learning of decimal numbers at primary level (grades 4 and 5) in France. We are especially interested in the role played by registers of semiotic representation. Three classroom episodes are analyzed by considering the role played by the discursive register of numeration units in conceptualizing decimal numbers.*

*Keywords: Decimal numbers, registers of semiotic representation, numeration units.*

This paper focuses on the teaching and learning of decimal numbers at primary school (grades 4 and 5) in France. Many authors underline errors specific to decimal numbers (Baturu, 2000; Durkin & Rittle-Johnson, 2015; Steinle & Stacey, 2003). We rely on the theory of registers of semiotic representation by considering a crucial role played by registers (discursive, symbolic, iconic or material) in teaching and learning processes (Duval, 1995, 2017). We grant particular importance to the register of numeration units (tens, units...) or numeration-units-numbers. Most studies (Chambris, 2015; Houdement & Tempier, 2015; Van de Walle, 2010) have highlighted the potential of this register for teaching and learning whole numbers. In our study, we question the extension of these results to decimal numbers. We aim to tackle the role of this register of numeration units (tenths, hundredths...) for teaching and learning decimal numbers. The focus is on case studies based on classroom episodes that illustrate both difficulties and levers in teaching and learning decimal numbers with respect to the role played by this register.

## Theoretical frame: registers of semiotic representation of decimal numbers

In Duval's framework, a given mathematical object has multiple representations depending on registers of semiotic representation (discursive, symbolic, iconic or material) that express specific properties of the object while never embodying the object. These registers open the possibility of two fundamental cognitive activities: the activity of treatment (a transformation inside a given register), the activity of conversion (mobilization from one register into another). Duval (1995, 2017) discusses the double designation of mathematical object inside registers, that is, representations of a mathematical object that may be associated and have different functionalities. Duval considers this process a fundamental part of mathematics. Using this approach, we have identified different registers of semiotic representation of decimal numbers. These registers may be used in various teaching situations, sometimes simultaneously: symbolic (fractional notation, in particular those of the type  $\frac{1}{10}$ ,  $\frac{1}{100}$ ,  $\frac{1}{1000}$ , decimal notation and the sums associated to these symbolic writings); discursive (where numeration units - tenths, hundredths, thousandths - and numeration-units-numbers are involved which can be verbalized or written); mixed (in notations of the form 1 unit + 3 tenths + 2 hundredths or in place value chart); iconic, figurative, or material (such as a square made of 100 tiles 25 of which are grey). These registers may be used both verbally and on paper. For instance, we can "verbalize"

symbolic decimal fractional notation as numeration units ( $\frac{1}{10}$  as one tenth or  $\frac{15}{10}$  as fifteen tenths). We grant particular importance to the representation register of numeration units. This discursive register of numeration units allows conversions between different types of numeration units (Chambris, 2015; Houdement & Tempier, 2015) or reunitizing strategies (Baturu, 2000) possible by grouping units such as “10 tenths gives 1 unit” or “10 hundredths gives 1 tenth” or partitioning units “partitioning 1 unit into ten equal parts gives 1 tenth” or “partitioning 1 tenth into ten equal parts gives 1 hundredth”. We will name these conversions unit-conversions to distinguish them with conversions in Duval’s meaning. These unit-conversions provide various justifications of comparison and computation with decimal and whole numbers while shining light on decimal and positional principles (Ross, 1989). We hypothesize that the register of representation related to numeration units has specificities with respect to decimal numbers that may provide potential levers or difficulties in teaching and learning.

## Methodology

The research study takes place in a French primary school, with a voluntary group of 4 experienced and reflexive teachers involved in a collaborative research effort about the teaching of decimal numbers at primary school. A total of 50 decimal numbers lessons taught in 9 classes of grade 4 or 5 were recorded during 4 years. In this collaborative study, most of the time, teachers have been responsible for the design of tasks for students and researchers have been in charge of the analysis of the mathematical activities of both students and teachers. Even if this methodology differs from engineering design, we have used classical methodological tools such as confrontation between *a priori* analyses of tasks and *a posteriori* analysis of data collected (Artigue, 1992; Hodgson, Kuzniak, & Lagrange, 2016). According to our theoretical point of view we have focused on classroom episodes in which register of numeration units or numeration-units-numbers was specifically used. We focus on both the activity of treatment inside the register of numeration units and the activity of conversion from this register to others (Duval, 2017). Particular classroom episodes allow us to illustrate three types of phenomena related to the use of semiotic register of representation (summarized in the Table below). These episodes are also about different steps in the teaching decimal numbers and symbolic notations, related to the French curriculum.

episodes	tasks	phenomena	indicators
1 (grade 4)	place decimal fractions on number line	difficulties in invoking relations between a unit and its subdivisions	registers: fractional notations, numeration units unit-conversions
2 (grade 5)	compare decimal numbers	difficulties in coming back to the register of numeration units in order to justify comparison techniques	registers: decimal notations, numeration unit unit-conversions
3 (grade 4)	convert sums of decimal fractions (length measurements) to decimal notations.	potential for bringing together numeration units and measurement units	registers: decimal and fractional notations, numeration units, measurement units

**Table 1: Tasks, phenomena and indicators used in the analysis process****First classroom episode: unit-conversions and decimal numbers**

According to the French curriculum, students of grade 4 begin to learn decimal numbers as decimal fractions. In this first episode, students have made a decimal number line marked in hundredths. Hundredths have already been introduced as follow: if we divide a unit into one hundred equal parts, one hundredth is one part of these parts. Similarly, tenths arise from partitioning one unit into ten equal parts. Students are able to place five hundredths, both used verbally (five hundredths) and on paper ( $\frac{5}{100}$ ) on this number line. They should place “ $\frac{15}{10}$  – fifteen tenths” on the number line marked in hundredths. Such a mathematical task seems to be difficult for most students. In the transcript below, a student solves the problem on the board. An incorrect response is first proposed as students have mistaken hundredths for tenths (count 15 hundredths instead of 15 tenths).

Teacher: What can we try to plot?

Student: Fifteen tenths [*teacher writes  $\frac{15}{10}$  on the whiteboard*].

Teacher: How did you do?

Student: We count on fifteen.

Teacher: You count on fifteen? [...] Ok, if I count on fifteen, you said, the number you stop at fifteen hundredths [*teacher writes  $\frac{15}{100}$  on the blackboard*] But we want fifteen tenths. How do we do?

Then, students use unit-conversions, in grouping point of view (such as ten tenths is equivalent to one unit and a hundred of hundredths is equivalent to one unit): fifteen tenths are equivalent to one unit and five tenths. A student notices “it only needs five”, allowing students to focus on five tenths. A brief exchange between the teacher and students points out that five tenths is equivalent to fifty hundredths. Other students seem to be confused about this unit-conversion, both in symbolic register of fractional notation and verbal register of numeration units.

Student: Five tenths are equivalent to fifty hundredths. We add fifty hundredths and get fifteen tenths.

Teacher: OK [*she is writing  $\frac{5}{10} = \frac{50}{100}$  on the whiteboard*] What do you think about it? Is that true?

Student: It is the same thing. Ten hundredths are equivalent to one tenth.

Teacher: Show me five tenths [...]

Teacher: Good to you. How many hundredths in one tenth? [...]

Teacher: OK. To make five tenths, we need fifty hundredths.

Students have difficulties with unit-conversions involved in this task. This task relies on understanding relationship between tenths and hundredths (ten hundredths is one tenth). Such a relationship relies on relationship between tenths and units (hundredths and units) built in *grouping way*, that is, not in the way (*partitioning way*) they have been introduced. In that way, decimal numbers differ from whole numbers in regard to numeration units. For whole numbers, numeration units are necessarily introduced in grouping way and partitioning way and grouping units for

reunitizing (Baturu, 2000) can be seen as more evident for students. For decimal numbers, as numeration units (tenths, hundredths...) are introduced in a *partitioning way*, it is necessary to teach explicitly the grouping of such numeration units in order to allow treatments as reunitizing or units-conversions inside this register. Students seem not to be able to (re)build it by themselves.

## Second classroom episode: unit-conversion and comparison of decimal numbers

This second episode takes place in a class of grade 5: students have already been introduced to decimal notation and are used to work with it. In this episode (see the transcript and the Figure 1 below), students have to place decimal numbers in ascending order. Decimal numbers are represented in the semiotic register of symbolic writing, using decimal notation. The teacher tries to lead students to justify how they compare decimal numbers. More precisely, she asks a student why he added zeroes ending “1,9” to compare this number to “1,589”. Such a strategy of “similar writing” can be seen as treatment inside the symbolic register of decimal notations. It is possible to justify this treatment by a discourse about unit-conversion in the verbal register of numeration unit: “nine tenths” is converted to “nine thousandth” because “one tenth is the same as a hundred of thousandths”.

Student: So for example here [*E points the decimal notation 1,589 at the interactive whiteboard*] it is not because there are more digits that it is greater than one comma nine.

Figure 1: Compare decimal numbers

[...] because the tenths, it is what we are looking at first in order to know if it is less than. For example / Here we see [*Student points the digit “5” of the decimal notation “1,589”*] five tenths and here nine.

Teacher: How could you justify to someone who believes that five hundred eighty nine is greater than nine? Because five hundred eighty nine thousands is greater than...

Student: Nine is nine tenths.

Teacher: How could we see it? What could prove us it is the greater?

Student: We add two zeroes [*by drawing with his finger at interactive whiteboard*] if for nine we can put two zeroes / and then he will understand that nine is greater than one comma five hundred eighty nine [*Another student: Yes I agree*].

Teacher: And what is it useful for? Putting these zeroes as he did? For example?

Another student: To do the same... the same numbers at each side/ to make easier the//

During this episode, discursive register of numeration units seems to be used by a student to justify the comparison of “1,9” and “1,589” (nine tenths and five tenths). Nevertheless his mathematical explanation remains incomplete and related to place values. Then, the student is not able to justify why it is possible to put two ending “0” at the decimal notation “1,9” by using the unit-conversion from tenths to thousandths. After this classroom episode, most of the students have taken the action

of “adding zeroes” to decimal notations in order to achieve symbolic writings with similar numbers of digits. However, such a transformation of symbolic writings seems to be deprived of mathematical possible reasons. In order to specially focus on the use of unit-conversions, with the help of the researchers, the teacher designed a set of tasks, as follow. Such tasks make various symbolic and discursive semiotic registers appear:

Exercise 1: Compare 45 tenths and 440 thousandths

Exercise 2: Compare  $2 + \frac{34}{100}$  and 2,034

Exercise 3: Compare 0,17 and 0,2

Exercise 4: Compare  $3 + \frac{4}{10}$  and  $4 - \frac{7}{10}$

Exercise 5: Compare  $5 + \frac{37}{100}$  and  $\frac{54}{10}$

First, most of the students convert given representations of numbers to decimal notations (converting 45 tenth to 4,5). The former session that was devoted to decimal notations and the fact that such tasks (with diverse representations of decimal numbers) may be unusual for French students highlight this point. Furthermore, some of treatments in symbolic register of decimal notations are invalid. For example, a group of students concludes that “ $2 + \frac{34}{100}$ ” is equal to “2,034” after adding a “0” in front of the “3” of “2,34”. This confirms students’ difficulties in treatments related to comparison of numbers, in symbolic register of decimal notation. It also seems difficult for students to formulate justifications in the register of numeration units even if the teacher or the researchers try to seek explanations about their strategy of comparison. The transcript and Figure 2 below (related to interactions between a researcher and a small group of students) illustrate it is not so easy for students to explain why they can add an ending “0” at the decimal notation “5,4” to compare this number to “5,37”. At the end, students manage to formulate the unit-conversion in register of numeration units, saying that four tenth is the same as forty hundredths but it is tough to lead them to this point.

Student 1: The greater would be that one [*by pointing 5,4 at the whiteboard*].

Student 2: Because here, you add a zero [*by adding a zero / writing 5,40 at the white board*].

Researcher: But what does it mean that zero that you are adding?

Student 1: Actually, it is the hundredths. It is zero thousandth here and seven hundredths here.

Student 2: It is to get the same number of digits in the decimal part.

Researcher: Wait, I look at the end [...] when I hide that [*the researcher hides the integer part and the comma*] what do you do when you are adding a zero?

**Figure 2: Hide the integer part and the comma**

Student 1: Then it makes forty and thirty seven. Actually we can't add the thing [*by pointing the zero*].

Student 2: Yes you can as it doesn't add anything. No...

- Researcher: But why does it add nothing?
- Student 2: So it is zero. It is... ha [...] because it is as if it was zero hundredth more [...]
- Student 1: But it doesn't mean anything at all, zero hundredth more! [...]
- Researcher: You see. If I want to explain to a friend why I am allowed to add a zero.
- Student 1: The zero it does not add anything.
- Researcher: Yes but what can I say? The zero that adds nothing, you agree that it is not so, as you earlier explained it.
- Student 1: Yes! Because the four is the same as forty hundredths [Researcher: The four what?].
- Student 1: Four tenths is the same as forty hundredths [Researcher: And why?].
- Student 1: Because... ten hundredths, it makes one, one tenth.

### Third classroom episode: numeration units and measurement units

This third episode takes place in grade 4: students have to build relations between decimal fractional notation and decimal notation. The teacher has introduced a mixed numeration place value and length measurements chart. The columns of this chart are fixed and related to numeration units (hundreds, tens, units, tenths and hundredths) and the units of length measurement (decimeters, centimeters and millimeters) move inside these columns. For example, the centimeters can be fixed in the unit column if a length measurement is given in centimeters or in the tenths columns if the measurement is given in decimeters. This mixed chart has already been used by students to convert given decimal notations of length measurements (as for example “18,2 cm”) to length measurements units values (as for example “1 dm – 8 cm – 2 mm”) and *vice versa*. During this classroom episode, students use the chart to convert sums of decimal fractions (corresponding to length measurements) to decimal notations. This trajectory is not so easy: under this innovative scenario, the conversion of fractional notations to decimal notations has not been taught before. First students convert “ $3 + \frac{5}{10}$  cm” to “3,5 cm”. The transcript and Figure 3 illustrate how the mixed chart numeration place value and length measurements is then used by students to convert the sum “ $1 + \frac{2}{10} + \frac{8}{100}$  dm” to “1,28 dm”.

**Figure 3: mixed numeration place value and length measurements chart**

- Teacher: You can indicate here, measurement units, one is.
- Student: It is decimeters.
- Teacher: One is decimeters [Student is adding “DM” over the “1” in the column of units of the place value chart]. Two you told me. Two tenths of decimeters. It is [Student: Centimeters] Centimeters [Student is adding “CM” over the “2” in the column of tenths of the place value chart]. And hundredths remain.
- Student: Millimeters [Student is adding “MM” over the “8” in the column of hundredths of the place value chart].

Teacher: I agree. So we would have on centimeter, one decimeter, plus two tenths of decimeters, it is the same as two centimeters, plus eight hundredth of decimeters. OK and where is comma, yes, just after units [...] thus it would make one?

Student: One comma twenty eight [...] Centimeters.

Such an innovative scenario of decimal notations teaching reveals that the role of the comma “,” in symbolic registers of decimal notations as numbers or as length measurements may be different. In the case of measurement units, the comma of a decimal notation indicates the measurement unit that is the point of reference. This reference can change (being centimeters or decimeters, etc.). The mobile place of measurement units in the columns of the place value chart highlights this property. At the opposite, in the case of numbers and numeration the comma always refers to the “same” numeration unit, *the unit*. It is the positional mark of the place of *the unit* and then, of the other numeration units (as hundreds, tens, tenths, hundredths, etc.) in decimal notations. So if numeration and measurements units have similarities, they also have differences that it is important to consider.

## Conclusion and discussion

Our work unravels the conditions under which results obtained regarding the register of numeration units on whole numbers (Chambris, 2015; Houdement & Tempier, 2015; Van de Walle, 2010) can be extended to decimal numbers. First, the semiotic register of numeration units is linked to the earlier introduction of decimal fractions defined as parts of a whole unit. However, unit-conversions in this register remain difficult. Such treatments inside this register rely on a deep conceptual understanding of relationship between unit, tenths, hundredths... To allow unit-conversions and reunitizing (Baturu, 2000), a more explicit teaching of grouping meaning is needed, especially in the case of reunitizing – these numeration units being built in a sharing meaning in French curriculum. Second, it seems difficult for students to associate the numeration units with the decimal notation. Once this symbolic representation has been introduced, it is commonly verbalized as a couple of integers. For example, the decimal notation “2,58” is mostly verbalized as “two comma fifty eight” and not “two units and fifty eight tenths” by students. Then, the support of the discursive register of numeration units is difficult to make appear in order to justify strategies of decimal numbers comparison. The verbalization of “writing gestures” related to transformations of decimal notations takes precedence in students’ discourse. Those “writing gestures” are also deprived of justifications and coming back to unit-conversions is not so easy. It seems to be important that discursive register remains in use and that they are not replaced by a verbalization of decimal notation with couples of integers. From this point of view, conversions between symbolic register of decimal notation and register of numeration units must be reinforced in technique justification (comparison, calculus...). Third, even if it is possible to think about closer ties between symbolic registers of decimal notations as numbers and as length measurements, we have to be careful with the asymmetric role played by comma for either, or both these two registers. New perspectives to bring measurements units and numeration units closer in the teaching of decimal numbers can be outlined: with the design of specific tasks particularly related to the use of an unusual numeration place value chart mixing the use of numeration units and the units of length measurement.

# The offer of tasks to work on multiplication in grades 2 and 3

Sandra Gleißberg<sup>1</sup> and Klaus-Peter Eichler<sup>2</sup>

<sup>1</sup>PH Schwäbisch Gmünd, Germany; sandra.gleissberg@ph-gmuend.de

<sup>2</sup>NORD University Bodø, Norway; klaus-peter.eichler@nord.no

*In this paper, we present an analysis of four teaching materials of grades 2 and 3, which are widely used in Germany. We analyzed the tasks in these textbooks and workbooks with a focus on developing and consolidating the operational understanding of multiplication. For this purpose, we present a framework developed by us. Its foundations are the levels of representation according to Bruner and the fact that mathematical terms are concepts. The analysis shows a homogeneous picture across all four textbooks and workbooks: Already in class 2, the vast majority of tasks require working on the non-verbal–symbolic level alone. Only a small part of the tasks promotes connections to the iconic, to the enactive or to the verbal-symbolic level and challenges students to intermodal translations from one level of representation to another. In grade 3, compared to grade 2, an even larger proportion of tasks are limited to the non-verbal–symbolic level.*

*Keywords: Elementary school mathematics, multiplication, textbook analysis.*

## Context of the study.

Multiplication is a core content of teaching mathematics in primary school. The learning objectives in regard to multiplication are that students firstly should acquire a conceptual understanding of the operation multiplication, secondly, should be able to solve any task using different strategies and finally they should be able to retrieve more and more basic multiplication facts directly from memory (e.g., Kling & Bay-Williams, 2015; CCSSI, 2010 p. 23; KMK, 2004, p. 9).

There seems to be an international consensus nowadays that students should both acquire a sound conceptual understanding of multiplication and eventually solve all basic tasks accurately and effortlessly (Gaidoschik, 2017, p. 2).

However, three problems can very often be observed up to the secondary school level. *First*, there are deficits in the mastery of the basic facts<sup>1</sup>, i.e. in their retrieval as fact knowledge. Often students have forgotten basic multiplication facts they have once memorized and are unable to reconstruct this knowledge. This can be seen, for example, if they are unable to reduce fractions in secondary school because they cannot identify common factors.

*Second*, while students are often able to reproduce the basic task equations from memory, they are unable to solve multiplication tasks with a factor greater than 10.

*Third*, we repeatedly observe difficulties with the conceptual understanding of multiplication: students know that  $5 \times 4 = 20$ , but they are unable to justify this because they do not know the meaning of this term. Often, they just argue that  $5 \times 4$  is a shortened notation for the addition task  $4 + 4 + 4 + 4 + 4$ .

---

<sup>1</sup> Basic fact means in this paper an equation of multiplication in which both factors are less than 10 or equal 10.

All three problems have the same reason: A lack of the conceptual understanding of multiplication. In light of these observations, it is necessary to investigate the causes and to provide information to improve the teaching and its results. We are sure that no teacher works with the intention of bad results. There are obviously factors with a negative influence on teaching and its results. Such a factor is, for example, practicing with spontaneously chosen tasks, in which subjectively important, especially familiar or widespread tasks dominate, and the exercise then does not meet the need. In our opinion, teachers are obviously not aware of the negative influence of such factors.

Undoubtedly, the success of teaching depends on the selection of tasks and the way teachers work with them (cf. Fanghänel, 2000). One essential source of such tasks is the teaching material<sup>2</sup>. Therefore, the impact of teaching materials such as textbooks and workbooks is given. That is why we investigated four teaching materials of grades 2 and 3 which are widely used in Germany. The objective of our analysis is the suitability of the tasks contained in the materials in regard to promote understanding of the operation multiplication.

### About the matter: Understanding multiplication.

Terms like  $3 \times 4$  or  $6 \times 8$  are non-verbal-symbolic representations of *concepts*. They are mental reflections of objective reality and describe classes of situations. In this sense, the product  $m \times n$  can be represented both by the union of  $m$  equal and pairwise disjunctive sets with the cardinality  $n$  or by a combinatorial representation:

Def.: If  $a, b \in \mathbb{N}$  and  $a = |A|$ ,  $b = |B|$ , then is  $a \times b = |A \times B|$  the product of  $a$  and  $b$ <sup>3</sup>.

Def.: If  $a, b \in \mathbb{N}$  and  $|B_1| = |B_2| = |B_3| = \dots = |B_a| = b$  and " $i, k$  mit  $i \neq k$ :  $B_i \cap B_k = \emptyset$ " then is  $a \times b = |B_1 \cup B_2 \cup B_3 \cup \dots \cup B_a|$  the product of  $a$  and  $b$ .

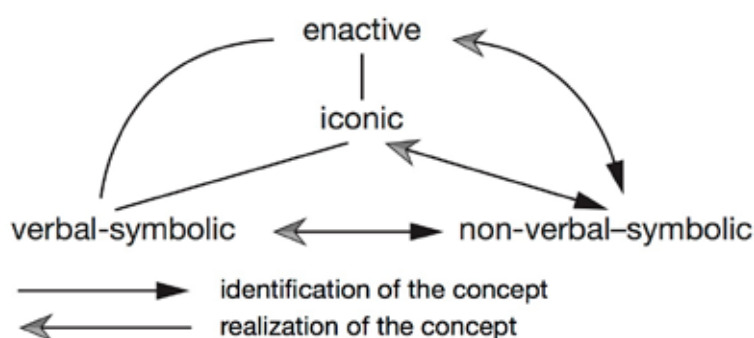

Both possibilities of representation can be spatial-simultaneous as well as temporal-successive.

This is consistent with the findings of Anghileri and Johnson (1992). They identify six key aspects of multiplication (and division): equal grouping, allocation/rate, number line, array, scale factor, Cartesian product. Regarding the so-called "axiomatic" definition of multiplication as a repeated addition, Park and Nunes (2001, p. 771) emphasize "that the origin of children's understanding of multiplicative relations is in their schema of one-to-many correspondence." and that the „repeated addition is only a procedure for solving multiplication problems, not its conceptual basis" (ibid.).

Content-related understanding of a concept means to be able to identify, realize and systematize it. When identifying a term like  $3 \times 4$ , an appropriate example is found in an enactive, an iconic, or a verbal-symbolic representation. Realizing a term such as  $3 \times 4$  means to create an enactive representation (e.g., an action), an iconic representation (e.g., a picture) or a verbal-symbolic representation (e.g., a suitable story, a word problem), which is consistent with this term. This is illustrated in Figure 1. When students systemize terms, they find relationships between two terms.

<sup>2</sup> The terms "teaching material" and "program" mean in this paper the unity of textbook and workbook.

<sup>3</sup>  $|M|$  means the cardinality of the set  $M$ .

**Figure 1: Levels of representation according Bruner (1964)**

This can be referenced with an enactive or an iconic representation. Often this relationship is created without any references only on the non-verbal-symbolic level.

The importance of the conceptual understanding of the operation multiplication consists on the one hand in the fact that students can apply this knowledge to describe reality,

e.g., to solve word problems. On the other hand, it enables students to solve every multiplication task, especially those with factors greater than 10, by drawing e.g., dots and skip counting, laying e.g., cubes and skip counting and deriving answers using reasoning strategies based on known facts. (Baroody, 2006, Kling & Bay-Williams, 2015).

Mastery of the basic facts of multiplication must be distinguished from fluently multiplying: Fluently multiplying means to solve tasks using strategies, properties of the operation, means determine the value of a term by calculating at skill level (Kling & Bay-Williams, 2015, p. 550). Mastery of all the basic tasks of multiplication means to be able to retrieve from memory all products of two one-digit numbers. In our opinion, mastery is indispensable at the latest in middle of grade 3 because then this knowledge is needed as a tool for solving tasks with factors greater than 10.

Even if the final goal here is to retrieve the facts from memory, the ability to solve the basic tasks of multiplication is the basis for this and must consequently be secured before memorizing the basic tasks of multiplication. Only if students have a conceptual understanding of the operation multiplication and are able to determine the value of the terms, they can reconstruct forgotten basic facts. The reconstruction of forgotten facts can be done by using connections to other facts, e.g., by using properties of multiplication, by activities with manipulatives or by using mental representations.

### **Framework for the classification of tasks for the consolidation of arithmetic operations.**

Because a suitable work with tasks in the sense of Fanghänel (cf. 2000) is essential for the quality of teaching and its results, we examined this work with tasks and the selection of tasks in more detail. The choice of tasks undoubtedly depends on the range of tasks offered by published programs (textbooks, workbooks etc.). To assess this offer of tasks, we analyzed four widely used programs<sup>4</sup>. We decided to analyse textbooks and workbooks for both grade 2 and grade 3 because teachers

<sup>4</sup> There were the programs „Fredo Mathematik“ and Super M (both Cornelsen Schulbuchverlag) as well as „Denken und Rechnen“ and „Welt der Zahl“ (both Bildungshaus Schulbuchverlage).

usually use these materials anyway. Supplementary materials such as software or online resources were therefore not analyzed.

Many frameworks exist for analyzing textbooks regarding different aspects. A short overview gives for example O’Keeffe (2013). A specific framework which focusses the appropriation of arithmetic operations and takes in consideration that terms like  $3 \times 4$  are concepts was not available until now. We developed the following framework to classify tasks for the appropriation of multiplication. It is generally usable for all arithmetic operations. This framework is not limited to analyzing printed materials. It can also be used to analyze educational software etc. The understanding of the operation multiplication must be promoted. Therefore, we were looking for tasks which emphasize the identification, realization, and systematization of concepts, e.g., of terms. In ggrades 2 and 3, mastering the basic number sentences by memory should be supported. Finally, we determined the number of tasks which aim to determine the value of the term. So, we classified the tasks in the programs as follows:

**ICE:** Tasks for the **I**dentification of the **C**oncept starting from the **E**nactive level of representation. These are tasks such as ‘Place five times three cubes and write a matching task.’ (The word ‘task’ here means a term in the mathematical sense of the word.)

**ICI:** Tasks for the **I**dentification of the **C**oncept starting from the **I**conic level of representation. In these tasks, a picture is given and the students should give a task that matches the picture. (The word ‘task’ here means a term in the mathematical sense of the word.)

**ICV:** Tasks for the **I**dentification of the **C**oncept starting from the **V**erbal–symbolic level of representation. These are tasks such as ‘Three rows of five knights each come out of the castle. Write a suitable task’ or ‘Clown August has five trousers and three jackets. How many different possibilities does he have to be dressed?’

**RCE:** Tasks for the **R**ealization of **C**oncepts to the **E**nactive level of representation. These are tasks such as ‘Lay with cubes matching  $4 \times 3$ ’.

**RCI:** Tasks for the **R**ealization of **C**oncepts to the **I**conic representation level. These are tasks such as ‘Draw a picture matching  $4 \times 3$ ’.

**RCV:** Tasks for the **R**ealization of **C**oncepts to the **V**erbal–symbolic level of representation. These are tasks like ‘Write a story matching  $4 \times 3$ .’

**SCE:** Tasks for **S**ystematizing **C**oncepts with reference to the **E**nactive representation level. These are tasks such as ‘How do you go from  $5 \times 4$  to  $6 \times 4$ ? Lay with cubes and explain’.

**SCI:** Tasks for **S**ystematizing **C**oncepts with reference to the **I**conic representation level. These are tasks such as ‘How do you go from  $5 \times 4$  to  $6 \times 4$ ? Draw and explain’.

**SCW:** Tasks for **S**ystematizing **C**oncepts **W**ithout reference to the enactive or to the iconic level of representation. Such tasks are, for example, ‘You know  $10 \times 8$ . How can you then calculate  $9 \times 8$ ?’ Tasks like those shown below are also tasks for systematization without a reference to the enactive or to the iconic level of representation:

1	0	×	7	=			5	×	8	=			2	×	3	=			5	×	7	=		
	1	×	7	=			2	×	8	=			4	×	3	=			7	×	5	=		
	9	×	7	=			7	×	8	=			8	×	3	=								

**VT:** All tasks where the **V**alue of a **T**erm must be determined without any reference.

Our framework offers the possibility to validly classify all tasks in teaching materials, as we implemented all possible forms of representation as well as all steps of the process of learning concepts, as described above.

We are well aware that the determination of term values is indispensable in math lessons. Similarly, it is essential to establish relations between equations without always referring them in enactive or iconic mode. Mastering both requirements - determining the value of a term and establishing the connection between two terms - at skill level is crucial for successful work in the next grades. We use the term skill level as described in the IDMT assessment framework (cf. Brendefur et al., 2016, pp. 177). Nevertheless, these skills can only be used meaningfully if students can represent non-verbal-symbolic expressions at the enactive or the iconic level. The present study, therefore, focuses on those tasks that challenge students to an intermodal translation between the levels of representation.

## Findings.

The findings of our analysis are presented in more detail in table 1 below:

		program 1		program 2		program 3		program 4	
		grade 2	grade 3	grade 2	grade 3	grade 2	grade 3	grade 2	grade 3
<b>tasks</b>		1368	368	1421	585	1147	430	1499	731
1	<b>ICE</b>	57	0	0	0	21	3	9	4
2	<b>ICI</b>	175	21	164	0	104	3	175	8
3	<b>ICV</b>	31	3	35	30	94	10	51	12

<b>ratio</b>		<b>75.9%</b>	<b>92.7%</b>	<b>73.3%</b>	<b>94.9%</b>	<b>76.9%</b>	<b>93.7%</b>	<b>80.1%</b>	<b>95.3%</b>

**Table 1: Tasks of multiplication offered in four different programs (textbooks and workbooks)**

Table 1 shows the results of our analysis. It shows that the offer of tasks across all four analyzed programs is approximately equal, one-sided and qualitatively unsatisfactory.

## Findings of our analysis of second grade programs.

The result of our analysis shows that tasks requiring translations between the levels of representation are significantly under-represented in all four programs. The only tasks to be found are those in which the students are challenged to draw a matching picture for a given term (RCI). Not every program

contains tasks that require the students to lay or build something with material suitable to a given term (RCE). In three of the programs, there are 5, 16, and 6 tasks. The total number of these tasks is far too small.

Tasks that challenge students to represent a term verbal-symbolically (RCV) are extremely rare. Only two of the programs offer such tasks at all and this only seven respectively three times. This finding explains the well-known shortcomings of the students in solving word problems.

The four programs contained 0, 0, 3, 0 tasks for systematization with reference at the iconic level. Not one of the four programs meets our expectations. The systematization of the basic number sentences on a purely non-verbal-symbolic level plays a major role in all four programs: 279, 82, 212 and 318 tasks are represented here. The tasks of systematization on a purely non-verbal-symbolic level are wrapped in different manners. According to the mathematical core, they are tasks like the ones shown below.

$$3 \times 8 = 24 \triangleright 6 \times 8 = 48 \text{ (doubling),}$$

$$5 \times 8 + 1 \times 8 = 6 \times 8 \text{ or } 10 \times 7 - 1 \times 7 = 9 \times 7 \text{ (so-called neighbourhood tasks),}$$

$$5 \times 8 = 8 \times 5 \text{ (so-called commutativity tasks).}$$

Such tasks are undoubtedly essential and indispensable. In solving these tasks, however, the students do not have to think about the meaning of the operation. They can undoubtedly use these tasks to acquire networked knowledge, the meaning of which they do not necessarily have to grasp: New equations are developed from equations. For quite a few students, this is exactly the picture of mathematics lessons: lessons in which new strings are created from existing strings. Hence it is not surprising that some students consider multiplication as a trick of mathematicians to shorten long equations of addition.

### **Findings of our analysis of third grade programs.**

First of all, it is apparent that the range of tasks offered for multiplication in third grade is considerably less than in second grade: In total there are 368, 585, 430, and 731 tasks for multiplication. This is not even half of the amount that is offered in second grade. The rate of tasks that promote the understanding of the content of the operation by establishing references to the enactive, iconic or verbal-symbolic level drops markedly: the four programs contain only 27 (7.3%), 30 (5.1%), 27 (6.3%) and 34 (4.7%) of such tasks. Tasks that support an active construction of meaning are thus almost completely missing.

The emphasis is on the determination of term values. With regard to networked memorization, it should be noted that, as in second grade, the systematization of equations is always carried out only at the non-verbal-symbolic level. Tasks that promote the development of memorizing techniques, thematize such techniques, etc. are in fact not included: In all four programs there are altogether only 4 (!) such tasks.

### **Discussion.**

The operation multiplication is acquired in grade 2. Here, the focus is first of all on the conceptual understanding of multiplication. This is usually developed on the basis of contexts. Therefore, it is to be expected that the programs of this grade will offer a qualitatively and quantitatively wide range of

tasks with reference to the enactive or iconic level, to ensure the understanding of the meaning of the operation. We expected, that also the grade 3 programs would contain a variety of tasks to systematize and to consolidate the meaning of the operation. We hoped to find a lot of tasks for identification, realization or systematization with reference to the enactive or iconic level.

Accordingly, there are – as expected – in grade 2 many tasks in all the programs in which students have to *identify* a suitable term, particularly to pictures and – more rarely – to actions.

Because the cognitive process that takes place in mathematics lessons only finds a preliminary, relative completion when applying the acquired knowledge, we expected to see many tasks in which the students have to *realize* the term. We expected that students would be challenged to draw a picture that represents a term, to represent the term using manipulatives or to tell a story fitting the term. The evaluation of the four programs in grade 2 shows that in the programs are only 67 (5%), 181 (12%), 43 (4%), and 63(4%) such tasks and that the tasks are mostly from the type ICI.

The range of tasks that support a conceptual understanding is insufficient in both grades, while the dominance of tasks which aim determining the value of a term is remarkable. It starts in second grade and dominates in third grade. In each of the investigated programs, the teacher must use additional tasks that she/he chooses from other sources or that she/he independently develops.

Right from the development of the first basic facts onwards, it makes sense to network these and build up connected, systematic knowledge. Therefore, we expected already in second grade many tasks that promote the systematization of the basic number sentences with reference to images (iconic level - SCE) or actions (enactive level - SCI). The analysis of the programs shows that such systematization, in fact, did not take place. Not one of the four programs contained a task with a suggestion for systematization with an enactive reference.

If the teacher does not supplement the range of tasks offered by the programs, the students have too little opportunity to grasp the meaning of multiplication and to consolidate this knowledge.

The analysis of the grade 3 programs shows that if a child in grade 2 has not understood the meaning of the operation multiplication, the materials in grade 3 hardly offer any chance for building up this understanding.

Based on our findings we cannot draw conclusions regarding classroom practice. But, we can assume that the examined materials are a basis for learning multiplication in math classrooms. The teacher always can compensate deficits of the materials. Therefore, further research is needed, especially the teachers' choice of tasks has to be analyzed.

# Considerations on developmental stage models, learning trajectories and maybe better ways to guide early arithmetic instruction

Michael Gaidoschik

Free University of Bozen – Bolzano, Italy, [michael.gaidoschik@unibz.it](mailto:michael.gaidoschik@unibz.it)

*Current learning trajectories and stage models of arithmetic development advocate the elaboration of counting on as an intermediate computation strategy. At the same time, there is empirical evidence that a considerable share of children fail to overcome this procedural approach to addition and subtraction, with damaging effects to their further mathematical thinking. This theoretical essay argues that it is fundamentally faulty to justify instructional measures by stage models that claim to capture a development without considering that its stages themselves reflect the conditions of children's learning, inter alia: the very instructional measures. As an alternative, the paper uses structure-genetic didactical analysis to delineate a teaching design that derives addition and subtraction out of part-whole thinking from the very beginning, rendering counting on superfluous.*

*Keywords: Early arithmetic instruction, counting on, computation without counting, part-whole thinking, derived facts strategies.*

## Preliminary remarks

In this paper, “early arithmetic instruction” refers to contents and aims that are constitutive for first grade primary school in *German* speaking countries. Thus, I write about 6–7-year-old children who, as a rule, have attended kindergarten before; but to what extent and in which ways they have already received targeted *mathematic* education, will differ considerably – within and between German speaking countries – due to different educational plans and levels of specific competences of kindergarten staff. To enable colleagues from other nations to compare with their respective educational systems, I shortly outline just three important areas of goals for first grade arithmetic instruction that (besides others) seem to be widely accepted in the pertinent German literature (cf. Gaidoschik, 2010, pp. 207–232, for details):

First, building upon the rather heterogeneous competences they have thereto already acquired, children should (further) develop and consolidate their knowledge about natural numbers. This starts from being able to count forward and backward fluently and to establish quantities by counting, and should reach the comprehension of numbers as being composed of other numbers at least up to 10, if not 20 (*part-whole concept of numbers*, cf., e.g., Schipper, Ebeling, & Dröge, 2015).

Second, and connected with the former, children should understand addition and subtraction as two arithmetic operations inverse to each other, and learn how to add and subtract *fluently* within the number range up to 20. More precisely: up to 20, they should learn how to *compute without counting* already within year one (cf., e.g., Schipper et al., 2015; Häsel-Weide & Nührenbörger, 2013).

Third, together with all this, they should (further) develop a positive attitude towards mathematics as a worthwhile activity for which it is constitutive to deal with problems which include detecting, exploring, carrying forward, communicating and arguing about patterns and structures, not only but also in the field of natural numbers (cf., e.g., Krauthausen, 2018).

As far as my knowledge of *international* mathematics education reaches, these goals are widely accepted in other nations as well, even if institutional frameworks and time expectations may be quite different. Therefore, for some nations, the following considerations might count for children slightly younger or older than those who attend first grade in German speaking countries; but they should count for them at *some time* of their educational career, if they are of any relevance at all.

## **Some critical notes on current stage models and learning trajectories**

### **Shortcomings of “developmental stage models” that disregard instructional influences**

Within the German speaking literature, in the last decade two competing, quite similar stage models of arithmetic development have been widely noted, both developed by psychologists (Krajewski & Schneider, 2009; Fritz & Ricken, 2008). Fritz, Ehler and Leutner (2018) recently claimed to have validated the latter by longitudinally testing children between 9 months before and 8 months after school-entry. Now this is not the place to discuss these models in detail (see Gaidoschik, 2010, for a critique on a former version of Fritz & Ricken, 2008). This paper is about the question whether and in what way stage models *of that kind* can be helpful for mathematics educators and pedagogues in supporting children to learn arithmetic. In this vein, I outline in the following the construction of Fritz and Ricken (2008) as a paradigmatic example of a certain approach to mathematical learning.

The model in question encompasses six “levels” that its authors do not want to be interpreted as following strictly distinctly one after the other, but rather in the sense of “overlapping waves”, a metaphor also used by Siegler for his models of strategy development (cf. Siegler & Alibali, 2005). According to Fritz et al. (2018), children, on Level 1, would learn how to establish quantities precisely by counting within a certain number range. On that same level, they would be able to subitize small quantities. Only on Level 2 would children relate numbers to each other by ordering them on a “mental number line”. Building upon this, they now would be able to solve additions and subtractions by “counting all”. “Counting on”, however, would be characteristic for Level 3. Fritz et al. (2018, p. 15) state that only on that stage children would grasp cardinality and the irrelevance of order principle. Cardinal understanding would include knowing that numbers can be composed of and decomposed into other numbers. On Level 3, however, this understanding would be restricted to situations where children use manipulatives, whereas on Level 4 they would “transfer” this concept on a “symbolic-algebraic level” (Fritz et al., 2018, p. 16). However, this would not encompass the understanding of “relationality”. Only on Level 5, children would use numbers to state precisely the difference between two numbers. This, together with Level 6 (bundling and unbundling), would form an indispensable precondition for understanding multiplication, division, and place value (Fritz et al., 2018, p. 17).

Fritz et al. finish their publication with “didactic implications” that remain on a rather general level, yet demand that school instruction should follow the “hierarchy of arithmetic concepts” as described by the model. As children would go through that hierarchy at different pace, this would include the need of differentiating within a class (Fritz et al., 2018, pp. 35–37).

The mathematics education community will certainly acknowledge the latter. However, before taking a closer look at how to *apply* such a model, let us reflect upon its *epistemological status*. What does it really tell us about children’s *thinking*? Fritz et al. (2018) claim to capture a *development* within a certain time span. They describe single stages referring to children’s *performance* in certain tasks,

and interpret what children might be able or not to *conceptualize* on that level. From the mathematics education point of view, at least some of their interpretations lack clearness and coherence. For instance, the model is rather vague about what might distinguish the number *concept* of a child on Level 3 from that on Level 4, as well as on Level 4 and 5. It seems to be that the authors are more interested in differentiating levels of *test performance* than really of arithmetical *concepts*.

What is more fundamental is the model's lack of consideration of the fact that children develop their ideas while constantly dealing with inputs coming from adults as well as from other children. As for counting on, which constitutes Level 3 of the model in question: There is ample evidence that in many countries pedagogues in kindergarten and primary school, and presumably parents as well, encourage children and in fact *show them how* to solve addition problems by counting on instead of counting all (cf. Gaidoschik, 2019). They certainly do so because they think this to be conducive. I will gather some evidence that casts doubt on this assumption in the following paragraph. What has to be stated at this point, is a fundamental *theoretical shortcoming* of any model of learning development that disregards the possibility that what the model claims to be “normal” or even “necessary” within the presumed “nature of children” might rather be the consequence of circumstances that are man-made.

### **Counting on: A “natural” stage that still needs to be pushed by learning trajectories?**

There is a *logical inconsistency* in this shortcoming that becomes even more apparent in the case of “The Learning Trajectories Approach” (Clements & Sarama, 2009) or stage models that are directly formulated to *guide* teacher's actions, such as the “Mathematics programme of study” (UK Department of Education, 2013) or the “Number framework” (New Zealand Ministry of Education, NZME, 2008, 2012). All three guidelines stress that *eventually* children should learn to add and subtract fluently without counting. The “Number framework” is especially clear in that point:

It is important for you to recognise that part-whole thinking is seen as fundamentally more complex and useful than counting strategies. One reason is that counting methods are strictly limited, whereas part-whole methods are more powerful. Counting strategies are an inadequate foundation for these ideas, and this means that for counters, many advanced number ideas are inaccessible. Therefore, your major objective is to assist students to understand and use part-whole thinking as soon as possible. (NZME, 2008, p. 7)

Nevertheless, all three guidelines recommend that teachers *actively work out* counting on as a short-cut strategy for addition, and analogue counting strategies for subtraction with their classes. Thus, if a teacher who follows the “Number framework” notices a child to add by counting all using materials (Stage 2), s/he should work with that child so that it first reaches Stage 3 (“Counting from One by Imaging”) and then Stage 4 (“Advanced Counting”). For that purpose, the teacher should orchestrate activities so that children learn to put “the bigger number first” and count on when confronted with an addition problem (NZME, 2012, p. 36). Only after having reached that stage, the teacher should guide children further to Stage 5 where they should “develop the idea” that “addition and subtraction problems can be solved by part-whole strategies instead of counting” (NZME, 2012, p. 37).

I did not find an explicit justification for this recommendation in the pertinent publications I reviewed, but it seems to be that the authors deem it *indispensable* to intentionally *guide children from one stage to the next* and *not skip a single of these stages* as defined by the underlying stage model.

Thus, these models extract stages of “development” from the evidence that many children progress from *counting all* over *counting on* to finally computing without counting. Nota bene: *Many* children progress in that way; yet, a considerable number stick to counting strategies in higher grades (Cowan et al., 2011; Hopkins & Bayliss, 2017), and doing so forms an essential part of learning difficulties (Gaidoschik, 2019). Then, there is evidence that the share of children who finally quit counting on strongly relates to instruction. In nations with a tradition of *not* encouraging children to count on, but rather use derived facts strategies already at an early stage, this share seems to be much higher (Geary, Bow-Thomas, Fan, & Siegler, 1996). Intervention and field studies indicate that putting the focus of early instruction on derived facts strategies *instead of* counting on, will reduce the number of children who cling to counting for computing (e.g., Steinberg, 1985; Gaidoschik, Fellmann, Guggenbichler, & Thomas, 2017). Notwithstanding all this, the cited models postulate a *quasi-natural* progression:

“Children follow natural development progressions in learning and development. As a simple example, they learn to crawl, then walk, then run [...] They follow natural developmental progressions in learning math, too [...]” (Clements & Sarama, 2009, p. 2)

Thus, on the one hand, the authors regard counting on as part of a “natural development”. On the other hand, they take their model as a justification to *instruct* children how to count on. However, doing so is a didactic decision, and by no way “natural” nor necessary, as I will argue in the following. Presumably, the authors would deny intervening in this way in a supposedly inevitable process to be logically inconsistent and put forward their endeavor to “promote children’s growth” (Clements & Sarama, 2009, p. 5), so that what is “natural” may move forward without avoidable impediments. Yet, as stated above, research indicates that in fact it may *impede* children when teachers quite *artificially* guide them to count on for addition and subtraction problems (Gaidoschik, 2019).

### **An alternative approach: Structure-genetic didactical analysis**

Whereas learning trajectories and stage models suggest teachers stick to what is supposedly inherent in the “nature” of *children*, Wittmann’s (2015) “structure-genetic didactical analysis” advises instruction to follow the “nature of *mathematics*”. Of course, Wittmann not at all advocates disregarding what empirical research indicates about the ways children learn mathematics, the difficulties they meet, and the misunderstandings that may arise based on their “prerequisite knowledge” as well as on what happens in the classroom. He explicitly rejects the “‘broadcast’ method of transmitting knowledge from the teacher to the student” that he ascribes to “the traditional ‘subject matter mathematics’” dominant in German mathematics education for a long time (Wittmann, 2015, p. 17). Therefore, his idea is *not* that we would only need to unfold the logic of any subject matter to children in order to secure they grasp it step by step. Still he insists that what a subject matter “is about and how it should be introduced in the classroom, cannot be decided by means of empirical methods imported from psychology, but should be based on a sound mathematical and epistemological analysis” (Wittmann, 2015, p. 7).

In the following, I will try to delineate in brief what, in my understanding, such an analysis would imply for the subject matter in focus of this paper, i.e. the introduction of addition and subtraction. In doing so, I take into account the pertinent empirical research, but without considering immutable what might rather be consequence of a certain type of instruction that we could at least try to change.

### Deriving addition and subtraction out of part-whole thinking: A sketch

“Emerging from the [mathematical] subject” (Wittmann, 2015, p. 6), addition and subtraction are inverse operations, with the laws of commutativity and associativity being central for addition. Applying these laws allows for powerful computation strategies. Subject matter analysis as well as empirical evidence indicate that in order to grasp these concepts, it is crucial to think numbers as composed of numbers. Young children encounter numbers in many ways, but counting is dominant in the first years. For a child who uses numbers primarily to *count* quantities, *numerical* part-whole relations are not at all obvious; rather, the child might take any number as a single entity, so that e.g. six is conceptualized as being *before* seven, rather than being a *part* of it (cf. Gaidoschik, 2010).

Therefore, if early arithmetic instruction strives to help children acquire a solid fundament of addition and subtraction, it seems sensible *first* to focus on activities that foster *part-whole understanding* of numbers. *Only on that basis*, we can and should convey *addition and subtraction* as two ways of operating with parts and wholes that supplement each other. Following that order, which is of course not dictated by stage models, but advocated by subject matter analysis, we have a good chance to render computation by counting *superfluous from the very beginning* (Gaidoschik, 2019).

In more detail: In order to be able to explore and internalize part-whole relations, when quantities exceed subitizing (see below), a child needs to know how to determine the number of the quantity by counting. Therefore, one main-topic (A) of early arithmetic activities certainly should be *counting* as a means to establish precisely *how many of whatever* you have. This includes the targeted working out of the “counting principles” described by Gelman and Gallistel (1978). Any first-year classroom or group of kindergarteners will be quite heterogeneous in that respect. As a basis for the steps to follow, all children should at least consolidate counting skills and knowledge up to 10, the basis of our number system; most children will exceed that number by far, so there is a need for differentiation.

At the same time (B), it is important to build upon what children, partly independently from their counting competences (cf. Fritz et al., 2018), have already acquired in the field of *subitizing* of quantities up to four and *perceptual subitizing* of bigger quantities structured in a way that allows for establishing their number without counting (cf. Clements & Sarama, 2009). This could start with numbers up to five (number of fingers on a hand) or six (maximum of dots on one side of a die). Yet, we would gain little for the following if a child identifies these quantities with a glance but *without* noticing them as *composed* (four as two and two or three and one, five as four and one or three and two, etc.). Thus, activities should focus on the *structured* perception of these quantities. Schultz and Gerster (2017) delineate how this could form the starting point of targeted elaboration of part-whole thinking: We may request children to construe operations of joining, separating, missing addend etc. as just different interpretations of dot structures, for example, “I see five dots altogether. If I take away the outer four, the central one will remain.” We may then encourage the children to transfer these *nuclei of number knowledge* to real-world situations: “I’ve got one Euro. If mummy gives me four more, I will have five.” Note that the intention of such early activities is *not* that children solve these problems by counting, but by referring to the part-whole interpretation of structured dots, first supported by *seeing* the dots, then by *knowingly imagining* their structures (Schultz & Gerster, 2017).

A third “construction site” (C) of early activities, once again building upon the rather diverse competences that children will already have acquired in that field, is *comparing* quantities and numbers. As a precondition for further arithmetic, children should learn and/or consolidate that two quantities are the same number if it is possible to establish a continuous one-to-one correspondence between their items; no counting is needed for that. On that basis, they should learn that “one more” means that a mapping of the items results in one item left for the bigger quantity (Gaidoschik, 2007).

I use the metaphor “construction sites” to indicate that we should *work* with children in all three Fields A to C more or less *concurrently*, which is, bearing on German speaking countries, within the first weeks of grade one. Certainly, we may concentrate activities on only one site for some days, but switch to another the next day or even combine working on all sites on the same day. This is sensible, as many children in single areas will need quite a lot of practice over a longer period to reach the level required as a basis for next steps. Yet, to achieve desirable *automatisms*, e.g. in counting forward and backward, it would not help to stick to one single theme for too long in a row, but rather provoke tedium. More importantly, the sites relate to each other. We should link *counting* to *comparing*, to help children realize that each number in the sequence is “one more” than its predecessor (and not only “the next number”, see above). Working on *perceptual subitizing* should include *comparing*, etc.

Such as the three sites merge into one another, the next important step is only an extension of the above-mentioned exercises: advanced activities that fit for exploring and internalizing part-whole relations, but now for *all numbers* at least *up to 10*. Gaidoschik (2007) describes in detail how the use of fingers which are not being counted nor unfolded one by one, but moved and perceived in groups simultaneously, could form a starting point for first acquiring *mental pictures* and finally *automatized knowledge* of at least some important compositions of all numbers up to 10. Thus, children could first learn how to “stretch out eight fingers without counting”, then describe how they would do so without really doing it (“I need one full hand and three more fingers”). Then, if already available to the child (see below), s/he could use symbols to record the action ( $5+3=8$ ), think about what could be done subsequently (“So this is eight fingers. What if you take away the one full hand?”), and record that action as well ( $8-5=3$ ). Already at that stage, children can and should try to apply this knowledge to real-world situations, for instance by inventing word problems. In that way, the acquisition of part-whole knowledge is (almost) from the beginning closely linked to addition *and* subtraction.

Note that I am not talking about *writing* equations from the very start, but *operating* with *real*, then *imagined* material. Fingers are very useful “material” at the beginning, as they allow to experience clearly and convincingly the difference between using structure-knowledge (take away five means take away one full hand at once) and counting (take away quite tediously one single finger after the other). In the following, for some purposes, ten-frames are useful, then twenty-frames and 100 dot arrays. Also with these materials, yet, it is paramount to work out *how to see and use structures*, how to *relate* other numbers to 5 and 10; only this enables to operate without having to count one by one.

Fingers might be most convincing to work out the five-plus-x structures of the numbers 6 to 10. Another indispensable structure that should be in the focus of early activities are doubles and halves (6 as  $3+3$ , 8 as  $4+4$  etc.). Therefore, a next step could be to concentrate on these very structures, and again connect them with tasks that elicit their *application* in solving addition and subtraction tasks.

Once more, it will turn out that counting is superfluous to solve these tasks. Presumably, some children might still apply counting strategies; yet, in this context there is high probability that the teacher or other children will convince these children that there is a better, much easier way, by thinking about and applying knowledge of the part-whole structure of the numbers involved.

## Closing remarks

This is not the place to unfold a detailed guideline for teaching early arithmetic. The aim of the above sketch is to illustrate the paper's main message: Structure-genetic didactical analysis allows developing a teaching design that avoids engaging children in using counting on for computation *from the very beginning*. It does so in full consideration of pertinent research on how children develop their thinking under certain conditions. However, it strives to change these conditions where analysis shows that they may lead to unnecessary delay, if not continuing problems. Research indicates that the widespread tradition to foster counting on is such an unfavorable condition. Structure-genetic didactical analysis opens an alternative in line with the needs of the children as well as of the subject matter. Of course, an indispensable next step would be to implement these ideas in classrooms, and evaluate and further develop them based on reflected experience – a clear case for educational design research. I have started such research on a small scale, yet this paper is deliberately *not* about the ongoing pilot study. I had rather put the basic concept up for international discussion. After all, it would not make sense to trial on larger scale a design that does not withstand careful scrutiny.

*This qualitative and interpretative study aims to identify grade 5 students' knowledge of rational number operations in order to ascertain their rational number sense and operation sense before and after a teaching experiment. Data was gathered using two tests and four individual semi-structured interviews. The results show that, in the pre-test, children performed rational number operations based on their whole number knowledge. In the post-test, after the teaching experiment, they showed conceptual understanding of the operations, demonstrating rational number sense and operation sense.*

**Keywords:** Rational numbers, fractions, fractions operations.

## Introduction

Rational numbers are important mathematical entities, with an important place in the mathematics curriculum, particularly in early years. They involve complex ideas, which represent conceptual obstacles for children (Behr & Post, 1992). Mathematics education researchers have identified difficulties in children's work with these numbers, for example, regarding operations (Hansen, Drews, Dudgeon, Lawton, & Surtees, 2014). Teaching methods used in schools, typically oriented towards the application of rules, lead students to perform sequences of procedures without understanding their meaning (Braithwaite, Pyke, & Siegler, 2017), for example, obtain equal denominators and then add or subtract numerators; multiply numerators and denominators on fraction multiplication; and “invert and multiply” on fraction division. Consequently, children do not develop rational number sense (Lewis & Perry, 2014) nor operation sense (Huinker, 2002). Thus, this study aims to identify grade 5 students' knowledge of rational number operations in a pre-test, before a teaching experiment, and in a post-test, after that teaching experiment, in order to ascertain their rational number sense and operation sense.

## Rational number operations

### General aspects

Students often demonstrate not understanding what happens when they add, subtract, multiply or divide fractions because the teaching of this topic is typically based on the presentation of rules that they do not understand. Usually, they apply their knowledge of integers on rational number operation tasks, and they operate with rational numbers as if they were integers. Thus, children make mistakes that demonstrate misunderstandings in their conceptual understanding: “strategy errors”, for example, applying the operation to numerators and denominators, independently; and “execution errors”, for example, incorrect performing a calculation procedure or failing to change numerators or denominators when attempting to obtain equivalent fractions (Braithwaite et al., 2017).

Rational number understanding involves rational number sense, that is, understanding: (i) that a fraction is a number; (ii) partitioning fractions; (iii) the meaning of denominators; (iv) knowing what is the whole; (v) fraction size; and (vi) fractions can represent quantities greater than one (Lewis & Perry, 2014). Operation sense is another component of rational number sense. According to Huinker (2002), it includes the following understandings: (i) meanings and models for operations, e. g., rectangular, circular or area models, used to represent the operations; (ii) ability to recognize and describe real-world situations for specific operations; (iii) meaning of symbols and formal mathematical language; and (iv) knowledge the effects of operation on numbers. In the perspective of Brown and Quinn (2006), gaps in the conceptual understanding of rational number operations are the cause of poor student performance in these operations. Both number and operation sense represent a way of thinking about numbers and their operations. Problem solving allows children to explore and understand rich mathematical situations, in which operations arise. Thus, problems can more easily assign operations meaning and promote meaningful learning. The use of models can help children to understand the conceptual basis of each operation. As they establish a relationship between models and algorithms, children can understand what each step of an algorithm represent in practice (Behr & Post, 1992).

### **Addition and subtraction**

Fraction addition and subtraction are often taught based on the use of procedures, such as, “denominators have to be equal, and then you can add or subtract the numerators”. However, students often do not understand the need of common denominators or the role of equivalent fractions, which constitute fundamental understandings in these operations (Behr & Post, 1992). This procedure-based approach does not promote the conceptual understanding of fraction addition and subtraction. Together with the prior knowledge of whole numbers, it leads children to make common mistakes, because they confuse the procedures. In addition, children have more difficulty understanding questions involving subtraction than involving addition. Sometimes, they do not identify the correct operation (Behr & Post, 1992). Braithwaite et al. (2017) refer that most children’s difficulties are associated with the nature of denominators. When they are equal, children usually just add or subtract numerators; when they are different, they usually make independent whole number errors, that is, apply the operations to numerators and denominators (strategy errors). Behr and Post (1992) point out that the use of models can help children to understand the involved concepts when they add or subtract fractions.

### **Multiplication**

Multiplication is usually viewed as successive addition of “equal groups”. However, in the rational number field, this is an inappropriate idea because the product can be smaller than both factors and this is not compatible with an additive procedure (Greer, 1992). Tasks with a “multiplicative relation” meaning can be useful on learning rational number multiplication so that children overcome this misunderstanding. The use of models allows children to understand how the unit change during the problem and that the product is not always greater than each of the factors (Behr & Post, 1992). Children multiply both fractions but they do not understand how and why the algorithm works.

## Division

The division operation is often linked to sharing situations. In these situations, the goal is to get the unit value. However, learning division only based on this meaning leads students to the incorrect idea that division always decreases or that the dividend should be greater than the divisor (Greer, 1992). The meaning “measure” of division is another way to think about this operation, requesting the number of groups instead of the unit value. This meaning allows a more robust understanding of division. The use of models makes it easier for children to understand this meaning of division and allows them to verify how many times the divisor goes into the dividend. The common denominator algorithm is an interesting strategy to help children understand this situation and how the algorithm works because it represents the way children reason about this meaning of division.

## Research methodology

This is a pre-test-intervention-post-test study (carried out in 2017/18). Participants are four grade 5 students from a public school in Portugal, from a disadvantaged socioeconomic environment. They were selected because of their ease in oral communication and the fact that their performances on tasks were representative of the remaining class, as they had different performance levels. A pre-test, applied before a teaching experiment, involved different rational number concepts. Data analysis in this paper focuses on fraction addition and subtraction because these are contents already learned in previous years, so, children already had this knowledge. A post-test was applied after that teaching experiment (in the following lesson) and also involved different rational number concepts. However, the focus was on all four operations because multiplication and division operations were addressed during the teaching experiment since multiplication and division were new contents in this grade. The children solved the tests, individually, for 50 minutes, and then they were individually interviewed in order to explain their reasoning in each question. The interviews took place on the same day they solved tests and the following day.

The teaching experiment lasted six weeks, consisting of eighteen tasks (45 questions in total). The tasks involving all four operations were the last eleven ones. Addition, subtraction, multiplication and division, in problem solving situations, were addressed separately, in this specific order. These tasks involved 27 questions (13 questions involved the use of models). The teaching experiment followed an exploratory approach (Ponte & Quaresma, 2016), that is, tasks were presented to children and they worked individually, followed by a group discussion and synthesis. To solve the tasks, in an initial phase, the children were guided to use (circular or rectangular) models, provided in the task statements. The actions performed in the models were accompanied by the corresponding numerical sentence (numerical sentences changed as the models changed), so that the children understood the relationship between them. At a later stage, they could choose the solution strategy they preferred. The goal was to progress from the use of models to symbolic manipulation with understanding. On fraction addition, the children had two circular models to represent the quantities to be added. The denominators of fractions and the number of divisions in the models were equal, so, they just had to add the number of pieces. Later, the denominators of fractions and the number of divisions were different, so, they had to make divisions in the models because they could not add pieces with different sizes. Lastly, models had no division and the denominators of fractions were different so, the children had to make their own (equal) divisions to get the result. Subtraction of fractions followed the same procedure. Circular and rectangular models were used to promote understanding about these

operations, allowing to understand the need of equal denominators and the role of equivalent fractions.

On fraction multiplication (meaning “multiplicative relation”), a rectangular model was used. This model allowed the children to understand the role of different fractions when they are multiplied, for example, the role of operator and the change of the reference unit throughout the problem. When children are asked to solve  $\frac{1}{4} \times \frac{1}{2}$ , they find a half because is the initial quantity and then they find  $\frac{1}{4}$  of that part. Fraction division focused on the “measure” meaning and the common denominator algorithm was addressed. The rectangular model was effective in understanding this meaning of division and allowed to conceptually understand the algorithm. For example, “Luísa had  $2\frac{1}{2}$  meters of tape to put in hats and each hat takes  $\frac{1}{4}$  meters. In how many hats can she put tape?” The children represented the dividend in models by shading and then they could verify how many  $\frac{1}{4}$  are in  $2\frac{1}{2}$ .

For data analysis, the interviews were all audiotaped, transcribed and analysed in depth, as well as the children solution strategies in both tests. These two methods of data collection allowed us to analyse students’ rational number sense and operation sense according to the Lewis and Perry (2014) and Huinker (2002) categorizations, respectively, before and after the teaching experiment. These methods also allowed to ascertain how they evolved from pre- to post-test, and the role of the models in the development of children conceptual understanding.

## Results

### Pre-test

A fraction addition operation was involved in the question “Pedro, João and Gonçalo started running a path with 6 km in a park near their school but none of them got to the end. Pedro stopped after  $\frac{2}{6}$ , João run only  $\frac{2}{3}$  and Gonçalo  $\frac{1}{2}$ . What fraction represents the travelled distance by the three friends together?” Although most children had identified the implicit operation in the story problem, their performance was quite weak. They often added numerators and denominators independently, to get the result (strategy error), and presented the result  $\frac{5}{11}$ . When they were asked if it would be possible to add fractions with different denominators, they demonstrated not understand the question. Just one child, Ana, tried to use a rectangular model to support her reasoning, but it was not correctly built and she left the question unanswered. In a fraction subtraction question, “What is the difference between the boy who ran the longest distance and the boy who ran the shortest distance?”, again, the children subtracted numerators and denominators independently, to get the result (strategy error). Ana (Figure 1), again, tried to use rectangular models to reason about the question, however, these were not correctly built. She could not identify which operation should use.

"The difference is that the  $\frac{2}{6}$  smaller than the  $\frac{2}{3}$ "

**Figure 1: Ana's solution**

### Post-test

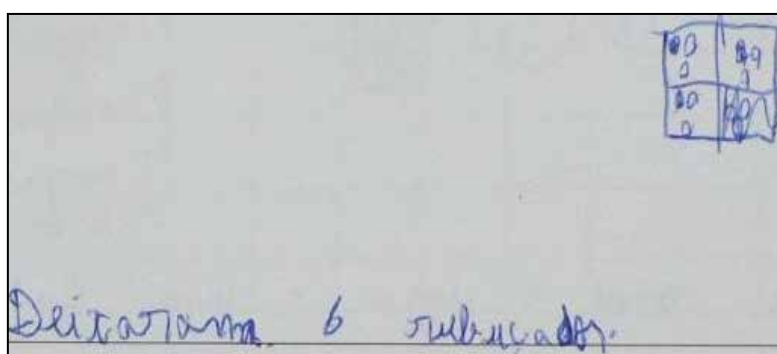

In the post-test, an addition question was posed to children "Clara, Maria and Gabriela started a path. Clara stopped to rest after  $\frac{2}{5}$  of the path, Maria stopped after  $\frac{4}{10}$  and Gabriela after  $\frac{3}{5}$ . What fraction represents the distance travelled by the three friends together until the moment they stopped to rest?" Most of children were successful both in identifying the operation and applied the correct algorithm. They demonstrated to understand the situation through the following statements "Here below not everything was the same size. I made it to be and I started here, with 10. [...] Then, I added all parts and left the bottom number which represents the size of the parts that are here!" (Ana), or "The whole course had five parts and all together made seven of these parts, seven bits of  $\frac{1}{5}$ !" (David). Just one child, Pedro, did not correctly add the numerators after obtaining equivalent fractions. He obtained the fraction  $\frac{10}{10}$  and said it was equal to one unit (Figure 2), making an execution error.

$$\frac{2}{10} + \frac{4}{10} + \frac{3}{10} = \frac{10}{10} = 1$$

$$\frac{4}{10} + \frac{4}{10} + \frac{6}{10} = \frac{14}{10}$$

**Figure 2: Pedro's solution (i)**

During the interview, Pedro identified and corrected his error and, after the new result  $\frac{14}{10}$ , he wrote that "together they did more than a whole path!" or "I think this is so because this boy made six. These only made four!" Fraction subtraction question was posed to children "In the end of the course, they decided to eat sweets from a bag with  $\frac{3}{4}$  kg. Together they ate  $\frac{1}{3}$  kg. How much did they leave in the bag?" Most children identified the correct operation and used it as solution strategy. They demonstrated understanding its meaning saying that "It's a subtraction operation! If they eat  $\frac{1}{3}$  [Kg] from the whole bag, we have to get that part [...] but we can't do three minus one because the parts are not equal and they have to be! We need equal fractions!" (David). Just one child, Pedro, tried to solve this question using a model (Figure 3).

**Figure 3: Pedro's solution (ii)**

He justified that “each friend ate  $\frac{1}{3}$ , so, since it is one of three, I counted one because it represents what they ate, and it is one of three because they were all the sweets they had!” Thus, he referred that six sweets were left, because it is the number of unshaded circles. Pedro considered the initial quantity as a continuous entity, as shown by the model that he tried to use, but considered the withdrawn part as a discrete entity. We do not know how much candy is in the bag but its weight. The child considered continuous and discrete quantities as measured with the same unit.

The division as measure was underlying in the following question: “Maria is making chocolate cakes for her sister’s birthday. She has  $2\frac{1}{4}$  kg of sugar and each recipe of chocolate cake takes  $\frac{1}{8}$  kg of this ingredient. How many chocolate cake recipes can she make?” Most of children had a good performance in this question. They identified the correct operation to be used in the problem, using the common denominator algorithm as solution strategy and demonstrated to understand its meaning “Here, I divided to see how many  $\frac{1}{8}$  fit in  $2\frac{1}{4}$  [...] she can make eighteen cakes!” (David). Only Ana did not identify the correct operation in this situation. She added both amounts and justified her choice saying that, “she wanted to make a cake with the whole amount, so, I made an addition!” This child also demonstrated difficulties regarding fraction simplification.

The following fraction multiplication question (multiplicative relation) was posed to children: “To decorate a cake, Maria put chocolate in  $\frac{5}{10}$  of the whole cake and coconut in  $\frac{2}{3}$  of the part that had chocolate. What fraction of the whole cake has both decorations?” Only David identified and used multiplication operation as solution strategy. He justified that “Maria put coconut over the chocolate part, so, I multiplied because it’s one part of another!  $\frac{2}{6}$  is the shaded parts twice!” When asked about the relationship between the operation and the model, he said “2 is the number of pieces and 6 is the size of the pieces. It’s just a little bit. [...] So, we have to multiply numerators and denominators!” The remaining children had a poor performance in this question. Nara subtracted both quantities, however, during the interview, she said that “ $\frac{5}{10}$  means there was half of the cake, but  $\frac{2}{3}$ ... well... it was in that part [ $\frac{5}{10}$ ]! I think it was not to subtract, it was to multiply!” So, she demonstrated some understanding about this meaning of multiplication. Pedro and Ana attempted to solve the problem using circular models but they demonstrated some difficulties in understanding this question. They also demonstrated misunderstandings related to divisions in the models. Horizontal and vertical divisions were made in the circular model. Pedro, after representing  $\frac{5}{10}$  on his model, said:

Pedro: Then it was  $\frac{2}{3}$  with coconut...

Researcher: Where could we shadow this amount ( $\frac{2}{3}$ )?

Pedro: Here [unshaded part]!

Researcher: Don't forget the coconut was in the chocolate part!

Pedro: Ah! I think I had to split this part [ $\frac{5}{10}$ ]... To put the coconut on top because it is "of"! Its  $\frac{2}{3}$  of  $\frac{5}{10}$ !

Although Pedro was unable to solve the problem correctly, during the interview he showed better understanding about the question as well as its relation with the fraction multiplication.

## Discussion and conclusion

The children who participated in this study had already learned fraction addition and subtraction in previous years. However, in the pre-test, their performance in questions involving these operations were very weak. They added and subtracted numerators and denominators to get the result, which constitutes a common mistake especially when denominators are different (Braithwaite et al., 2017). This solution strategy demonstrates lack of understanding that a fraction represents a single number. It also shows misunderstanding related to meaning of the denominator, since they added and subtracted fractions with different denominators, for example, on fraction addition ( $\frac{2}{6} + \frac{2}{3} + \frac{1}{2} = \frac{5}{11}$ ). These mistakes show that these children were unaware of the relationship between numerator and denominator, as in the study of Hansen et al. (2014), reflecting weaknesses in their rational number sense. Children's solutions also show that they did not conceptually understand these operations. Similar results were found in the study of Brown and Quinn (2006), which suggests that the poor performance is a consequence of gaps in the conceptual understanding of operations. These children did not understand the meaning of the operations and they have very limited knowledge of models to represent them, as shown in Figure 1. They also did not reason about the results obtained, which they did not understand to be inadequate in relation to the situation. Thus, their operation sense also had serious shortcomings. Their responses showed that they learned to solve operations applying rules (that they generalized in a wrong way from whole number operations) without understanding their meaning.

In the post-test, the children showed a better understanding of rational number addition and subtraction, compared to the pre-test. On these operations, they demonstrated to understand the use of equal denominators and what they represent, which was possible due to the use of models during the teaching experiment. The children know that it is not possible to add or subtract fractions with different denominators, as reported by Ana. That is, they understood that a fraction represents a number and not two independent numbers. This is an important understanding of student's rational number sense. Knowledge concerning to the meaning of the denominator, another component of rational number sense, was also observed, for example, "I kept the value down, which tells the size of the parts that are here!" (Ana). Justifications such as "The whole course had five parts and together they travelled seven of these parts. Seven bits of  $\frac{1}{5}$ !" (David), showed that these children know the fraction size and that a fraction can represent quantities larger than one. Regarding operation sense, they began to understand the different meanings of operations and to assign meaning to the symbols. The reasoning "Here I divided to see how many times this [ $\frac{1}{8}$ ] fits in  $2\frac{1}{4}$ " (David), was possible due to

the use of models. He showed that he conceptually understood this meaning of division. He reflected in the quantities and how they are related and also identified the appropriate operation. The children also demonstrated understanding the effect of operations on numbers when they analysed the reasonableness of results: “I think it is this way because this boy made six. These only made four!” (Pedro) or “ $\frac{2}{6}$  are the pieces shaded twice. [...] It’s just a little bit!” In general, these children demonstrated conceptual understanding of formal mathematical language. The division operation as measure and the multiplication operation as multiplicative relation, used in this teaching experiment, allowed a deep understanding of these operations. The children overcome the misconception that multiplication always increases and division always decreases. This was possible due to the use of models during the lessons, especially in an initial phase, as recommended by Behr and Post (1992). Therefore, we conclude that this teaching experiment based on the use of models, allowed the students to construct the algorithm from the models, and led them to develop some components of their rational number sense and operation sense. This study represents an alternative way of approaching rational number operations, promoting students’ conceptual understanding, which often does not occur.

*We have analyzed the written solutions to four arithmetic expressions comprising addition/subtraction and multiplication of 4 to 7 numbers from 235 students (112 in Greece and 123 in Sweden, 11-12 years old). Beside the order-of-operations and sequential (left-to-right) calculations, several students seem to calculate in an unconventional way by pairing numbers. That is, there are students who combine the numbers two-and-two, seemingly regardless of the operations, and then operate on these pairs when evaluating an expression. In our data, pairing seems to be as frequent as sequential calculations. We identify the characteristics of three qualitatively different ways of pairing. The different ways seem to be applied independent of the length of the numerical expression.*

*Keywords: Arithmetic, Order of operations, Precedence rules.*

### Introduction and theoretical background

In mathematics, we use conventions for arithmetic expressions to be unambiguously perceived. However, to design successful teaching on how to perceive and calculate arithmetic expressions, we need to first learn what ideas are present among the students. In this report, we present a study of those ideas and can show that evaluating numerical expressions by *number pairing* seems to be more significant in students' ideas than previously reported, and that it can emerge in different types.

Without the mathematical conventions like, e.g., the rules for the order of operations, there would be different ways in which numerical expressions can be evaluated. Accordingly, it has been shown that students who have not yet internalized these conventions use different ways in their calculations (Blando, Kelly, Schneider, & Sleeman, 1989; Glidden, 2008; Gunnarsson, 2016; Headlam, 2013; Libenberg, Linchevski, Sasman, & Olivier, 1999). This might result in errors such as exchanging a number with another number, exchanging an operation with another operation, or, simply, making computational errors. Blando et al. (1989) call these errors “careless” and “substitution errors”. But, there are also errors that are more related to the structure of the expression. Linchevski and Livneh (1999) showed that students, while being inconsistent in the computational aspects, can be very consistent in these structural errors.

There has been substantial research devoted to students' handling of arithmetic expressions from perception and cognitive points of view. It has been shown in several studies that the mere proximity of two numbers can result in that these are calculated first, regardless of the operator in between (Gómez et al., 2014; Jiang, Cooper, & Alibali, 2014; Landy & Goldstone, 2010; Rivera & Garrigan, 2016). More generally, it has been shown that the visual appearance of the mathematical notation can

cause students to disregard mathematical rules (Kirshner & Awtry, 2004). A particular effect of the visual appearance was pointed out by Linchevski and Livneh (1999). They showed that some students can dissociate two parts of an expression, often induced by an operation sign (typically minus), like, e.g., when  $50 - 10 + 10 + 10$  is evaluated as  $50 - (10 + 10 + 10)$ .

In addition, there are several educational research studies showing that students can perceive the structure of numerical expressions in different ways. Kieran (1979) has shown that the rule ‘to be calculated first’ can be perceived as ‘to be put to the left’. Conversely, it appears as if students perceive what is read first (i.e., to the left, if that is the reading order) should be calculated first. At least, several studies describe that students calculate expressions sequentially from left to right (Blando et al., 1989; Headlam, 2013; Liebenberg et al., 1999).

There have also been brief reports that some students pair up numbers when processing arithmetic expressions (Gunnarsson, 2016; Liebenberg et al., 1999; de Villiers, 2015). While de Villiers (2015) mentions it as one type of erroneous calculation (without further discussion) where order of operations should have been used, Liebenberg et al. (1999) describe students who break up expressions in parts. As example, they find students calculating  $4 + 5 + 5 \times 2 \times 6 + 4$  by grouping numbers in pairs and then processing these pairs as  $4 + 5 + 5 \times 2 \times 6 + 4 \rightarrow (4 + 5) + (5 \times 2) \times (6 + 4) = 9 + 10 \times 10$ . However, we have noted that, apart from the example above, the expressions used in most previous studies are quite short and contain two (or maximum three) different operators. Typically, the numerical expressions are of the form  $a + b \times c$ , occasionally  $a + b \times c + d$ . The exception found in the study of Liebenberg et al. (1999) with longer expressions (up to seven numbers, thus six operations), may have enabled them to observe a breaking-up-into-parts effect. Hence, in this study we would like to explore this effect further by using long expressions.

Therefore, with the idea that teaching arithmetic conventions must take its point of departure in students’ *actual* ideas on how calculations should be completed, the aim of this study is to further explore students’ idea of pairing when calculating arithmetic expressions. In short, we would like to find what forms of pairing mechanism occur when students evaluate arithmetic expression. This study is part of a larger project to design teaching to improve students’ arithmetic computational competence.

## Method

This study engaged 112 Greek students and 123 Swedish students, 11-12 years old (grade 5 in Sweden, grade 6 in Greece). In total students from nine different schools (five Greek schools and four Swedish schools) were included. The schools were chosen from mixed background to represent all achievement levels. According to the curriculum and the teaching traditions in the two countries, the students should have been taught the rules for the order of operations prior to the study. The students were given a written test and sufficient time (no time limit) to answer it. The test comprised several tasks, all typeset with the equation editor of a conventional word-processor, to avoid unintended influence from the visual appearances of the expressions. The test was aimed to test students’ understanding of arithmetic conventions. Four of the tasks were specifically designed to explore students understanding of the order of operations by expressions of different lengths. These tasks are shown in Figure 1.

- a)  $9 - 2 \cdot 3 - 2$
- b)  $5 \cdot 4 \cdot 3 + 6 \cdot 2 + 1$
- c)  $2 \cdot 3 \cdot 5 - 4 \cdot 2 + 6$
- d)  $5 \cdot 3 + 2 \cdot 4 \cdot 5 + 3 \cdot 2$

**Figure 1: The four different numerical expressions used in this study (in the Greek version of the test, the expressions were numbered a, b, g d, respectively)**

The data, comprising the students' written answers to the test – their written evaluations of the expressions in Figure 1 – was subject to a qualitative content analysis as described, e.g., by Leedy and Ormrod (2015). In the analysis, the correctness of the answers was not considered, instead the underlying mathematical idea were in focus for each solution of a numerical expression. In the first step we were looking for well-known ideas, like following the order of operations, sequential calculations (left-to-right), detachment (from Linchevski & Livneh, 1999), and signs of pairing. Hence, data, for each task separately, was first divided into different groups depending on what ideas seemed to have governed the students while solving the task. In some cases, the students used different ways throughout the process of evaluating a single expression. Then, the different groups were combined based on the main underlying mathematical idea the solutions seemed to be based on. This resulted in a few different categories of foundational mathematical ideas.

In the second round of analysis, we focused only on the solutions that have a character of number pairing. Here, no fixed categories were defined prior to the categorization. The categories of ways of pairing numbers emerged from the data in the analysis process. Data were examined separately by the two researchers and discussed to resolve discrepancies. We did not see any significant difference in the data of Swedish and Greek students. Hence, in this study we have not separated the data of the groups. The numbers below are the combined total numbers for the entire data set.

## Results and discussion

First, we note that only a minor part of the errors in the students' solutions is due to arithmetic errors. We do find the same type of errors as reported in previous studies (like, e.g., by Headlam, 2013), such as changing operators (e.g., multiplication is replaced by addition), changing numbers and simple arithmetic errors. But, the major part of the operations explicitly described in the data is correctly calculated. Even in the cases of changing numbers or simple arithmetic errors we find that it is easy to trace back the intention of the operation – the actual underlying mathematical idea. This is in agreement with the findings of Linchevski and Livneh (1999). Hence, we can conclude that to a large extent the data (the result of the evaluated numerical expressions) originate from students' ideas on how numerical expressions should be evaluated.

Second, we find three main 'ideas' that seem to influence students' solutions: *order of operations*, *sequential calculation* and *pairing*. In our data, we find students who follow the convention and use the (correct) order of operations, and we find students who use a sequential calculation (left-to-right), see Figure 2. As an example, a student that would have calculated the second expression (b in Figure

1) according to  $(((((5 \times 4) \times 3) + 6) \times 2) + 1)$  is considered to have followed a left-to-right, sequential, strategy. This does not mean that the specific student is always following that strategy, but at least did so in this specific expression.

**Figure 2: Strategies used to evaluate the different numerical expressions**

Some students indeed are consistent in their calculations, in the sense that they calculate all four expressions in the same way, or with the same apparent idea behind the calculation. Most of the students who are consistent have used the order of operations. But there are also students who consistently have used a sequential calculation on all four expressions. For instance, two students consistently used one specific type of pairing (which we denote ‘entangled pairing’ further down in the report). In total, we find that the order of operations was used in 47% of all expressions, sequential calculations in 12% of the expressions, and that pairing seemed to be the main idea in 16% of the expressions in the students’ solutions.

Typically, students’ difficulties with numerical expressions from other aspects of precedence, like e.g. detachment (as from Linchevski & Livneh, 1999) or visual salience (Kirshner & Awtry, 2004), are included in the category named “other”. In task c,  $2 \times 3 \times 5 - 4 \times 2 + 6$ , we note that many students evaluate the expression as  $(2 \times 3 \times 5) - (4 \times 2 + 6)$ . We believe this is directly related to the detachment-effect reported by Linchevski and Livneh (1999). However, the number of solutions that seem to be based on detachment is also the reason why the “other” category is relatively much more frequent for the (c) expression, as shown in Figure 2.

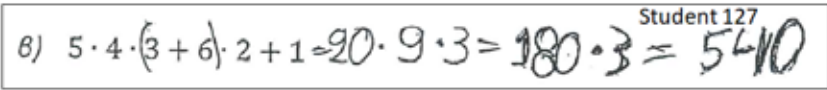

Additionally, as will be shown further down (Fig 4 c), there are examples in the data where students have used a pairing strategy in the first term ( $2 \times 3 \times 5$ ), but then, seem influenced by detachment and used that in the continuation of the calculation. Hence, it could be a combined pairing and detachment effect. In Figure 2, these examples have been counted as “pairing”.

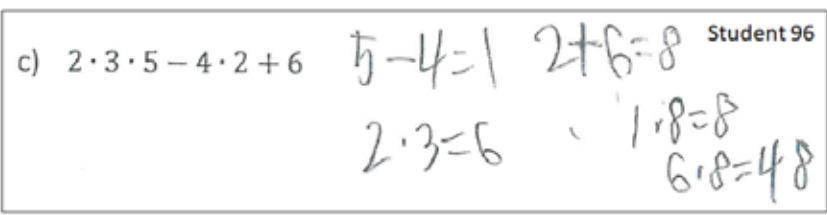

Particularly, in the data from the first task we found several students’ responses that could be described as due to pairing. Although, we cannot exclude the possibility that there are other ideas that have influenced the students’ behavior and made them evaluate the expression as  $(9 - 2) \times (3 - 2)$ .

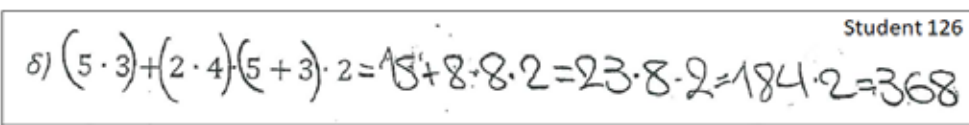

When we explored the mathematical ideas, we found that the pairing mechanism can come in qualitatively different forms.

### Pairing overall

The first type, and perhaps the easiest to separate from the others, is a mechanism of pairing throughout the entire expression. It is a pairing that goes overall. This occurs when the pairs span across different operations. It seems as when one pair of numbers has been “used”, the attention is directed to the next pair. No consideration is taken to the precedence of operations. Instead, it seems that numbers are the focus of the attention. Figure 3 shows three different examples where students have used pairing overall to evaluate the expressions. The brackets were made spontaneously by the students.

(a)  Student 127

(b)  Student 96

(c)  Student 126

**Figure 3: Three examples of students’ answers where pairs have been formed across the entire expression without consideration of what operation should precede the other (“pairing overall”)**

This type was particularly evident when there was an even number of numbers in the expression, as in the expressions a – c (cf. Figure 1). We also find examples where students seem to have started with the pairing approach in the expression d with odd number of numbers. One such example is shown in Figure 3(c). Here, the student has paired all the numbers, except the last, which could not form a pair in the same way. However, we also find examples in the data of students’ solutions that indicate that single numbers are explicitly included in the later step of the calculation, as, e.g., the student who explicitly writes  $(5 \times 3) + (2 \times 4) \times (5 + 3) \times 2 = (15 + 8) \times (8 \times 2) = 23 \times 16 = 368$ , with brackets inserted by the student. Hence, the student has indicated pairing as a mechanism that is applied overall the entire solution.

### Pairing within terms

Another type of pairing-mechanism observed in the data is pairs formed within the terms, that is, not across different operations. To some extent, this preserves the order of operations, not breaking the rule that multiplication should precede addition/subtraction. In that respect, this category appears to be some intertwining of the order of operations and the pairing mechanism. Figure 4 shows three examples of pairing within terms that we attribute to this category.

(a) Student 6  
 d)  $5 \cdot 3 + 2 \cdot 4 \cdot 5 + 3 \cdot 2$   
 $15 + 8 + 6 = 29$

(b) Student 31  
 d)  $5 \cdot 3 + 2 \cdot 4 \cdot 5 + 3 \cdot 2$   
 $5 \cdot 3 = 15 + 2 \cdot 4 = 23 + 4 \cdot 5 = 20 + 3 \cdot 2 = 6 = 26$

(c) Student 127  
 v)  $2 \cdot 3 \cdot 5 - 4 \cdot 2 + 6$   
 $6 + 15 = 21 - 8 + 6$   
 $21 - 14 = 7$   
 $2 \cdot 3 = 6$   
 $3 \cdot 5 = 15$   
 $4 \cdot 2 = 8$   
 $6 + 15 = 21$   
 $8 + 6 = 14$   
 $21 - 14 = 7$

**Figure 4: Examples of student answers indicating pairing considered within terms**

Pairing within terms is particularly evident when three factors are to be multiplied. Then many students seem to invent some pair where one number is disregarded, as in Figure 4(a), or added/multiplied in the end, similar to the pairing mechanism reported by Liebenberg et al. (1999). However, some students used the numbers twice, as in Figure 4(b, c). Hence, in the latter two examples, there is a double counting of one of the numbers (the centre factor of the term). In Figure 4(b), the number “4” is used both in  $2 \times 4$  and in  $4 \times 5$ , separately. In Figure 4(c), the number “3” is double counted. To us, it appears as if this type of pairing can be such a strong idea in the students’ minds that they form pairs regardless if the numbers are used more than once, as in Figure 4(b, c).

Unfortunately, our test did not include any term with four factors. We did not foresee this alternative. If such example would be used, we hypothesize that one could find students who paired the factors within that term without the invention of double-counting.

### Entangled pairing

In our data, we find students who are operating with *each* adjacent pairs of numbers. So far, we have only seen two students do like this, but, on the other hand, they are very consistent in this strategy. In this type of pairing mechanism, the operations are subordinate. No consideration is taken to what operations there are in the expression. In the end, the pairs are added. Examples of this type of idea of how numbers should be paired is shown in Figure 5.

Hence, compared to the “pairing overall”-strategy, this type of pairing disregards the operations even more, as pairing is conducted across all operations. In addition, similarly to the “pairing within terms”-type of strategy, double counting of numbers does not seem to be a problem for these students. In this “entangled”-strategy all numbers (except the first and last) are operated with twice.

(a) c)  $2 \cdot 3 \cdot 5 - 4 \cdot 2 + 6$  Student 92

$$\begin{array}{l} 2 \cdot 3 = 6 \\ 3 \cdot 5 = 15 \\ 5 - 4 = 1 \\ 4 \cdot 2 = 8 \\ 2 + 6 = 8 \end{array} \quad 6 + 15 + 1 + 8 + 8 = 38$$

(b) b)  $5 \cdot 4 \cdot 3 + 6 \cdot 2 + 1$  Student 113

$$\begin{array}{l} 5 \cdot 4 = 20 \\ 4 \cdot 3 = 12 \\ 3 + 6 = 9 \\ 6 \cdot 2 = 12 \\ 2 + 1 = 3 \end{array} \quad \begin{array}{r} 20 \\ 12 \\ 09 \\ + 12 \\ \hline 56 \end{array}$$

(c) a)  $9 - 2 \cdot 3 - 2$  Student 113

$$9 - 2 = 7 \quad 2 \cdot 3 = 6 \quad 3 - 2 = 1 = 14$$

**Figure 5: Three examples of where each adjacent pair of numbers are evaluated in an entangled way. In the end, the results of each operation are added**

## Concluding remarks

Apart from Liebenberg et al. (1999) and a short example by de Villiers (2015), previous research on students' solutions to numerical expressions have focused on arithmetic errors and on sequential (left-to-right) strategies. However, our data suggest that pairing is a much more abundant idea in students' evaluation of numerical expressions than previously shown, at least for longer expressions. We find that 16%, as an average over all students' solutions, are solved with pairing being the underlying mathematical idea. Hence, it seems that the idea of pairing could be as frequent as the idea of sequential calculations.

Moreover, we find three qualitatively different types of pairing ideas. We find ways of pairing bound within terms, and ways of pairing applied in the expressions overall. In addition, we have shown that expressions with an odd number of numbers in the terms can trigger an apparent adaption of the pairing to the order of operations – the double counting of numbers within terms. The origin of pairing seems a deeply rooted idea. We find that despite being taught the order of operations, a considerable amount of the students apply the idea of pairing nevertheless. In addition, as previous research has shown, the mere proximity of numbers can trigger these to be calculated first (Gómez, et al., 2014; Jiang, Cooper & Alibali, 2014; Landy & Goldstone, 2010). Hence, pairing could be closely related to deep cognitive processes. Nonetheless, pairing is a persistent and strong idea and needs to be considered and handled when designing teaching on how to perceive and calculate arithmetic expressions.

*In this paper, we explore the use of manipulatives in the classroom to solve an arithmetical task via the concept of affordance. Manipulatives are part of the elementary class culture in different countries, and even if some studies question the efficacy of manipulatives, there seems to have a consensus around the necessity of using it. However, little is known about how mathematics is done with manipulatives. The analysis of pupils' actions helps put to light different affordances of two manipulatives: base-ten blocks and abacus, in a classroom setting where the operations of addition and subtraction are explored with pupils.*

*Keywords: Elementary School Mathematics, Arithmetic, Manipulatives, Affordance.*

## Introduction

Research and mathematics education communities at elementary level agree that using manipulatives promote pupil learning (Moyer, 2001). Some researchers see the use of manipulatives as a less abstract way of reasoning than with formal mathematical symbols (Lett, 2007, Özgün-Koca, & Edwards, 2011). According to Domino (2010), Piaget (1964), Bruner (1977) and Diènes' (1973) theories support most of the work on the uses of manipulatives. These theories of learning are based on the idea that manipulatives are necessary for the development of mental images that pupils may eventually summon in situations without manipulatives. In a way, the need, more over the benefit, of manipulatives seems to be taken for granted by many researchers. It leads to many other assumptions such as “doing math with manipulative is a concrete version of doing math” or “manipulatives should support the construct of mathematical objects”. In our research about manipulatives uses, we challenge these assertions. Doing math with or without manipulatives aren't the same activity. Based on this premise, we developed a project called *MathéRéaliser*, in which, we want to understand what it is to do mathematics with manipulatives in a school setting.

Indeed, research shows that the context used to do mathematics structures mathematical activities (e.g. Lave, 1988; Nunès, Schliemann, & Carraher, 1993). These studies, mainly conducted in nonacademic contexts, highlight the situated aspect of mathematical knowledge (Noss, 2002). For example, Pozzi, Noss, and Hoyles (1998) mention that in the professional context (nursing, banking, engineering, etc.), the tools and objects available to actors shape their mathematical activity. In other words, mathematical reasoning is developed in coordination with the “noise” of the situations in which it takes place (Noss, 2002). In this perspective, doing mathematics with manipulatives could be something very different from a concrete version of doing mathematics without them (Corriveau & Jeannotte, 2015). Kosko and Wilkins (2010) were able to show that the use of manipulatives colors the mathematical discourse developed with it. This aligns with a sociocultural point of view where mathematical learning is shaped by the historical culture of the community where the learning takes place and by the learners' culture and experiences themselves (Sfard, 2008). Manipulatives when available during a mathematical activity bear a certain culture and shape the learner experiences.

In this paper, we aim to better understand what it is doing mathematics with manipulative in a calculation task at the elementary level. To do so, the concept of *affordance* is convoked to identify the potentialities of manipulatives in developing number sense through arithmetical operations.

## Conceptual Clarification

### Manipulatives and arithmetic

In the context of arithmetic, a plethora of manipulatives are available for elementary school. Poirier (2001) classified manipulatives used for developing number sense in three categories. The first category refers to manipulatives where units are visible and accessible. For example, if we use 3 free tokens and four transparent bags of 10 tokens to represent the number 43, the tens, represented by bags that contain 10 tokens, can be “broken” into 10 units (by ungrouping a bag). The second category refers to manipulatives where units are still visible but not accessible (not breakable). Base-ten blocks are a good example of this kind of manipulatives: we have to physically exchange one long for 10 units because the longs are usually unbreakable. The third category refers to symbolic manipulatives, where units are not visible in tens, nor in hundreds, etc. (e.g. abacus, money).

Furthermore, manipulatives can become a support or a constraint for the pupils’ mathematical activity. On the one hand, it can support pupils reasoning. For example, base-ten blocks may help to explain why an algorithm works. On the other hand, it can be considered as a constraint if we impose a certain manipulative to solve a task (Jeannotte & Corriveau, 2015). By imposing manipulatives, the task may gain in complexity.

### Affordance

Affordances is linked to interactions between an individual and the environment. Environmental characteristics (classroom setting, properties of the manipulatives, etc.) cannot be detached from pupils (their perceptions, their experiences, etc.). They form an inseparable pair. According to Clot and Béguin (2004), affordances are characterized, on the one hand, by the fact that objects are significant, the user’s experience relates on this signification. On the other hand, by its praxis value: “an object is immediately associated with a signification for action” (p. 53). Also, “[w]hether or not the affordance is perceived or attended to will change as the need of the observer changes, but being invariant, it is always there to be perceived” (Gibson 1977, in Brown et al., 2004, p. 120). So, depending on the needs, the uses and the properties exploited of manipulatives may vary. e.g., the base-ten blocks have been designed to help pupils perceived the structure of our numeration system. As an adult, we can see these properties and exploit them to expose some mathematical patterns. “We are seeing concepts that we already understand” (Ball, 1992, p. 5). What pupils see is also related to what they know. Since manipulatives aren’t solely used by pupils, but also by teachers, what teachers do with manipulatives is also inherently part of pupils’ experiences. Thereby, the concept of affordance can not only offer an insight on learning processes but also on teaching processes.

### Methodology

For the aims of this paper, we focus only on a part of the data collected from the *MathéRéaliser* Project. We conducted a collaborative research that solicits the participation of teachers. As Corriveau and Bednarz (2016) uphold:

[t]his perspective leads us to re-think [...] the relations between the researcher, as being the expert, and the teacher, as being the novice or the user, as frequently conceived in research in mathematics education [...] [T]he teacher is assumed to be reflective and knowledgeable (pp. 1–2).

In collaborative research, the concept of “double relevance” (Desgagné, 1998) is fundamental and refers to the construct of argumentation relevant to both communities, research and practice. A “double relevance” underlines every choice made in the collaborative work. For example, if a task is chosen to be experimented with pupils, it means that it makes sense for teachers and researches according to their respective sensible arguments.

### Description of the Task

The task we experimented is inspired by Cobb (1994). Three similar questions to the following were answered by the pupils. The task was presented orally.

“Represent 1009 with your manipulative and then, I’ll ask you a question. [Wait for the pupil to represent 1009 with base-ten blocks or homemade abacus.] I had a number, I subtracted 453. [Write it on the blackboard.] I now have 1009. How much did I have at the beginning?”

### Description of the co-constructed Lesson

The task was experimented with two grade 3 classes (9–10 years old) of 19 and 18 pupils. They already had learned an algorithm using drawing of base-ten blocks. They were not familiar with the abacus. Pupils worked by two using either base-ten blocks or homemade abacus. After teamwork, a whole class discussion took place about 1) the different answers obtained and 2) the strategies used to resolve the task. Table 1 presents the double-relevance of this task and its experimentation.

Plausible use of the task for teachers	Relevance of the task for researchers
<p>Task congruent with curriculum expectations (choice of operation, adding and subtracting 3–4 digit numbers).</p> <p>Curriculum fosters the use of manipulatives.</p> <p>Opportunity to reflect on the use of manipulative by their pupils.</p> <p>Manipulatives seen as a support to solve the task.</p>	<p>Task that could lead to mathematical argumentation (see Cobb, 1994).</p> <p>Manipulatives seen as a constraint in this particular task. Since pupils used to operate by drawing base-ten blocks, asking them to operate with real base-ten block or abacus is unfamiliar to them. This introduction of foreign elements may serve as a breaching experiment (Garfinkel, 1967) to put to light usual ways of doing.</p>

**Table 1. Double-relevance of the task**

### Characteristics of the manipulatives

To perform the task, two manipulatives were available. Either pupils worked with base-ten blocks or with a homemade abacus (see Figure 1).

**Figure 1: Base-ten blocks and homemade abacus**

As each manipulative has his own properties, we can conjecture that each manipulative, in relation with pupils and the whole class generates different affordances in the classroom (see Table 2).

Base-ten blocks	Homemade abacus
<ul style="list-style-type: none"> <li>• Proportional model;</li> <li>• Units visible but not accessible (not breakable);</li> <li>• The value does not depend on the arrangement of the manipulatives;</li> <li>• The same manipulative “object” can only take one value.</li> </ul>	<ul style="list-style-type: none"> <li>• Non-proportional model;</li> <li>• Symbolic manipulatives (units not visible nor breakable);</li> <li>• The value depends on the arrangement of the manipulatives;</li> <li>• The same manipulative “object” can change value.</li> </ul>

**Table 2: Characteristics of each manipulatives**

## Analysis and Results

Data analysis has involved three stages. First, to explore the affordance in the use of manipulatives by the pupils, we watched the videos multiple times (Powell, Francisco, & Maher, 2003). Secondly, we extracted every pupil’s actions we observed. Every action was then described in association with the characteristics of the manipulatives. Finally, we grouped actions related to three different mathematical activities involved with the task and the classroom setting (the use of manipulatives).

One may think that the main difficulties of this task is to choose the good operation and we are aware that using manipulatives do not help the pupils with this choice. However, in this experimentation, it did not appear as an issue. Moreover, the use of base-ten blocks and the abacus helped the teacher to see at a glance who chose the right operation. Actually, most errors arose from counting strategies. Table 3 presents the analysis of pupils’ actions in relation to the characteristics of each manipulatives. We grouped the different actions according to the mathematical activity involved: representing, operating and interpreting.

When representing numbers, most pupils were able to exploit the manipulatives. For base-ten blocks, they associated the right blocks (units, longs, flats, etc.) to each position. Nevertheless, few of them disposed the blocks in a way they can “recognize” rapidly the number in front of them. For the abacus, some pupils struggle with choosing the right column when representing the second term of the operation. Furthermore, more pupils relied on visual patterning, thus helping them later interpreting the number.

When operating, other than counting mistakes, difficulties arose from converting strategies. Even if pupils referred to changing 10 ones for 1 ten (for example) in their discourse, we observed more than once pupils changing eleven units for 1 long. When using the abacus, to convert a ten into ones, they move one chip from the tens column to the ones column AND add ten new chips in the ones column.

One pupil worked with the abacus inconsistently: he represented one thousand nine from right to left, he managed the calculations, but when interpreting the result, he read the number from left to right. This gave the opportunity to the teacher to talk about communication in mathematics.

Maths Activities		Base-ten blocks characteristics and actions observed	Homemade abacus characteristics and actions observed
<b>Representing</b>		<ul style="list-style-type: none"> <li>Counting the blocks needed for each “place value”: cubes, flats, longs, units.</li> <li>Disposing the blocks so the highest value is far left and the other ones on its right (no empty spaces for zero values).</li> <li>Piling the blocks (e.g. 9 units on a cube represent 1009).</li> <li>Using the space to differentiate positions: e.g. ten flats (instead of a cube), then the other flats, etc.</li> </ul>	<ul style="list-style-type: none"> <li>Counting correctly or not the chips and disposing them in the right or wrong column.</li> <li>Disposing the chips in the same order we read numbers. Only one pupil disposed it in the opposite order.</li> <li>In each column, using or not visual pattern disposition when placing chips in each column (e.g. 3 rows of 3 to represent 9).</li> </ul>

**Table 3: Actions made by pupils in relation to the characteristics of each manipulatives**

## Discussion

With the table presented above, we have tried to better understand what it means to do mathematics with manipulatives when developing calculation abilities at the elementary level. By examining the characteristics associated with action, we put to light different affordances. Even if some affordances are shared, some others are specific to only one of the manipulatives. In this section, we discuss further one idea that emerged from our analysis. This idea allows to put to light some differences in pupils' actions that are related to manipulatives characteristics. Also, speaking of affordance is speaking of seeing what could be observed but is not. Both, what is observed and what is not can inform of the manipulative practices in the classroom.

## Counting Over and Over

In the first grades of the elementary, children are used to count to solve problems. The teachers then try to enrich their number sense and to complexify their counting strategies (with number facts, adding to ten, visual pattern disposition, etc.). However, for most pupils, the counting aspect brought by the use of manipulatives clearly took over other calculation abilities and some control was lost in their mathematical activities. When using base-ten blocks, most pupils counted the blocks even for small quantities. For example, when adding three to nine units, we observed pupils counting three units, then counting nine units, putting them together, counting the total, obtaining twelve units, counting ten units to trade them for one long. This may seem trivial insofar as the counting strategy is achieved with success; it does not mean there is a lack of control. Nevertheless, we have observed several errors that arise from this way of doing even if pupils know their numerical facts. For example, a pupil took eight units, but counted nine. Thus, when he added three units and counted the total, he obtained eleven units (and not twelve). He continued his calculations with eleven units and obtained a very close answer, but the wrong one. However, we observed him mentioned to another pupil, further in the video, that nine and three give twelve.

Also, even if pupils are able to group by tens and ungroup, they do not rely on this property yet visible in the base-ten blocks. They rather count. For example, again, to add three to nine units, pupils could have taken one long and kept only two units directly, but they count as we described it above. However, while we observed the same way of doing with an abacus, we also saw more complex strategies. For example, when adding nine and three, a pupil added to ten. However, he was not able to coordinate his action with the abacus and the mental operation.

In short, the main action observed during the task was counting. Counting over and over seemed to divide the global task into counting sub-tasks. After each sub-task, most pupils had to think again about what they were doing sinking into a vicious cycle: thinking about the global task made them forget about the counting they did and counting again made them forget about the global task. With manipulatives, it is difficult, for pupils, to keep track of what is done and what has to be done.

Does this mean that using manipulatives only suggest this way of doing things for those pupils? There is more than one answer to that question. On the one hand, it does because even if it is not necessary all the time, there is always some counting to do. Using manipulatives to add or subtract involve counting physical objects. The physical aspect of manipulatives asks for this way of doing. However, counting is not always the most efficient strategy to use here. Of course, the environment, i.e. the usual class activities, certainly contributes to reinforcing this strategy. On the other hand, as mentioned years ago by researchers (e.g. Bednarz & Janvier, 1982), the tasks performed with the help of manipulatives relate essentially to number representation and “translation”, a work on the number representation in our numeration system. As pupils presumably used base-ten blocks to count in the first place and less to operate coordinating other strategies as well, we can think that the praxis of this manipulative associate it immediately to counting. While we tend to believe that the use of manipulatives supports mathematical reasoning, in this case, we rather observed that pupils refer to more basic reasoning than they could have used.

In fact, we observed more advanced strategies with the less familiar abacus than with base-ten blocks used since first grade. For McNeil & Jarvin (2007), working with familiar manipulatives might drive

the attention of pupils in the wrong. In our case, it is not a wrong direction, but it seems to lead to more basic strategies and to some lack of control. We could conjecture that using a less familiar manipulative does not drive pupils to usual uses. Indeed, in terms of affordance, the meaning constructed in the interactions between the abacus and pupil is less constraint by the experiences. It gives leeway to integrate skills in a new situation (e.g. visual patterning, use of number facts, etc.).

## Conclusion

Carbonneau, Marley & Selig (2013) said that “specific instructional variables either suppress or increase the efficacy of manipulatives suggests that simply incorporating manipulatives into mathematics instruction may not be enough to increase student achievement in mathematics” (p. 397). Looking at affordance help understand that not only the instructional setting, but the culture of the class and pupils’ experiences also play a role when talking about learning with manipulatives. As manipulatives used to solve this task are by definition physical object, counting can’t be detached from it. Doing math with manipulatives was not the same activity in this particular case. We observed that pupils rely mostly on what they used to do with a specific kind of manipulatives rather than what they used to do without them. The question is then how to help the pupils rely on other characteristics of these manipulatives? Drijvers (2003) stressed that the affordance that could be realized in the classroom rely not only on the tool itself, but rather on the exploitation of these affordances the educational context and the teacher drive that. As base-ten blocks are often used in grades 1 and 2 when pupils don’t master the table facts, the teachers’ role is here quite important. They have to help pupils go beyond counting and perceived the power of organizing manipulatives by exploiting the space to “see” table fact and not solely rely on it to count and to represent numbers. To do so, teachers could organize the educational context around manipulatives to provide wider learning opportunities for the pupils.

*Keywords: algebraic structure, the extension of number sets, the process of understanding*

## Introduction

Skemp (1976) made a distinction between “instrumental understanding” and “relational understanding”. This paper focuses on understanding in mathematics education and aims to construct models for grasping the condition and process of mathematical understanding of students. Understanding models can be roughly divided into two types: the condition model and the process model. First, the condition model describes the condition that students already understand. Second, the process model describes the process of students’ understanding. This process model has included transcendent recursion that Pirie and Kieren (1989) showed. Pirie and Kieren (1989) asserted that “what is needed is an incisive way of viewing the whole process of gaining understanding” (p.7), and argued the necessity of the process model. As stated above, it is important to analyze the process of understanding, and it is necessary to clarify the object. In our project we focus on the algebraic structure because we think that understanding the algebraic structure is a crucial prerequisite for students’ systematic understanding of mathematics, and helps them learning mathematics more deeply. The aim of this study is to clarify the process of understanding the algebraic structure of learners. This study targets student from seventh grade to twelfth grade and focuses on the extension of number sets in school mathematics.

## Method

This paper reflects a theoretical study. One of the main claim is to construct the theoretical framework for the empirical research (see Figure 1). Therefore, we reviewed and interpreted literature about the algebraic structure that Bourbaki (1943/1974) showed, and the dual nature of mathematical conceptions that Sfard (1991) showed. The mathematical structure is compounded of a set, an operation between elements and an axiom of structure. Bourbaki (1943/1974) defined the algebraic structure by the laws of composition and laws of action. Assuming that a set is  $S$ , an operation is  $*$ , an axiom of structure is  $P$ , and these three elements are paired,  $(S, *, P)$  indicates the structure. Sfard (1991) argued that mathematical conceptions can be grasped in two different methods. One of the two different methods is to think structurally as object and the other is to grasp operationally as process. She grasped the duality of mathematical conceptions and claimed that mathematical conceptions are developed by repeating the

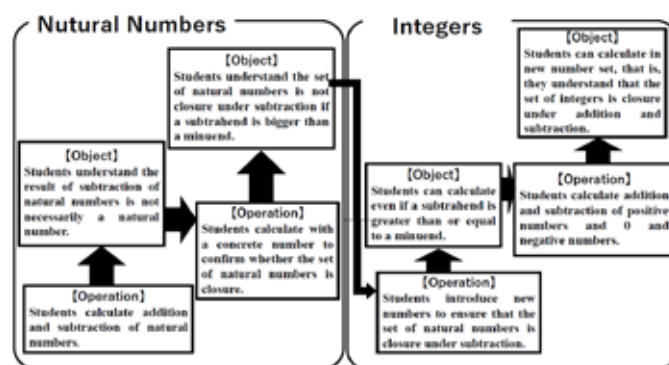

**Figure 1: The theoretical framework**

transition from operational conceptions to structural conceptions. Then, we focus on closure under an operation in the algebraic structure and clarify the process of understanding the algebraic structure.

## Results and Discussion

The generalized model of conception formation by Sfard (1991) shows that transition from operational conceptions to structural conceptions is repeated. We clarify the process of understanding the algebraic structure in the relation between sets focusing on the extension of number sets. So, we take an extension from the set of natural numbers to the set of integers and we focus on the general

model of conception formation that Sfard (1991) showed. In the process of understanding the algebraic structure with the extension of the set of natural numbers to the set of integers four stages are included (see Figure 2). At each stage the students transfer from the operational conception to the structural conception. In the first stage students add and subtract with natural numbers, and then they understand the result of subtraction of natural numbers is not necessarily a natural number. In the second stage they calculate with a concrete number to confirm whether the set of natural numbers is closure, thereby understanding that the set of natural numbers is not closure under subtraction if a subtrahend is bigger than a minuend. In the third stage they introduce new numbers to ensure that the set of natural numbers is closure under subtraction, and then they can calculate even if a subtrahend is bigger than or equals a minuend. In the fourth stage they do addition and subtraction with positive numbers, zero and negative numbers, and then, they can calculate in new number set. We show there are four stages in the process of understanding the algebraic structure with the extension the set of natural numbers to the set of integers. In this process of understanding the algebraic structure, the recognition that the set is closure under an operation is crucial. The second stage is the stage of understanding whether the set of natural numbers is closure under an operation, and the third stage is the stage of introducing a new number from viewpoint that the set is closure under an operation.

**Figure 2: The extension from the sets of natural numbers to the set of integers**

model of conception formation that Sfard (1991) showed. In the process of understanding the algebraic structure with the extension of the set of natural numbers to the set of integers four stages are included (see Figure 2). At each stage the students transfer from the operational conception to the structural conception. In the first stage students add and subtract with natural numbers, and then they understand the result of subtraction of natural numbers is not necessarily a natural number. In the second stage they calculate with a concrete number to confirm whether the set of natural numbers is closure, thereby understanding that the set of natural numbers is not closure under subtraction if a subtrahend is bigger than a minuend. In the third stage they introduce new numbers to ensure that the set of natural numbers is closure under subtraction, and then they can calculate even if a subtrahend is bigger than or equals a minuend. In the fourth stage they do addition and subtraction with positive numbers, zero and negative numbers, and then, they can calculate in new number set. We show there are four stages in the process of understanding the algebraic structure with the extension the set of natural numbers to the set of integers. In this process of understanding the algebraic structure, the recognition that the set is closure under an operation is crucial. The second stage is the stage of understanding whether the set of natural numbers is closure under an operation, and the third stage is the stage of introducing a new number from viewpoint that the set is closure under an operation.

*Although making appropriate strategy choices is arguably a key indicator of calculation fluency, recent curriculum reforms in England prioritise the teaching of formal algorithms. The impact of this policy on students' calculation choices is currently unknown. This paper, which derives from a wider sequential mixed methods explanatory study, consisting of a large-scale survey (N=590) followed by individual interviews (n=23), casts some light on this issue by investigating the strategy choices of the first cohort of Year 6 students (10–11-year-olds) studying under the curriculum reforms. The survey findings showed that gender, prior attainment and confidence were all significant predictors of the use of formal algorithms. The interview findings revealed knowledge of multiple strategies and a willingness to choose alternative strategies as other key variables.*

**Keywords:** Calculation, strategy, fluency, gender, confidence.

## Background

This study was motivated by recent curriculum reforms in England (DfE, 2013a) which compelled schools to prioritise the teaching formal algorithms (Figure 1) over and above other calculation strategies. Those reforms signposted a dramatic shift away from previous policy that had encouraged the teaching of a wider range of calculation strategies (DfES, 2007).

**Figure 1: Formal algorithms for the four operations (DfE, 2013a, pp. 46-47)**

Alongside the curriculum reforms (DfE, 2013a), corresponding adjustments were made to the assessment procedures; incorrect calculations would receive half marks if and only if students attempted a formal algorithm. The reforms swiftly appeared to have an impact on classroom pedagogy: McClure (2014, para. 3) noted that “Many schools are already interpreting this as practice, practice, practice of formal algorithms.” Although procedural fluency is recognised as a key factor of calculation fluency, the relevant literature highlights other factors too.

## Theoretical framework

The notion of *calculation fluency* (also known as *computational fluency*) has been defined in the literature as requiring students to satisfy several different criteria. For example, the US-based National Council of Teachers of Mathematics (NCTM, 2000) stated:

Students exhibit computational fluency when they demonstrate flexibility in the computational methods they choose, understand and can explain these methods, and produce accurate answers efficiently. (NCTM, 2000, p. 152)

The NCTM's definition was consistent with the way we conceptualised calculation fluency in this study as requiring accuracy, efficiency, flexibility and understanding of the chosen strategy. In light of the DfE's (2013a) reforms prioritising formal algorithms, *flexibility* received special attention in our work; due to the particular curricular context and policies, students in this study were deemed to be working flexibly when they deviated from choosing the formal algorithm. Examining the impact of teaching formal algorithms on 9–10-year-old boys in Belgium ( $N=21$ ), Torbeyns and Verschaffel (2013) reported that most of the students prioritised formal algorithms within a year of their introduction to those strategies, even for calculations suited to other strategies such as  $482 - 299$ .

The DfE's (2013a) reforms prioritising formal algorithms in primary schools were accompanied by an increased focus on problem-solving in secondary schools. The DfE's reforms across both levels of schooling appeared to assume that they satisfied the needs of all students. However, Villalobos (2009) argued that the gender differences in mathematical attainment observed in US schools could be explained by the different curricula that students experienced in their primary and secondary schooling. Her model predicted that young girls might respond positively to the increased focus on formal algorithms but their early success might hamper their later mathematical attainment studying under a problem-solving curriculum. Indeed, significant gender differences already existed in UK schools before the reforms; the DfE (2013b) released data indicating that similar numbers of girls and boys consistently achieved age-related expectations in primary mathematics, yet boys were outperforming girls at higher levels. Examination of the assessment descriptors (DCSF, 2009) revealed that pupils working at age-related expectations were expected to satisfy objectives addressing number recall and performing written calculations whereas pupils working above age-related expectations were expected to demonstrate more problem-solving skills.

The literature also revealed gender differences in calculation strategies. For example, Carr and Davis (2001) conducted a choice/no-choice study with 6–7-year-old students in the US ( $N=84$ ) comparing their addition and subtraction strategies; the boys tended to prefer counting in their heads whereas the girls were more likely to choose counting on their fingers. Also, Hickendorff, Van Putten, Verhelst, and Heiser (2010), investigating the division calculations of 12-year-old students in the Netherlands ( $N=362$ ), reported that boys tended to prefer informal written calculation strategies whereas girls were more likely to adopt formal strategies. Furthermore, when the researchers asked the students to record their division strategies, the boys tended to record fewer steps and work more intuitively than the majority of the girls in the sample. However, the reforms (DfE, 2013a) adopted a 'one size fits all' model which ultimately expected all pupils to use the formal algorithm and did not appear to take into account the differences described above. Moreover, the Programme for International Student Assessments (OECD, 2009) confirmed that 15-year-old English students had one of the largest gender differences favouring boys in mathematical performance.

The role of confidence in the calculation choices of boys and girls remained unexplored in the literature despite evidence revealing that confidence could interact with gender in shaping students'

dispositions, decisions, or achievement. For example, Brown, Brown and Bibby (2008) reported that almost twice as many UK 16-year-old girls than boys indicated that they would not consider studying mathematics post-16 because it was perceived as ‘too difficult.’ Moreover, US-based Heilbrunner (2013) found that confident students were more likely to continue studying mathematics post-16 than their less confident counterparts. Exploring the factors surrounding gender participation in the various STEM-related career paths, Heilbrunner also reported a gender imbalance across the STEM-related subjects where females were less likely to choose engineering or mathematics than males. Hence confidence was regarded as a key issue in this study. For the purposes of this study, we adopted the definition of mathematical confidence as being an individual’s belief in their ability to ‘do’ mathematics (Fishbein & Azjen, 1975).

Research design was another concern. Prior calculation studies tended to adopt choice/no-choice designs which limited their opportunities to explore calculation choices. Few studies explored the reasons behind the strategy choices of the students. Moreover, the DfE’s (2013a) reforms prioritised formal algorithms for the four operations but prior studies tended to focus on a single operation, such as addition. The limited number of studies which did address all of the four operations did not consider gender or confidence. Hence this study adopted a sequential explanatory mixed methods research design which addressed the following research question: *To what extent do gender, prior attainment and confidence predict use of formal algorithms across all of the four operations?*

## Method

### Participants

For the quantitative phase, 19 schools were randomly selected from a larger cohort taking part in a regional Mathematics Specialist Teacher (MaST) programme, an initiative which aimed to place a Master-level trained teacher in every primary school. This approach resulted in a potential sample of 670 10–11-year-olds. The actual sample consisted of 590 students (324 boys, 266 girls) with 79 students removed (35 - newly arrived in the UK with English as a second language, 33 - working below the required level, 6 - absent, 1 - poor behaviour and 4 - no evidence of parental permission).

### Data collection

The quantitative survey consisted of a workbook containing 16 calculations, a mathematics Confidence Questionnaire (CQ) and the prior attainment scores from students’ most recent national assessment at age 7 (Level 1 = below average, Level 2 = average, Level 3 = above average). The class teachers delivered the materials under national assessment test conditions.

The workbooks reflected the overall focus of the study by including some calculations which were deemed suitable for using formal algorithms ( $456+372$ ,  $5412+2584$ ,  $632-154$ ,  $27\times 63$ ,  $568\times 34$  and  $517\div 19$ ) and others which were regarded as suitable for other approaches, such as rounding to the nearest multiple of ten or counting the difference between two numbers ( $299+532$ ,  $245+256$ ,  $500-76$ ,  $702-695$ ,  $382-199$ ,  $20\times 46$ ,  $35\times 99$ ,  $693\div 3$ ,  $480\div 20$  and  $401\div 25$ ). The draft workbooks were piloted, revised and validated by five education professionals who were asked to confirm their suitability for the use of formal algorithms or alternative strategies; they were also asked to confirm their age-

appropriateness, and their scores exceeded the minimum score of 0.8 recommended for new measures (Rubio, Berg-Weger, Tebb, Lee, & Rauch, 2003).

The CQ was adapted from an existing measure which addressed mathematical competence as well as views on the importance of mathematics (Eccles, Wigfield, Harold, & Blumenfeld, 1993). The original version consisted of ten questions with a five-point Likert-style response scale which had been extensively trialed with similar age groups. For example, students were asked ‘How well do you expect to do in math this year?’ and ‘How good in math are you?’ The questionnaire could be efficiently administered by teachers to their whole class, but the terms *math* and *student* were replaced for my UK-based study. The internal consistency of the revised questionnaire was confirmed using Cronbach Alpha testing, achieving a high rating (10 items;  $\alpha=0.88$ ).

Twenty-four potential interviewees (12 boys, 12 girls) were drawn from three of the schools from the initial phase. This purposeful sample consisted of 12 high attaining students (6 boys, 6 girls) and 12 low confidence students (6 boys, 6 girls). One student, a high attaining girl, was absent which resulted in an actual sample of 23 interviewees. Each pupil was individually interviewed by the first author and the interview was audio recorded (video recording was not possible due to school policies). Since the purpose was to elicit the reasons underlying the students’ strategy choices, semi-structured interviews were deemed the most suitable approach; after a few introductory questions to confirm their name and willingness to participate in the project, the students were asked a series of questions addressing different aspects of their calculation fluency such as the reasons behind their strategy choices, their knowledge of alternative strategies and their checking procedures.

### **Data analysis**

The initial quantitative data analysis informed the subsequent qualitative analysis. Each workbook was checked for accuracy and the individual calculations were coded according to the chosen strategy. An individual’s flexibility was determined by the total number of times they chose formal algorithms across the 16 calculations. Quantitative analysis was conducted using ANOVA to compare the accuracy rates of different strategies and Multiple Linear Regression (MLR) to predict flexibility; the three predictor variables were gender, prior attainment and confidence, and the dependent variable was their use of formal algorithms.

The interviews were transcribed and coded using framework analysis (Richie & Spencer, 1994). This accommodated *a priori* issues from the quantitative phase as well as other themes emerging during the analysis. It began with a familiarisation stage, reading and re-reading the transcribed notes in order to become totally immersed in the data. The *a priori* themes were calculation accuracy, use of the formal algorithm (which reflected the flexibility aspect of calculation fluency), conceptual understanding, efficiency and the most accurate calculation strategies. The notes taken during this stage were organised into a draft thematic framework which was trialled and refined with a limited number of the transcripts, and the revised framework retained its original themes. Charting the data moved the analysis from working with individual transcripts towards analysing the whole data set. Each chart represented a single theme and the data was organised into the sub-themes identified in the previous stages of the process – these completed charts allowed the data to be analysed both

vertically (by sub-theme) and horizontally (by individual pupil). The charts enabled counting of the total number of coded items as well as consideration of the actual text.

## Findings

Although formal algorithms were the most frequently selected strategy for each of the sixteen calculations, ANOVA tests confirmed that other strategies were significantly more accurate for three of those calculations ( $702 - 695$ ,  $401 \div 25$  and  $517 \div 19$ ) and formal algorithms for two others ( $456 + 372$  and  $693 \div 3$ ). The MLR analysis revealed a statistically significant regression equation ( $F(4, 585) = 11.98$ ,  $p < 0.001$ ),  $R^2 = 7.57\%$  (Table 1) for predicting use of the formal algorithm.

Use of formal algorithm =  $5.5212 + 0.8893(\text{girl}) - 1.3026(\text{Level } 2) - 1.6688(\text{Level } 3) + 0.1439(\text{Confidence})$ .

The MLR analysis confirmed that gender, prior attainment and confidence were all significant predictors of flexibility, but the most significant factor was confidence. If a student rated their mathematics confidence with the maximum score of 50, then their predicted use of formal algorithms increased by seven calculations. However those findings did not explain why the confident students tended to choose formal algorithms. Nor did they either explain why the girls tended to choose formal algorithms for one more calculation than the boys, or explain why the high attaining pupils tended to choose formal algorithms for two fewer calculations than the others. Due to the sequential nature of this study, each issue was addressed in the subsequent qualitative analysis. Moreover, the regression model indicated that just under 8% of the variance in choosing formal algorithms was explained by the three predictor variables so the qualitative phase also offered an opportunity to explore other possible variables to account for the remaining variance.

Coefficient	Estimate	Standard Error	t-value	p-value
Intercept	5.5212	0.9884	5.5862	3.56E-08
Girl	0.8893	0.3091	2.877	0.0040
Level 2	-1.3026	0.5379	-2.4217	0.0158
Level 3	-1.6688	0.6225	-2.6806	0.0076
Confidence	0.1439	0.0229	6.2793	6.63E-10

**Table 1: Summary of revised coefficients for predicting use of the formal algorithm**

Consider the quantitative finding that the more confident students tended to choose formal algorithms: this finding might imply that those students were either confident in their abilities to apply those strategies or they felt confident because they were following their teacher's approach. Alternatively, this finding might appear to imply that the low confidence students drew upon a wider range of calculation strategies than their counterparts by not relying on formal algorithms. However, the interviews revealed that the situation was more complex than it initially appeared; two-thirds of the low confidence interviewees admitted that they only knew a single strategy for some of their operations, some of them had yet to encounter formal algorithms and others were unwilling to attempt

such strategies due to their lack of practice with the strategies. In particular, when asked to suggest another strategy for working out their answers, most of the low confidence students struggled to name an alternative strategy for multiplication or division calculations.

For gender, the quantitative findings showed that the girls were more likely to choose formal algorithms than the boys, and the interviews revealed that the girls preferred to use the same strategy for calculating and checking too. When the girls did know another strategy, such as rounding for  $35 \times 99$ , several of them either did not identify suitable opportunities to apply it or were reluctant to apply it. Several students stated that their choice of strategy was influenced by their knowledge of the assessment procedures for national tests. However, most of the boys were willing to adopt different strategies such as applying their knowledge of divisibility rules or checking their answers using inverses.

The quantitative findings also showed that the high attaining students were less likely to choose formal algorithms than other students, and their interviews revealed that they knew a greater range of strategies than the other students which enabled them to select alternative approaches. This was most noticeable when the high attaining students were discussing how they checked their answers; half of them employed more than one checking procedure or estimated their answers. Their flexibility ensured that they had a higher mean accuracy score than the other students too.

The interviews also shed further light on the unaccounted for variance in the regression model. Knowledge of multiple strategies and checking procedures emerged as important factors to consider regarding use of formal algorithms. More specifically, the transcripts revealed that students checked their calculations in different ways and at different times, and that those differing strategies might account for different accuracy rates too. The most accurate students were the minority who checked at least some of their answers using multiple strategies such as divisibility rules and using inverses; the majority simply checked each of their calculations by repeating their initial strategy. The students also checked their answers at different times but most of them checked as they went along. Around a fifth of the students, mostly boys, delayed checking their answers until they had finished all of their questions. However, the findings relating to the optimum time for checking their calculations were inconclusive, due to the small numbers of students involved. The interviews also highlighted the potentially negative influence of national testing on calculation flexibility; several students said that their choice of formal algorithms was influenced by national tests.

## Discussion

Exploring different calculation strategies offers an opportunity for young students to experience working flexibly in the mathematics classroom, rather than relying exclusively on formal algorithms. However, the findings revealed that formal algorithms were the most frequently selected strategy for each of the 16 calculations in this study, including those deliberately included due to their suitability for other strategies. The subsequent interviews revealed that less confident students tended to be unaware of multiple strategies for multiplication or division calculations, possibly indicating that the renewed emphasis on formal algorithms might have steered some schools towards teaching a narrower range of strategies. The interviews also revealed that failing to recognise an opportunity to work flexibly often resulted in students choosing a less efficient, potentially error-prone, strategy.

The finding that the girls were more likely to choose formal algorithms than the boys was consistent with the early stages of Villalobos' (2009) theoretical model whereby young girls experience *strategy socialization* when they choose to follow algorithms. If the model is correct, those girls may struggle to adapt to the demands for more flexible approaches of later mathematics courses, such as those related to problem-solving. The results also showed that the high attaining students were less likely to choose formal algorithms than others. Their willingness to work flexibly would present a clear advantage for those high attaining students when problem-solving; knowing more than one strategy would enable them to adopt a different strategy if they got stuck (Russell, 2000).

Moreover, the most accurate students were the minority who checked at least some of their answers using multiple strategies, including estimation which was highlighted as important in the literature (e.g., Doreneles, Duro, Rios, Nogues, & Pereira, 2017). Readiness to consider other strategies was also recognised as a key aspect of fluency (McClure, 2014); comparing two answers from different strategies would allow students to identify any possible errors which might not have been noticed by simply repeating their initial strategy.

All study designs have their limitations. Although this project focused on gender, prior attainment and confidence, we accept that future studies might address social class or the enacted curriculum. Due to financial and time restraints, the student interviews were limited to three schools; widening the range of schools might uncover further factors too.

The above findings have clear implications for schools, researchers and policy makers. The decision to focus on all four operations, contrary to most prior research, exposed differences in the extent of students' knowledge of multiple strategies between operations. Also the sequential explanatory mixed methods research design, another notable difference from most prior research, enabled further exploration of the initial quantitative results by revealing potential issues arising from focusing too heavily on formal algorithms. Such issues include: low confidence students lacking knowledge of multiple strategies, restricting their options when they encounter difficulties; girls prioritising algorithmic fluency above all other aspects of mathematics, possibly to the detriment of their future mathematical development; and, students limiting themselves to a single calculation and checking procedure, reducing their opportunities to spot errors. Next steps in this study involve disseminating these findings to a variety of audiences, especially policy makers through contributions towards parliamentary access groups, national conferences and teaching publications.

## Number line estimation and quantitative reasoning: two important skills for mathematical achievement<sup>1</sup>

Camila Peres Nogues and Beatriz Vargas Dorneles

Universidade Federal do Rio Grande do Sul, Brasil;

[camilapnogue@gmail.com](mailto:camilapnogue@gmail.com), [beatriz.dorneles@ufrgs.br](mailto:beatriz.dorneles@ufrgs.br)

*Number estimation and quantitative reasoning have been indicated as significant skills for mathematical achievement. In this sense, this paper aims to analyse the students' performance in these two skills and verify possible relations between both. For that, 143 students from 3<sup>rd</sup> and 4<sup>th</sup> grades of elementary school were evaluated using two number line estimation tasks. Results showed that there is a direct relation between children's performance in both abilities. From this, it is suggested that both number estimation and quantitative reasoning tasks can be used in daily classroom activities to promote the learning of initial mathematics concepts considering the importance of estimation in daily activities.*

*Keywords: Number estimation, quantitative reasoning, mathematical learning.*

### Introduction

Mathematics is an important area of knowledge for children's cognitive development, as it involves several domain-specific skills related to numerical knowledge. Learning mathematics requires the understanding of initial concepts about numbers, quantities and relations, and the ability to make connections between these concepts (Nunes, Bryant, Sylva, & Barros, 2009). Therefore, it is important to provide different teaching and learning situations with the intention of promoting children's mathematical development. In this sense, our study highlights two skills indicated in the literature as significant for mathematical learning: number estimation and quantitative reasoning. Number estimation is a cognitive ability that has been studied and pointed out as important for mathematical performance (Geary, 2011; Moore & Ashcraft, 2015; Schneider et al., 2018; Siegler & Booth, 2004; Siegler, Thompson, & Opfer, 2009). The evidence is that the ability to estimate is related to arithmetic, number categorization and numerical magnitudes (Laski & Siegler, 2007; Link, Nuerk, & Moeller, 2014; Schneider et al., 2018; Siegler et al., 2009). In number estimation tasks, students identify numerical magnitudes and perform number decompositions. More than that, studies have shown that children's ability to accurately locate numbers on a number line is predictive of later mathematical achievement (Geary, 2011; Siegler & Booth, 2004). The number line estimation task, in the version number-to-position (NP), is the task most commonly used to evaluate the ability to estimate numerical magnitudes. In this task, participants are given a number, in the form of Arabic numerals, and are asked to locate that number on a line usually bounded in a numerical range. This task has been used to trace the development of the pupil's comprehension of numerical magnitude throughout the school grades (Booth & Siegler, 2006; Schneider et al., 2018; Siegler & Opfer, 2003).

---

<sup>1</sup> This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES)

- Finance Code 001

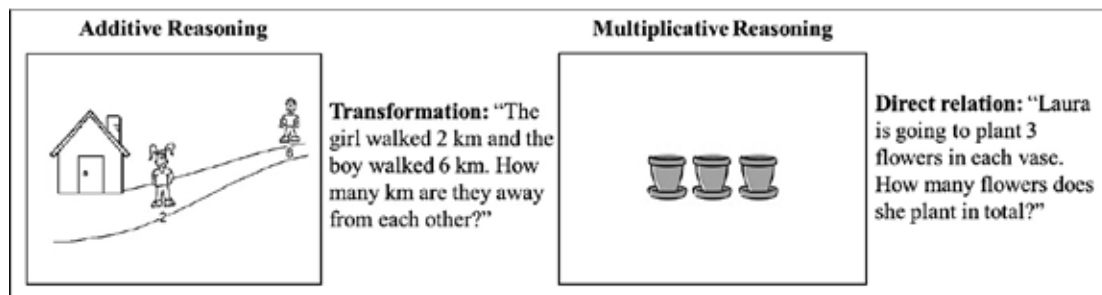

An alternative version of the number line estimation task has also been proposed. The intention of this version is to investigate estimation accuracy differences between tasks and to gain a broader understanding of the development of the ability to estimate. In this version, called position-to-number (PN), participants are asked to estimate a number corresponding to a location on a number line also bounded by a numerical range. Figure 1 shows examples of NP and PN tasks.

**Figure 1: Examples of the number estimation tasks NP and PN**

These two versions of the number line estimation task are complementary since they embody the central property of the ability to estimate, which is the translation between numerical and spatial representations (Siegler & Opfer, 2003).

Regarding quantitative reasoning, we can say that it is essential for the construction of initial mathematical concepts, since it is based on the understanding of the relations between quantities, for example, if they are increasing or decreasing (Nunes, Dorneles, Lin, & Rathgeb-Schnierer, 2016). Evidence indicates that quantitative reasoning developed from the beginning of elementary school contributes significantly to mathematical achievement and that understanding the relation between quantities is essential for learning numerical and arithmetic representations (Nunes et al., 2007; Nunes, Bryant, Barros, & Sylva, 2011). Quantitative reasoning is divided into two categories, additive and multiplicative reasoning, which are classified by situations according to the relation established between quantities (Nunes et al., 2016). Additive reasoning is characterized by the ability to join or separate quantities from a total quantity (quantity composition problems), to recognize the inverse relation between addition and subtraction (transformation problems), and to understand comparative situations (comparison problems). Multiplicative reasoning involves the ability to perform one-to-many correspondence and to perform distributions equally. It is classified in situations of direct or inverse relations between quantities and product of measures, in which a third quantity is formed by two other quantities (Nunes et al., 2016). Examples of these quantitative reasoning tasks that were used in this study are presented in Figure 2.

**Figure 2: Examples of quantitative reasoning problems**

Thus, we perceive that different quantitative relations are necessary in order to understand mathematical concepts and operations. When students understand the relation between quantities and operations, it becomes easier to correctly decide the strategies and schemes to be used to solve the problems. Consequently, this understanding will have a direct influence on mathematical achievement.

Concluding this review, some studies on this topic have been presented in a previous edition of CERME. About number estimation, we found a comparison study between two estimation tasks in 2<sup>nd</sup> and 3<sup>rd</sup> graders' performance (Dorneles, Duro, Rios, Nogues, & Pereira, 2017), and another comparing preschool children's performance in a number line estimation task with initial math skills (Elofsson, 2017). On quantitative reasoning, we highlight a study carried out with 2<sup>nd</sup> graders checking their solution strategies when solving transformation situations to support the development of their mathematical thinking (Serrazina & Rodrigues, 2017).

In this sense, what was intended in this study was to analyse the performance of 3<sup>rd</sup> and 4<sup>th</sup> grade students on number estimation and quantitative reasoning and to investigate the relation between their performance in these abilities. This relation, as far as we know, has not yet been the focus of studies. Therefore, this research fills a gap in the literature and provides more evidence of cognitive abilities important to mathematical performance.

## Method

The sample comprised a total of 143 children (62 girls and 81 boys) from two public elementary schools in Porto Alegre/Brazil. Schools were chosen by criteria of convenience, number of students and attending to communities of similar socioeconomic classes. The students were 3<sup>rd</sup> and 4<sup>th</sup> graders (76 from 3<sup>rd</sup> and 67 from 4<sup>th</sup> grade), and ages between 8 to 11 years old ( $M=9.8$ ,  $SD=.74$ ). They were evaluated using two number line estimation tasks (*NP* and *PN*) and one quantitative reasoning task. The 3<sup>rd</sup> and 4<sup>th</sup> school grades were chosen because in these grades the students are in similar moments of learning considering the curricular contents, especially in relation to numerical knowledge. And the tasks used require some numeric knowledge established to be solved, like the understanding of the numerical system and of the four mathematical operations. It is important to say that estimation and problem solving are part of the curriculum in Brazil, but these tasks specifically of number estimation and quantitative reasoning are not usual in classrooms. Even though, the children were able to solve the tasks after the researcher's explanation.

To evaluate number estimation ability, two number line tasks were used adapted from Siegler and Opfer (2003). The first one was number-to-position (*NP*) task, which consists in locating the position of a number on a number line bounded by 0 on the left and 100 on the right. The second one was position-to-number (*PN*) task, which consists of estimating a value that corresponds to a mark indicated on a number line also bounded by 0 and 100. There were 22 numbers to be estimated (2, 3, 5, 8, 12, 17, 21, 26, 34, 39, 42, 46, 54, 58, 61, 67, 73, 78, 82, 89, 92, 97), taken from the study by Laski and Siegler (2007). These numbers were presented in a random order and children wrote down their estimates in a notebook containing a number line and a number to be estimated on each page. The task was applied in groups of 10 students and lasted about 30 minutes per group.

The quantitative reasoning task was adapted from Nunes (2009) and aimed to evaluate children's arithmetic reasoning in problem solving. The quantitative relations involved were additive reasoning (including composition of quantities, situations of transformation and comparison) and multiplicative reasoning (containing situations of direct and inverse relations between quantities and product of measures). The task was composed of 18 situations, nine of each kind of reasoning. Task application occurred collectively in groups of 10 students. Each participant received a notebook containing one situation per page, in which only illustrations were presented without written information. The instructions were given orally by the assessor, so the children did not depend on their reading ability.

The analysis of performance in number estimation was determined by calculating the accuracy with which the students estimated each number requested, that is, by calculating the percentage of absolute error of each child's estimate. This computation is adapted from Siegler and Booth (2004) and can be explained by dividing the difference between the child's estimate and the number to be estimated by the number line scale (which in this task is 100). For example, consider that the number to be estimated was 40 and the child made a mark on the number line corresponding to number 30, then the computation will be done as follows:  $|30-40|/100$ , obtaining an accuracy of 0.1. Therefore, the lower is the value found, the more accurate is the estimation made by the participant.

For the quantitative reasoning task, the total score of correct answers in the task and the hits per reasoning category (additive and multiplicative reasoning) were considered.

Initially, the quantitative analyses were conducted to identify any differences in performance on number estimation and quantitative reasoning tasks according to gender, age and school grade. Then, an association analysis between the performance in the two types of number line estimation tasks was conducted. After which, the children's performance in quantitative reasoning and number line estimation tasks was compared.

## Results

Firstly, the results are presented by task type, describing the students' performance in number line estimation tasks and in the quantitative reasoning task. Finally, the results for the correlation between both math abilities evaluated are shown.

The ability to estimate was evaluated using two number line estimation tasks (*NP* and *PN* tasks). The performance in both tasks was organized according to the mean accuracy of each child by task.

In a first analysis, the performance in each of the two number line estimation tasks was related with gender, age and school grade, and a statistically significant difference was only found (*NP*:  $U=1827$ ,  $p<.05$ ; *PN*:  $U=1767.5$ ,  $p<.05$ ) with school grade. This indicates that 4<sup>th</sup> graders accuracy (mean *NP*=.086,  $SD=.038$ ; mean *PN*=.074,  $SD=.037$ ) was better than 3<sup>rd</sup> graders (mean *NP*=.11,  $SD=.055$ , mean *PN*=.099,  $SD=.056$ ) in both tasks. After this, from a correlation analysis, accuracy of *NP* ( $M=.10$ ;  $SD=.05$ ) and *PN* ( $M=.09$ ,  $SD=.06$ ) showed a moderate but significant correlation ( $r=.66$ ,  $p<.01$ ), indicating that, the better is the accuracy in *NP* task, the better it is in *PN* task. A descriptive analysis was also conducted to identify which proposed numbers the participants estimated more accurately. From this, we can observe (Figure 3) that children were more accurate in numbers at the ends of the number line (numbers 2, 3, 5 and 97).

Figure 3: Accuracy mean on NP and PN tasks

### Quantitative reasoning

The quantitative reasoning task assessed the children's ability to solve situations involving arithmetic reasoning using the four fundamental mathematical operations. The results were computed by the total of correct answers in the task and by the number of correct answers in each reasoning category (additive reasoning and multiplicative reasoning). In general, students presented a mean of 10.55 hits ( $SD=3.22$ ). When scores were verified according to the reasoning category, the students obtained better scores in additive reasoning ( $M=6.03$ ,  $SD=1.92$ ) than in multiplicative reasoning ( $M=4.51$ ,  $SD=1.81$ ). When correlating performance in the quantitative reasoning task with the variables gender, age and school grade, there was a statistically significant difference with school grade ( $U=3256$ ,  $p<.05$ ) and a direct but weak correlation with age ( $rs=.18$ ,  $p<.05$ ). These results indicate that there was an increase in total score from 3<sup>rd</sup> to 4<sup>th</sup> grades (3<sup>rd</sup> grade:  $M=9.74$ ,  $SD=3.32$ ; 4<sup>th</sup> grade:  $M=11.46$ ,  $SD=2.87$ ). However, this increase was significant ( $U=3486.5$ ,  $p<.05$ ) only for additive reasoning (3<sup>rd</sup> grade:  $M=5.42$ ,  $SD=2.06$ ; 4<sup>th</sup> grade:  $M=6.73$ ,  $SD=1.47$ ).

When analysing the situations involved in both additive and multiplicative reasoning (Figure 4), there is a higher percentage of correct answers in situations of additive reasoning involving quantities composition and transformation. Concerning situations of multiplicative reasoning, students obtained higher scores in situations involving direct and inverse relations between quantities.

Figure 4: Scores Organized by Category of Problem Types

### Number line estimation and quantitative reasoning

A correlation analysis was conducted to verify associations between the measures of number line estimation and quantitative reasoning. Thereby, moderate and significant correlations were found between quantitative reasoning total score and both the NP task ( $r_s = -.39$ ,  $p < .01$ ) and PN task ( $r_s = -.42$ ,  $p < .01$ ). In the same way, there were also moderate and significant associations between score by reasoning category and accuracy in both number line estimation tasks. Correlations index can be seen in Table 1.

Measures	Number Estimation		Quantitative Reasoning		
	1	2	3	4	5
1. NP	1				
2. PN	0,660**	1			
3. AR	-0,378**	-0,394**	1		
4. MR	-0,292**	-0,328**	0,502**	1	
5. QR – Total	-0,389**	-0,420**	0,857**	0,864**	1

\* $p < 0,05$ ; \*\* $p < 0,01$

### Discussion and conclusions

The aim of this research was to verify the relation between number estimation and quantitative reasoning performance of a third and fourth graders group, as well as to analyse their performance in each of these abilities. For this, two number line estimation tasks (NP and PN tasks) and a quantitative reasoning task were used.

Among the research results, we can highlight the significant difference found between the school grades, with 4<sup>th</sup> graders performing significantly better than 3<sup>rd</sup> graders in both abilities. These findings indicate that experience and increased schooling improve accuracy in number line tasks, as found in previous studies (Booth & Siegler, 2006; Laski & Siegler, 2007; Siegler & Opfer, 2003). This is a consequence of children becoming more aware of numbers and their relations, learning that larger numbers are located to the right on a number line, and that the distance between 10 and 20 is the same as that between 80 and 90, for example (Friso-van den Bos et al., 2015; Laski & Siegler, 2007).

An association was also found between children's performance in both number line estimation tasks, that is, participants who performed well in the NP task also performed well in the PN task. When analysing the numbers in which children obtained better performance, it was found that in the NP and PN tasks the numbers with the best precision (2, 3, 5 and 97) are close to the extremities of the number line. The worst performances were found in different numbers for each task. Nevertheless, in both cases, the majority of the numbers are located between 25 and 50 and between 50 and 75. This result is similar to previous studies that indicate that children up to the 4<sup>th</sup> grade are not very accurate in numbers far from the extremities of the number line, (Laski & Siegler, 2007; Siegler & Opfer, 2003).

In quantitative reasoning task, 4<sup>th</sup> graders scored better than 3<sup>rd</sup> graders as expected. When analysing the reasoning categories separately, 4<sup>th</sup> graders presented better scores in both additive and multiplicative reasoning, but this difference was only significant for additive reasoning. This indicates that due to the similarity of contents proposed in the Brazilian school curriculum in these grades, students are learning multiplicative reasoning, that is, the relations between multiplication and division operations, which may explain the fact that the difference between 3<sup>rd</sup> and 4<sup>th</sup> graders was not significant for these types of reasoning.

A direct association between number line estimation and quantitative reasoning was found. Students' performance in the quantitative reasoning task showed a correlation with both number line estimation tasks, specifically additive reasoning, which had the highest correlation index in both NP and PN tasks.

However, one limitation of the research must be considered: the collective application of the tasks proposed. Nevertheless, the findings of this study contribute to the planning of tasks that may improve abilities that are not currently approached in classrooms, such as number estimation. As previously mentioned, the development of the ability to estimate can improve students' skills in arithmetic computations. There are several daily situations when an estimation is enough, without the need to get an exact answer, for example, to choose the smallest cashier row in a supermarket, or if it is necessary to run to get to school on time. Therefore, in mathematics teaching it is important to highlight the use of alternative strategies to solve problems, allowing students to increase their set of solution methods. In this way, the use of number estimation in mathematics classes is an option to develop ability in arithmetic computations and may help to explain and to check the results of computations, while allowing students to establish their own solution strategies and appropriate different ways to solve mathematical tasks.

These results add new elements to the discussion of the role of number estimation in math achievement and provide evidence regarding estimation ability. However, future research on the subject is needed, such as longitudinal studies that describe the development of the ability to estimate and studies that verify the strategies used by students in each school grade.

*In this study primary, secondary and tertiary education students try to calculate mentally the very same tasks involving operations with rational numbers (mainly fractions and mixed numbers). The aim was to record the range of strategies used by the students and at the same time to examine how these strategies are distributed across these three educational levels. The findings give evidence that no matter the educational level, the dominant strategy is the use of mental form of the written algorithm. All the other strategies are underrepresented. Moreover, it seems that the use of rational numbers in mental calculation is in itself an obstacle for the students since a great percentage of them either did not give any answer or the answers they gave were incorrect or non-codable.*

**Keywords:** Mental calculations, rational numbers, written algorithm.

## Introduction

Mental calculations in arithmetic refers to the process of calculating the exact result of an arithmetical expression given that the solvers use neither a calculating device nor any kind of writing and which usually demands an application of mental strategies. In 1924, the well-known mathematician Carathéodory, during a lecture he delivered for the Hellenic Mathematical Society highlighted the vital importance of the students' ability "to calculate mentally instead of merely writing down, for example, simple subtractions or multiplications" (p. 87). The main interest of the majority of the relevant research studies lies particularly in identifying and organizing the strategies the solvers use. A considerable body of these studies examines mental calculation in the realm of whole numbers and their four basic operations (Rezat, 2011). Lately, researchers express a growth interest on the mental calculations in the set of rational numbers concerning either comparison of rational numbers (Yang, Reys & Reys, 2009) or operations with rational numbers (Caney & Watson, 2003).

In this study our focus lies on the strategies used by students across all the educational levels when they mentally make calculations that involve rational numbers. More precisely, our research questions are:

- What is the range of the strategies used by the solvers while they mentally make operations that involve rational numbers?
- How are these strategies distributed across the three different educational levels and what similarities or/and differences are identified?

## Research literature

Cathy Seeley (2005), NCTM president for 2004-2006, in her "Do the Math in Your Head!" article is making a call to the educational community to realize the significance of the ability to perform mental calculations. She associates mental math with both the students' ability to perform calculations quickly, and their conceptual understanding and problem solving. Furthermore, mental calculations

constitute a useful means for calculations, given that they are used by almost everyone on a daily basis, as a direct and quick way of calculating. According to relevant studies (McIntosh, 2006) over three quarters of the mathematical operations performed by individuals in their daily lives are based on mental calculations. Moreover, they promote creative and independent thinking, develop sound number sense, constitute the basis for developing estimation skills, and finally they facilitate a natural progression through informal written methods to standard algorithms (Thompson, 2010).

As it has already been mentioned, the majority of the research studies focus on mental calculations involving whole numbers, and a wide variety of strategies associated to the four operations has been recorded. However, the corresponding body of research concerning mental calculations with rational numbers is rather limited. A systematic documentation of the strategies used by students in primary and secondary education in operations with fractions, decimals and percentages have been realized by Caney and Watson (2003). One main finding of their study was that many of the strategies used in operations with whole numbers are also used for operations with rational numbers. Furthermore, they identified two kinds of strategies for mental calculations with rational numbers: instrumental and conceptual strategies. The instrumental work refers to the use of procedural strategies learned by rote. Moreover, this work is not accompanied by an explanation displaying conceptual understanding of the involved processes. On the contrary, conceptual work takes place when students make use of their knowledge on the specific set of numbers and operations to calculate mentally. Finally, Caney and Watson (2003) added the ‘mixed’ strategy in case the students combine a rote procedure with a conceptual explanation. In their study they identified a series of strategies the students used to solve 12 problems. More specifically, the students ‘*changed operation*’ (division to multiplication, subtraction to addition), ‘*changed representation*’ (fractions to decimals and vice versa, percent to fractions), ‘*used equivalents*’ (use of equivalent fractions), ‘*used known facts*’ (times table), ‘*repeated addition/multiplication/division*’ (by doubling, halving), ‘*used bridging*’ (bridged to one/whole), ‘*worked with parts of a second number*’ (split by place value or by parts), ‘*worked from the left/right*’, ‘*used mental picture*’, ‘*used mental form of written algorithm*’ and ‘*used memorized rules*’. Carvalho and da Ponte (2015) examined grade-6 students’ mental calculations involving fractions, decimals and percentages. They found that students mainly changed representations (fractions to decimals) or used the relationship between numerical representations when possible. Moreover, data analysis showed that pupils utilized depictive representations such as models or images and descriptive representations like the propositional representations in the sense that these mental models arise as a representation of the real world (i.e., the students used the context of money, clocks, pizzas, etc.). Callingham and Watson (2004) working with students in grades 3 to 10 found that fractions items were easier than decimals and percents and that multiplication and division operations with fractions were more difficult for students than addition and subtraction, thus mirroring similar findings for whole numbers. In the same spirit Lemonidis, Tsakiridou and Meliopolou (2018) found that teachers exhibit a lack of flexibility in the use of strategies in mental calculations with rational numbers. McIntosh (2006) examined the errors students make during mental calculations with rational numbers and identified two different kinds: procedural and conceptual errors. Procedural errors are connected with simple operations between the terms of fractions. They are mostly careless errors or errors that appear while carrying a step of a strategy even though the steps are known to the student. For example, the student knows that multiplication of fractions means to multiply separately the numerators and

denominators of the participating fractions but calculates mistakenly the product of these terms. So, if the numerators of the fractions are 6 and 7 the student might find that  $6 \times 7 = 48$ . Conceptual errors are connected with a limited understanding of the rational numbers or the operations they have to execute.

In this context our study focuses mainly on the strategies (rather than on the errors, although they have been recorded) used by primary, secondary and tertiary education students given that all of them had to calculate mentally the very same operations involving rational numbers.

## Study design and methodology

The participants were 295 students on a voluntary basis from all the three educational levels (primary, secondary and tertiary education). More specifically, there were 78 grade-6 students [SP], 97 grade 10-12 students [SS] and 120 University students (63 from the Department of Primary Education [SU1] and 57 from the Mathematics Department and the Faculty of Engineering [SU2]). These last ones were chosen due to their strong mathematical background that would provide flexibility in their strategies. The tasks and the process were identical for all the three different groups.

Eleven tasks (Figure 1) were posed and the participants were asked to calculate mentally their results. The tasks included all the four operations and their design incorporated two main principles. First, the answers can be calculated in more than one way thus giving freedom to the participants to work in the way they feel more familiar. Second, the tasks are amenable to a fast and easy calculation if the correct mental strategy is chosen. For example, in task-a the answer is obvious if the solver can see that it is about the sum of two halves. Similarly, in task-f the wanted operation is  $2 \times 3.5$ . Aiming to cover a variety of different combinations within the spectrum of the operations with rational numbers we included operations between fractions, whole numbers and fractions, mixed numbers and fractions, mixed and whole numbers. The criterion for each task was always to meet the standards for primary school students.

a) $\frac{1}{2} + \frac{4}{8}$	b) $4 \times \frac{3}{4}$	c) $4 \times \frac{2}{8}$	d) $\frac{5}{6} + \frac{4}{3}$
e) $1\frac{1}{2} - \frac{1}{4}$	f) $3\frac{4}{8} \times 2$	g) $3\frac{1}{4} - \frac{1}{2}$	h) $\frac{3}{4}$ of 20
i) $6 \div \frac{2}{6}$	j) $\frac{1}{2} + \square = \frac{7}{8}$	k) $1\frac{3}{4} \times \frac{1}{4}$	

**Figure 1: Tasks posed to the students**

Individual interviews were used and each participant was asked to solve one-by-one the whole collection of tasks in the order presented in Figure 1. The students were asked to vocalize their thoughts while solving the tasks and were prohibited from taking notes or making written calculations. There was not time limitations and the duration of the interviews varied from 4 to 9 minutes since the solvers could skip tasks they couldn't solve. Neither help nor any feedback were provided to them. The only clarification that was given concerned mixed numbers since they are used mainly in primary education and the older students confuse mixed numbers with the case of

multiplication in algebra. Given that  $2x$  means the multiplication 2 times  $x$ , in a similar way the  $3\frac{1}{4}$  was mistakenly translated as  $3 \times \frac{1}{4}$ . All interviews were recorded and transcribed. These transcribed protocols constituted our data. The students' efforts were coded according to the following two levels: (i) whether the answer was correct, incorrect, left unanswered, or non-codable, and (ii) whether the strategy used by the student fits to a certain category of the Caney and Watson (2003) model.

The data were coded independently by the authors and validity and reliability were established by comparing sets of independent results, clarifying codes and re-coding data until agreement.

## Results and Discussion

Table 1 summarizes the distribution of the total number of answers (3274 answers in total) across the various categories of strategies according to the categories of Caney and Watson (2003). It is worth mentioning that not all their strategies were identified in our sample and also a new one has been added. We've been able to identify the '*changed representation*', '*used equivalents*', '*used known facts*', '*repeated addition/ multiplication*', '*worked with parts of a number*', '*used a mental picture*', and '*used mental form of written algorithm*' strategies. The new one is named '*used reduction*'. Finally, the incorrect, non-answered and non-codable strategies have also been recorded.

Strategy	Changed representation	Equivalents	Known facts	Repeated add/ multip	Parts of a number	Mental picture
Frequency	56 (1.71%)	59 (1.80%)	43 (1.31%)	3 (0.09%)	31 (0.95%)	30 (0.92%)
Strategy	Written algorithm	Reduction	Incorrect	Non-answered	Non-codable	
Frequency	1406 (42.95%)	177 (5.41%)	907 (27.7%)	519 (15.85%)	43 (1.31%)	

**Table 1: Distribution of answers across strategies**

The '*changed representation*' strategy refers to the conversion of a fraction or a mixed number to decimal. Some students considered  $1\frac{1}{2} - \frac{1}{4}$  (task-e) as  $1.5 - 0.25$ . In task-b some preferred to use also decimal numbers to calculate  $4 \times \frac{3}{4} = 4 \times 0.75 = 3$ . In a similar way some students made use of this strategy to reach faster the answer in task-f converting the product  $3\frac{4}{8} \times 2$  to  $3.5 \times 2 = 7$ . We identified the '*used equivalents*' strategy when a fraction is replaced by an equivalent with an explicit reference to this. Some students' mental solution for task-a was  $\frac{1}{2} + \frac{4}{8} = \frac{1}{2} + \frac{1}{2}$ , but this was not because they made an immediate reference to the fact that there are two halves but to the fact that  $\frac{1}{2}$  is equivalent of  $\frac{4}{8}$ . The '*used known fact*' strategy was mostly used in task-h ( $\frac{3}{4}$  of 20) since the solvers made use of their knowledge of the times table. They started reciting the multiples of 5 and they noticed that  $4 \times 5 = 20$  and  $3 \times 5 = 15$  which made them to say that the answer is 15. All the three strategies presented until now had a very low frequency (less than 2%). This frequency becomes even lower for the next three strategies. '*repeated addition/multiplication*' was only used by two participants in three different tasks. The first example is from task-b. The solver's reaction to the task was to calculate the

product  $4 \times \frac{3}{4}$  as follows:  $\frac{3}{4} + \frac{3}{4} + \frac{3}{4} + \frac{3}{4}$ . The next example is drawn from another student's effort to cope with task-g ( $3\frac{1}{4} - \frac{1}{2}$ ). The solver considered more convenient to substitute 3 with  $\frac{4}{4} + \frac{4}{4} + \frac{4}{4}$ . This substitution facilitated the addition that follows since all the fractions have now the same denominator.

SS14.7.1: I will substitute 3 with  $\frac{4}{4} + \frac{4}{4} + \frac{4}{4}$ .

SS14.7.2: Then,  $\frac{4}{4} + \frac{4}{4} + \frac{4}{4} + \frac{1}{4} = \frac{13}{4}$ .

SS14.7.3: And then,  $\frac{13}{4} - \frac{2}{4} = \frac{11}{4}$

The '*used parts of the numbers*' strategy was recorded only in task-e and task-f. In the first case the solvers decomposed the mixed number to its parts, (i.e., the whole number and the fraction) and then made use of the equality  $a + b - c = a + (b - c)$ :  $1\frac{1}{2} - \frac{1}{4} = 1 + (\frac{1}{2} - \frac{1}{4})$ . In the second case the students decomposed again the mixed number and applied the distributive property of multiplication over addition:  $3\frac{4}{8} \times 2 = (3 \times 2) + (\frac{4}{8} \times 2) = 6 + 1 = 7$ . The '*mental picture*' strategy is connected to the solvers' effort to visualize the activity as a means to mentally calculate the result (Carvalho & da Ponte, 2015). So, some students while trying to solve task-h preferred to consider 20 as a whole unit, 'like a circular pie' which was divided mentally in 4 equal pieces and 3 of them were taken.

SS17.8.1: I am thinking of a circular pie and draw its  $\frac{3}{4}$ .

However, the strategy that dominated with extremely high percentage (42,95%) was the '*used mental form of written algorithm*' strategy. Solvers worked mentally in a way that appeared to reflect the written algorithm. For task-d a relevant reaction was "I will make sure that denominators are the same...  $\frac{5}{6} + \frac{4}{3} = \frac{15}{18} + \frac{24}{18} = \frac{39}{18}$ ," (SP7.4.1). For task-f the students converted the mixed number to fraction and then they followed the rule for multiplying a whole number with a fraction: "3x8=24, plus 4...28, times...56, 56/8...therefore, 7" (SU1.55.6.1). The '*used reduction*' strategy was the one added by the research team. Instances of this strategy were identified in three tasks. The students simplified the whole number (in tasks b, c and h) with the denominator of the fraction. So, in task-b, they simplified the 4s:  $4 \times \frac{3}{4} = 3$ . In task-c, the simplification (4 and 8 were divided by 4) resulted in a fraction equal to one:  $4 \times \frac{2}{8} = \frac{2}{2} = 1$ . In task-h, the word 'of' was translated as 'times' and then the whole number was again simplified with the denominator:  $\frac{3}{4}$  of 20, which means  $\frac{3}{4} \times 20 = 3 \times 5 = 15$  (20 and 4 were divided by 4).

Sometimes it seems to exist an overlapping between the '*used reduction*' strategy and strategies such as the '*used equivalence*' or the '*written algorithm*'. But it was the solver's aim as this was expressed verbally that made us to decide if the solution is associated with one strategy or another. For example, in task-a, the solution  $\frac{1}{2} + \frac{4}{8} = \frac{1}{2} + \frac{1}{2} = \frac{2}{2} = 1$  might be considered as the '*use of equivalence*'. However, the student's wording reveals pure use of fraction reduction: "I will simplify the fraction 4/8 which...I divide by 2... is 2/4 which in turn is 1/2. Therefore, 1/2 + 1/2" (SU1.45.1.1). In the same spirit, for the same task, the answer  $\frac{1}{2} + \frac{4}{8} = \frac{4}{8} + \frac{4}{8} = \frac{8}{8} = 1$  sometimes was considered as '*use of equivalence*' and others as '*written algorithm*' (see below extracts SU1.9.1.1-2 and SU1.58.1.1-3 respectively)

SU1.9.1.1: I will make two equivalent fractions. I will multiply both the numerator and denominator by 4.

SU1.9.1.2: It makes  $\frac{4}{8} + \frac{4}{8} = \frac{8}{8} = 1$

.....

SU1.58.1.1: I will make fractions with the same denominator and I will add them.

SU1.58.1.2: I need the Least Common Multiple which is 8.

SU1.58.1.3: It becomes  $\frac{4}{8} + \frac{4}{8} \dots \frac{8}{8}$ , therefore 1.

Errors were surprisingly the second most popular result (McIntosh, 2006). Both procedural and conceptual errors were detected. Procedural errors were mainly due to miscalculations, for example:  $\frac{5}{6} + \frac{4}{3} = \frac{5}{6} + \frac{8}{6} = \frac{12}{6}$ . Conceptual errors were mirroring students' limited understanding and misconceptions relevant to fractions. We could mention the flawed idea that when we add fractions we just add separately numerator and denominators,  $\frac{5}{6} + \frac{4}{3} = \frac{9}{9}$  (task-d) or  $\frac{1}{2} + \frac{4}{8} = \frac{5}{10}$  (task-a). We could also add the misconception that when we multiply a whole number with a fraction then the whole number must be multiplied by both the nominator and the denominator:  $4 \times \frac{3}{4} = \frac{12}{16}$ . Moreover, some the students hesitated or were not able to give an answer. Almost 16 out of 100 instances were actually non-answered. Finally, we sorted as non-codable answers that did not reveal any kind of thought. In this category we also included efforts that were based in a strategy that was not suitable for the specific task. In task-k some solvers tried to calculate the results as  $1\frac{3}{4} \times \frac{1}{4} = 1.75 \times 0.25$ . This last multiplication was quite demanding, and the students decided to abandon the task.

	SP (Primary)	SS (Secondary)	SU1 (stud. teachers)	SU2 (Math, Engin)
Changed representation	–	3 (0.28%)	17 (2.41%)	36 (5.63%)

Written algorithm	<b>373 (43.42%)</b>	<b>330 (30.78%)</b>	<b>326 (46.31%)</b>	<b>377 (58.99%)</b>
Reduction	12 (1.40%)	24 (2.24%)	40 (5.68%)	101 (15.81%)
Incorrect	<b>296 (34.46%)</b>	<b>406 (37.87%)</b>	<b>147 (20.88%)</b>	<b>58 (9.08%)</b>
Non-answered	151 (17.58%)	264 (24.63%)	88 (12.50%)	16 (2.50%)
Non-codable	5 (0.58%)	18 (1.68%)	11 (1.56%)	9 (1.41%)

**Table 2: Number of total responses per strategy per group**

It is more than evident the dominance of the written algorithm approach over the remaining strategies. This might raise questions about the effectiveness of the way we teach. This becomes more interesting if we take account of the incorrect, non-answered and non-codable answers. The total percentage of these three categories is 44.86% which actually is more than the percentage of the algorithm. If we consider together these two broad groups of participants (those who used the written algorithm and

those who had difficulties in answering) then it can be said that almost 9 out of 10 participants either used the written algorithm or were unable to solve the tasks ( $42.95\% + 44.86\% = 87.81\%$ ).

Table 2 presents in detail how students' answers are distributed across the groups in the different educational levels. The percentages in each column correspond to the specific group of students and not to the total sample and confirm the strong influence of the written algorithm in each group. A closer look reveals also some interesting issues. On the one hand it appears that both groups of university students rely more than primary and secondary students to the written algorithm (which by far dominates the landscape). Forty five out of 100 preservice teachers and 6 out of 10 Mathematics and Engineering students resorted back to the written algorithm to respond to the tasks. Moreover, it is seeming paradox that the highest percentage for algorithmic use (Table 2) is got by students from the Mathematics Department and the Faculty of Engineering [SU2] who are the ones with the strongest mathematical background.

On the other hand, it appears that as we move from primary to tertiary education there is an increased variety of the correct strategies used (though very small number of instances compared to the total number of answers). We refer to all but the '*written algorithm*' correct strategies. In total 3.96% of the primary school students' answers used these strategies. This percentage is more or less the same for secondary education students (5.04%). However, for the tertiary education students this becomes almost three times bigger (13.07%). This is not because the use of the '*written algorithm*' strategy has been reduced. On the contrary, the relevant percentages of the algorithmic use for SU1 and SU2 students are extremely high and greater than the corresponding ones for younger students. It is the number of the incorrect answers that became smaller.

Having said that, it remains impressive that the main finding of this study is the dominance of the algorithmic use across all the educational levels (Rezat, 2011). This students' preference becomes more interesting because the tasks were designed to be amenable to a variety of strategies for their solution. For example, task-f ( $3\frac{4}{8} \times 2$ ) can be solved directly if one notices that the wanted is the double of 3 and half. But there are other possibilities also. According to the '*changed representation*' this can be seen as  $3.5 \times 2$ . According to '*written algorithm*' it is  $3\frac{4}{8} \times 2 = \frac{28}{8} \times 2 = \frac{56}{8} = 7$ . There is also the case of the '*worked with parts*' strategy:  $(3 \times 2) + (\frac{4}{8} \times 2) = 6 + 1 = 7$  or its modified version  $(3 \times 2) + (\frac{1}{2} \times 2)$ . In this last version the fraction  $\frac{1}{2}$  might be the result of the '*equivalence*' or the '*reduction*' strategies. However, for this specific task, according to our data, 3 out of 4 who answered correctly preferred the '*written algorithm*' which obviously is not a straightforward calculation. On the contrary it is rather demanding and time consuming. The situation is more or less similar for the total set of the tasks. This highlights the students' obsession with the use of the written algorithm which disqualifies the core idea of mental calculations.

## Conclusions

Given the importance of the ability to execute mental calculations involving rational numbers it became evident that although the students exhibit a broad range of different strategies the majority of these strategies is underrepresented. The students mainly follow the steps of the written algorithm. Moreover, it seems that this is not an age-dependent reaction. Very interestingly, the '*written*

*algorithm*' strategy was the most frequent choice for primary, secondary, and tertiary education students. We do not doubt that possibly the solvers were aware of alternative strategies and able to use them for mentally calculating the results. What can be said on the basis of the data is that their first choice was the application of the written algorithm. Moreover, there was a great number of participants (44.86%) who either did not give any answer or the answer they gave was incorrect or non-codable. This makes evident the difficulty the students have with rational numbers especially when they are invited to handle them mentally. Additionally, it seems that university students exhibit flexibility in their choice of strategies but in an extremely small percentage. All these deepen our understanding of the topic but at the same time challenge us for a future study that will try to give answers to questions such as: Why do they choose these strategies? What alternative strategies do they know? Why do they not use those alternative strategies? Would the results be the same if the students were asked to solve written the same tasks?

# Students' ability to compare fractions related to proficiency in the four operations

Pernille Ladegaard Pedersen<sup>1</sup> and Peter Sunde<sup>2</sup>

<sup>1</sup>Aalborg University, Faculty of Learning, Denmark; [pelp@via.dk](mailto:pelp@via.dk)

<sup>2</sup>Aarhus University, Department of Bioscience, Denmark; [psu@bios.au.dk](mailto:psu@bios.au.dk)

*In this paper, we investigate the relationship between 99 fourth-grade students' ability to compare fractions ( $\frac{1}{4} = \frac{2}{8}$  and  $\frac{5}{11} < \frac{3}{5}$ ) and solve tasks in each of the four operations ( $68 + 753$ ,  $547 - 64$ ,  $12 \times 72$   $78 \div 3$ ) in a Danish primary school. The students faced more challenges answering the question where the fractions were equal compared to the non-equal fraction items (32% vs 49% correct answers) although the probability of solving the two types of questions were significantly positively associated (odds ratio = 11.0). Relative to the four operations items, solving the non-equal fraction item associated significantly positively with solving the multiplication (odds ratio = 4.5) and division item (odds ratio = 3.9) while the correct solving of the equal fraction associated significantly positively with the solving of the division item (odds ratio = 2.6). These results support the notion that the understanding of fractions is closely connected to multiplicative reasoning.*

*Keywords: Arithmetic, whole number division, fractions.*

## Introduction

Research has shown that students' knowledge of fractions in middle school greatly affects their overall progression in general mathematics (e.g., Bailey, Siegler, & Geary, 2014). There is also evidence that students need to have mathematical proficiency in the four operations of whole numbers to enable them to effectively comprehend rational numbers (Behr & Post, 1988). Additionally, multiplicative reasoning seems especially connected to the development of students' understanding of fractions (Thompson & Saldanha, 2003). Therefore, it is relevant to further investigate the variety of associations between the students' proficiency in the four operations and in fractions. This paper aims to uncover the fourth grade students' abilities to answer equations that require an understanding of fractions as well as the relationship between their abilities to answer tasks and their understanding of the four operations. The primary research question for this paper is: How do students' abilities to solve arithmetic tasks in the four operations (e.g., division) relate to their abilities to answer items that require them to compare fractions?

We expect that the students' proficiency in division and multiplication, but not their capability related to addition and subtraction, will show a strong association to their ability to answer fraction equations because we assume that an understanding of fractions is closely connected to multiplicative reasoning. This paper primarily focuses on students' difficulties with comparing fractions and how this is associated with the four operations. Therefore, the theoretical framework is based on theories of fractions and how these are connected to, for example, multiplicative reasoning.

## Theoretical framework

Over the last three decades, several researchers, such as Bailey, Siegler and Geary (2014), Behr and Post (1988), and Ni (2001), have studied aspects of students' understanding of fractions and the complexities related to teaching and learning these concepts. For example, Kieren (1976) described how fractions can be seen as a multifaceted construct. He characterized the understanding and knowledge of rational numbers as sets of sub-constructs, which have since been further developed by Behr, Lesh, Post, and Silver (1983). They defined these sub-constructs as: Part-whole, decimal, ratio, quotient, operator, and measure. They recommended that the sub-construct part-whole should be considered to be distinct from the others as a fundamental scheme. Although we are aware of the limitation, in this paper we choose to focus on the sub-construct of quotient even though rational numbers are a more complex system of sub-constructs, and we are aware of for example the importance of ratio in the proportional understanding of fraction (Behr, Lesh, Post, & Silver, 1983; Behr & Post, 1988).

### Quotient

For the sub-construct quotient, the denominator designates the amount of recipients, and the numerator represents the amount of quantities that have to be shared (Behr & Post, 1988; Toluk & Middleton, 2001). Thus, the sub-construct of quotient has a connection to partitive division, also known as sharing division, where an object or a group of objects are divided into a number of equal parts (Fischbein, Deri, Nello, & Marino, 1985). Moreover, division is the only one of the four operations where a rational number can be the outcome. Therefore, division can be regarded as an integral part of an understanding of rational numbers; hence students must develop an understanding of the connections between division and fractions (Behr & Post, 1988; Toluk & Middleton, 2001). Toluk and Middleton (2001) conducted a case study of students' development of fraction schemes and the importance of division in the progression from the part-whole sub-construct to the conceptualisation of the quotient sub-construct. They illustrated the developmental process from Fraction-as-Part-Whole and Whole Number Quotient Division-as-Operation to the final stage, which was Division-as-Number ( $a \div b = a/b$ , "  $a/b$ ) (Toluk & Middleton, 2001). When comparing fractions, it is necessary to understand that the magnitude depends on the relation between the two quantities; the denominator and the nominator (Ni & Zhou, 2005), rather than simply viewing the fraction notation as two independent cardinal numbers above and below a bar (Stafylidou & Vosniadou, 2004).

### Equivalent fraction

Overall, there is substantial support that students' whole number multiplicative understanding is an important resource for developing fraction knowledge (Hackenberg & Tillema, 2009). In addition, multiplicative reasoning appears to be essential for the effective understanding and accurate representation of equivalent fractions. One basic fraction perception is to understand fraction equivalence (Ni, 2001). Fraction equivalence can be explained as the constancy of a quotient and as the constancy of the multiplicative relationship between the numerator and the denominator (Behr, Harel, Post, & Lesh, 1992). Here, the quotient is involved in an understanding of equivalence; for example,  $\frac{1}{2}$  can be viewed as a division, which represents the equivalence between  $\frac{1}{2}$  and 0,5 (Behr,

Lesh, Post, & Silver, 1983). Each fraction belongs to a unique equivalence class represented by a multiplicative equation. Each class denotes a distinct rational number; for example  $\frac{1}{2} = \frac{2}{4}$ . Difficulties related to the understanding of equivalent fractions have been connected to the students' lack of multiplicative reasoning (Ni, 2001). If the students do not develop this understanding of equivalence, they will view for example tasks that involve adding two fractions with different denominators as a purely technical algorithm (Arnon, Nesher, & Nirenburg, 2001). Therefore, both multiplication and division of whole numbers might be more closely connected to understanding fractions than additional reasoning. Hence, we expect to find an association between the fraction equations and the multiplication and division items, meaning that if the students can solve items involving the two operations correctly, they will more likely be able to solve the fraction equations. However, if the students have not developed a proficiency with multiplication and division, we expect that those students will experience difficulties answering the fraction equations correctly, especially the equivalent fraction equations. We will analyse how the two fraction items differ in proportion of correct answers as well as whether and how they differ in association with the four operations.

## Methods and analysis

Data consisted of answers provided by fourth-grade students (ages 10–11) on a computerised test. The test consisted of 110 items, including problems on the four operations, fractions, and algebra as well as word problems. The test was time restricted (45 minutes), so not all students finished all of the items. The questions on fractions included in the analysis were items 50 and 52, and only the students who answered these items within the timeframe were included in the analysis. However, we are aware of the constraints of interpreting the students' answers on a computerised test in which the student just enters the answer to the item. This only allows us to review a student's correct or incorrect answers and not the working process itself. In addition, we are aware that neither a whole number multiplication nor a division item can be seen as a strong indicator of student's multiplicative reasoning. A quick review of these answers showed that the students who answered this section were generally quick at calculating and, on average, had the highest scores in the first section of the test (whole number arithmetic operation tasks). In other words, the students who reached the fraction items (items 50 and 52) scored above average on the test ( $N = 99$ ). The items we chose to analyse were items where the students were asked to compare  $\frac{1}{4}$  to  $\frac{1}{5}$ ,  $\frac{5}{11}$  to  $\frac{3}{5}$ , and  $\frac{1}{4}$  to  $\frac{2}{8}$ . The students could choose between the following three symbols:  $<$ ,  $>$ , and  $=$  (Figure 1).

<p><b>A. Indsæt det manglende tegn: <math>&gt;</math>, <math>&lt;</math> eller <math>=</math>.</b></p> <p>Tryk på pilen.</p> <p><math>\frac{1}{4}</math> <input type="text" value="&gt;"/> <math>\frac{1}{5}</math></p> <p><math>\frac{5}{11}</math> <input type="text" value="&lt;"/> <math>\frac{3}{5}</math></p> <p><math>\frac{1}{4}</math> <input type="text" value="="/> <math>\frac{2}{8}</math></p>	<p><b>B. Regn opgaverne.</b></p> <p><math>68 + 753 =</math> <input type="text"/></p> <p><math>547 - 64 =</math> <input type="text"/></p> <p><math>12 \cdot 72 =</math> <input type="text"/></p> <p><math>78 : 3 =</math> <input type="text"/></p>
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 1: The items used in the analysis. Translated to: A. Choose the right symbol:  $>$ ,  $<$  or  $=$ . (No symbol was preselected). B. Calculate the task**

Earlier in the test, the students were asked to solve a whole number equation using the same symbols. There were not any significant differences found in the items containing the equal sign. The first item was created to see the students' answers on a unit fraction equation. Often, students have whole number biases in their learning processes of fractions such that they look at the biggest digit and conclude that this is the largest number; for example 5 is larger than 4 (Ni & Zhou, 2005). The second item,  $\frac{5}{11}$  compared to  $\frac{3}{5}$ , was likewise designed to examine the students' answers on an item where there is a whole number bias since both 5 and 11 are bigger than 3 and 5. In the solving process of this item, the student might use a different strategy, such as the benchmark strategy where  $\frac{5}{11}$  is smaller than a half and  $\frac{3}{5}$  is bigger than a half (Clarke & Roche, 2009). We considered this item to be the most difficult item for the students to solve because of the different numerator and denominator as well as the fact that the item did not contain any unit fraction. The last item was the equal fraction item where  $\frac{1}{4}$  is equal to  $\frac{2}{8}$ . This item included the unit fraction  $\frac{1}{4}$ , which we considered to be a commonly used fraction in the fourth-grade curriculum. Therefore, we assumed that the students might have a good mental representation of this fraction. As for the analysis of the relationship between the four operations, we have selected one whole-number problem from each of the operations ( $68 + 753$ ,  $547 - 64$ ,  $12 \times 72$ ,  $78 \div 3$ ) based on the following criteria: The item where the students had the fewest correct answers, the most wrong answers, and the most times it was not answered, in that order. Each of the arithmetic items was designed to evoke solution strategies based on number sense approaches. For example, in the case of item  $12 \times 72$ , it involves breaking up one of the factors 12 into a 10 and a 2 and then multiply it in parts  $(10 \times 72) + (2 \times 72)$ .

## Analysis

The analysis focused on how the students' answers to one fraction equation associated to the other fraction equation and to answers on the four operations items. The association between the probability of returning a correct answer as opposed to an incorrect one or omitting an answer for one item in relation to whether the student answered another item correctly was analysed as a binary logistic regression (Logistic procedure in SAS 9.5) function. Logistic regression models yield similar  $p$ -values for statistical significance of associations as conventional  $2 \times 2$  contingency  $\chi^2$ -tests as well as additionally producing predictions of the conditional probabilities of returning a correct answer for one item in relation to whether the student had answered the other item correctly. The difference between these two predicted probabilities on a logit scale (coefficient of the difference between the two levels in the regression equation) furthermore serves as a coefficient of association in the response patterns between the two items.

The anti-log of this coefficient (the odds ratio 'OR') equals how many more times a student is likely to answer item  $Y$  (e.g.,  $\frac{1}{4} = \frac{2}{8}$ ) correctly if he/she has answered item  $X$  (e.g.,  $78 \div 3 =$ ) correctly as compared to if he/she has not answered  $X$  correctly. Hence, an association coefficient of 1.0 indicates that the students answering item  $X$  correctly are  $\exp(1.0) = 2.71$  times more likely to answer item  $Y$  correctly as compared to the students who did not answer item  $X$  correctly. Note that the ORs derived from the logistic regression equation exceeds the ORs calculated from the arithmetic values of the probabilities because of the infinite state space on the logit scale, whereas values are on the arithmetic

scale  $\hat{I} \in [0;1]$ . The conditional probabilities of getting correct answers as a function of correct vs. incorrect or missing answers in other item types were modelled and illustrated graphically for the item  $\frac{1}{4} = \frac{2}{8}$  as a function of the item  $\frac{5}{11} < \frac{3}{5}$  and  $\frac{1}{4} > \frac{1}{5}$ . The same was modelled and illustrated for the item  $\frac{5}{11} < \frac{3}{5}$  as a function of item  $\frac{1}{4} > \frac{1}{5}$ . A matrix table of association coefficients between items that represent the different concepts of fractions, addition, subtraction, multiplication, and division was calculated for each of the items.

## Results

When analysing data from the test, it was found that the students showed difficulties solving items involving equivalent fractions. Only 32% of the students answered  $\frac{1}{4} = \frac{2}{8}$  correctly while 49% answered  $\frac{5}{11} < \frac{3}{5}$  correctly (Figure 2). Overall, the two non-equal fraction equations were similar in their answer patterns since both had about 50% correct, about 30% incorrect, and 20% with no answer.

**Figure 2: Percent of correct, incorrect or no answer to the three fraction items ( $N = 99$ )**

When comparing, the probability of answering the three items representing equation problems correctly were all strongly and highly statistically significantly associated (Figure 3, association coefficient values: 2.4–4.0, i.e. ORs: 11–54).

**Figure 3: Percent of correct answers on one item type conditional to whether the student answered another item type. Error bars indicate 95% confidence intervals. All differences were highly significant ( $p < 0.0001$ )**

The two non-equal fraction items showed the same pattern when compared to the equal fraction. Hence, in all comparisons, the probability of answering correctly on the item  $\frac{1}{4} = \frac{2}{8}$  was about 90% if the student had answered the predictor item  $\frac{5}{11} < \frac{3}{5}$  correctly compared to about 50% if they had

answered it incorrectly (Figure3). When comparing the two non-equal fraction items, we found that if the students had answered the predictor item  $\frac{1}{4} > \frac{1}{5}$  correctly, only about 10% could then not solve  $\frac{5}{11} < \frac{3}{5}$ . Therefore, we chose to focus on the equal fraction item  $\frac{1}{4} = \frac{2}{8}$  and the non-equal fraction item  $\frac{5}{11} < \frac{3}{5}$ . When comparing all problem types (Table 1), correct solutions were most strongly associated with the two equation problems (OR = 11.0,  $p < 0.0001$ ), followed by the association between the addition and subtraction (OR = 6.8,  $p < 0.0001$ ), multiplication and division (OR = 5.4,  $p < 0.0001$ ), and subtraction and multiplication (OR = 5.0,  $p = 0.001$ ) items, respectively. The results of the equation item  $\frac{5}{11} < \frac{3}{5}$  were highly significantly positively associated with the results of the multiplication (OR = 4.5,  $p = 0.0009$ ) and division items (OR = 3.9,  $p = 0.003$ ). The results of the equation item  $\frac{1}{4} = \frac{2}{8}$  only associated positively with the division item (OR = 2.6  $p = 0.02$ ) (Table 1). The lowest associations (all non-significant) were found between the results of two equation items and the results of addition and subtraction items (all four ORs 1.7–2.4), between equation item  $\frac{1}{4} = \frac{2}{8}$  and the multiplication item (OR = 2.1) (Table 1).

	1/4 = 2/8	5/11 < 3/5	68+753	547-64	12×72	78÷3
5/11 < 3/5	2.40 ****					
68+753	0.85	0.53				
547-64	0.75	0.88	1.91 ****			
12×72	0.72	1.51 ***	0.83	1.60 ***		
78÷3	0.96 *	1.36 **	1.02 *	0.68	1.68 ****	
N items:	99	99	142	142	142	142
N correct items:	50 51%	67 68%	32 23%	49 35%	98 69%	87 61%

**Table 1: Coefficients of association (log odds ratios) of correct vs. incorrect/missing answers of different problem items: The higher the coefficient value, the more likely a correct answer of one item type associated with a correct answer of the other item type. Significance levels: \*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , \*\*\*\*  $p < 0.0001$ . (A log odds ratio of 1 equals a difference of  $\exp(1) = 2.7$ )**

## Discussion

This statistical investigation of the two fraction items' differences and their associations to the four operations revealed the following three results: Firstly, when comparing the three items with each other, the students' answers showed that the equal fraction item (30% correct answers) was more difficult than the two non-equal fraction items (50% correct). This was unexpected since one of the fractions in the equal item was a commonly referenced unit fraction of  $\frac{1}{4}$ . It is a fraction which is common in the introduction of fractions in the fourth grade, whereas  $\frac{5}{11}$  is a rare fraction notation in school curriculums. As referred to earlier, we therefore expected the item to be easier than the other one. The students' difficulties with the equal item could indicate that the students have difficulties

understanding fractions as an *equivalence class* made by a multiplicative equation (Ni, 2001). This is emphasized by the results in Figure 3, which show that the probability of answering correctly on the item  $\frac{1}{4} = \frac{2}{8}$  was still only 50% if the student had answered  $\frac{5}{11} < \frac{3}{5}$  incorrectly. However, a probability of only 10% was found for answering  $\frac{5}{11} < \frac{3}{5}$  correctly if they had answered  $\frac{1}{4} > \frac{1}{5}$  incorrectly, which indicates that the comparison of equal fraction items differed. This could be due to the fact that when solving the equivalent fraction items, the students have a whole number bias (Ni & Zhou, 2005), the equivalence can be difficult for the students to comprehend because it is the first time they have experienced numbers that can be labelled differently and still refer to the same numerical quantity. Secondly, we found that the result of the non-equal  $\frac{5}{11} < \frac{3}{5}$  fraction was highly associated with the result for both the multiplication (OR = 4.3) and the division (OR = 3.9) items, whereas there was no significant association with the results of the addition and subtraction items. This result coheres well with the theory that fractions have a stronger connection to multiplicative reasoning than to additive reasoning (Thompson & Saldanha, 2003). According to this theory, one should have expected a closer association with division than with multiplication (Toluk & Middleton, 2001). A possible explanation might be that the result patterns of the two operations were also closely related (OR = 5.4), suggesting that the basis of the understanding necessary for solving division and multiplication problems is so closely related that they could not be discriminated in the analysis.

Thirdly, we found that the results of the non-equal item correlated more strongly and significantly with the results of the division and multiplication items than was the case for the result of the equal fraction item (that only associated modestly with the result of the division item). Thus, there is a component of the equal fraction item making this more difficult for the students to answer. An explanation could be that students have not yet developed the conceptualisation of the *quotient* as *Division-as-Number* (Toluk & Middleton, 2001). Hence, when students look at equal fractions, they can see a *quotient* as a division, which represents the equivalence between both  $\frac{1}{4}$ ,  $\frac{2}{8}$  and 0.25 (Behr, Lesh, Post, & Silver, 1983). Overall, these results support the notion that the understanding of fractions is closely connected to multiplicative reasoning; however, it is essential to pursue further investigation since there seems to be a different pattern in the students' proficiency in the equivalence concept. Otherwise, they will experience difficulties in understanding other concepts, like common denominators (Arnon, Nesher, & Nirenburg, 2001). Further research should collect qualitative data to examine the students' working process to overcome the strong limitations of a computer test, which can only offer limited insights. We need to investigate further ways in which the students experience difficulties in the equal fraction task. It may be that this is strongly connected to their understanding of the equal sign or that there is a connection to a whole number bias. On the one hand, the students' whole number multiplicative understanding might support their understanding in some fraction contexts, and on the other hand, the students' understanding of whole numbers can distract them in other fraction contexts.

# Flexible mental calculation skills of freshmen and graduates

Charlotte Rechtsteiner

PH Ludwigsburg, University of Education, Institute of Mathematics and Computer Science,  
Ludwigsburg, Germany; [rechtsteiner@ph-ludwigsburg.de](mailto:rechtsteiner@ph-ludwigsburg.de)

*Keywords: Flexible mental calculation, teacher education, students' content knowledge.*

## Theoretical Framework

Researchers and mathematics educators agree on the importance of flexibility in mental calculation, and in the last two decades a lot of research on students' development in flexible mental calculation was conducted (brief overview see Rathgeb-Schnierer & Green, 2017). Torbeyns et al. (2011) investigated flexibility and adaptivity in adults and revealed that they frequently and efficiently apply indirect addition on subtraction problems up to 100.

Baumert & Kunter (2011) describe four professional competences: beliefs, motivational orientations, self-regulation and professional knowledge. Professional knowledge is again subdivided in five category groups. The performance of flexible mental calculation can be considered as content knowledge. During their teacher training program students should acquire the competences which are important for their future teaching activity. Therefore, it is necessary to know about students' knowledge at the beginning and the end of university.

Regarding the described aspects, we summarize that teachers are supposed to be flexible in mental calculation. Furthermore, we expect all students who currently entered university to perform flexibly since this has been a central aim in German primary schools for the last 15 years.

## Overview on the Project

Due to the fact that there is hardly any research on teachers' professional knowledge regarding flexibility in mental calculation, this study focuses on this aspect. Thereby, there is a special focus on the comparison of freshmen and graduate students as well as students with mathematics as major and minor subject. Three questions are posed in this study: Do freshmen and graduates use adaptive expertise? Do students with mathematics as major subject perform better than students with mathematics as minor subject? Can we find differences both between freshmen and graduates and between students with mathematics as subject and those with mathematics as basic education?

## Design

A CRF 2x2 experimental design is used to test the research hypothesis. There are two independent variables: the area of studies (Factor A: a1 = mathematics as major; a2 = mathematics as minor) and the length of study (Factor B: b1 = freshman, b2 = graduate). The dependent variable is a survey with ten different tasks to solve up to 1000.

## Procedure and data analyses

The sample size is determined with a type II power analysis – N as a function of power ( $1-\beta$ ),  $\Delta$ , and  $\alpha$ . The desired power ( $1-\beta$ ) is 0.99, and medium effects ( $\Delta = 0.50$ ) in relation to the dependent variable

are classified as significant; the significance level is  $\alpha=0.05$ . Our sample were drawn from the university courses for freshmen and graduates, and comprised 77 freshmen and 75 graduates.

We used seven tasks with special problem characteristics (851–426, 960–320, 923–398, 906–891, 999–699, 672–335, 853–497). Firstly, every task was coded with a range zero to three. Therefore, the maximum benchmark for flexibly solving all seven tasks was 21, the minimum benchmark for correctly solving all seven tasks was seven. Secondly, we developed a score for flexible mental calculation from one to six. Score one represents high flexibility, and score six rigidity. This score for flexibility was subsequently mapped with the points of the coding.

For analyzing our empirical data four steps were carried out: (1) First, we screened the data and replaced missing data by the multiple imputation approach. (2) Second, we analyzed the data descriptively. (3) Third, we conducted a two-way ANOVA in accordance with the CRF 2×2 design. (4) We did *a posteriori* *t*-tests to analyze several factor levels.

## Results and Discussion

The main effects A (area of studies) and B (length of study) were significant at the  $\alpha$  level of .05 ( $F_{1,148} = 4.38$ ,  $p < .04$ ;  $F_{1,148} = 14.40$ ,  $p < .01$ ). The corresponding  $H_0^A$  and  $H_0^B$  were rejected in favor of  $H_1^A$  and  $H_1^B$ . According to the mapping score, the results show as well that students with mathematics as a major subject start with the mean score of 3,95 and improve to 3,00. Likewise do students with mathematics as minor subject: They improve from 4,16 to 3,61 in mean. Regarding these score-levels, there is an improvement in both groups. However, the reached scores are not adequate at all for prospective primary teachers. Our results suggest a modification of the teacher training program in math courses as well as math education courses in terms of targeting teaching towards flexibility. This could be accomplished by focusing on inherent structures and discussing them on a meta-level in arithmetic and algebra classes, as well as by collaboration of teacher trainees and school students in classes which explicitly emphasize flexible mental calculation.

## Acknowledgment

I would like to thank Prof. Dr. Andreas Zendler for his support with the quantitative data analysis. This study is financed by the Pädagogische Hochschule Ludwigsburg, University of Education.

*In this paper a tool to evaluate students' performance in solving particular fraction word problems is described. It is a pencil and paper test with seven tasks, which have been designed ad-hoc from a previous historical-epistemological study of this kind of problems. The tasks have in common that all of them involve iterative processes to calculate part of the part complement. The test was validated through reliability and content validity. The difficulty of each task was obtained through the resolution success probability based on the analysis of the responses of 202 Mexican students between 15 and 16 years old. Difficulty of the task is increased when its structure is more complex. Surprisingly, only a small number of students used algebra to solve the problems.*

### Introduction

Currently, problem solving emerges with renewed interest in curricular proposals because it is considered a basic competence, particularly in the development of arithmetic and algebraic thinking. An example of this assertion is that it appears explicitly in the curriculum of basic education of various countries (i.e., in Mexico (SEP, 2011)). Word problems have played a central role in the school context (Puig & Cerdán, 1988). Textbooks include a wide range of these problems, whose wording includes a setting, which is not expected to give answer to some practical situation. In Polya's typology (cited by Puig & Cerdán, 1988) such problems are referred as "finding problems" –it is requested that, under certain conditions, a quantity be determined from others that are therefore known–.

The fact that they appear in school curriculum does not imply that their teaching or learning is simple. A big number of authors have studied how this type of problems is a source of serious difficulties for many students (Korpershoek, Kuyper, & Van der Werf, 2015; Nesher & Teubal, 1975; Riley, Greeno, & Heller, 1983; Verschaffel, De Corte, & Pauwels, 1992). Daroczy, Wolska, Meurers, and Nuerk (2015) show that difficulties can be caused by: a) the linguistic complexity of the statement, b) the numerical complexity, or c) the relationship between the linguistic and numerical complexity. Other

<sup>1</sup> This research has been supported by Conselleria d'Educació, Investigació, Cultura i Esport through the GVPROMETEO2016-143 project, the Ministerio de Educación through EDU2017-84377-R (AEI/ERDF, EU) project, and the University of Valencia and Cinvestav within the framework of the Iberoamerica-Santander Research Scholarship Program.

authors consider the problem difficulty as the probability to solve them correctly (Ivars Santacreu & Fernández-Verdú, 2015; Riley, Greeno, & Heller, 1983).

More often than not, these studies about word problems are based on statements that involve whole numbers. However, in the case of fraction word problems the literature is scarce, both regarding its classification, and the identification of students' difficulties encountered when solving them. This lack in the literature leads us to the first aim of the study described in this paper: To characterize students' performance when solving particular fraction word problems and to measure their difficulty through the probability of solving them correctly.

The word problems chosen for this research have a common feature: an unknown quantity, which is partitioned into parts expressed by fractions. These problems repeatedly appear in the history of Mathematics, in books from different times and cultures, often solved in different ways (Gomez, Sanz, & Huerta, 2016). In this report, we chose to focus on problems with the common syntagma "of what remains", that is referred to a part of another part, which is the complement to the unit. The following is an example of this type of problems:

I found a stone, but I did not weight it; after taking away a  $\frac{1}{7}$  and then a  $\frac{1}{13}$  [of what remains], I found that its weight was 1 manna. What was the original weight of the stone? (Mesopotamian origin, Katz 2003, p. 27)

The common syntagma is often repeated, as in the next example:

A pilgrim carried a certain amount of money. He gave away half the amount (to Brahmins) at Prayaga. He spent two-ninths of the remaining amount in Kashi. One-fourth of the remainder was paid as duty. He spent the  $\frac{6}{10}$ th part of the remainder in Gaya. Finally, he returned home with 63 *niskas*. If you know the fractional residues, find the amount he carried. (Lilavati, 1150/2006, p. 59)

This situation allows us to raise the second aim of the research: To determine if the increase of steps in the statement entails an increase in the problem difficulty.

## Methodology

Students between 15 and 16 years old were considered for the research. In the inquiry carried out in a public school at Mexico City a sample of 202 individuals was formed.

For data collection, a paper and pencil test was designed with seven fraction word problems of the type aforementioned. A previous study was taken into account in which those problems were classified and mathematical elements necessary for their resolution identified (see Gómez, Sanz, & Huerta, 2016).

In a 90-minute session, students completed individually the test. They were allowed to use a pen, but not calculators, or correctors that could interfere with qualitative analysis that was going to be carried out.

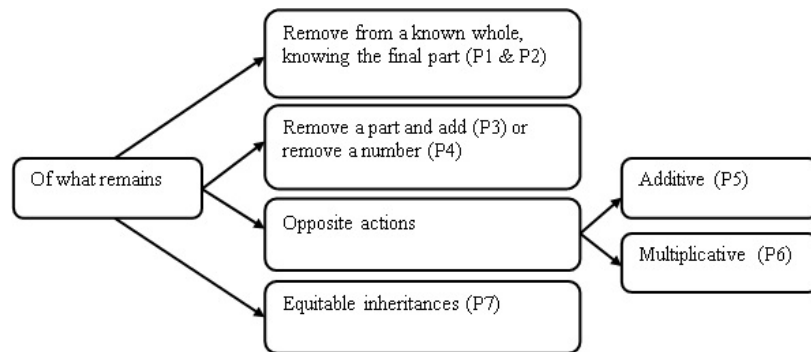

The answers to the tasks were categorized following the guidelines of Taylor and Bogdan (1987), and a validation of the test was carried out according to Lacave, Molina, Fernández and Redondo (2016), as well as an analysis of the answers with a descriptive approach using IBM SPSS Statistics 22.

## Design of the test

Paper and pencil test design was structured taking into account two aspects: a Historical and Epistemological Analysis (hereinafter HEA) and a Didactic Analysis (hereinafter DA). According to Gómez (2003), the first aspect allows to investigate how the teaching of mathematics has been configured at different moments in history. In particular, regarding the solving of fraction word problems, it provides information about structure, context, quantities involved and solving methods that most relevant authors have included on documentary sources. The second aspect has the purpose to identify analytical readings, that is, the quantities involved in a problem and relationships between them (Puig & Cerdán, 1988).

### Test problems

To design the test's tasks, previous work is considered. Gómez, Sanz, and Huerta (2016) and Sanz and Gómez (2018) made a classification of fraction word problems through an HEA study. In Figure 1, part of this classification is shown; in it, the problems under study in this inquiry are included.

**Figure 1: Classification of word problems of the type: “of what remains”**

Table 1 shows the problems used in the test, they are an adaptation of the classical problems identified through HEA. Despite the fact that P1 and P2 have the same structure (see Table 1), P1 needs two steps to be solved, and P2 needs three. Given that the easier type was initially considered due to its analysis-synthesis scheme, it was decided to explore a possible change of students' performances when introducing an additional step (aim 2 of this research).

**P1.** A pole is painted in red, blue and black. The black part is a  $\frac{1}{3}$  of the length of the pole, the part in red is  $\frac{2}{3}$  of what remains, and the blue part measures 2.70 meters. How long is the pole?

**P2.** Miguel plays a video game. He has to end it in the time indicated on the screen. He plays one-third of the time scheduled, pauses the game and goes to have dinner. When he comes back, he moves up one-fifth of what remains. After supper, he moves up one-seventh of what remains. A message appears on the screen: ‘32 minutes left’. What time was indicated on the display at the beginning of the game?

**P3.** A thief went into a palace and found a bag full of coins. When he tried to escape, a palace doorman caught him; the thief offered him half of the coins to let him escape. The doorman gave back 80 coins to the thief and let him go. Another doorman took the thief by surprise, and again the thief offered half of the coins of what remained in the bag to let him escape. The second doorman received the number of coins but he gave 50 coins back. Finally, when the thief goes out, he has 200 coins in the bag. How many coins were there in the bag at the beginning?

**P4.** A man who has been picking up some oranges returns to his hometown. He visited two friends and he gave to one of them half of the oranges and half an orange. He gave half of the rest of oranges plus the other half orange to his second friend. After his visit, he left 10 oranges. How many oranges had he picked up?

**P5.** Carlos has a glass of wine and drinks  $\frac{1}{4}$  of it. He fills it with water and drinks  $\frac{1}{3}$  of the mixture. He refilled it with water and drank  $\frac{1}{2}$  of the liquid obtained. What part of pure wine does he have left to drink?

**P6.** Juan went on an excursion and took a bottle of water. When he found a faucet, he duplicated the content of the bottle and drank  $1\frac{9}{10}$  dl. Later, he doubled the content that he had left and drank  $1\frac{9}{10}$  dl. Surprise! The bottle was empty. How much water was in the bottle at the beginning of the excursion?

**P7.** A man made his will and divided the heritage among his sons. One received a thousand pesos and  $\frac{1}{7}$  of the rest; other received 2000 thousand pesos and a  $\frac{1}{7}$  of the rest; another received 3000 thousand pesos and a  $\frac{1}{7}$  of the rest, and so successively for all his sons. One of his sons said the distribution was not fair, but the father said all had the same amount of money. How much did each son receive? How many sons did the man have?

**Table 1. Fractions word problems included in the paper and pencil test**

### Theoretical resolution of problems (analysis-synthesis)

The analysis of students' performances took into account ways to solve problems. In order to obtain all possible strategies that a student can follow in a problem solving procedure, an AD was carried out through an Analysis-Synthesis (A-S) scheme (Puig & Cerdán, 1988) using the graphic symbols employed by Cerdán (2007), see Figure 2.

**Figure 2: Symbols for A-S: (a) Unknown quantities, (b) Known quantities, (c) Relationships among them, (d) Operation/relationship between them, and (e) Nesting between quantities**

In order to show the process followed, an analysis of problem P1 is recorded. Two A-S schemes of the first task (P1 in Table 1) are included in Figure 3 to show that solving procedures are not unique and that each one represents a form of reasoning, a way to relate the quantities involved. For the case of P2, the process starting from Q (see Figure 3) is repeated (due to shortage of space in this paper, the A-S scheme of P2 is not included).

**Figure 3: A-S Scheme for P1. a)  $x$ =total pole,  $p_1$ =part painted in black,  $Q$ =the rest after painting in black,  $p_2$ =part painted in red. b)  $x$ =total pole,  $p_1$ =part painted in black,  $Q$ =the rest painted in red and black,  $p_2$ =part painted in red,  $q_1$ =the rest after painting in black**

## Categorization for the analysis of resolutions

The A-S scheme allows us to categorize the task resolutions. These categories will enable to identify profiles of students' performances and to carry out a subsequent qualitative analysis of the answers. In addition, the quantitative analysis, both descriptive and inferential (to be done with a large amount of data), requires this type of categorization in order to obtain more precise analysis.

Table 2 shows an example of the categories and encoded resolutions for a task, in this case P1 (Table 1). There are two different types of categories. On the one hand, the C3, C4, C5 and C6 codes are related with the analysis of students' solving procedures through A-S schemes. For example, C3 is related with  $p_1$  (see Figure 3) or C4 is related with Q (in Figure 3). On the other hand, C1, C2 and C7 codes have the intention to collect other types of information. For example, the method used in C1 could be: graphic, direct arithmetic, algebraic, inverse arithmetic, or trial and error (methods identified by Gómez, Sanz and Huerta (2016) using HEA). Moreover, if a graphic support is used for solving the problem, C2 has been included, since the literature shows how graphic support during solving procedure leads to greater success in finding the solution (Greeno & Hall, 1997). Finally, a category is introduced to value the numerical results obtained, C7, that is, if the solution is correct or not.

It should be pointed out that 'Nothing' is included in all categories; there are students who do not write anything or who wrote calculations, but without any answer highlighted, and this situation must be considered in the analysis.

	C1	C2	C3	C4	C5	C6	C7
Code	Method	Graphic support	Part of a whole	What remains	Part of a part	What remains	Correct Solution
0	Graphic	No	No	No	No	No	No
1	Direct Arithmetic	Yes	Yes	Yes	Yes	Yes	Yes
2	Algebraic	Nothing	Nothing	Nothing	Nothing	Nothing	Nothing
3	Inverse Arithmetic						
4	Trial and Error						
5	Nothing						

**Table 2. Categories and encoded resolutions for Problem P1**

## Test Validation

As mentioned before test validation is done according to Lacave, Molina, Fernández and Redondo (2016). Reliability was tested with the Alpha Cronbach coefficient as a measure of the internal consistency, obtaining 0.9248. The selected coefficient is higher than 0.90 (George & Mallery, 2003, p.231), so reliability is excellent. In addition, the homogeneity index was calculated to decide if any task had to be eliminated, but it was not necessary. Content validity was made through a peer discussion with nine colleagues from different educational levels in México. They modified the wording to adapt it according to students' use of Spanish in Mexico City, but the content and structure of the problems was not modified.

## Results

The measure of the difficulty ( $d$ ) of the fraction word problems (those in Table 1) is shown in Table 3. It is calculated as the probability of solving them correctly according to  $d = \frac{\text{Correct}}{\text{Total}-\text{Nothing}}$ , where Correct is the number of students who obtained the correct answer; Total is the sample size; and Nothing is the number of students who have left the problem without an answer.

	P1	P2	P3	P4	P5	P6	P7
Correct	25	8	54	6	35	11	1
Nothing	7	58	24	17	14	51	51
Total	202	202	202	202	202	202	202
$d$	0.128	0.056	0.303	0.032	0.186	0.073	0.007

**Table 3: Summary of correct solutions by problem**

From results of Table 3 it can be asserted that for Mexican students between 15 and 16 years old, P1 is easier than P2 ( $d_1=0.128>0.056=d_2$ ), this confirms the second aim of this study: to add a step in the statement of the fraction word problems makes its resolution more difficult.

To expand the study about students' performances, a detailed analysis, related to the categorization, for problem P1 is shown. Table 4 exhibits details of the analysis' categories for such problem. C3, C4, C5, and C6 are subsequent categories, that is, if a student reaches C5 it means that C3 and C4 have been achieved. Beside absolute frequencies, percentages are in brackets. Even though the A-S scheme indicated that P1 was the most straightforward problem, only twenty-five students gave a correct solution.

Code	0	1	2	3	4	5	Total
C1 Method	24 (11.88)	162 (80.20)	8 (3.96)	0	0	8(3.96)	202
C2 Graphic support	77 (38.12)	117 (57.92)	8 (3.96)				202
C3 Part-whole	140 (69.31)	54 (26.73)	8 (3.96)				202
C4 What is left	147 (72.77)	47 (23.27)	8 (3.96)				202
C5 Part-part	150 (74.26)	44 (21.78)	8 (3.96)				202
C6 What is left	163 (80.69)	31 (15.35)	8 (3.96)				202
C7 Pole height	164 (81.19)	25 (12.38)	13 (6.44)				202

**Table 4: Students' frequencies in each category of analysis, percentage is shown in parenthesis**

Seventy-seven students used graphical representations, but always as support for the resolution; the part of a part can be seen only in twenty-four cases. The rest is as indicated: a rectangle is divided into three parts, and each is painted in one colour without pointing out a relationship between them.

Regarding category C7, incorrect answers were very varied, among them the following are highlighted: a) No answer (8/202); b) Pole height 8.10 m (34/202); in this case students considered all parts as equal, 2.7 m long, and since the pole was divided into three parts, they multiplied 3 times 2.7; c) Pole height 3.7 m (46/202), students added  $1/2$  plus  $2/3$  plus 2.7 m. They could not identify that such fractions did not represent a number but an operator; d) Pole height 10.8 m (16/202), in this

case students computed the part of the whole and the part of the part but could not accomplish correctly the last step of what is left to reach the solution.

## Conclusion and Future Research

This research is a part of a project with a general aim: to include this type of problems in an Intelligent Tutorial System (ITS) to help students accomplish learning, by predicting their performance in a following task. A mathematical model to predict student's performance and to provide a sequence of problems adapted to his capabilities will be used. This model will be build up from data obtained from the ITS, but it is necessary to dispose previous information, for instance, the difficulty of each problem, diverse solving methods, previous fraction knowledge, learning comprehension or student's age. Such information is collected by means of paper and pencil tests, and in this paper, we present some of them.

With the tool described in this paper, information about solving a particular word fraction problem was collected, which have a common characteristic, in its statement the syntagma "what remain" appears. The mathematical meaning of this syntagma refers the part of the part of the complement. The information provided is diverse. On the one hand, the difficulty of each problem increases when the steps of the problem as mentioned before increases. This result will be used in the mathematical model as initial information to start the specific sequence for each student. On the other hand, the different solving methods for the same problem have been obtained through the different A-S scheme. This information will be written in the ITS to help the student when they choose one way to solve the task.

Other kind of results obtained in this study remark the arithmetic solving methods in contrast to a remarkable lack of an algebraic approach, even though students had previous contact with algebra in secondary education (SEP, 2011). Moreover, difficulties with fraction knowledge learned in primary and secondary, such as graphic representation or operations, were observed. This result leads us to believe that basic fraction knowledge should be examined previously and therefore, the relationship between them and the solving of fraction word problems should be investigated further.

Finally, note that this research is done with a sample of Mexican students between 15 to 16 years old. But, the ITS can be used by students with different ages and different nationalities, then other random and statistically significant student samples of different ages should be studied.

*In this paper, we aim to quantify students' development of mental strategies in single-digit addition over a five months period in six Danish year one classes dependent on their initial stage based on assessment interviews of 83 year one students' strategy use when answering 36 single-digit addition tasks. Students were interviewed twice (autumn and spring). Students using direct retrieval the least at interview 1 had the highest increase in proportional use at interview 2, whereas students using it the most showed no mean increase. For counting and derived fact, the change from interview 1 to 2 was constant irrespective of initial use. Analysis of how much of the variation in change in proportional use of different strategies was explained by different factors showed that 60-83% of the total variation was explained by the students' initial strategy use. Factors attributable to the specific learning environment and instructional practice did not explain any significant variation.*

**Keywords:** Mental computation, addition, primary education, individual differences.

### Background

Whole number arithmetic is a foundational subject in early years' mathematics. The first arithmetic operation students encounter in school is addition and simple arithmetic, which is related to number sense according to Gersten, Jordan, and Flojo (2005). Thus, knowledge on students' early use and development of strategies in addition contributes to the understanding of students' development of arithmetic proficiency in general (e.g., Laski, Ermakova, & Vasilyeva, 2014). Furthermore, students' early qualitative use of strategies in mental arithmetic has been shown to influence development of mathematics competence and to be a valid predictor of later mathematical achievement and difficulties (Carr & Alexeev, 2011; Dowker, 2014; Gersten et al., 2005; Ostad, 1997).

Strategies for single-digit mental addition can be divided into three categories as described by Carpenter and Moser (1984): (1) Direct modelling strategies with fingers or physical objects, where counting sequences are used to count all concrete objects. (2) Counting strategies, where mental counting is used in counting-all or counting-on from either the first or, later, the largest addend. (3) Number fact strategies, which involve either a) direct retrieval, which is the direct recalling of the sum, or b) derived fact strategies, where known facts are used to derive the answer. Interesting to note that derived fact strategies has been the focus for many recent studies (e.g. Dowker, 2014; Gaidoschik, 2012; Laski et al., 2014).

Students strategy use in arithmetic is influenced by many factors related to the individual student, for example working memory (e.g., Imbo & Vandierendonck, 2007) and gender (e.g., Carr, & Alexeev, 2011), as well as the learning environment, such as instructional practice (e.g., Timmermans, Van Lieshout, & Verhoeven, 2007), and parents and teachers' strategy preferences (Carr, Jessup, & Fuller, 1999). Thus, Carr et al. (1999) found that boys would use the strategies their parents use, which

include the use of retrieval strategies. These strategies were also those their teachers were more likely to teach them.

Furthermore, students tend to use the strategies they are confident with in a feedback loop as described by Bailey, Littlefield, and Geary (2012), where early preference for a strategy predicts later use, which in turn predicts later preference. Students, who primarily use counting in early arithmetic at the expense of derived fact strategies, will get less practise in working flexibly with numbers. As a consequence, they will have fewer options to develop the more complex comprehension required in advanced arithmetic (Gersten et al., 2005). Thus, students change in strategy use are found to be dependent on individual factors, such as gender and initial strategy use, as well as factors related to the learning environment and learning opportunities, such as instructional practice.

The study of Gaidoschik (2012) is an example of a study where students' development of strategies for single-digit addition in year one are investigated in relation to both, students' prior knowledge and teachers' instructional practice. Gaidoschik (2012) found that strategy development was significantly related to students' prior number knowledge. Furthermore, he found in a qualitative analysis that although teachers' instructional practice focussed on counting strategies in year one, many students developed derived facts and automatized sums. This finding indicates instructional practice had minor influence on these students development of strategies. Although several studies have documented effects of students' prior knowledge and instructional practice, there is less evidence on the relative contribution of individual differences and instructional practice for students' development of strategies.

## **The current study**

The data presented here are part of a larger project on the relationship between students' development of mental strategies in single-digit addition, teachers' perceptions of the learning of number and arithmetic in year one, and classroom instruction. In this paper, we aim to quantify students' development of mental strategies in single-digit addition over a five month period in six Danish year one classes dependent on their initial strategy use. Furthermore, we investigate how much different variance components contribute to the overall variation in year one students' development of strategies. We are specifically interested in quantifying how much of the total variation in the students' strategy use at time 2 that could be explained by their strategy use at time 1, instruction time and possible differences between classes in general as well as in interaction with time as the latter would include all variation due to possible effects of instruction.

## **Methods and analyses**

### **The study and participants**

The study consisted of 155 assessment interviews on strategy use for single-digit addition conducted on 83 year one students (46 girls; age 7) from six Danish year one classes. In each class, between 11 and 18 students were selected randomly though balanced with respect to gender. 72 students were interviewed in November 2015 and April 2016. 11 students were interviewed only once due to absence. To evaluate differences and similarities in the learning environment of the six classes, the six teachers (three female and three male) were interviewed on the teaching and learning of arithmetic

and number. Furthermore, their instructional practice was documented through classroom video observations. These data will be analysed and discussed in detail elsewhere, but initial analysis indicated the teachers differed with respect to emphasis on teaching mental strategies for arithmetic and focus on procedural as opposed to conceptual knowledge. For example, two teachers emphasised rote learning of facts and procedural learning of counting strategies, two teachers focussed on students' skilled use of derived fact strategies and taught these explicitly, and two teachers were conscious of both rote learning of facts and derived fact strategies but did not emphasise one over the other. Furthermore, a previous study showed that the teachers' expectations for their year one students' development in number and arithmetic differed substantially (with one to two years of learning) (Sunde & Sayers, 2017). Thus, with respect to differences in teachers approach to teaching and learning arithmetic the six classes represents a continuum from high level of focus on explicit instruction of strategies with conceptual understanding to an instructional practice focussing on automatization of facts and procedural understanding.

### **Assessment of students' strategy use**

Students' use of mental strategies for single-digit addition was assessed in one-to-one assessment interviews where students were presented with flashcards of the 36 addition tasks with numerals 2-9, including doubles. Manipulatives, paper and pencil were not accessible for the student. The flashcards were presented with tasks of increasing difficulty to avoid less confident students to give up or only use counting if presented with difficult questions at the beginning of the interview. Interviews took place in a quiet room at the school and each session lasted 10-30 minutes. We asked the student to explain how he or she found the answer. Based on students' explanations and the interviewer's observation, answers were categorised in four categories. 'Error' was used if the student gave up or miscalculated. For correct answers 'Counting' included all variations of counting procedures on fingers, verbal or self-report as mental counting, 'Direct retrieval' was used for automatized sum, and 'Derived fact' included all variations of decomposing addends and using automatized sums to calculate the answer (e.g.  $4+5 = 4+4+1$  or  $5+5-1$ ) (for more detail see Sunde, Sunde, & Sayers, 2019).

For each assessment interview, we calculated a strategy use profile on the basis of the proportion of answers (denoted 'proportional strategy use' hereafter) to the 36 addition tasks scored as 'error', 'counting', 'direct retrieval', and 'derived fact'. Hence, if a student used 'counting' to solve 6 of the 36 tasks, the proportion for counting,  $p_{\text{counting}}$ , was  $6/36 = 0.1667$ . Original values were logit transformed prior to the analysis ( $\text{logit } p_i = \ln[p_i / \{1 - p_i\}]$ ). Before transformation, we substituted zero values (not defined on the logit scale) by 0.01, which is 2.8 times lower than the minimum achievable value larger than 0 (1 of 36 items = 0.028).

### **Analysis of change in proportional strategy use**

Development in mean use of each of the four strategies over half a school year was analysed by modelling proportional strategy use in the second assessment interview ( $p_{i2}$ ) as a linear regression function of the students' proportional strategy use in the first assessment interview ( $p_{i1}$ ) five months earlier. From this regression function ( $\hat{p}_{i2} = \beta_0 + \beta_1 p_{i1}$ ) the mean change in (logit-transformed)  $p_i$  from a given level in autumn to the next spring could be derived as the vertical distance between the regression line and the reference line  $y=x$  that indicated no change in mean strategy use between the

two test sessions. Hence, the more students increases the proportional use of a given strategy from autumn to spring, the higher above the  $y=x$  line will the data points and the regression line be located and vice versa. From the slope of the regression line, it is furthermore possible to test whether the change in use of a given strategy is conditional on how much it was used in the first interview. If the mean change in proportional use (on logit scale) of a given strategy from interview one to interview two is equal for all students irrespective of how much they used the strategy on the first assessment interview, the slope of the regression line would not be significantly different from 1. On the contrary, a slope  $< 1$  indicate a greater change in proportional use of a strategy by those students that used the strategy least in the first interview whereas a slope  $> 1$  would indicate the opposite, i.e. that those students that used a strategy least in interview one are also those that have developed relatively less from interview one to interview two.

Before the linear regression functions were established, we tested for possible quadratic and cubic relationships between  $p_{i2}$  and  $p_{i1}$ , as well as for possible effects of class (for the case development in strategy use varied between classes between interview one and two) and sex (for the case boys and girls differed in change of strategy use between interview one and two) without finding any significant effects of those predictors.

### **Analysis of variance components**

We quantified how much of the variance in proportional use of each strategy was explained by different factors. The factors were time (difference between interview one and two), student identity nested within class (the systematic difference between students over the two interviews within a given class), class (the systematic difference between students in different classes) and the interaction between class and time (systematic differences in how much students from different classes changed from interview one to two). We calculated variance components as each of the aforementioned factors' sum-of-square compared to the total sum-of-squares in General linear models with all 155 interview results as observation units and the aforementioned variables and interaction terms as fixed effects. In this respect, the interaction term class\*time encompasses all variation that could be explained by differential instructional practice because it represents the time a student has received instruction in a specific classroom. We derived statistical significances of each factor from F-tests.

## **Results**

### **Change in proportional strategy use: Conditional on initial strategy use**

As expected, mean use of all four strategies significantly changed from autumn to spring (all p-values  $\leq 0.001$ ) as the proportions of errors and counting decreased and direct retrieval and decomposition increased. The coefficients of determination ( $R^2$ ) when modelling results from assessment interview two as functions of the results from interview one showed that the changes in the students' proportional use of a strategy was highly conditional on initial strategy use (Figure 1:  $R^2$ -values: 0.26-0.69). The slopes of the regression lines were significantly  $< 1$  for 'error' ( $t_{71} = 6.52$ ,  $P < 0.0001$ ) and 'direct retrieval' ( $t_{71} = 2.18$ ,  $P = 0.03$ ), but did not differ from 1 for 'derived facts' ( $t_{71} = 1.75$ ,  $P = 0.08$ ) and 'counting' ( $t_{71} = 0.6$ ,  $P = 0.4$ ).

For ‘error’, the slope lower than 1 indicates that students with the highest error rates in interview one displayed the highest reduction in error rates between assessment interview one and two, probably as the mere result of the vast majority of the students solving all items correctly in general and especially in interview two. For ‘counting’ and ‘derived fact’ slopes not significantly different from 1 indicated that the mean change in use of these two strategies from interview one to two (decrease in counting, increase in derived fact) were constant no matter how much the strategies were used in the first assessment interview situation. For ‘direct retrieval’ a slope lower than 1 and inspection of the confidence zones of the regression line suggested that students using direct retrieval least in the first interview expressed the highest increase in use of this strategy in interview two. Whereas, students with the highest use of this strategy in interview one did not show any mean increase in use of this strategy in interview two.

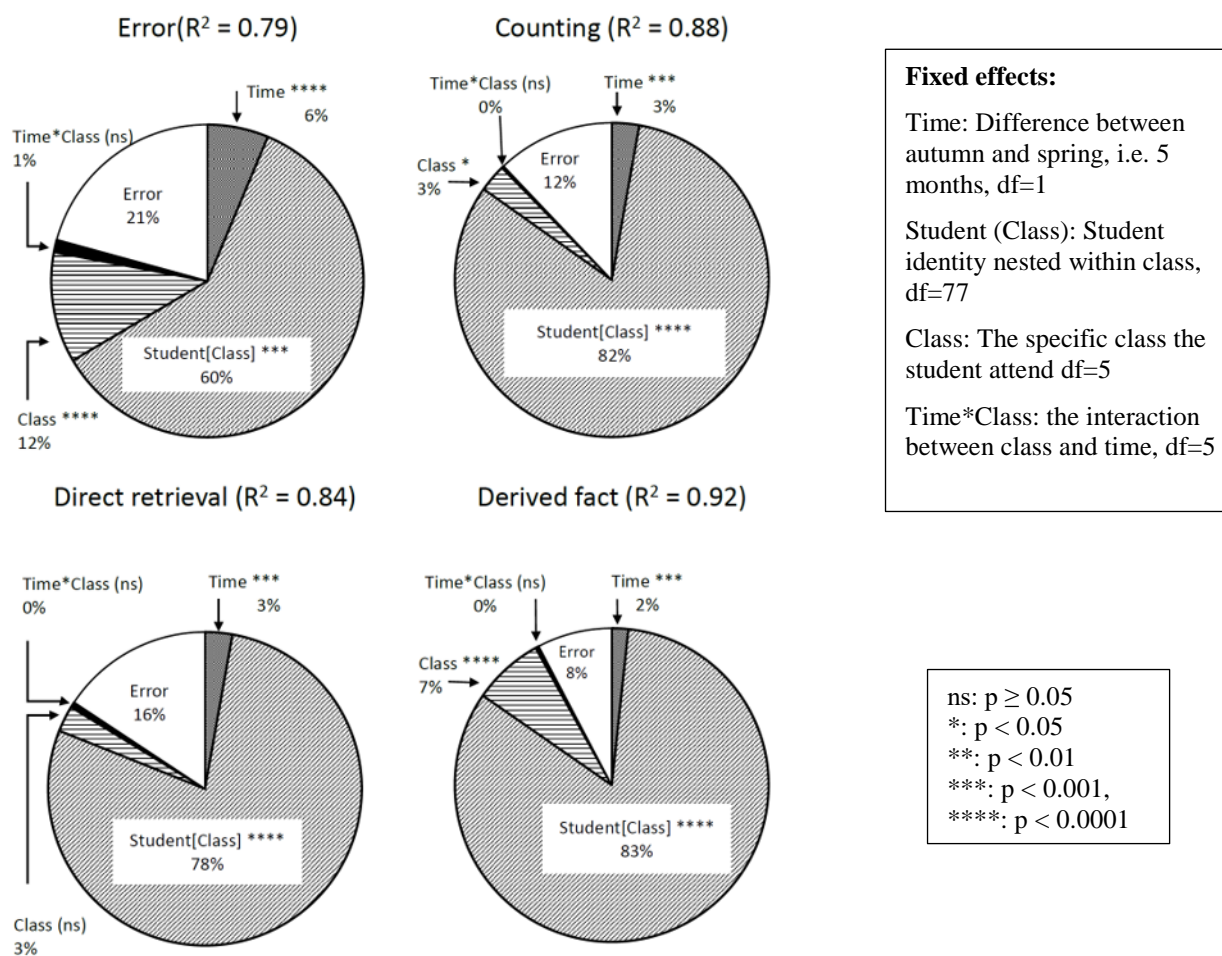

**Figure 1: Proportional use (logit-scale: zero-values replaced by 0.01 before transformation) of strategies of 72 year one students in spring (April) plotted against their results achieved in the same assessment interview the preceding autumn (November)**

From inspection of Figure 1, one can see that girls generally used counting substantially more than boys, and boys significantly used derived fact more than girls. These sex differences that were already present at interview one are dealt with elsewhere (Sunde et al., 2019). As regards changes from

interview one to interview two, boys and girls did not differ for any of the strategies (additive effect of sex if included in regression models: all p-values > 0.2).

### Variance components: Effect of individual differences, time and class

The half school year represented by the mean difference in strategy use between assessment interview one and two explained 3-6 % of the total variation in use of the four strategies, as compared to 60-83% explained by student identity nested within class (all p-values  $\leq 0.001$ ) and 3-12 % by class (statistically significant for 'error', 'counting' and 'derived facts': Figure 2). The time-by-class interactions (representing specific instructional practice) explained 0-1 % indicating no measurable class differences in mean progression from interview one to two (Figure 2).

**Figure 2: Variance components in terms of Type 3 sum-of-squares of strategy use assessed twice in year one (autumn and spring), derived from general linear models**

### Discussion

This statistical investigation of strategy use in single-digit addition amongst year one students revealed the following three results worth noting. First, the slopes of the regression lines of strategy use at interview two as function of strategy use at interview one demonstrates that in at least two of four strategies the mean change in strategy use from interview one to two differed significantly between those students who used the strategy most and least. In the present case those students with

highest proportion of errors in interview one expressed the largest reduction in error frequency in interview two five months' later. Those who used direct retrieval least in the first interview expressed the highest increase in use of this strategy to interview two. For counting, the mean change in strategy use did not differ significantly between students with high and low initial use. This corresponds with Bailey et al.'s (2012) feedback loop of relationship between skills and preference for specific strategies.

Considering that use of derived fact strategies are related to high arithmetic ability (Dowker, 2014) and the relationship between excessive use of counting and mathematical difficulties (Ostad, 1997), it is concerning that the students with high initial proportional use of counting do not decrease the use of this strategy more than students with a low initial use. These findings underline the importance of analysing and reporting changes in strategy use (or any other achievement measure) as function of a given time period or intervention type differentially for student groups with different start level. In that respect, the here used graphical and statistical method based on testing the nil-expectation of a slope = 1, may provide an easily used and comprehensible method. One implication for practice of these results is that instruction should support students in developing a diverse strategy use.

Second, albeit mean use of all four strategies significantly changed over the five months between interview one and two (as expected), these changes, reflecting the fundamental 'effect' of learning and maturation, were modest compared to the variation in strategy use between students (evident as the high correlation coefficients of the scatter plots in Figure 1, as well as the amount of variance components explained by student ID in Figure 2). This illustrates the importance of acknowledging the long known but sometimes implicitly forgotten notion that students within a class may vary in strategy use patterns equalling several years' education time.

Third and finally, our analysis revealed that for Danish primary school children little variation (1-7%) appeared to exist between classes in general (main effect of class), and even less (0-1%) between classes and time (class-by-time interaction). Given that the five months' time span represents a big part of the students' first formal mathematics education, we find it interesting that the different classes in effect appeared to develop similarly between interview one and two despite considerable differences in teaching practice.

We want to stress that from this, one cannot conclude that differential teaching practices do not influence learning outcome, just that such differences were barely measurable over a time scale of five month's education time. A delayed effect of different instructional practices in year one on later arithmetic ability is thus possible. It is also important to notice that effects of differential teaching practices may have occurred before November, when interview one took place. Significant main effects of class for counting and especially derived fact indicate that this might have been the case.

In conclusion, Danish year one students' developmental change of strategy use for single-digit addition is primarily determined by their strategy use when entering year one. Development patterns were similar between classes, suggesting no influence of instructional practice, but mean change in error rate and use of direct retrieval differed for students with high or low initial use. The relatively small influence of five months teaching on strategy use patterns and the lack of difference between

classes with different instructional practice is stunning. The findings call for qualitative research on what role different instructional practice play in year one students' development of strategy use.

*As part of a general study, a teaching model for fractions based on applets created with GeoGebra and the number line as a conceptual and didactical resource was designed. The model has eight stages; each one is composed of an interaction-exploration part, and questions to favour students' thinking about their interaction with the applets. The purpose of the model is to contribute to the building up of better fraction mental object of students who finished elementary school. The performances of two students are characterized in this paper; both improved their fraction mental object. Before the teaching experiment, they only had ideas related to the use of fractions as fracturer. After working with the applets, those ideas changed. Both students could do tasks related to fractions as number and as measurer, particularly, they could represent fractions on the number line, identify which of two fractions was bigger, and distinguish proper and improper fractions.*

*Keywords: Aspects of fractions, applets for teaching, fractions on number line, teaching models.*

## Introduction

Investigating the processes of teaching and learning fractions has been a significant theme in the field of mathematics education. The previous statement can be linked to the fact that fractions are part of the basic education curriculum in the world (NCTM, 2000; SEP, 2011). Nevertheless, fractions have been considered as one of the complex concepts studied in basic education (Siegler, Fazio, Bailey, & Zhou, 2013), and as a consequence, students have low performance in mathematics. Therefore, it is necessary to design tools that promote the improvement of students' fraction mental object, in Freudenthal's (1983) sense; since a good mental object of this concept will allow pupils to have adequate performance in mathematics from elementary to high school (Siegler, Duncan, Davis-Kean, et al., 2012). Due to the inclusion of digital technologies as a cognitive resource for teaching mathematics (Drijvers, 2013), the design of a teaching model based on the aforementioned resources is one of the main purposes of the research described in this paper.

## Research objectives

The main objective is to construct a teaching model in order to enrich the current one for Mexican elementary school. In this context, two particular purposes for students who finished elementary school are 1) to characterize their fraction mental object, and 2) to promote the building up of better fraction mental objects. The aim of this paper is to show evidence of the purposes defined above.

## Theoretical framework and related literature

The Local Theoretical Model (LTM) (Fillooy, Rojano, & Puig, 2008) is used as a theoretical and methodological framework. The LTM serves to focus on an object of study through four interrelated

components: (1) formal competence, (2) teaching models, (3) models for cognitive processes, and (4) models of communication. These components serve to design a teaching model.

**The formal competence component.** From the example of the didactic phenomenology of fractions elaborated by Freudenthal (1983), and taking into account ideas of other authors, for example, those of Kieren (1992) and Behr et al. (1983), the formal component of the LTM is constructed. This component is summarized in a scheme by means of which uses and aspects of fractions and their relationships are identified from everyday language to formalization through mathematical constructions. The aspects of fractions that are considered according to Freudenthal (1983) are descriptor, fracturer, comparer, measurer, operator, and number. For more about those uses and aspects of fractions see Valenzuela, Figueras, Arnau and Gutiérrez-Soto (2017a).

**The teaching models component.** A characterization of the teaching model of the last cycle of the Mexican primary school - 5<sup>th</sup> and 6<sup>th</sup> grades, children between 11 and 12 years old- was made. Results allowed the identification of situations in which all aspects of fractions underlie, and different representations and models are used. However, greater emphasis is placed on fractions as fracturer and as number. This led to design a new teaching model based on technology and focusing on fractions as measurer and as number; in particular, the emphasis is placed on notions of equivalence, order, density and the characterization of proper and improper fractions. To obtain the link for using the teaching model write to the authors (an English version will be available soon).

**The cognitive processes component.** As part of this component, reference is made to errors, difficulties, and students' actions when they use fractions. An important purpose of this study is to have a catalogue that serves as a reference for analysis of students' performances. Among the difficulties students have, informed by other researchers, are the following: 1) difficulties to identify a fraction represented in a figure with more than one fractional unit (Saxe, Taylor, McIntosh, & Gearhart, 2005); 2) difficulties to identify improper fractions (Tzur, 1999); 3) consideration of the whole as the entire segment and not the defined unit segment in segments of a number line with more than one unit (Ni & Zhou, 2005); and 4) lack of association of a fraction with a point or the right end of the segment on the number line (Petitto, 1990).

**The communication component.** This component is related to the processes of communication between different actors in a teaching and learning situation. In this case, the fundamental process considered is established between the teacher/researcher and the students via their interaction with the applets. Figure 1 shows how technological tools in this research are designed to promote the communication process. Through a series of codes, the teacher/researcher provides information to students; this favours interaction between student and applet. Students' information provided through applet interaction is saved in a database, which is used for the analysis of their behaviour.

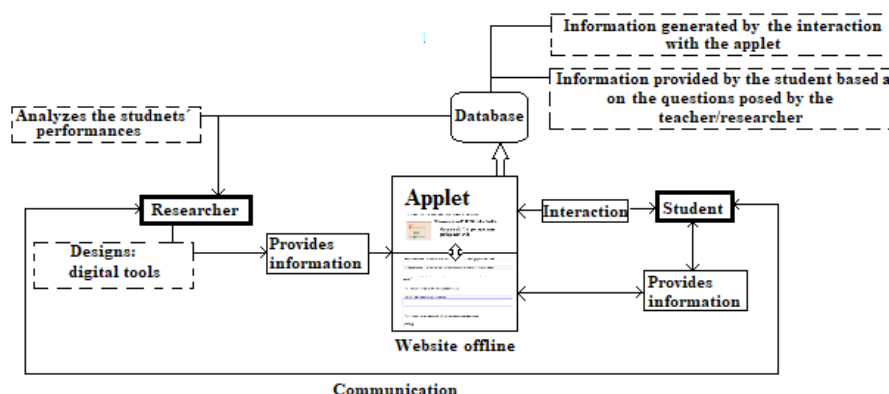

Figure 1: The communication process between Teacher/Researcher-Applet-Student

## The teaching model

The final teaching model is formed by eight phases (see Figure 2); in each one, students' interaction is similar as the description in Figure 1, but every phase has a different purpose, related to the study of order, equivalence, density, and characteristics of proper and improper fractions. The design of the first two applets is described in Valenzuela, Figueras, Arnau and Gutiérrez-Soto (2017b).

## Population and method

The experimentation component of the study had two phases. A pilot study; 45 students (4 groups) of a public secondary school located in a troubled zone of Valencia, Spain, took place. It helped to validate the teaching sequence, modify questions and verify applets' operation, and was considered necessary to realize an introductory activity to explore GeoGebra. In the main trial, 10 pupils of a public primary school in a marginalized zone of Zacatecas, México participated. In both, students worked individually and no help was given. Teachers only participated when applying the initial and final paper and pencil tests (evaluation and validation instruments). For analysis, the evidence stored in the computer as a product of the student-applet interaction was used. This report concerns Alvaro and Fernanda's performances. Alvaro is a 13-year-old student with low grades who participated in

the pilot study, he had already used a computer before the experimentation. Fernanda is 12 years old, and has medium-high grades, she participated in the main trial and had never used a computer.

The pilot study was carried out in 5 sessions of 45 minutes each, the main trial in 6 sessions from 60 to 90 minutes, including the activity to explore GeoGebra. In both approaches, an initial test was applied, the teaching sequence was carried out, and a final test was used. The tests are employed as evaluation instruments that help to validate the teaching sequence, in which aspects of fraction as measurer, as number and as fracturer are taught. Tests have 6 tasks. The first three assesses aspects related to the use of fraction as fracturer in continuous and discrete models. In task 4, the uses of fraction as measurer and as fracturer in the number line model are evaluated. Task 5 deals with the use of fraction as number, and in task 6, different uses of fractions appear in a context of problem-solving. Following this order, Alvaro's and Fernanda's performances are described below.

### Alvaro's performance

Alvaro's answers in the initial test, confirms that his fraction mental object allows him to establish a fracturing relation in a graphic representation of a fraction, particularly when using discrete and area models. In Figure 3, the processes to establish the fracturing relation is shown, the student extends the linear partitions to identify the minor fractional unit (items b, e, f, and h). The trace of the pen allows seeing that there is a tendency to count the number of parts, especially when the partition has a "large" number of parts (items d and f).

Instructions: In the following figures, what fraction represents the part that is painted? Write your answer on the line in the box.

**Figure 3: Alvaro's answers to represent fractions symbolically in an area model, initial test**

Alvaro is also successful representing graphically fractions from a symbolic expression (proper and improper), except in the case of a triangle to represent  $1/3$ , see Figure 4. In the processes of partitioning, Alvaro estimates the equality of the parts by congruence. He has technical difficulties to make a partition, but not conceptual ones as sustained by Streefland (1991).

Instructions: In the following figures, represent the indicated fractions.

**Figure 4: Alvaro's answers to represent fractions in an area model, initial test**

Alvaro was not able to represent fractions on the number line. Apparently, he fails to transfer his knowledge about partitioning in an area model to a linear model -number line-. He attempts to answer task 5, however, there is a tendency to use decimal numbers to provide fractions between two integers,

but has difficulties to supply fractions. He does not recognize the terminology of proper and improper fractions and faces difficulties in solving problems; he did not answer task 6.

Answers given by students during the interaction with the applets in the teaching sequence are analysed to identify: 1) processes they follow to represent fractions on the number line, 2) recognition and justification of fraction comparison, 3) recognition of equivalent fractions, and 4) characterization of proper and improper fractions.

During the teaching sequence, Alvaro did not achieve the purpose of stage 1. A tendency to dissociate numerator and denominator in his interpretation of symbolic and graphic representations of fractions on the number line was identified. But, this idea changed. In stage 3 he recognized a fracturing relationship between part and whole. In stage 2 the student wrote three proper fractions ( $1/2$ ,  $2/3$  and  $2/4$ ) but no improper ones. To justify the order of fractions he focuses on the length of the segment that represents a fraction; he justifies his answer writing: “ $2/4$  is smaller because it occupies less than the others”. In stage 4, Alvaro faces difficulties to express characteristics of proper and improper fractions, but in stage 5 characterizes an improper fraction, comparing the numerator and denominator, he wrote: “the numerator is larger than the denominator”. In the teaching sequence, the student only managed to identify two equivalent fractions:  $4/1$  and  $40/10$ .

As mentioned in the initial test, Alvaro failed to represent fractions on the number line, but after exploring the applets of the teaching sequence, in the final test (solved in a paper), he succeeded locating fractions on the number line, as shown in Figure 5.

**Figure 5: Alvaro's answers in the final test to represent fractions on the number line**

As observed, the student makes the complete partition for representing each fraction. One strategy he uses is to make stripes of different sizes to distinguish the different fractional units. In addition, a trace of counting the parts is observed.

Also in Figure 6, there is evidence that Alvaro improved his partitioning processes to represent fractions in tasks related to an area model, although this was not the focus of the teaching sequence.

**Figure 6: Alvaro's answers to represent fractions in an area model, final test**

## Fernanda's performance

In the initial test, Fernanda showed solid ideas about fraction as a fracturer, both to establish a fracturing relation in continuous (Figure 7) and discrete models, as well as its use in a fracturing

operator aspect (Figure 8). She only faced difficulties in establishing a fracturing relation in graphic models where the difference in the size of the parts is not so evident (items e and f of Figure 7). But after studying the teaching sequence, the student managed to respond even to this type of situations.

Instructions: In the following figures, what fraction represents the painted part? Write your answer on the line in the box.

**Figure 7: Fernanda's answers to represent fractions symbolically from area model, initial test**

The processes used by Fernanda to establish the fracturing relation are based on counting the number of parts (items d, f, and g). In fact, in item f she did not distinguish the differences between the sizes of parts. The student also extends the partitions to identify the minor fractional unit (items b, e, and h). In item e, probably she had a counting error. Moreover, Fernandas' fraction mental object allowed her to use partitioning processes to establish a fracturing relation in a graphic representation from a symbolic expression of a fraction (see Figure 8).

Instructions: In the following figures, represent the indicated fractions.

**Figure 8: Fernanda's answers to represent fractions in an area model, initial test**

Fernanda could express the fracturing relationship in continuous models, but did not manage to extend the model to represent improper fractions (item b), she changed numerator by the denominator. She also showed difficulties in fracturing a whole in a large number of parts -12-. With respect to the number line, Fernanda was not able to transfer her knowledge about partitioning in an area model to a linear model -number line-. In the initial test, she did not answer tasks related to representing fractions on the number line, nor those regarding the use of fractions as a number.

Fernanda's performance in the teaching sequence was among the best in her group. She only showed less ability in stage 2, the criteria used to establish order between fractions was a comparison of numerical values of a fraction, which led to errors. However, with respect to the other subjects taught, she was more successful in stages 1 and 3, related to fractions as fracturer and as measurer. She also managed to characterize proper and improper fractions comparing numerator with denominator. Fernanda was able to establish several equivalent fractions during her interaction with the applets in the teaching sequence, but also later, since in the final test she showed skills to write equivalent fractions of some given fraction. After studying the teaching sequence, in the final test, Fernanda was able to answer correctly tasks related to fraction's uses as measurer and as number. Particularly, she managed to represent fractions on the number line (see Figure 9).

Instructions: Represent the following fractions on the number line.

**Figure 9: Fernanda's answers in the final test to represent fractions on the number line**

In the process to represent fractions, Fernanda made lines of different sizes to distinguish partitions. Apparently, she did not split all the unit segments. For example, to represent fraction  $7/3$ , only a third part was indicated in the interval  $[2, 3]$ . Also, she expressed  $2/12$  and  $1/6$  in the same place, which shows that she recognizes their equivalence, and she puts  $2/10$  to the right of  $1/6$ , an idea about order between fractions. Additionally, the student improved her partitioning processes to establish a fracturing relation in both static and dynamic processes.

## Conclusions

Although in the experimentation a small period of time was devoted to interacting with the applets, there is evidence that students learned other aspects of fractions, mainly those related to their location on the number line. In the initial test, it was observed that Alvaro and Fernanda's fraction mental object allowed them to solve mainly tasks related to the use of fracturer in continuous and discrete models. However, this knowledge could not be transferred to represent fractions in a linear model. So the teaching in a single approach is not a guarantee for students to be able to transfer that knowledge to solve tasks where other uses of fractions are required. The proposal to use new technological resources that allow visualization and manipulation of actions that are done on the objects (fracturing, comparing and ordering) helped students to improve their ideas related to fractions as measurer and as number. Moreover, there is evidence that despite the fact that in the teaching model emphasis is not placed on the area model, students were able to improve their partition processes in order to establish a fracturing relation in this type of models. That is, a teaching model based on the number line and the use of applets helps students to improve their ideas about the use of fraction as fracturer in an area model. The use of a computer in a marginalized community did not involve difficulties in the teaching model, in fact, students were able to transfer ideas from the manipulative computer task to the "non-manipulative" paper task.

## Acknowledgments

The research described was part of a larger project involving David Arnau and Juan Gutiérrez-Soto from the Department of Didactics of Mathematics of the University of Valencia, Spain (EDU2017-84377-R (AEI/ERDF, EU) Ministerio de Economía y Competitividad/FEDER). Also, thanks to CONACYT for the scholarship (reference number 230188) to obtain first author's Ph. D.

### **Conceptual and procedural knowledge in mathematics learning**

The distinction between procedural and conceptual knowledge has elicited considerable research and discussion among researchers in the fields of cognitive-developmental psychology and mathematics education. Procedural knowledge is typically defined as the ability to execute action sequences to solve problems and is usually tied to specific problem types, whereas conceptual knowledge is defined as knowledge of concepts pertaining to a domain and related principles (Rittle-Johnson & Schneider, 2015). This definition has been contested on the grounds that it depicts a very narrow picture for procedural knowledge as something that one either has, or does not have, ignoring different qualities that such knowledge may have (Star, 2005). Still, this definition captures the distinction between carrying out a procedure that pertains to a domain, and understanding of the entities (e.g., mathematical objects and mathematical relations) that are involved in the procedure. This distinction is valuable, particularly from the point of view of mathematics education that has been tantalized by the phenomenon of procedural skill without understanding before acknowledging that conceptual and procedural knowledge are equally important for students' mathematical development (e.g., De Corte, 2004).

The relation between the two types of knowledge has been difficult to establish empirically, in particular with respect to the order of acquisition (i.e., which type of knowledge develops first). The current prevailing model is the *iterative model* that assumes that there is a bi-directional relation between conceptual and procedural knowledge and accounts for many empirical findings, notably the well-documented finding that the two types of knowledge are typically highly correlated (Rittle-Johnson & Schneider, 2015). However, such correlations found at group level do not accurately reflect what happens at the individual level. Indeed, research shows that there are individual differences in the way students combine the two kinds of knowledge putting a challenge to the

iterative model (e.g., Canobi, 2004; Hallett, Nunes, & Bryant, 2010; Hallett, Nunes, Bryant, & Thrope, 2012). In particular, Hallett and colleagues (2010, 2012) were the first to systematically study such individual differences in the area of fraction learning. They assessed conceptual and procedural knowledge of students at Grade 4 and 5 (2010) as well as at Grade 6 and 8 (2012) and they identified groups of students who were either strong or weak in both types of knowledge. However, they also consistently traced two substantial groups of students for whom there was discrepancy between the two types of knowledge (i.e., students in one group exhibited stronger procedural fraction knowledge, compared to their conceptual knowledge, and vice versa for students in the other group). Hallett and colleagues found that such discrepancies became less salient with age.

Before more progress can be made in understanding the relations between conceptual and procedural knowledge, more attention should be paid to the validity of measures of conceptual and procedural knowledge (Rittle-Johnson & Schneider, 2015). This is a challenging endeavor, particularly with respect to conceptual knowledge, which is considered a multi-dimensional construct; and it becomes even more challenging when it comes to the concept of fraction, itself a multifaceted construct pertaining to a vast variety of situations (Moss, 2005).

In this paper we present an overview of four studies investigating secondary students' conceptual and procedural knowledge of fractions qualitatively as well as quantitatively. We reflect on the challenges we met and we draw on the findings to discuss the problem of measuring conceptual and procedural knowledge; the issue of individual differences in conceptual and procedural fraction knowledge; and related educational implications.

## **Conceptual and procedural fraction knowledge of Greek secondary students**

### **Study 1: General trends**

In this study (Bempeni & Vamvakoussi, 2014) we looked at the development of conceptual knowledge of fractions in the first three years of secondary level (7<sup>th</sup> to 9<sup>th</sup> grade in Greece). We administered an open-ended questionnaire to 80 seventh and ninth graders. The questionnaire consisted of 24 items targeting many aspects of fraction knowledge. The tasks included interpreting and constructing fraction representations using the area model and the number line; fraction magnitude estimation and estimation of outcomes of arithmetical operations; fraction comparison tasks that could be tackled with conceptual strategies (e.g., comparing  $\frac{3}{2}$  and  $\frac{13}{27}$ , for which 1 can be used as benchmark); tasks targeting the inappropriate transfer of natural number knowledge to fractions (e.g., “how many numbers are there between  $\frac{2}{5}$  and  $\frac{3}{5}$ ?”); and contextualized problems where physical quantities were involved, requiring understanding of the unit of reference (see Task 1 in Figure 1 for an example of the latter, albeit in multiple-choice format). The difficulty of items varied, from very simple ones (e.g., representing a proper fraction using the area model) to quite challenging ones (i.e., items targeting the dense ordering of fractions). In addition, the questionnaire included 4 procedural items on standard school-taught procedures, namely on fraction operations (e.g., “compute the sum  $\frac{10}{63} + \frac{8}{9}$ ”). The students were asked to solve the conceptual tasks and explain their solutions; and to carry out the fraction operations.

The results showed no significant difference between the two age groups' overall performance, and no significant difference in the overall performance for conceptual tasks, nor for procedural tasks.

However, we found that older students relied significantly more on procedural strategies (i.e., school-taught procedures). Looking at each task separately, we found that ninth graders performed significantly better in 3 conceptual tasks, albeit relying on transformation strategies. For example, they converted fractions into decimals in order to place them on the number line; and they converted  $\frac{3}{2}$  and  $\frac{13}{27}$  into similar ones in order to compare them. Performance in procedural tasks was fairly good (at least 70% succeeded in each task), whereas performance in conceptual tasks varied widely (as expected). An interesting pattern emerged: Although the great majority of students were apt to carry out the four fraction operations, about 60% failed in tasks targeting conceptual understanding of the operations (e.g., in estimating the sum  $\frac{12}{13} + \frac{7}{8}$ ). In addition, although practically all students were able to construct an area model for a proper fraction, about 25% asserted that a shaded part of a shape that was partitioned in 3 unequal parts was “one-third”; and more than half of the students failed to represent an improper fraction, or explicitly stated that “it is not possible to take five parts out of three”. Further, about half asserted that “eating  $\frac{3}{5}$  of a pie” necessarily means “eating 3 pieces of a pie” (see Task1, Figure 1). Finally, we also traced some students who were flawless in the procedural tasks, but failed in even the simplest conceptual tasks, indicating an asymmetry between the two types of knowledge. We focused on this issue in Study 2.

### **Study 2: Individual differences in conceptual and procedural knowledge of fractions**

In Study 2 (Bempeni & Vamvakoussi, 2015) we recruited 7 ninth graders to participate in in-depth interviews. The selection of the participants was not random. First, based on their school grades, all participants could be characterized as medium to high level students in mathematics. Second, they shared the same mathematics tutor. Based on information provided by their tutor, we had reasons to expect some variation in their conceptual and procedural knowledge of fractions. We used an instrument with 30 fraction open-ended tasks, adjusting and extending the collection of conceptual tasks used in Study 1, and adding few procedural tasks (e.g., operations with mixed numbers). We added one more task focusing on the role of the unit of reference, in contexts where physical quantities were involved (see Task 2 in Table 1, albeit in multiple choice format). We also explicitly asked students not to apply typical school taught procedures in certain fraction comparison tasks that could be tackled with conceptual strategies (e.g., one proper and one improper fraction). The participants were asked to solve the tasks thinking aloud and explaining their answers.

Based on the analysis of their responses in terms of accuracy and strategy used (procedural/conceptual), the participants were distributed in three profiles. The *Conceptual-Procedural* profile consisted of three students who showed advanced conceptual knowledge of fractions, combined with procedural fluency. The *Procedural* profile consisted of three students who succeeded in practically all tasks that could be solved via the use of procedures taught at school (e.g., fraction and mixed numbers operations), but failed systematically in conceptual tasks (e.g., in representing an improper fraction; or in comparing dissimilar fractions when they were not allowed to apply the typical procedure). All three failed in both tasks targeting the role of the unit of reference. Finally, the *Conceptual* profile was represented by one student that failed in all tasks requiring procedural knowledge but managed to deal successfully with most of the conceptual tasks, including the ones targeting the role of the unit of reference.

Thus the findings of Study 2 are consistent with the findings of Hallett et al. (2010, 2012), indicating that there are individual differences in the way students combine the two types of knowledge. Moreover, they illustrated the possibility that these differences can be extreme, even at grade 9. In following studies, we attempted to further investigate this issue, shifting from qualitative to quantitative methods.

### **Study 3: Developing and evaluating an instrument to measure for conceptual and procedural knowledge**

Bearing in mind Rittle-Johnson and Schneider's (2015) plea for valid measures of procedural and conceptual knowledge, we developed a new instrument measuring conceptual and procedural knowledge of fractions (Bempeni, Pouloupoulou, Tsiplaki, & Vamvakoussi, 2018). In its initial form, the instrument consisted of 39 items, 12 procedural items and 27 conceptual items, a total of 39 items. The procedural ones were paper-and-pencil tasks requiring knowledge of procedures taught at school (e.g., to carry out fractions operations and operations with mixed numbers, to find an equivalent fraction, to cross-multiply, to simplify complex fractions, and to compare dissimilar fractions using the standard procedure). The conceptual tasks were based on extensive literature review (e.g., Baroody & Hume, 1991; Van Hoof, Verschaffel, & Van Dooren, 2015) and on our materials from Study 1 and Study 2 which were adjusted and enriched when necessary, based on our experience with testing these tasks with students. First, we opted for multiple-choice items, instead of open ones (see also Van Hoof et al., 2015), with a view to discourage the use of procedural strategies in conceptual tasks (e.g., in comparison tasks), an issue that is highlighted in the literature (e.g., Rittle-Johnson & Schneider, 2015) and was noticeable in Study 1. Second, we added more tasks on fraction representations that proved good indicators of conceptual knowledge (or the lack thereof) in our previous studies (see, for example, Task 4 in Figure 1).

We conducted a clinical pilot study with 61 students and asked 6 mathematics education experts to assist in the evaluation of the instrument. The instrument was assessed with respect to a) face validity and content validity, through the experts' feedback on clarity, accuracy, and relevance of the instrument; b) convergent and divergent validity, via multitrait analysis; c) internal consistency, calculating Cronbach's alpha; and d) external consistency with the test-retest method, calculating the intra-class correlation coefficient.

The instrument showed strong face validity given that all items were assessed as clear and accurate by the experts, who were also highly consistent with each other in rating the relevance of each item to the aim of the instrument (Content Validity Index = 1 > .83). All items of the procedural scale showed convergent validity and divergent validity by demonstrating high correlation with the procedural scale and low correlation with the conceptual scale, respectively. However, eight items of the conceptual scale showed low correlation with the conceptual scale or higher than expected correlation with the procedural scale. Further, the value of intra-class correlation coefficient was high (above 0.8) for all procedural items, but below 0.5 for five conceptual items.

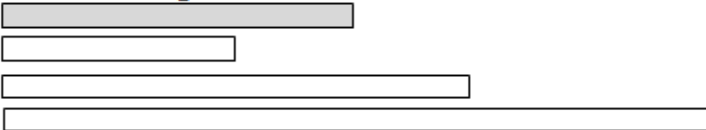

The problematic items were removed, resulting in an instrument consisting of 14 conceptual and 12 procedural tasks, with good indicators of validity, reliability, and objectivity, which we used in

Study 4. However, removing conceptual items from the questionnaire is not an insignificant matter, and we will come back to this issue in the discussion.

1. Somebody ate  $\frac{3}{5}$  of a pie. This person ate:
  - a. 3 pie slices
  - b. 3:5 pie slices
  - c. None of the previous responses
2. Maria bought one pizza from Lucullus and ate one quarter of it. John bought one pizza from Vesuvius and ate half of it. Who ate more pizza?
  - a. Mary
  - b. John
  - c. None of the previous responses
3. *Helen has two sock drawers. One half of the socks in the first drawer are white. One third of the socks in the second drawer are also white. How many white socks does Helen have?*

➤ Which operation do you believe is the correct one to solve this problem?

  - a.  $\frac{1}{2} + \frac{1}{3}$
  - b.  $\frac{1}{2} \cdot \frac{1}{3}$
  - c. None of the previous responses
4. The gray bar is  $\frac{3}{2} X$ , where X is one of the white bars. Which one is X?
 

  - a. The first white bar
  - b. The second white bar
  - c. The third white bar

#### Study 4: Individual differences in conceptual and procedural knowledge of fractions: a quantitative study

In Study 4 (Bempeni et al., 2018) we administered the aforementioned instrument to 126 ninth graders and we analyzed the data using cluster analysis, testing for individual differences. Following Hallett and colleagues (2010, 2012), we used in the analysis the residualized scores of the procedural and the conceptual scales, the raw scores being the percentages of correct answers out of the total of answered questions. This is because the two scales are expected to be correlated (Rittle-Johnson & Schneider, 2015), and this method provides a way to exclude the common part of variation from both scales (Hallett et al., 2010, 2012). It should be noted that these scores do not represent absolute magnitudes of each type of knowledge; rather, they indicate discrepancies between the two types of knowledge. For example, a positive residual with respect to procedural knowledge means that a person's procedural knowledge is stronger than expected given their conceptual knowledge, and vice versa for negative residuals.

The cluster analysis used the k-means method and Euclidean distance as a distance measure and the optimal number of clusters was determined via statistical methods to be four. Two of these clusters comprised students who did not show great discrepancies between the two types of knowledge and their performance was either rather high in both type of tasks (N=22, 17.5%) or rather low in both types of tasks (N=31, 24.6%). On the contrary, the two remaining clusters comprised students who either performed better than expected in conceptual tasks given their performance in procedural tasks (*Conceptual Profile*, N=21, 16.7%); or performed better in procedural tasks given their performance in conceptual tasks (*Procedural Profile*, N=52, 41.3%).

These results supported the hypothesis that there are individual differences in the way that students combine the two type of knowledge and were consistent with the findings of our previous studies, and also with the results of Hallett et al. (2010, 2012). Moreover, our findings provided evidence that these differences may persist and remain salient for older students.

We note that within the *Procedural Profile*, we traced few extreme cases of students who excelled in the procedural items, but showed a severe lack of conceptual understanding, similar to students in Study 2. For example, one student achieved 100% score in the procedural tasks but only 14.29% in conceptual tasks, failing even in some of the simplest ones. However, we did not trace extreme cases within the *Conceptual Profile*.

## Conclusions - Discussion

In a series of studies we examined secondary students' conceptual and procedural knowledge of fractions, qualitatively as well as quantitatively. The findings of these studies converge on the conclusion that there are individual differences in the way that students combine these types of knowledge (i.e., there are students who exhibit stronger procedural than conceptual knowledge, and vice versa); that these differences remain salient up to ninth grade; and that they may even be extreme (Study 2, Study 4). These findings put a challenge to the assumption that conceptual and procedural knowledge develop in a hand-over-hand manner (Rittle-Johnson & Schneider, 2015).

The findings are strengthened by the fact that we measured conceptual and procedural fraction knowledge reliably and validly via a new instrument (Study 4). However, there were several theoretical and methodological issues that we had to tackle in the process of developing the instrument, and some difficult decisions to make. First, measures of procedural knowledge were easy to construct and validate. However, this is due to the fact that we adopted a simple, perhaps over-simplified, definition of procedural knowledge (Star, 2005), as discussed in the introduction.

Second, measures of conceptual knowledge were particularly challenging. On the one hand, it is important to address various aspects of conceptual knowledge (Rittle-Johnson & Schneider, 2015), which requires the use of a great variety of tasks. On the other hand, this variety makes it difficult to construct a measure with good indicators of convergent validity, resulting to the exclusion of tasks (Study 3). Further, the use of multiple-choice items does not exclude the possibility that students in fact use procedural strategies when dealing with conceptual tasks, which was observable in Studies 1 and 2, but not in Studies 3 and 4. This might be an explanation for the fact that some conceptual tasks showed higher correlation with the procedural scale than expected (Study 3), and they also needed to be excluded. For example, locating fractions on the number line were among the problematic conceptual tasks in Study 4, presumably because the students, similarly to the students in Study 1, used transformation strategies to deal with the task. Excluding items may result in a more robust instrument; however, a lot of useful insights in students' understandings are lost. Consider, for example, the three first tasks in Figure 1. These tasks address students' understanding of the role of the unit of reference, in a context where it is necessary to take it into account (Baroody & Hume, 1991). All three had to be removed from the instrument, because the great majority of students, even the ones with overall good performance, failed. Thus, these tasks were not useful in discriminating

between “conceptual” and “procedural” students but removing them meant ignoring an important aspect of conceptual knowledge that students appear to lack.

This brings us to a consistent finding across all four studies: Students fail in elementary, yet fundamental conceptual tasks. Consider Task 1 (Figure 1) which was used in all studies. This task was challenging for half the students in Study 1; for three out of seven middle-to-high level students (based on their school grades) in Study 2; and for the great majority of students who participated in Study 3. This raises certain issues for instruction. First, Study 1 indicates that conceptual knowledge does not improve from seventh to ninth grade, despite the fact that during these years Greek students recapitulate content regarding fractions and are introduced to rational numbers. However, what seems to change is that students tend to rely more on procedural strategies. This may conceal their lack of conceptual fraction understanding in some cases (e.g., when placing fractions of the number line), but not in tasks that cannot be tackled with school-taught procedures (e.g., Tasks 1-3 in Figure 1). Second, it appears that students with very poor understanding of fractions still manage to get good grades at school (Study2). Third, the majority of the students in Study 4 was placed in the *Procedural* profile (i.e., they did better in the procedural tasks, than one would expect based on their performance in the conceptual tasks). These are quite strong indications that students’ school experiences are more favorable to the development of procedural knowledge. In other words, instruction appears to still over-emphasize procedural knowledge, neglecting students’ conceptual difficulties with fractions (Moss & Case, 1999).

This assumption cannot, however, explain the existence of (fewer) students who have stronger conceptual than procedural knowledge. In a more general fashion, the source of individual differences in conceptual and procedural knowledge is still an open question, despite the fact that several hypotheses have been formulated. Factors such as prior knowledge in the domain (Schneider, Rittle-Johnson, & Star, 2011), cognitive profile (Gilmore & Bryant, 2008; Hallett et al., 2012), general conceptual or procedural ability as well as school attendance at different schools have been tested (Hallett et al., 2012), with unsatisfactory results. Further theorizing and research is needed in this respect.

*This paper describes a study that investigated the metacognitive strategies used by fifteen Year 6 children while working individually on a non-routine mathematics problem. After attempting the problem, the students completed a questionnaire that elicited their retrospective reports on the metacognitive strategies they had employed while working on the problem. The analysis of the participating students' written work and questionnaire responses revealed that independently of how many metacognitive strategies were observed; children's problem solving success was not guaranteed. Interestingly, children's use of metacognitive strategies was found particularly low. Educational implications for metacognition in both mathematical problem solving and in the learning of mathematics are discussed.*

## Introduction

In the last decades, metacognition and its development have been identified as having an important role in education and thus underlay in the center of primary and secondary school curricula. Metacognition is popularly defined as 'knowledge, awareness and deeper understanding of one's own cognitive processes and products' (Desoete, 2008, p. 190) and as 'thinking about thinking' (Anderson, 2002). It is often presented as comprising three phenomena: metacognitive knowledge, metacognitive experiences and metacognitive skills (Efklides, & Vlachopoulos, 2012). Moreover, it is commonly divided into two components: knowledge of cognition and regulation of cognition. Knowledge of cognition refers to the individuals' awareness of their own knowledge and includes their declarative, procedural and conditional knowledge. Regulation of cognition, on the other hand, pertains to the procedural aspect of knowledge that enables the effective linking of actions needed to perform a given task. It includes planning, monitoring and regulation, and evaluation.

Of central concern for researchers and educators is the crucial role that metacognition plays in children's academic performance in general as well as in mathematical achievement in particular (Desoete, 2009). Fostering metacognition, students avoid "blind calculations" or a superficial "number crunching" approach in mathematics (Verschaffel, 1999) and learn how to use the acquired knowledge in a flexible way. Through metacognition, students become able to effectively discern information they know from those they do not know and retain new information (Dunning, Johnson, Ehrlinger, & Kruger, 2003). Metacognitive learners have an increased understanding of the control

over their thinking, they employ this control and, thus, they are able to thrive across the curriculum (Zimmerman, 2008).

Different procedures and measures have been used to assess mathematical metacognition. A systematic review of the metacognition assessment in children aged 4–16 years over a 20-year period made by Gascoine, Higgins, and Wall (2017) revealed that the off-line methods, namely the self-reports measures, are the more commonly used, mainly because these measures are perceived as valid, reliable, easy to use and their application doesn't require much time. However, Desoete (2008) asserts the importance of distinguishing the use of different tools or methods when examining different facets of metacognition in relation to other factors such as children's age range among others. Her statement 'how you test is what you get' (p. 204) highlights this importance.

Mathematical metacognition is often examined in terms of monitoring skills with respect to solving problems (Desoete, 2009, 2008; Panaoura, Philippou, & Christou, 2004). Children demonstrating metacognitive functions are usually aware of their own learning and are able to control their learning process. Associated learning skills like these are essential to the development of effective problem-solving ability as well as to academic success in mathematics (Magno, 2009). When working metacognitively students are able to correctly represent and solve mathematics problems, evaluate the effectiveness of strategies and recognize mistakes. In addition, they learn to clarify goals, understand concepts, monitor their understanding, predict outcomes and choose appropriate actions (Pappas Schattman, 2005).

Wilson and Clarke (2004) view children's problem solving as the purposeful alternation between cognitive and metacognitive activities. In particular, the completion of a mathematical problem is a cognitive process that requires the use of cognitive strategies (e.g., adding up). The selection and use of these cognitive strategies, however, shows the solver's reflection on her existing knowledge (e.g., what do I know about the problem to help me work it out?). This is when metacognitive behavior is coming to the fore.

It is possible that school practice could inhibit the development of metacognition during problem solving, since the mathematics problems used within school context are often solved by means of a known method or formula. It is of great interest to study children's engagement in metacognitive activity when solving problems that are unfamiliar to them, like 'non-routine' problems. These problems 'make cognitive demands over and above those needed for solution of routine problems, even when the knowledge and the skills required for their solution have been learned' (Mullis et al., 2003, p. 32). Because non-routine problems require a flexible and strategic way of thinking, children often have difficulties and appear low success (Elia, Van den Heuvel-Panhuizen, & Kolovou, 2009). Interestingly, even good calculus students are not able to solve non-routine problems successfully. Such a failure does not necessarily result from restricted mathematical knowledge, but may be linked to ineffective use of that knowledge (Van Streun, 2000).

Based on the hypothesis that metacognitive functions are more likely to employ during challenging tasks and knowing that metacognition and problem solving is usually studied with older students and adults (Schneider, & Artelt, 2010), the present study aimed to investigate the relationship between metacognition and non-routine problem solving in primary school children. Investigating young

children - apart from providing us with information concerning their ability to reflect upon their problem solving - will make us more sensitive about how metacognition might be further fostered. Research questions are as follows: a) to what extent do children use metacognitive strategies when solving a non-routine mathematics problem?, b) is there an association between children's success in problem solving and their deployment of metacognition?

## Method

### Participants

Fifteen Year 6 children (8 male, 7 female), coming from the same class of a state primary school in a Greek island, participated in the study. They were randomly selected as they covered from low to high socioeconomic and academic statuses. The average age of the students was 11 years and 8 months (range: 11 years and 4 months - 12 years). The participating students had not received any training on metacognition.

### Design of the study - Instrument

All participants were presented with a non-routine mathematics problem that was designed for the purpose of the study in order to examine children's mathematical achievement as well as to establish a situation for revealing their problem solving strategies. The problem was also used as a basis for participating students' reflections on their metacognitive strategies. After attempting the problem, the students completed a questionnaire that asked them to report retrospectively on the metacognitive strategies they had used while working on the particular problem.

More specifically, the non-routine problem used in the present study (see Figure 1) did not require a particular algorithm to be applied neither was connected to a specialized mathematical concept. Because it is recognized that routine mathematics problems often require little student reflection, it was tried to follow the criteria that define the non-routine problems and reveal solvers' critical thinking (e.g, Kolovou, Van den Heuvel-Panhuizen, & Bakker, 2009).

The questionnaire was based on the 'How I Solve Problems' measurement tool of metacognition developed by Fortunato, Hecht, Tittle, and Alvarez (1991), after taking into consideration relevant instruments for measuring metacognition compiled from the literature (e.g., Jr MAI developed by Sperling et al., 2002). The particular instrument was chosen as it is considered valid for research and useful for assessment and intervention in classrooms (Gascoine et al., 2017; Sperling et al., 2002). A few modifications were done to the original version of the tool, mainly concerning rewording a few items in order to make the questionnaire more appropriate for younger children. In the present study, the questionnaire consisted of twenty-one action statements, as many as in the original version. The statements covered a range of likely metacognitive activities during problem solving process. Students were asked to respond to these statements using a five-point Likert scale (ranging from '1=never to 5=always') based on their way of working when solving the mathematics problem.

'The cost of the theater 'Avlea' with 250 seats for a two-hour play is 750€ Last Sunday 30% of the seats were empty. Which will be the profit of the theater if the cost of the ticket for the audience is 9 €each?'

### Figure 1: The problem used in the present study

The questionnaire was subdivided into four sections. The first, named '*Before you started to solve the problem*' section referred to reading and understanding the problem as well as planning of a solution method (6 statements). The second, the '*As you worked on the problem*' section involved employment of the solution method when working on the problem (5 statements). The third, the '*After you finished working on the problem*' section presented with ways of confirming and checking for the solution (4 statements). And the '*Ways of working on the problem*' section listed particular heuristics as strategies that a student might have used when working on the problem (6 statements).

### Procedure

All participants were asked to solve the problem and answer the questionnaire individually in their classroom during school hours. Their anonymity was ensured.

They were initially required to read carefully the non-routine mathematics problem. The first section of the questionnaire was then given and a 30 minutes period was allocated for solving the mathematics problem. The students were provided with a specific area on a paper in which they were asked to write their working and solution. Immediately after solving the problem, the rest of the questionnaire was administered: the students were required to respond to the statements that were included in the last three sections of the questionnaire regarding specific metacognitive strategies they might have or might have not used.

### Results

#### Problem solving success

Of the fifteen students who attempted the problem, only eight solved it correctly and, for the purposes of the data analysis, they are called 'successful students', whereas those who failed in solving the problem (seven students) were called 'unsuccessful students'. Although children's problem solving strategies were recorded, their analysis will not be described as it goes beyond the purpose of the present paper.

In order to examine whether the successful and unsuccessful students provided similar or different responses to the questionnaire regarding their metacognitive strategies, an independent samples t-test was conducted. The analysis revealed that, although the overall metacognitive level mean score of the successful students (3,46) was higher than that of the unsuccessful students (3,09), this difference was not found statistically significant ( $t=-1,159$ ,  $df=13$ ,  $p=.267$ ). When the same analysis was repeated for each questionnaire section separately, the original results were confirmed ( $t=-1,182$ ,  $df=13$ ,  $p=.258$ ,  $t=-1,100$ ,  $df=13$ ,  $p=.291$ ,  $t=-,383$ ,  $df=13$ ,  $p=.708$  and  $t=-,926$ ,  $df=13$ ,  $p=.371$  for Sections A, B, C and D, respectively). Thus, no statistical significant differences were observed in

children's responses to the total of the statements in each section of the questionnaire among successful and unsuccessful students. Table 1 shows these findings.

The mean level of students' metacognitive strategy for the 'Ways of working' section (Section D) was the lowest mean level of all the sections for both successful and unsuccessful students (3,02 and 2,76, respectively). This finding shows that the heuristics listed for children to indicate whether they had used when working on the problem were rather under-recognized. In particular, more than 80% of the students reported that they never/ rarely draw a picture or a diagram for the better understanding of the problem (55, 3% and 26, 7%, respectively for never/rarely).

Questionnaire Sections	Problem Solving Success		Total
	Successful	Unsuccessful	
A. Before you started	3,62 (0,93)	3,07 (0,87)	3,34 (0,91)
B. As you worked	3,5 (0,93)	3,03 (0,69)	3,26 (0,81)
C. After you finished	3,85 (0,58)	3,71 (0,73)	3,78 (0,65)
D. Ways of working	3,02 (0,69)	2,76 (0,29)	2,89 (0,49)
Overall	3,46 (0,66)	3,09 (0,54)	3,27 (0,61)

**Table 1: Mean scores<sup>1</sup> (and standard deviations) for children's metacognitive level in the questionnaire by their success in problem solving**

On the contrary, children's response rates for the 'After you finished' section (Section C) that might imply their use of strategies for verifying their solutions were quite high (3,85 and 3,71 for successful and unsuccessful students, respectively). For example, 53% of the students said that they always go back and check if their calculations are correct. However, no participant was found to say that she always thinks about a different way to solve the problem.

### **Correlation between metacognitive strategies and problem solving success**

Aiming to investigate the existence of correlations between children's responses to the statements in the four sections of the questionnaire (metacognitive strategies) as well as between children's questionnaire responses and their written working of the problem (problem solving success), correlation analysis was conducted, as presented in Table 2. Interestingly, no correlations were found either between problem solving success and overall metacognition (Pearson's  $r=.306$ ,  $p=.267$ ) or between problem solving success and metacognitive strategies at each questionnaire section separately (Pearson's  $r=.312$ ,  $p=.258$ , Pearson's  $r=.292$ ,  $p=.291$ , Pearson's  $r=.106$ ,  $p=.708$  and Pearson's  $r=.249$ ,  $p=.371$ , for sections A, B, C and D, respectively). However, participants' overall metacognition was positively correlated to their responses to each questionnaire section (Pearson's  $r=.953$ ,  $p<.01$ , Pearson's  $r=.817$ ,  $p<.01$ , Pearson's  $r=.869$ ,  $p<.01$  and Pearson's  $r=.691$ ,  $p<.01$ , for

<sup>1</sup> Responses were measured on a scale from 1 (Never) to 5 (Always)

sections A, B, C and D, respectively) This result shows that participants who responded highly to statements at one section tended to respond highly to statements at any other section.

## General Discussion

The present study has attempted to investigate the metacognitive strategies used by sixth graders while working on a non-routine mathematics problem. The analysis of students' written work and questionnaire responses revealed two main findings. First, students reported that they are using metacognition. However, their demonstration of metacognitive strategies is quite low both in general and at different stages of the solution process. In particular, a few reported that they greatly made connections to their previous experiences, reviewed their progress towards the problem solution, checked their calculations while they worked, attempted to verify the accuracy and sense of their answer to the problem. Additionally, an unequal use of metacognitive strategies at different stages of the solution process was also observed.

	<b>Overall Metacognition</b>	<b>Section A</b>	<b>Section B</b>	<b>Section C</b>	<b>Section D</b>
<b>Problem Solving Success</b>	.306	.312	.292	.106	.249
<b>Section A</b>	.953**		.684**	.854**	.603*
<b>Section B</b>	.817**			.657**	.338
<b>Section C</b>	.869**				.430
<b>Section D</b>	.691**				

\*Significant correlation at the  $p < .05$  level    \*\*Significant correlation at the  $p < .01$  level

**Table 2: Correlations between overall metacognition and problem solving success**

Second, a successful solution to the problem was found not necessarily connected to the employment of metacognitive strategies. Although a challenging problem was chosen for use in this study –mainly because it would raise the opportunity for metacognitive strategies to be called into play- so few students succeeded in obtaining a complete solution. This finding is consistent with previous studies in which the success in a mathematical problem is considered a cognitive process that requires the use of cognitive strategies (e.g., Wilson & Clarke, 2004); thus, low metacognitive strategies during problem solving do not undoubtedly lead to failure. This issue further reveals that even if students behave metacognitively (e.g., they are able to recognize when they are stuck), their difficulty with solving the problem remains (e.g., they fail to solve the problem). It is possible that their worthy efforts for metacognitive strategies will be restricted if they are unable to identify alternative successful strategies in the problem solving process. More needs to be known about the impact of the school practice on the development of problem solving and metacognitive strategies in children and implications for teaching should be considered.

From a methodological perspective, it is important to note that a self-report questionnaire as the one used in the present study might provide only a little about children's metacognitive strategy use.

Further research with larger samples is required in order to get detailed information on both children's actual problem solving behavior and children's actual use of metacognitive strategies. Multi-method approaches (Desoete, 2008), such as on-line procedures, might work towards this aim. Interestingly, metacognitive instruction leads not only to the empowerment of students' metacognition but also to the development of the practices from the part of the teachers concerning metacognition in both mathematical problem solving and in the learning of mathematics (Magno, 2009). As many factors as possible need to be further considered in order that any teacher intervention on metacognitive engagement can be informed and effective.

## About the authors

Aikaterini Vissariou is a Ph.D student at the Aristotle University of Thessaloniki in the Faculty of Education, in the field of Didactics of Mathematics. She is also doing her second Bachelor degree at the School of Philosophy and Pedagogy at the Aristotle University. She works as a primary school teacher at the Ministry of Education.

Despina Desli is associate professor of mathematics teaching and learning at the Aristotle University of Thessaloniki in the Faculty of Education. Her main research interests concentrate on children's mathematical reasoning, teacher education and mathematics curricula. She has worked on research projects in both primary and secondary schools concerned with mathematics education and in-service teacher training.

*Keywords: Algebra, early algebra, functions, research frameworks, teaching and learning algebra.*

### The working group

In CERME11, the Thematic Working Group 3 “Algebraic thinking” continued the work carried out in previous CERME conferences. There was a total of 23 papers and 4 posters with a total of 33 group participants representing countries from Europe and other continents: Germany, Cyprus, Finland, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, Turkey, UK, and USA.

### Structured overview of papers

Papers presented at TWG3 show a broad range of methods, subjects and theoretical underpinnings. It is thus not an easy task to cluster them in a fashion that reflects the structure of the field, however, we have identified the following clusters: Technology innovations and curriculum development; Early algebra; Empirical research in secondary algebra; Conceptual development; and Theoretical issues.

Technological innovations and curriculum development have been discussed in several papers. Ricardo Nemirovsky et al. investigated in “Body motion and early algebra” young students who graph their distance to a wall together with the sum or difference graphs of two sensors. In the conception phase different kinds of abstraction were used to guide the design. James Gray, Bodil Kleve and Helga Tellefsen evaluated in “Students’ expected engagement with algebra based on an analysis of algebra questions on 10th grade exams in Norway from 1995 till 2018” national exams and found a decrease of context, but an increase of the amount of text and moreover a decrease of decisions to be made by students. What kind of tasks work well in teacher education? Iveta Kohanova and Trygve Solstad gave some answers to this question in “Linear figural patterns as a teaching tool for preservice elementary teachers – the role of symbolic expressions” by identifying problems preservice teachers had in finding symbolic rules.

Early Algebra is of central interest and several papers from this research tradition investigated this further. This was done by Margarida Rodrigues and Lurdes Serrazina who showed young students’ ability to establish quantitative relationships involving unknowns in “Dealing with the quantitative difference: A study with 2nd graders” showed young students’ ability to establish quantitative relationships involving unknowns. Similarly, Denise Lenz in “Relational thinking and unknown quantities” monitored the increase in ability to express relations between known and unknown quantities of marbles in boxes from kindergarten to grades 2 and 4. María D. Torres González et al. looked at 2nd graders functional thinking in “Structures identified by second graders in a teaching experiment in a functional approach to early algebra”. While the 2nd graders could think

symbolically, they also had the tendency to stick to the structural form (e.g.  $x+x$ ) that reflected the original problem structure. Eder Pinto et al. in “Representational variation among elementary grade students: A study within a functional approach to early algebra” found that the variety of types of representations used by students was wider when they worked with specific values than with the general case. Thus, the importance of teaching representations explicitly was highlighted. Anna-Susanne Steinweg reported on an unusual experiment in “Short note on algebraic notations: First encounter with letter variables in primary school” where she found that about one out of six primary school pupils without any introduction to formal algebra could spontaneously interpret algebraic expressions for figural patterns in a sensible way.

Empirical research in secondary algebra formed another cluster. Mara Otten et al. showed in “Fifth-grade students solving linear equations supported by physical experiences” that the use of a physical balance can improve performance in solving systems of linear equations. In “Students in 5th and 8th grade in Norway understanding of the equal sign”, Hilde Opsal showed that the operational understanding of the equal sign still dominates in 5th and even the 8th grade. Per Nilsson and Andreas Eckert showed exactly what the title “Time-limitation and colour-coding to support flexibility in pattern generalization tasks” indicates. Marios Pittalis and Ioannis Zacharias in “Unpacking 9th grade students’ algebraic thinking” and Maria Chimoni et al. in “Investigating early algebraic thinking abilities: A path model” both performed confirmatory factor analysis to bring out the structure of algebraic competence. The first paper found that functional thinking and meta-algebra (e.g. proving) are similar, so they concluded that there are three components: generalized arithmetic, transformational ability and meta-algebra. The second paper mainly agreed but used modeling as a third factor. Obviously, this asks for unification. On College level, Claire Wladis et al. in “Relationships between procedural fluency and conceptual understanding in algebra for postsecondary students” showed by latent class analysis that college students showing procedural fluency in standard problem contexts still often lack deeper conceptual understanding.

Next is the group of papers on conceptions and conceptual development. Joana Mata-Pareira and João Pedro da Ponte documented how abductive reasoning can be triggered in “Enhancing students’ generalizations: a case of abductive reasoning”. The context was that of students solving linear equations and discovering the fact that not all of them have solutions. Peter Kop et al. in “Graphing formulas to give meaning to algebraic formulas” used graph drawing by hand and card sorting to improve recognition of function types and graph features and qualitative reasoning about functions. For younger students, Eva Arbona et al. in “Strategies exhibited by good and average solvers of geometric pattern problems as source of traits of mathematical giftedness in grades 4-6” found that a variety of factors influence the way students solve problems. Simon Zell noted student’s inflexibility in performing algebraic tasks and gave in “Provoking students to solve equations in a content-oriented fashion and not using routines” not only empirical evidence, but also suggested how tasks can be used to improve on this.

Several papers considered theoretical issues. Dave Hewitt’s contribution “Never carry out any arithmetic” argued for more complex examples where learners are discouraged from counting and instead are urged to identify structure in figures. Cecilia Kilhamn and Kajsa Bråting, in “Algebraic thinking in the shadow of programming”, reported on ideas to implement computational thinking in

school and especially use programming in algebra and algebraic thinking in the Swedish mathematics curricula. While these activities are computer oriented, for Christof Weber in “Comparing long division and log division algorithms as a way to understand them” the important aspects of algorithms were the insight they provide and the mental models they formulate. Norbert Oleksik considered in “Transforming equations equivalently? – Theoretical considerations of equivalent transformations of equations” different mental models of equivalence relations based on the German tradition of ‘Grundvorstellungen’ and Tall’s notions of concept image and concept definition. Reinhard Oldenburg, in “A classification scheme for variables”, started from the idea to differentiate Grundvorstellungen further according to the linguistic categories of syntax, semantics and pragmatics and claims that there are different kinds of variables (e.g. container vs. reference) that can be identified using these lenses.

## Outlook

The discussions in the group identified several questions that cannot be answered in a satisfactory manner based on the current state of research. An eclectic sample of these questions may give an idea about this and may provide motivation for further research.

Figural patterns remain an active domain of investigation. Yet, many discussions showed that not all aspects are understood well enough to guarantee consensus between researchers. One question concerned what kind of tasks might be motivating for what kind of students. Another, and intensively discussed, question concerned the structuring process and how it can be supported. Papers presented at TWG3 already provided important insights in this but still a deeper understanding would be helpful, e.g. concerning the transformation from the visual structure to the algebraic structure.

Work is still going on to build a competence model of algebraic thinking that can be tested by confirmatory factor analysis. Especially Kaput’s model (2008) attracted researchers and proved to be a good basis for empirical research (with slight modification). It would be interesting if this model can also be confirmed with college level students.

How are continuous and discrete relations related? We had papers that investigated how students dealt with relations of the form  $a - b = 1$  both in a discrete context (number of marbles in boxes) and in a continuous application (distance measurement). So the question arises, if the same logical structure extends to students’ thinking so that students who master one of these domains will also perform well in the other domain and if training in one can boost understanding in the other.

What benefits do algorithms and programming provide for algebra? After the Logo and Basic period the interest in programming in math education declined partly in reaction to research that showed mostly disappointing (but maybe from too high expectations) effects on algebraic understanding. But now there are several reasons to reinvestigate the issue. First, in several countries programming entered the curriculum for reasons outside of mathematics and this offers opportunities for linking the two subjects without the demand on mathematics to invest time to introduce programming. We had a report on ongoing work in Sweden that explores the possibilities. As many approaches are possible, research needs to investigate them and identify more effective ones. Second, tools are more sophisticated today and hence one might expect students to have less frustrating experiences. And third, the view on algorithms today is more elaborate. On the one hand, they are part of the bigger

concept of computational thinking that still gains momentum. On the other hand, there is a meta-mathematical view on algorithms, i.e. reflecting on algorithms can provide mental models of mathematical concepts. The potential of this has to be explored in much more detail than the important first existing examples on the concepts of long and log division that we discussed in the group.

Another issue that was raised during discussions in TWG 3 is related to task design and the role of tasks in research on algebraic thinking. Accounts of principles for task design, and epistemological analyses of the knowledge aimed at by the tasks, would strengthen the justification of research results. Several other topics could be mentioned but we leave this open – future TWG3 meetings will certainly shed light on some of these and many other issues. We have not yet discussed in the group the longterm effects of early algebra, i.e. how do students that encountered algebra in the first grade perform in the middle grades (Dougherty has done some work on this), in high school, and in the long run, in university?

# Teachers' Conceptions of Algebra and Knowledge of Task Purposes

Burcu Alapala<sup>1</sup> and Isil Isler-Baykal<sup>2</sup>

<sup>1</sup>University of Wisconsin-Madison, Madison, USA; alapala@wisc.edu

<sup>2</sup>Middle East Technical University, Ankara, Turkey; iisler@metu.edu.tr

*Keywords: Teacher conceptions of algebra, Teacher knowledge of task purposes, in-service teachers*

## Background of the study

Teachers are the key stakeholders of the prekindergarten-12<sup>th</sup> grade algebra reform and their conceptions about algebra is utmost important. Stephens (2008) working with elementary preservice teachers found that they held narrow conceptions of algebra centered around symbols and symbol manipulation. This study aimed to investigate in-service teachers' conceptions of algebra and their knowledge of task purposes across three tasks that focused on equivalence and equations, functional thinking, and variable.

## Theoretical framework

Kaput (2008) defined two core aspects of algebra as “a) algebra as systematically symbolizing generalizations of regularities and constraints” “(b) algebra as syntactically guided reasoning and actions on generalizations expressed in conventional symbol systems” (p. 11). This framework was used in the study to help categorize teachers' conceptions of algebra.

The second framework used in the study was Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008). This study investigated teachers' knowledge of task purposes (their awareness to engage students in algebraic thinking) which can be categorized under the pedagogical content knowledge (PCK) of the MKT framework across three tasks that focused on algebra.

## Methods

The study was conducted with five female mathematics teachers who were working at the same school with the first author. Three teachers were teaching at the primary and middle school levels and two were teaching at the middle school level. Semi-structured individual interviews were conducted. The interview protocol comprised of three parts and developed based on Stephens (2008), and a functional thinking task was taken from Blanton et al. (2015). The first part included demographic information. The second part focused on understanding teachers' conceptions of algebra including the open-ended question “How would you describe what algebra is to someone who has never heard of it before?” This part also included three tasks. Teachers were asked the possible aims of the task. Also, teachers were asked to categorize the tasks as algebraic or not with their justifications. The last part included two student solutions provided to each of the three tasks. Participants were asked to categorize these student solutions as algebraic or not by explaining their reasoning.

The coding was conducted according to a coding scheme that was developed in previous studies (see Alapala, 2018; Stephens, 2008). The second author coded a randomly selected 20% of the data and the agreement between the coders was found as 80%. The disagreements were resolved, and changes were reflected to the analysis.

What number goes in the box? $37 + 54 = \square + 55$
----------------------------------------------------------

**Figure 1: Task 1**

## Results and discussion

When teachers were asked the possible of aims of each task, their awareness regarding the opportunities to engage students in algebraic thinking varied from task to task. For instance, in Task 1 (see Figure 1) while four teachers focused on having students find the unknown using a computational approach, one teacher focused on the relationship between numbers in her response. When they were asked how they would describe what algebra is to someone who has never heard of it before, the majority of the teachers focused on the presence of an unknown or an equation in their responses. Teachers' categorizations of tasks as algebraic or not providing their justifications revealed a similar finding. They mentioned surface features such as the presence of an unknown or an equation in their categorizations. For instance, all teachers categorized Task 1 as "algebraic" because of the presence of an unknown or an equation. T4 said "I think it is an algebra task because there is an unknown. We didn't say  $x$ ,  $y$  but we used an empty box." Lastly, teachers' categorizations of student solutions indicated that the majority of the teachers ranked student solutions that included manipulations and equations as "algebraic" while they ranked solutions that focused on the structure of the equations and patterns as "non-algebraic." For example, in Task 1, while all teachers rated the student response who used a computational approach to find the unknown as "algebraic," only one teacher rated the response that focused on the relationships between numbers (indicating relational thinking) as "algebraic." Therefore, even though teachers demonstrated some awareness regarding the opportunities the tasks can offer in terms of algebraic thinking (PCK regarding algebra), their conceptions were mostly aligned with Kaput's (2008) manipulation of formalisms. This was similar in Stephens (2008). Given what teachers see as "algebra" could be foregrounded in the classroom, researchers should pay further attention to teachers' conceptions of algebra and pose tasks and hypothetical student responses that help uncover these conceptions.

# Strategies exhibited by good and average solvers of geometric pattern problems as source of traits of mathematical giftedness in grades 4-6

Eva Arbona<sup>1</sup>, María José Beltrán-Meneu<sup>2</sup> and Ángel Gutiérrez<sup>1</sup>

<sup>1</sup> Universitat de València, Valencia, Spain; [eva.arbona@uv.es](mailto:eva.arbona@uv.es), [angel.gutierrez@uv.es](mailto:angel.gutierrez@uv.es)

<sup>2</sup> Universitat Jaume I, Castellón, Spain; [mmeneu@uji.es](mailto:mmeneu@uji.es)

*We describe and analyse the strategies used by students in primary grades 4, 5 and 6 to solve linear and affine geometric pattern problems. Based on two problems posed in a teaching experiment, we have identified several profiles of strategies used by students to solve the problems. We consider the profiles of students who were good geometric pattern problem solvers as traits that may help identify mathematical giftedness. Our results show that average students used very often incorrect functional strategies and were consistent in using incorrect proportional strategies along the grades. On the other hand, good geometric pattern problem solvers tended to use correct functional strategies, although, when they had difficulties in identifying the structure of a pattern, they tended to switch to correct recursive strategies, because they are easier to apply and more reliable.*

*Keywords: Early algebra, geometric pattern problems, mathematical giftedness, primary school.*

## Introduction

Learning algebra is a very fruitful way to boost mathematical abilities of all primary school students, in particular mathematically gifted students (gifted students hereafter). Algebra is also an essential tool in secondary school, since it is needed to solve problems in the different areas of mathematics. However, most secondary school students have difficulties to understand and learn algebra, which hinder their mathematical progress. Some of those difficulties are understanding the meaning of letters and the equal sign, distinguishing between the notions of variable and unknown, and transforming word statements into algebraic expressions (Banerjee & Subramaniam, 2012; Jupri, Drijvers, & Van den Heuvel-Panhuizen, 2015).

In the early grades, algebra can be introduced through algebraic thinking that allows working and operating with variables and unknowns, avoiding the use of symbolic alphanumeric expressions (Radford, 2011a). The context of geometric pattern problems (gp problems hereafter) has proved to be successful in developing algebraic thinking in primary school (García-Reche, Callejo, & Fernández, 2015; Rivera, 2013).

Gp problems (Figures 1 and 2) present a graphical representation of the first few terms of an increasing sequence of natural numbers and ask for values ( $V$ ) or positions ( $n$ ) of specific terms of the sequence. These problems are especially useful to facilitate the access of gifted students to basic algebraic concepts. Furthermore, gp problems are an adequate context to identify possible gifted students, since they have to use their abilities for generalization, abstraction and symbolization. Those abilities are important components of mathematical reasoning, more developed in gifted students than in the majority of students of the same age or the same school grade (we refer to them as *average students*) (Krutetskii, 1976). Amit and Neria (2008) analysed strategies used by gifted students in grades 6 and 7 when solving gp problems, while Fritzlar and Karpinski-Siebold (2012) distinguished

a set of five components of algebraic thinking by observing algebraic abilities of gifted and non-gifted primary school students when identifying and generalising patterns. However, there is little research reporting mathematically gifted students' behaviour when solving gp problems, so it is of interest to inform on traits of mathematical giftedness in the specific context of gp problems.

Teachers should provide all their pupils with opportunities to develop high order thinking. In particular, gifted students require more complex problems compared to average students; thus, it is important to provide teachers with tools to identify their gifted students. Students' solutions to gp problems may be very diverse, depending on the ways of reasoning and performing calculations used, since they reflect different levels of mathematical talent. Gifted students are unusually good problem solvers compared to average students, so a reliable way to identify gifted students, used by most researchers, is to observe their problem solving profiles.

In this context, we present results from a research project aimed to identify and analyse profiles of good gp problem solvers in grades 4, 5 and 6 when solving linear and affine gp problems, to characterise profiles that could differentiate gifted students from average students, and also gifted students in different school grades. The specific objectives of the part of the research presented here are:

- To identify differences between profiles of good gp problem solvers and average students in their solutions of gp problems, as possible traits of mathematical giftedness.
- To identify differences in students' strategies along 4, 5 and 6 primary school grades.

## Theoretical framework

Gp problems present realistic contexts to help students give meaning to the pictorial representations of sequences and their numerical values and answer questions (Billings, Tiedt, & Slater, 2007). *Direct questions* ask for values of *immediate*, *near* and *far* terms (Stacey, 1989), i.e., the number of pieces in the graphical representation of those terms, and also ask to write a *general rule* and an *algebraic expression* to calculate the value of any term of the sequence. *Inverse questions* ask for the position of the term with a given value (Rivera, 2013). Here we focus on answers to direct questions.

Gp problems could have several levels of complexity depending on their characteristics. Friel and Markworth (2009) analysed 18 different geometric patterns and ordered them from less to more complex, the most basic patterns being those based on linear relationships  $V=an$  (Figure 1). Patterns based on affine relationships  $V=an\pm b$  (Figure 2) increase their difficulty. Lastly, patterns based on quadratic relationships  $V=an^2\pm bn\pm c$  are more complex than the previous ones.

Several authors (García-Reche, Callejo, & Fernández, 2015; Radford, 2011b; Stacey, 1989) have identified different strategies used by students to solve direct questions in linear or affine gp problems. As some strategies are labelled differently by those authors, we have merged them into a single categorization of students' answers: the *counting* strategy is based on drawing the graphical representation of the term asked and counting its pieces. The *recursive* strategy uses the constant difference between the values of two consecutive terms to calculate the value of another term, by adding this difference to the value of a known term as many times as necessary. The *proportional* strategy assumes that there is a proportional relationship between the positions of a known term ( $n$ ) and the asked term ( $m$ ) and their values,  $V(n)$  and  $V(m)$ : if  $m=a\times n$ , with  $a\in\mathbb{N}$ , then  $V(m)=a\times V(n)$ . The *functional* strategy

consists of calculating the value of a term by using an arithmetic or algebraic expression based only on the position of the term in the sequence, and not on the value of a known term. The counting, recursive, and functional strategies give the correct answer if applied properly, while the proportional strategy is correct for linear problems but it is wrong for affine problems.

*Gifted students* are those who show “a unique aggregate of mathematical abilities that opens up the possibility of successful performance in mathematical activity” (Krutetskii, 1976, p. 77), their problem solving abilities being higher than those of average students. Greenes (1981), Krutetskii (1976), and Miller (1990) detailed several characteristics that gifted students can present, some of them being particularly important to solve gp problems, like identifying patterns and relationships among elements, generalising and transferring mathematical ideas or knowledge between numeric and algebraic contexts, locating the key of problems, abbreviating solution processes, or inverting mental procedures in mathematical reasoning.

The experimental part of our research took place in ordinary classrooms, where, quite often, there are gifted students who have not been identified by their teachers. We did not have any external way to identify gifted students in the sample of our research (e.g., their IQ), so we looked for *good gp problem solvers*. By comparing the solutions provided by the good gp problem solvers and the other students in their classrooms, we aim to identify specific good gp problem solvers’ solution profiles that could be considered as traits of mathematical giftedness and used, together with other procedures, to identify gifted students in ordinary classrooms.

## Research methodology

We present results from a study based on grades 4, 5 and 6. These are the last grades in Spanish primary schools, just before students start learning algebra, in grade 7. Two classroom groups in each grade followed an experimental teaching unit for early algebra based on gp problems. There were 43, 34, and 41 students in grades 4, 5, and 6, respectively.

The teaching unit took place during three 45-minutes ordinary mathematics classes. It was aimed to work on: i) the generalisation of functional relationships from the geometric representations, ii) the meaning and use of basic algebraic concepts and symbols, like letter notations and the translation of verbal expressions into algebraic ones, and iii) the reinforcement of the algebraic contents previously learned. The teaching unit was based on linear and affine gp problems similar to those shown in Figures 1 and 2. Students solved individually about 3 problems in each session, depending on their ability and quickness. The teacher (the first author) provided some guidelines to the students; after they had solved each problem, she collected the students’ answers, encouraging them to share on the blackboard their different strategies and debate whether they were correct or wrong. Finally, the teacher explained why the wrong strategies did not work. In this paper, we analyse two problems (Figures 1 and 2) posed in the third session of the experiment.

The two problems are based on the same well-known context of tables and chairs. Both have the same wording (Figure 1), with 2 direct questions (*a*, *b*), an algebraic generalisation question (*c*), another direct question (*d*) aimed to check their generalisation, and an inverse question (*e*). However, they have a difference: the first problem (Figure 1) presents tables (*T*) with chairs (*C*) only at the sides, so the sequence is linear ( $C=2T$ ); the second problem (Figure 2) presents tables with chairs both at the

sides and the ends, so the sequence is affine ( $C=2T+2$ ). The problems were posed to induce students to generalise the relationships, write an algebraic expression, and use it.

María is organising her birthday party with her friends and relatives. She wants to calculate how many tables and chairs she needs to sit people as in the pictures:

- How many people will sit around 6 tables? How do you know it?
- How many people will sit around 50 tables? How do you know it?
- Explain to a friend how she can calculate how many people will sit depending on the number of tables. Write down the formula you have mentioned.
- Use the previous formula to find how many people will sit around 15 tables.
- If there are 22 people sitting, how many tables will be? How do you know it?

**Figure 1: The linear gp problem**

**Figure 2: The affine gp problem, with the same wording as in Figure 1**

After analysing the answers to the direct questions in the problems (*a*, *b*, and *d*), we have identified different profiles of students' solutions, depending on which strategies were used. For example, the *recursive-functional* profile identifies those students who used a recursive strategy in the linear gp problem and a functional strategy in the affine one.

### Analysis of students' answers

We have analysed the types of students' strategies in the direct questions in both gp problems. We have considered as *good gp problem solvers* those students who solved correctly, or with minor errors, all the gp problems in the teaching unit. We identified as good gp problem solvers three students in grade 4, four in grade 5, and three in grade 6. Table 1 shows the number of good gp problem solvers and average students in each grade that used each profile to answer the direct questions. In the average students' profile functional-functional, we use brackets to show the number of their correct answers.

In grade 4, two out of the three good gp problem solvers based their solutions to both problems on functional strategies. On the other hand, 23 average students in grade 4 used functional strategies in both problems, but only 7 students solved them correctly. The other students used a diversity of combinations of functional and proportional strategies, all incorrect.

Linear problem	Affine problem
Student 5B-13: $6 \times 2 = 12$ <i>Because you must multiply the table x2.</i>	Student 5B-13: 14 <i>Because I've been adding.</i>

**Figure 3: Functional and recursive strategies in a good gp problem solver's answers to question a**

In grade 5, the good gp problem solvers provided solutions based on functional and recursive strategies, half of them changing from using the functional strategy in the linear problem to the less complex recursive strategy in the affine problem (Figure 3), or vice versa. On the other hand, average students mostly used the functional strategy in both problems, but only 8 students produced correct answers in both problems. The change of strategy made by the good gp problem solvers seems illogical, but it allowed them to succeed in solving the problem. On the contrary, the average students used the same strategy in both problems, maybe because they were comfortable using it or considered that both problems were analogous, but many average students produced incorrect answers (Table 1).

Profiles of solutions		Good gp problem solvers			Average students		
Linear	Affine	4th	5th	6th	4th	5th	6th
Recursive	Functional	0	1	0	0	0	0
Functional	Recursive	0	1	0	0	0	0
Functional	Functional	2	2	3	23 (7*)	20 (8*)	27 (22*)
Functional	Proportional	0	0	0	6	2	0

Other solutions		1	0	0	8	6	5
Total		3	4	3	40	30	38

(\*) Number of average students in this profile producing correct solutions to both problems.

**Table 1: Profiles of solutions to the direct questions (a, b, and d) in both problems**

In grade 6, all good gp problem solvers and most average students used functional strategies in both problems, with a few average students using such strategies incorrectly. As in the other grades, some average students used proportional strategies. The fact that all good gp problem solvers in grade 6 used correct functional strategies, while a part of the average students used wrong proportional and functional strategies, points to traits of mathematical giftedness in the context of gp problems, namely identification of patterns and relationships among different elements, and generalising and transferring mathematical ideas from a numeric context to an algebraic one.

A profile typical of students when they start solving gp problems is that they tend to move from a strategy to another in the consecutive questions of the same problem (Gutiérrez, Benedicto, Jaime, & Arbona, 2018). However, as the problems we are analysing were posed in the third class session of the teaching experiment, the students had already learned that the final aim of the gp problems was to state a generalisation. Then, all students but one in the sample used the same strategy for all direct

questions in each problem, although some students used different strategies for the linear and affine problems, showing diverse profiles in their solutions. Students had also learned that recursive strategies are efficient only for the immediate or near terms.

After comparing the data in Table 1 for the different grades, we get the following conclusions:

- i) The good gp problem solvers used, in each problem, a strategy with which they felt confident and that they were sure it was correct, even using a different strategy in each problem (Figure 3). They were more successful than average students in using simpler recursive strategies, and avoided the proportional strategy even in the linear problems, were it provides a correct answer. The good gp problem solvers also became more efficient along the grades using functional strategies.
- ii) Average students in all grades used mostly functional strategies, with an increase of the percentage of correct answers along the grades, but we do not observe a reduction in the use of (incorrect) proportional strategies in the affine problem.

Due to the relevant number of average students using the same strategy in the linear and affine gp problems, we have analysed the errors caused by this profile. We have identified three types:

### Constancy of proportional relationship

Some average students used a (correct) proportional strategy in the linear problem and they used it again in the affine problem, although now it was wrong. Students did not analyse the whole pattern, but only one term: they calculated proportionally the value of the term requested, considering only the number of guests sitting around one table in the first or the second term of the pattern. Figure 4 shows the written answers of an average student who only considered the number of chairs around the table in the first term.

Linear problem	Affine problem
<p>Student 5A-6: <math>50 \times 2 = 100</math></p> <p><i>Because there are twice as many guests as tables.</i></p>	<p>Student 5A-6: <math>50 \times 4 = 200</math></p> <p><i>Because, if there are 50 tables, there are 4 guests for each table.</i></p>

Figure 4: Constancy of proportional relationship in an average student's answers to question b

### Constancy of recursive relationship

Some average students identified the difference between the values of two consecutive terms and used it in a repeated addition or a multiplication. In Figure 5, the student did not pay attention to the chairs at the ends of the tables in the affine problem and used the increment of 2 chairs ("two more chairs") as proportional ratio.

### Error of analysis of diagrams

Some average students did not analyse correctly the parts of the patterns. They identified a wrong difference between the linear and the affine patterns and used it to create a wrong formula. In Figure 6, the student did not identify correctly the chairs at the ends of the tables and, furthermore, he did not use correctly the number of chairs around the first table (4).

Linear problem	Affine problem
Student 5A-11: $50 \times 2 = 100$ <i>Because each time there are 2 [more] chairs and 50 tables [multiplied] by 2 chairs too.</i>	Student 5A-11: $50 \times 2 = 100$ <i>I multiply the number of tables by 2 more chairs.</i>

**Figure 5: Constancy of recursive relationship in an average student's answers to question b**

Linear problem	Affine problem
Student 5A-1: $50 \times 2 = 100$ <i>Because, each time, 2 chairs are added with one table.</i>	Student 5A-1: $50 \times 2 = 100$ ; $100 + 3 = 103$ <i>Because there are 4 guests in 1 table, but 2 guests are added each time.</i>

**Figure 6: Error of analysis of diagrams in an average student's answer to question b**

## Conclusions

We have presented a comparative analysis of strategies of solution used by a sample of good gp problem solvers and average students in grades 4 to 6 when solving direct questions in a linear ( $V=an$ ) and an affine ( $V=an+b$ ) gp problems posed as part of an experimental teaching unit. The analysis of students' answers to those problems shows some significant and original findings: most students used mainly functional strategies, although good gp problem solvers showed a tendency to follow profiles using functional and recursive strategies, which were less complex but more successful than the profiles followed by average students, based on functional and proportional strategies. There is a tendency of average students in all grades to use wrong proportional strategies. According to Van Dooren, De Bock, Hessels, Janssens, and Verschaffel (2005), students are prone to apply proportional strategies when they should not be applied. The frequency of such strategies seems to be higher when students start learning proportional reasoning, which, in Spain, usually happens in grade 4.

The analysis of the data collected suggests a difference between the profiles of good gp problem solvers and average students in the use of recursive strategies of solution in the (more difficult) affine problem. Data also seem to show a clear difference between the profiles of both types of students in the use of proportional strategies, even when they were correct. Hence, a contribution of this research is the suggestion that a trait of giftedness in solving gp problems seems to be the use of correct recursive and functional strategies and the absence of proportional strategies to solve gp problems.

Respect to the differences between grades, we have observed an increment in the amount of solutions based on functional strategies, and an increment in the percentage of correct functional strategies. However, it is not apparent a (expected) reduction in the use of incorrect proportional strategies.

## Acknowledgments

The results presented are partially funded by the research projects EDU2017-84377-R (AEI/ERDF, EU) and GVPROMETEO2016-143, and by the predoctoral aid FPU16/04513 (Spanish Ministry of

Science, Innovation and Universities), aimed to train new university teachers.

## Investigating early algebraic thinking abilities: a path model

Maria Chimoni, Demetra Pitta-Pantazi and Constantinos Christou

University of Cyprus, Department of Education, Nicosia, Cyprus; chimoni.maria@ucy.ac.cy, dpitta@ucy.ac.cy, edchrist@ucy.ac.cy

*The introduction of algebra in the elementary school mathematics is expected to navigate students from concrete, arithmetical thinking to increasingly complex, abstract algebraic thinking required in secondary school mathematics and beyond. Yet, empirical studies exploring this idea are relatively scarce. Drawing on a sample of 684 students from grades 4, 5, 6, and 7, this study explored a path model which tested associations between students' abilities in solving different types of early algebraic tasks: generalized arithmetic, functional thinking, and modeling languages. Results emerging from latent path analysis showed that students were more successful in generalized arithmetic tasks and only when this was achieved they were able to solve functional thinking tasks; once these were achieved, they could proceed to solve modeling languages tasks. Qualitative analysis of students' solutions provided further insight into these findings.*

*Keywords: Early algebraic thinking, generalized arithmetic, functional thinking, modeling languages, path model.*

### Introduction

While the traditional arithmetic-then-algebra curricula have been proved to be unsuccessful in developing deep understanding of abstract algebra in the secondary grades, it has been suggested that algebra should become a cohesive thread in mathematics curriculum from K to 12 grades (Carraher & Schliemann, 2007). Yet, introducing algebra in the early grades does not mean to move the content of secondary algebra courses to elementary mathematics. Instead, it means setting the ground for students to develop ways of thinking that can support the later learning of algebra. To make this idea more clear, different approaches have been pursued, ranging from the identification of core algebra content strands, such as generalized arithmetic, functional thinking, and modeling languages (Kaput, 2008), to the examination of fundamental algebraic concepts, such as the equals sign (Matthews et al., 2012), to the analysis of essential algebraic processes, such as generalization and representation (Blanton & Kaput, 2005). Moreover, several researchers examined developmental paths where intuitive forms of algebraic thinking become more sophisticated through the mediation offered by appropriate instruction in specific areas of early algebra (e.g. Radford, 2014; Stephens et al., 2017).

The findings of these studies imply that the development of early algebraic thinking lies in the extension of arithmetic that is typically taught in elementary school so that students become aware of its underlying structure and properties and gradually develop the ability to identify and describe functional relationships between quantities that co-vary. Yet, more studies are needed to empirically test this idea. Towards this end, this study aimed to investigate the validity of an algebraic thinking path model which describes early algebraic thinking abilities that students seem to develop first and the way these are associated to other abilities that students seem to develop later on.

The rest of this manuscript is structured as follows: The next section provides an overview of studies that explored the nature of early algebraic thinking, its processes and mathematical content. Following

that, the research question is presented and the hypothesis tested. The methodology, including information about the participants, tasks, and analyses, is outlined next. After presenting the main findings, conclusions and implications for practice are discussed.

## **Theoretical Framework**

### **Algebraic processes that mark the emergence of early algebraic thinking**

A critical issue within the field of early algebra has been the way in which early algebraic thinking might occur and be expressed by students. Several researchers tend to agree that students exhibit early algebraic thinking by the time they begin to formulate generalizations about mathematical relationships, properties, and structure (Blanton & Kaput, 2005). Particularly, the process of generalizing is considered as an undisputed characteristic of early algebraic thinking. Generalizing is interrelated with the process of representing, as students make efforts to articulate and represent their generalizations (Blanton et al., 2015). At the same time, a variety of other processes frame generalizing and representing, such as noticing, hypothesizing, and validating (Blanton et al., 2011).

Algebraic processes are not developed or expressed by students in a mere single way (Stephens et al., 2017). For example, students' use of natural language, gestures or diagrams might be an indicator for the emergence of early algebraic thinking, which will in turn mediate the long-term development of alphanumeric symbolism. Particularly, Radford (2003) exemplified that the way students communicate generalizations might differ, varying from concrete numerical actions (*factual* generalization), to situated descriptions of the objects of the actions (*contextual* generalization), to actions with symbols or signs (*symbolic* generalization). Summing up, algebraic processes seem to be central to students' engagement with early algebraic tasks. The following section describes further the content areas in which these processes and forms of thinking are expected to emerge and grow.

### **Core algebra content strands and concepts**

Kaput (2008) suggested that three core content strands involve algebraic thinking from K to 12 grades: generalized arithmetic, functional thinking, and application of modeling languages. These strands, which are interconnected with the processes described in the previous section, provide a unified framework for analyzing the multidimensional and complex nature of early algebraic thinking (Chimoni, Pitta-Pantazi & Christou, 2018).

Generalized arithmetic refers to the study of structure and relationships that are inherent to numbers and arithmetical operations. The emphasis in this strand is about looking at the structure of arithmetical expressions and computations rather than their results (Kaput, 2008). In generalized arithmetic, students are expected to use the properties of operations and relationships on classes of numbers, interpret the equals sign relationally, and solve single-variable equations and inequalities.

Functional thinking involves generalizing relationships between quantities that co-vary and representing them through multiple tools, such as natural language, alphanumeric symbols, pictures, function tables, and graphs (Blanton et al., 2017). Central in this strand are the concepts of variable and functional relationships, such as recursive patterns, co-variational relationships, and correspondence relationships (Stephens et al., 2017).

Modeling languages refers to the application of a cluster of modeling languages both inside and outside mathematics (Kaput, 2008). In this strand students begin with problem situations and make attempts to mathematise the regularities that are implicitly presented through the situation, using appropriate models, such as verbal expressions, equations, and graphs.

### Research question and hypothesis

The research question that guided this study was the following: *Is there a consistent trend in the level of difficulty across generalized arithmetic, functional thinking, and modeling languages tasks that describes students' early algebraic thinking abilities?* In addressing this question and based on theoretical implications described in the previous section, this study tested the following hypothetical path model: *Students are able to solve generalized arithmetic tasks first. Once this is achieved, they proceed to solve functional thinking tasks. Solving modeling languages tasks is achieved last.*

### Participants

A convenience sample of 684 students was involved in the study. The sample consisted of 170 fourth-graders (10 years old), 164 fifth-graders (11 years old), 184 sixth-graders (12 years old) and 166 seventh-graders (13 years old). The selection of these grades was done purposefully, since some of the concepts embedded in the three algebra content strands are not covered in earlier grades; at the same time, formal algebra is taught in later grades. Moreover, the existence of four age-groups enabled the examination of the stability of the path model or possible changes across age-groups.

### Test

The test used to measure students' early algebraic thinking abilities consisted of 18 tasks that were adapted from previous research studies (e.g. Blanton & Kaput, 2005). The test included generalized arithmetic, functional thinking, and modeling languages tasks. Table 1 presents indicative examples.

Example	Strand
Is the value of the following expressions the same or not? Justify your answer. <div style="display: flex; justify-content: space-around; align-items: center;"> <div style="border: 1px solid black; padding: 5px; margin: 2px;"><math>7 + 5</math></div> <div style="border: 1px solid black; padding: 5px; margin: 2px;"><math>7 + 5 + 2 - 2</math></div> </div>	Generalized Arithmetic
At a table that has the shape of a trapezium, 5 children can be seated. If two tables are connected, then 8 children can be seated. <div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;"> <p>Table 1</p>  </div> <div style="text-align: center;"> <p>Table 2</p>  </div> </div>	Functional thinking
(a) How many children can be seated at 3 tables? Justify your answer. (b) How many children can be seated at 10 tables? Justify your answer.	
Joanna will take computers lessons twice a week. Which is the best offer? Justify your answer. Offer A: €8 for each lesson Offer B: €50 for the first 5 lessons of the month and then €4 for every additional lesson	Modeling languages

**Table 1: Examples of tasks included in the algebraic thinking test**

Considering that students had adequate time to complete the test during administration, tasks with no response were graded with 0 marks. For the multiple choice tasks which had four alternative

responses, one mark was given to each correct response and zero marks were given to each incorrect response. For the tasks that had sub-questions, partial credit was given, considering the maximum sum of the marks of the sub-questions to be equal to 1. In the tasks where students had to justify their answers, the scoring was as follows: 0 mark for fully incorrect responses, 0.50 for giving a correct answer without justifying the answer or giving a wrong justification and 1 mark for giving a correct answer and a proper justification. In some tasks, where students were expected to use various strategies to solve them, a second identification mark was given based on the strategy used. Yet, the variation in students' strategies is not under investigation in the current paper.

## Analysis

To analyze the quantitative data collected from the test, Latent Path Analysis was used. This kind of analysis is part of a more general class of techniques called Structural Equation Modeling (SEM). Specifically, Latent Path Analysis is used for testing whether a set of factors that are measured from multiple indicators (latent factors) are connected via directional regression paths. In this study, Latent Path Analysis was used for testing whether the three algebra content strands are connected via a specific path model. The analysis was conducted separately for each age-group and for the whole sample as well.

Firstly, the model described in the study's hypothesis was examined (Model 1). Moreover, two alternative models were also examined (Models 2 & 3). Model 2 assumed that students are able to solve both generalized arithmetic and functional thinking tasks first, and then they proceed to solve modeling languages tasks. Model 3 assumed that students are able to solve modeling languages tasks first, then they proceed to solve functional thinking tasks, and finally they are able to solve generalized arithmetic tasks.

Three fit indices were computed for each model: the chi-square to its degree of freedom ratio ( $\chi^2/df$ ), the comparative fit index (CFI) and the root mean-square error of approximation (RMSEA). For a model to be validated, the observed values for  $\chi^2/df$  should be less than 2, the values for CFI should be higher than .9, and the RMSEA values should be close to or lower than .08. The analysis was carried out using the MPLUS software (Muthén & Muthén, 1998).

In order to better interpret the quantitative results and illustrate examples of students' thinking in each strand, qualitative information from students' tests was analyzed: ten students were selected and their solutions were examined. The selection of these students was based on the method of purposeful sampling (Patton, 2002) which suggests the selection of cases that provide rich information about the phenomenon under investigation.

## Results

The results of the Latent Path Analysis suggested that the best fitting model was Model 1, since it had the best fitting indices and high regression coefficients for each of the three latent factors. This result was the same for each of the four age-groups and for the whole sample. Figure 1 presents the structure of the model and the regression coefficients, as resulted from the Latent Path Analysis conducted to the data of the whole sample. Specifically, the fitting indices were adequate to provide evidence that supports the structure implied in the model (CFI=.959,  $\chi^2=201.853$ ,  $\chi^2/df=1.73$ , RMSEA=.033). This,

supports the hypothesis of the existence of a consistent trend. Particularly, it appears that students are first able to solve generalized arithmetic tasks, such as using properties of numbers and operations, solving equations and inequalities, and analyzing expressions that involve symbols and numbers. Once they develop these abilities, they are able to solve functional thinking tasks, such as identifying distant terms in patterns, analyzing tables that represent correspondence relationships, and interpreting graphs. Generalized arithmetic and functional thinking appear as stepping stones for students to move on to modeling languages, where they are able to identify relationships between quantities that are presented through a situation and mathematize the situation using an appropriate model.

*Note. \* $p < .01$ . The first number indicates the regression coefficient and the number in parenthesis indicate the proportion of variability that can be explained ( $r^2$ )*

**Figure 1: Associations between students' abilities in different types of early algebraic tasks**

The results of descriptive statistics analyses showed that the students' highest performance mean was in generalized arithmetic tasks ( $M=.530$ ). The second highest mean score was in functional thinking tasks ( $M=.507$ ). Students' lowest mean score was in modeling languages tasks ( $M=.303$ ), indicating that these tasks were more difficult for them.

The qualitative analysis of students' responses to specific tasks provided insights into the way students develop and apply the processes of generalizing and representing in each content strand. At the same time, these data allow further interpretation of the trend outlined from the latent path analysis. Figure 2 presents indicative examples of students' responses to three different tasks.

In the generalized arithmetic task (Fig. 2a), the student seems to directly recognize that the value of each expression is the same, without performing computations and comparing their results. The student expresses verbally the observed structure and seems to use the numbers  $-2$  and  $+2$  in a general way, as "quasi-variables" (Fujii & Stephens, 2001), to represent a regularity. Student's response shows that a familiar context, as the one of arithmetical expressions, enables noticing structure and regularities, generalizing from these regularities, and using means other than alphanumeric symbols to represent these generalizations, such as verbal descriptions.

The abilities developed within a generalized arithmetic perspective seem to facilitate students to begin making "factual" generalizations from concrete actions (Radford, 2003). Based on the quantitative data, these abilities seem to prompt students to look for structure and relationships in more complex contexts. As shown in Figure 2b, in a figural pattern, the student approaches the first question based on numerical actions, by drawing the next table and seats and probably counting the number of seats. The student seems to focus on one variable (the number of seats) and finds the answer based on the identification of a recursive pattern. Yet, the second question prompts the student to reason about two quantities that co-vary, since drawing and counting would not be a convenient strategy for finding a far term. The student seems to notice the pattern's structure and the relationship between the number

of tables and the number of seats. In this case, the student recognizes that tables at the edges always have 4 seats each and tables in the middle always have 3 seats each, and writes two distinct expressions to reach the final answer. However, the student seems to acknowledge that there is a general rule, despite the fact that there is no use of alphanumeric symbols. The student's generalization at this point seems to be, in terms of Radford (2003), a "contextual" generalization based on a situated description.

### a. Generalized arithmetic task

Is the value of the following expressions the same or not? Justify your answer.

A.  $7+5$  B.  $7+5-2+2$

Cyri xai kai xoti to  $7+5$  einai  
konia kai to  $-2+2=0$

***Yes because  $7+5$  is the same in both expressions and  $-2+2=0$ .***

### b. Functional thinking task

(a) How many children can be seated at 3 tables? Justify your answer.

11 παιδια.  
children

(b) How many children can be seated at 10 tables? Justify your answer.

32 *palida*. children

2 edges  
 2 edges  $\times 4 = 8$   
 8 *palida*  $\times 3 = 24$   
 8 between  $8 + 24 = 32$

### c. Modeling languages task

Joanna will take computers lessons twice a week. Which is the best offer? Justify your answer.

Offer A: €8 for each lesson

Offer B: €50 for the first 5 lessons of the month and then €4 for every additional lesson

$1 \text{ month} = 4 \text{ weeks}$   
 $\downarrow$   $1 \text{ month} = 4 \text{ weeks}$   
 $8 \times 8 = 64$   $1^{\text{st}} \text{ offer} = \text{€}64$   
 $50 = 5$   $4 \times 3 = 12$   
 $2^{\text{nd}} \text{ offer} = \text{€}62$   
Offer B is more advantageous

**Figure 2: Indicative examples of students' responses**

In the modeling languages task (Fig. 2c), the student identifies first the quantities involved: the dependent variable (the monthly cost of the lessons) and the independent variable (the number of lessons during a month); the student considers the number of monthly lessons to be 8. Furthermore, the student formulates expressions for Offer A and B, taking into consideration all variables described in the problem. In this sense, the student develops the processes of generalizing and representing in order to establish a general mathematical relationship that fits the situation. The student's response implies that arithmetical expressions are used to build a "contextual" generalization (Radford, 2003).

## Discussion and Conclusions

In this study, we attempted to validate a path model which describes early algebraic thinking abilities that students seem to develop first and the way these are associated to other abilities that students seem to develop later on. The abilities examined were extracted from Kaput's (2008) theoretical framework about the three core algebra content strands: generalized arithmetic, functional thinking, and modeling languages. The results of the quantitative analyses provide evidence that there is a consistent trend in the level of difficulty across the three strands. It appears that students find it first easiest to solve generalized arithmetic tasks, and then functional thinking tasks. Once this is achieved, they can proceed to solve modeling languages tasks. These results complement but also extend the findings of previous studies that reported the significant role of content strands, such as generalized arithmetic and functional thinking in setting foundations in elementary mathematics for the longterm development of students' algebraic thinking (e.g. Carraher et al., 2006). Particularly, the findings of this study verify the ideas of a number of researchers (e.g. Fujii & Stephens, 2001) that the development of early algebraic thinking lies in the arithmetic that is taught in elementary school so that students pay attention to its underlying structure and properties and gradually develop the ability to identify and describe functional relationships between quantities that co-vary.

The data from the qualitative analysis exemplify the nature of students' thinking while they try to solve these types of tasks. Moreover, these data provide a plausible explanation for the idea that, in generalized arithmetic, students' pre-acquired arithmetical knowledge serves as a turning point for introducing them to early algebraic thinking. Generalized arithmetic encompasses familiar contexts that allow students to develop the processes of generalization and representation, without necessarily using alphanumeric symbols. The strand of functional thinking seems to strengthen the interplay between arithmetic and algebra, by introducing students to the concept of functions (Radford, 2014). Modeling languages appear to involve more advanced forms of algebraic thinking (Blanton & Kaput, 2005) that require the use of algebra as a tool in order for students to generalize, model, and justify relationships that are implicitly presented through problem situations.

Overall, this study provides empirical data that document students' capability to develop essential forms of early algebraic thinking that are foundational for the development of formal and abstract algebraic thinking. Moreover, the results imply that a comprehensive and sustained early algebra approach must build on developing students' abilities not only on one specific content strand but across the strands of generalized arithmetic, functional thinking and modeling languages. It should be noted that the model proposed in this study was formulated based on Kaput's theoretical framework and involved a sample of students with specific mathematical experiences. Future studies may examine the stability of this model in earlier or later grades of schooling. Following recent suggestions (e.g. Blanton et al., 2017), future studies might also confront generalized arithmetic and equation solving as two separated strands and test the associations between them as well as with the strands of functional thinking and modeling languages.

# Students' expected engagement with algebra based on an analysis of exams in Norway from 1995 till 2018

James Gray<sup>1</sup>, Bodil Kleve<sup>1</sup> and Helga Kufaas Tellefsen<sup>1</sup>

*Using the definition of algebra from the TIMSS framework, algebra questions were identified on a sample of Norwegian mathematics examinations for 10<sup>th</sup> grade students from 1995 to 2018. These questions were then analysed using a discursive framework to look at the specialisation of the mathematical language. The analysis revealed consistency in the density of the language, a decreasing expectation of the depth of engagement with real world contexts, and a recent tendency to processes that direct the students in solving problems. It is argued that this gives an indication of the expected engagement with and implementation of the algebra curriculum in Norwegian schools.*

*Keywords: Algebraic thinking, Assessment, Specialised and non-specialised mathematics discourses.*

## Background and context

An ongoing issue in debates about Norwegian students' performance in mathematics is related to performance on algebraic tasks. On TIMSS tests since 2011, Norwegian 5<sup>th</sup> grade students were among the top performers in mathematics in Europe (Bergem, 2016). They performed significantly higher than students in the other Nordic countries. However, the performance of 9<sup>th</sup> grade students on the most recent TIMSS test in 2015 was at an intermediate level in a European perspective. Overall this was an improvement on previous years, but it was "particularly due to low scores in Algebra" (Bergem, 2016 p.22), which have decreased since 2011 and were at a very low level in 2015.

In Norway, the only externally set high-stakes written examination based on the mathematics common curriculum occurs at the end of grade 10. We consider tasks on these mathematics examinations to be important with regard to how students are expected to engage with the mathematical discourse. Like Morgan and Tang (2016), we assume that mathematics examinations mirror how mathematics curricula are implemented in the classroom (Broadfoot, 1996). From a discursive perspective, Morgan and Tang (2016) investigated differences in the language used in mathematics questions on examinations in England and Wales. The identified changes are discussed in the light of debates about 'standards', highlighting engagement with algebraic manipulations and independent problem solving. It is interesting to see if similar changes have occurred in other countries, to which our study may contribute.

Within this context, we investigated how algebra questions on the 10<sup>th</sup> grade examinations have developed since 1995. During this period, there have been several curricula (M87, L97 and LK 06 introduced in 1987, 1997 and 2006 respectively), which differ substantially in their treatment of algebra and contextualisation. In **M87** (*Mønsterplan for grunnskolen: M87*, 1987) "Algebra and Functions" was one topic and "Mathematics in everyday life" was integrated into all topics. **L97** (1999) had the following as separate topics: "Algebra and Number"; "Graphs and Functions"; and "Mathematics in everyday life". In the current curriculum **LK 06** (Kunnskapsdepartementet, 2006),

there is an emphasis on basic skills. In contrast to M87 and L97, in which the goals were knowledge oriented, each main area in LK 06 is formulated in terms of competence goals. As in L97, “Numbers and Algebra” and “Functions” are still separate topics. Mathematics in everyday life is no longer a separate topic, but integrated into all topics, as it was in the M87.

In light of this, we will investigate the following research question:

How has the nature of students’ expected application of algebra in both mathematical and non-mathematical contexts developed since 1995 in 10<sup>th</sup> grade school mathematics in Norway?

## Theoretical framework

As analytical framework, we have drawn on the work of Morgan, Sfard, and Tang (Morgan & Sfard, 2016; Morgan & Tang, 2016). Related to their project The Evolution of the Discourse of School Mathematics (EDSM), they developed a substantial conceptual framework for analysing examinations. This framework has a theoretical foundation in social semiotics and Sfard’s communicational theory (Sfard, 2010). For the purposes of this paper, it is sufficient to say that mathematics being a human activity is defined in terms of the discourse that one engages in when doing mathematics. Morgan and Tang (2016) argue that the language used on the exams is crucial and that the language use in examinations may change the nature of the mathematics students are expected to engage with. Dowling (2001) emphasised how the language used in school mathematics may both enable and deny access to mathematics. By analysing the language students used when telling stories about their own learning in mathematics Kleve and Penne (2016) found that students who were successful in mathematics, used the subject specific language to a greater extent than those less successful. That is, the successful students were inside the mathematical discourse.

In our project, we aim to apply the whole EDSM framework to our selection of algebra questions. This paper will report on just one section of the framework. It is intended that the framework can be used in this way, and we are following the work of Morgan and Tang (2016) in focusing on the part of the framework that deals with specialisation of the discourse.

To analyse the algebra questions, nouns and verbs were allocated as SM (specialised to the discourse of school mathematics) or NSM (non-specialised). Specialised to the discourse of mathematics means that they were “used in accordance with mathematical definitions or in ways distinctive to school mathematics” (Morgan & Tang, 2016, p. 145). Then the whole questions could be classified as (entirely) SM, (entirely) NSM or *Mixed* (both SM and NSM). Although NSM was not included as a question code in the EDSM framework it was revealed during our analysis. Questions classified as SM were termed *Abstract*. Whole Questions classified as NSM or *Mixed* were further classified according to the depth of engagement with the context in terms of *Ritual* (repetitive exercise or following patterns widely used in text-books), *Mundane* (containing some unfamiliar elements, however requiring minimal engagement) and *Deep* (demanding more extensive engagement to determine how specialised mathematical discourse should be used). Illustrative examples of these categories appear in Morgan and Tang (2016). With regard to vocabulary, we identified objects in terms of nouns, and processes in terms of verbs, coding each word as either SM or NSM.

## Method

To explore our research question we needed a representative sample of examinations. We took examinations every five years from 1995 together with the most recent examination from 2018. This yielded a sample that was manageable within the remit of our project, had an even coverage of the study period, and that included an early and a late examination in each curriculum cycle. The sampled examinations and the curricula reforms are illustrated on the timeline below.

**Figure 1: Timeline showing sampled examination years (dots), and curricular reforms**

To identify the algebra questions from each paper the authors made an initial selection individually. The selections were compared and the selection criteria discussed. It is now common to distinguish between algebra as cultural artefact and algebraic thinking as a human activity (Hodgen, J., Oldenburg, R., & Strømskag, H., 2018). Ideally, we would be able to pick out the questions that the majority of students would be expected to use algebraic thinking. However, we do not have access the thoughts of the candidates and examination setters so we could not identify questions by this criteria. We considered the curricula, but these did not provide us with an adequate definition because algebra has been grouped with different topics in the different curricula (see Background and context). Our project is partially motivated by the poor results in algebra in TIMSS (see Background and context), so we decided to use their definition of algebra to guide our selection ("TIMSS 2019 Mathematics Framework," 2017). For example, the questions asking students to use the Pythagorean theorem to work out the length of one side of a triangle were categorized as geometry and not algebra (as they are in the published TIMSS questions). An example of an algebra question involving geometry is given at the end of the Findings and analysis section. Using the definition from TIMSS, the authors adjusted their initial selection and reached a consensus.

Questions were coded as SM, *mixed* or NSM, and then *mixed* and NSM questions were coded as *ritual*, *mundane* or *deep* (see Theoretical framework). Working individually, one of the authors coded all the questions in the sample of examinations and the other two shared the sample. Revision and recoding of all the data set was then done by two authors in consultation with one another. Similarly at the level of specialised vocabulary. One of the authors coded the process (verbs) as SM or NSM and the other two coded the object (nouns) as SM or NSM. The authors consulted each other during this process so that difficulties could be resolved by a consensus decision. Inter-rater reliability was not calculated because the purpose of the project is to compare examinations and for each coding category each data set was coded completely by one of the authors.

## Findings and analysis

### Proportion of algebra questions and degree on contextualisation

Figure 2 shows the percentage of algebra questions on each of the examination papers. In the examinations in 2000 and 2005, candidates were given a choice of six questions from 22 (covering a

range of topics) in the last part of the examination. In each of these years, it was possible to avoid, or choose almost exclusively, algebra questions in this part. These two extremes are shown in Table 1, and in Figure 2 by two data points for each of these years. We do not have any data about how many algebra questions a student would typically choose. We note that candidates had the opportunity to make a significant reduction in the proportion of algebra questions in these years, and from the authors' experience, it is very unlikely that many chose the highest proportion possible.

Year	1995	2000	2005	2010	2015	2018
Number of questions on examination	56	32	40	64	55	53
Number of algebra questions (% of questions)	18 (32%)	6 (19%)–12 (38%)	6 (15%)–11 (28%)	16 (25%)	21 (38%)	20 (38%)

**Table 1: The number of questions and algebra in each examination in the sample**

LK06 was revised in 2013 and more algebra was included (Utdanningsdirektoratet, 2014). The proportion of algebra questions on the examinations in our sample has also increased significantly since 2013. For comparison, the target proportion for algebra in the TIMSS assessment is 30%. The examination in 1995 was approximately at this level. The examinations in 2005 and 2010 were below this level, whereas the examinations in 2015 and 2018 were above this level.

**Figure 2: The percentage of algebra questions in each examination in the sample.**

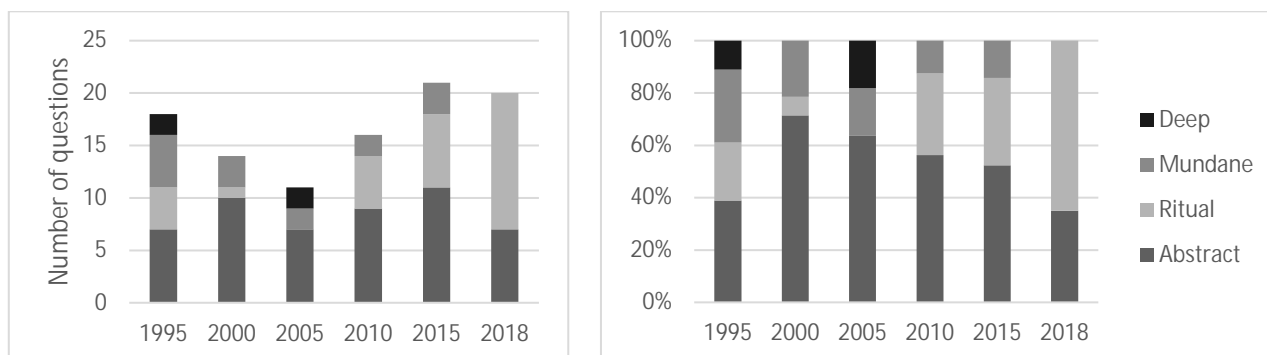

Figure 3 shows the number of questions coded as *abstract*, *ritual*, *mundane* and *deep*, and these as a proportion of all of the algebra questions. In the years 2000 and 2005, we have included all the algebra questions that the students could choose in the last part of the examination. (In the year 2000, candidates could not do more than twelve algebra questions, but the figure shows the results for all fourteen algebra questions.) If we exclude the last part of these examinations, there were six abstract and one ritual questions in 2000, and eight abstract and one mundane questions in 2005. (There were fewer questions in total on the examinations under the curriculum L97, but the time given to the candidates has remained constant for all the examinations in the sample.) Thus, there was only one compulsory contextualised algebra question for candidates in each of these years.

There were no questions coded as *deep* in the examinations after 2005 in our sample. Moreover, the questions coded as *deep* in 2005 were all in the last part where the candidates had a choice of questions. Thus, the examination in 1995 was the only one in our sample where candidates were expected to engage in 'deep' algebraic context.

The proportion and number of ritual questions has increased significantly in the examinations in our sample that occurred after the introduction of the present curriculum (2010, 2015 and 2018). In addition, the proportion of abstract questions has decreased. This indicates a trend where there are more contextualised algebra questions, but that the degree of depth with which the students are

expected to engage with the context has fallen. We noted earlier that the proportion of algebra questions had increased significantly in the last two years of our sample. If the motivation for doing this was to raise standards in algebra, then our data indicates that the quality as well as the quantity of algebra questions needs to be addressed. This may be related to the emphasis placed on algebra in the curricula referred to above. However, it is beyond the scope of this paper to go into this further.

**Figure 3. The degree of contextualisation**

### Specialised and non-specialised processes and objects

The first two rows of Tables 2 and 3 shows the frequency and rate per question of SM processes (verbs) and objects (nouns) respectively. The rate of SM processes and objects per question is lower in 2005 which will be discussed more below. In the other years, the rate of SM processes is similar over the sample. There is more variation in the percentage of SM objects, and the rate of SM objects per question. These appear to increase after each curriculum reform and then decrease, but a larger sample would be required to confirm this.

	1995	2000	2005	2010	2015	2018
SM (% of all processes)	29 (64%)	23 (66%)	13 (42%)	24 (52%)	42 (62%)	34 (60%)
Rate of SM per question	1.6	1.6	1.2	1.5	2	1.8
Distinct SM processes (rate per question)	18 (1.0)	14 (1.0)	11 (1.0)	14 (0.9)	19 (0.9)	17 (0.9)

**Table 2: Specialised processes**

The number distinct SM processes and SM objects are shown in the third rows of Tables 2 and 3 respectively. This measure gives an indication of richness of the discourse, and the data indicates that this has remained constant over the sample. The number of SM symbolic objects as a percentage of the SM objects is an indicator of the mathematical density of the discourse. This has also remained constant over the sample period apart from the year 2005.

	1995	2000	2005	2010	2015	2018
SM (% of all objects)	68 (64%)	70 (80%)	39 (60%)	118 (90%)	140 (83%)	109 (57%)
Rate of SM objects per question	2.5	3.1	1.8	4.6	4.4	3.5
Distinct SM non-symbolic object words (rate per question)	24 (1.3)	25 (1.8)	14 (1.3)	30 (1.9)	35 (1.7)	30 (1.5)
SM objects in symbols (% of all SM objects)	23 (34%)	26 (37%)	19 (49%)	45 (38%)	48 (34%)	39 (36%)
Total objects (rate per question)	106 (5.9)	88 (6.3)	65 (5.9)	131 (8.2)	169 (8.1)	190 (9.5)

**Table 3: Specialised objects**

The examinations in the sample under the present curriculum (2010–2018) contained a larger total number of objects, and a larger number of objects per question. However, the number of distinct object words has not increased proportionately to this. This indicates a more lengthy written style and not a richer expected discourse. A recurring feature in these examinations is supplementary information in the text with for example historical notes about mathematicians. This may be a consequence of the greater emphasis on basic skills (in this case reading) in LK 06 (Kunnskapsdepartementet, 2006).

In 2005, the rate of SM processes and objects per question is lower than the other years. A closer inspection of the data revealed that the rate of SM processes was similar with other years on *abstract* questions. However, the only SM processes on a *mixed* question was *find* which occurred just one time. In addition, there were only six SM objects in total on the *mixed* questions. Thus the algebra questions in 2005 were either almost entirely SM or NSM. This may be a consequence of the curriculum having “Mathematics in everyday life” as a separate topic and not integrated into other topics (L97, 1999). The lack of specialisation in the language on *mixed* questions meant that candidates were required to engage with the content, so all of these questions were coded as either *mundane* or *deep* (see Figure 4). However, as noted earlier, students could choose not to do these questions and so these questions may have had less impact on teaching and learning.

Sorting the data by year revealed that, of the 18 distinct SM processes in 1995 and 17 in 2018, there were just seven of these that occurred in both years. This change in language was the result of incremental changes over the sample period. There were, for example, no significant introductions of new processes with the curricular reforms. For objects, there were 17 common objects out of the 24 distinct SM objects in 1995 and 30 in 2018. When the objects were sorted by topic and the largest category was geometry with a total of 25 objects. Nine of these occurred in the exams under the previous curricula, whereas 20 of these occurred in the exams under the current curriculum. This shows the increased use of geometry as a context for algebra questions.

	1995	2000	2005	2010	2015	2018
Solve	2	3	2	6	8	4
Calculate	4	3	1	1	7	1
Use	1	1	0	4	5	6
Show (illustrate)	4	1	0	2	2	7
Draw	2	3	1	2	1	2
Find	6	0	1	0	1	0
Show (prove)	1	1	0	1	2	2
Make	0	1	0	1	2	3
Set	3	1	1	1	0	0
Determine	0	0	0	0	2	4

**Table 4: Frequency of the most commonly occurring SM processes**

The frequencies of the most commonly occurring SM processes are shown in Table 4. *Find* and *calculate* are the most commonly occurring instructions in 1995. These have not been used so frequently in recent years. The current examination guidelines (Utdanningsdirektoratet, 2014) state that candidates can choose their own solution method when answering questions that are formulated with *find*, *solve* or *determine*. Questions that are formulated with *calculate* require the candidate to use algebraic methods. (Although *calculate* was used as an instruction seven times in 2015, it was only used twice to indicate symbolic manipulation. The other five times were to evaluate expressions,

e.g. “Calculate which Pythagorean triple you get if  $n = 6$ ” (2015 paper, p.11).) The data appears to show a tendency away from *find* and *calculate* (regn ut) over to *solve* and *determine* (bestemme) in algebra questions. The word for determine in Norwegian (bestemme) is also used to mean decide, and thus we would argue that *determine* belongs to a less specialised discourse than the other instructions.

The verb *use* has occurred significantly more often since the last curriculum reform. This is often in formulations such as “Use the [given] formula to calculate Monica’s maximum pulse rate” (Question 6, 2018 examination, our translation), and “Use a graph tool to...”. Such formulations give more explicit instructions to candidates, and may also reduce candidates’ role in decision making (Morgan & Tang, 2016, p. 53). Another consequence is that the question becomes an instruction to complete a process, rather than solve a problem. That is, that the discourse becomes one that is about performing actions rather than engaging in mathematics. This reflects the formulation of the current curriculum which is formulated in terms of competency goals and has an emphasis on basic skills (see Background and context). ICT is one of the basic skills (Kunnskapsdepartementet, 2006), so explicit instructions to use ICT tools have been included on the examination (Utdanningsdirektoratet, 2014).

### An illustrative example

The following question appeared in the 2018 examination. It contained a picture of Archimedes (not reproduced here), the diagram shown in Figure 4, and each sentence was on a separate line.

A sphere has diameter equal to  $2r$ . A cone and a cylinder both have height equal to  $2r$ . Archimedes showed that the volume of the cylinder is equal to the combined volume of the sphere and the cone. Use the formulas below, and show that this holds. (2018 examination, our translation)

Figure 4: Diagram from question 19 on the 2018 examination

This question was coded as *abstract*: there is a context for algebra, but it is within the SM discourse. Our analysis suggests that geometry contexts have been more prevalent under the current curriculum. The last sentence directs the student as to how to solve the problem. This is further emphasised by the use of the plus sign and equals sign in Figure 4. These prompts reduce the candidates expected engagement with the discourse of the question. The mention of Archimedes is not essential to the question and his picture may be a distraction, especially for weaker candidates (Dowling, 2001).

This example shows that our analysis gives us insight into some of the changes in the expected mathematical discourse of 10<sup>th</sup> grade students in Norway. However, we see the importance of other factors such as the use of diagrams, and the role of human actors in the discourse. These factors can be analysed by other parts of the EDSM framework, and will be part of our further research.

## Concluding remarks

Our sample indicates that the proportion of algebra questions on 10<sup>th</sup> grade examinations in Norway has increased since the last curriculum reform in 2006. The quantitative analysis at the question level suggests that the expected engagement in real-world contexts has become more ritual. At the level of objects and processes, the analysis suggests that the density of the discourse has remained constant over the sample period. The examination questions have contained more objects under the present curriculum, and the processes have become more directive. This indicates a discourse that reduces the need for decision making on the part of the student. These factors may contribute to the ongoing underperformance of Norwegian students in algebra on international test, but an inspection of the examination questions reveal many more factors that are in play. These need to be researched and synergised with our results to gain a better understanding of Norwegian students' algebra discourse.

## **“Never carry out any arithmetic”: the importance of structure in developing algebraic thinking**

Dave Hewitt

Loughborough University, Centre for Mathematics Education, UK; d.p.hewitt@lboro.ac.uk

*The use of tasks which ask learners to find general rules for growing figural patterns is widely reported in the algebra research literature. Such tasks are sometimes seen as a way to develop early algebra thinking. This paper looks at examples of such activities from the literature and presents a theoretical argument against the common practice of learners creating a table of values and seeking patterns within the numbers. Instead an argument is made for learners to focus on more complex examples where learners are discouraged from counting and turning the original figures into numbers. Instead, it is suggested that learners seek structure within complex examples and express what they see without carrying out any arithmetic but instead just writing down what arithmetic they would do.*

*Keywords: Early algebra, pattern spotting, algebraic thinking, structure.*

### **Introduction**

The difference between arithmetic and algebra has been discussed at some length in the literature. For example, Filloy and Rojano (1989) talked about a didactic cut existing when a letter appears on both sides of an equation. This is, of course, an attribute of the equation rather than a statement about ways of thinking which might differentiate between arithmetic and algebraic thinking. Herscovics and Linchevski (1994) spoke about the need for learners to work with the unknown for something to be considered as algebraic activity. This places a greater emphasis on the learner rather than the object, such as the form of an equation, with which they are working. With the emphasis on a learner, Radford (2010a) talked of a *zone of emergence of algebraic thinking* where expressions of generalisation can be expressed in a variety of forms such as gesturing and actions as well as writing. For Radford, there was not a need for letters to be present for algebraic thinking to be emerging. Kieran (2004) allowed the possibility of thinking algebraically about something even if that something is not explicitly on the list of algebra content within the curriculum. This allows for algebraic thinking to happen in many different areas of the curriculum, one of which is number. In this paper I argue for the case to place structure at the forefront of developing the algebraic thinking of learners. Several researchers have included structure as a key aspect of algebra work, including Kieran (2004). Usiskin (1988) included the study of structures within his four conceptions of algebra; Kaput (1995) did the same within his five aspects of algebra; and NCTM's (1998) discussion document included structure within four organizing themes for school algebra. Yet, I will argue that a number of reported teaching practices do not assist learners in placing their attention on structure; indeed often practices do the opposite and turn attention away from structure and onto what I would consider to be more arithmetic thinking.

Radford (2000) posited that algebraic thinking differed from arithmetic thinking in the form of the mathematical practice in which learners were engaged. For him it was about the focus being on, for example, investigating and expressing the general term of a pattern. At one

level, arithmetic is involved in generality in that  $3+4=7$  is an expression of generality: it does not matter what we are talking about, 3 things plus 4 more of the same things result in 7 of those things. This is true no matter what those things are. However, algebra, as generalised arithmetic, requires a second level of generalisation. It stresses the structure of the given situation rather than a 'result'. Thus,  $3+4=4+3$  can be judged to be correct through arithmetic thinking, by carrying out calculations and stressing the similarity of the results from both sides of the equation (both sides result in 7). Algebraic thinking will stress the structure inherent within the operation of addition, that of commutativity; the two sides are the same because it does not matter which way round you do addition. Thus algebraic thinking stresses operations as objects of attention and structure whereas arithmetic thinking stresses processes and with the results being the object of attention. Linchevski and Livneh (1999) introduced the notion of structure sense and since then other authors have developed the notion further (e.g., Hoch & Dreyfus, 2004; Mulligan & Mitchelmore, 2009). In particular, they have in common the idea of pattern, connections and relationships. Mulligan and Mitchelmore (2009) offered an example of seeing a 3 by 5 rectangle as three rows of five columns or as five columns of three rows. Each of these views placed a structured way of seeing the object rather than seeing it just as a whole. My own definition of algebraic structure which will be used in this paper is:

*A way of viewing an object or expression such that it is seen as a combination of recognizable parts along with recognizable patterns which connect those parts together. Such a way of viewing results in an expression of the object in terms of the parts and connections which places the object as a particular example of a more general type.*

The use of figural patterns (either based upon quasi-real life situations, such as the number of chairs around a line of tables, or purely geometrical, such as the length of the perimeter of a line of regular hexagons joined together) is widely reported in the literature (e.g., Montenegro, Costa & Lopes, 2018; Blanton et al., 2015b). I will analyse some examples of such tasks and consider ways in which the students have worked towards trying to find a functional rule for a given initial figural growth pattern. I will argue that taking students' attention away from the original figural situation and onto numbers generated from those patterns reduces the likelihood of students finding functional rules. A key to generalising is to keep attention with the figurative context and to focus on noticing structure. Carrying out arithmetic hides any inherent structure which had been noticed and thus reduces still further the opportunity to express generality. I start off by looking at the common practice of looking at the first few cases of a figural grown pattern and creating a table of values.

## **Tables of values**

Asking learners to create a table of values for the first few cases is a common strategy which is either suggested by teachers or included in the task instructions. Transferring learners' attention from the original problem situation to a table of values means that they can lose contact with three important elements to assist with generality. Firstly the structural properties inherent within the original situation can be lost as learners stare only at numbers. Secondly, the nature of a classic table of values is that it is structured to be in term order from

1 onwards. This brings a natural temporal aspect where recursive rules are more likely to be articulated. Thirdly, if a functional rule is found for the numbers, there can never be certainty by looking at the table of values that the rule will apply to the original situation. I will now consider each of these three elements in turn.

### **Losing connection with the context**

In Blandon et al.'s (2015b) study, one task involved finding the number of people sitting round a certain number of square tables which were joined in a line. Drawings of the first two cases were given and then the learners were asked to record their results in a table of values. They were asked to find patterns in the table. One 1<sup>st</sup> grade learner noticed a pattern in their table of values (Figure 3) where the numbers were the same along diagonals. Whilst this is, indeed, a pattern in the table, Blanton, Brizuela, Gardiner, Sawrey, and Newman-Owens (2015a) report that this could have been any symbol set where the symbols were the same along a diagonal and was not an observation which necessarily related to a sense of number let alone the contextual situation. Indeed, the creation of a table of values takes away the context within which those numbers were generated.

I observed a group of lower attaining 12-13 year olds spending half an hour building examples of the first few cases of a ring of tiles surrounding a 1 by  $n$  rectangle. The task was to find a general rule for how many tiles would be needed to surround such a rectangle. They began by making the first few cases with multi-link cubes and constructed a table of values for these first few cases. They then spent a long time looking at the numbers in the table and not getting further than noticing the recursive rule of the numbers going up in twos. They did not turn their attention back to the multi-link cubes but instead kept staring at the numbers in the table of values. I will say more about how this activity was concluded in a later section. The point here is that they no longer paid attention to the original situation.

These examples are in contrast to when learners' attention remains with the original context and where a structured way of viewing that context can lead to finding a functional rule, as can be seen from the following example. For example, Ferrara and Ferrari (2017) discussed a group of 10-11 year olds working on finding the number of circles in further terms of the sequence shown in Figure 1.

**Figure 1: A figural pattern of dots**

They were also asked to explain to someone from another class how to find the number of circles in any term in this sequence. An example of work from a group of three students showed how they justified their rule by seeing the figural patterns in a structured way. For example, Figure 2 shows a link between the notational expression and the pictorial situation for the 6<sup>th</sup> term.

**Figure 2: Re-drawn version of a learner's response from Ferrara & Ferrari (2017, p. 28)**

They also showed an alternative way of structuring the geometric figure when one of them explained that “The figure is made of two rows: First row, second row, which, the second row is equal to the first row, plus 1” (p. 28). The written explanation for the 6<sup>th</sup> term (Figure 2) and the more verbal articulation in terms of the two rows, reveal two ways of imposing a structured way of viewing the geometric figure rather than seeing it as a single collection of circles. Both of these ways of viewing reveal a sense of generality where I feel confident they would be able to calculate the number of circles for any term in this sequence.

### **The seduction towards finding recursive rules**

The second concern I have about tables of values is that their usual sequential nature can seduce students into noticing recursive rules rather than functional rules. Recursive rules give a way in which the next term can be generated from the previous term. This can involve the carrying out of a long series of arithmetic operations if a ‘far’ term in a sequence is to be found. Learners can also find it difficult to make use of a recursive rule in order to generate a functional rule; recall, for example, the case of the learners trying to find a rule for a ring of tiles surrounding a 1 by  $n$  rectangle. They had a recursive rule but this did not help them towards finding a functional rule.

Montenegro et al. (2018) described a class of 18 Portuguese students aged between 10 and 13 working on a sequence of growing geometric figures in the shape of an ‘L’. Two of the four groups were not able to find a functional rule even though they had found a recursive rule. All groups had turned their attention to working with numbers from the first six cases as this had been encouraged from the questioning of the task. The teacher decided that the students had missed the potential within the visual representation of the ‘L’ shapes and focused their attention on the shapes; asking students to say what was the same and what was different about the figurative representations. This led to students making comments such as “Figure 15 has one common square and 15 on each side” and “figure  $n$  will have a common square and  $n$  squares on each side”. This led to an exclamation of “Ahhhhh!” (p. 102) and the students were able to quickly find the functional rule. The focus being turned from trying to find patterns in numbers to looking for structure within the original geometric context was significant in the success obtained by those students.

The sequential nature of a table of values encourages learners to see a recursive rule, which is often ‘easier’ than a functional rule as it is usually additive rather than multiplicative, linear rather than quadratic, etc. It also does not always help with finding a functional rule.

### Is the rule correct?

The third concern I have about tables of values is that even if a functional rule is found for the data in the table, students can never know from the table alone if that rule is correct for the original contextual situation. For example, without me telling you, you would not know the context which the table in Figure 4 represented. The contextual situation has disappeared and the activity becomes one of pure number pattern spotting. There is a danger that this can lead to little awareness of the mathematical situation from which those numbers originated (Hewitt, 1992). Some patterns spotted may not actually apply to the general situation from which the numbers originated. The table in Figure 4 gives a strong sense of the rule  $2^{n-1}$ , however if the numbers came from the first five cases of looking at the maximum number of regions formed within a circle when  $n$  points on the circumference are joined to each other by chords, then this rule would not be correct. The case for six points produces a maximum number of 31 regions and not the 32 which might be expected from looking only at the table of values.

Justification or proof is never possible when attention is solely with a table of values. Palatnik and Koichu (2017) reported a pair of 9<sup>th</sup> grade students who obtained formulae connected with the problem of finding the maximum number of pieces a pizza can be cut into with  $n$  straight ‘cut’ lines. The students had a sense that their formulae were correct as they fitted with the numbers in the table of values. However, when challenged to work on why the formulae worked, the students had to return to the context of the problem to articulate reasons for why they were correct. So, the common practice of encouraging learners to construct a table of values (e.g., Blanton et al., 2015a; Blanton et al., 2015b) restricts any pattern spotting to the level of conjecture at best. Any sense of certainty of generality requires attention to be on the structure of the original problem situation, not a table of numbers.

### Never carry out any arithmetic

I will now return to the story of the lower attaining students who were trying to find a functional rule for the number of tiles surrounding a 1 by  $n$  rectangle. They spent a long time looking at their table of values without getting anywhere towards finding a functional rule. After a long while observing them, I asked them how many tiles there would be in a situation where the rectangle was 47 long. They replied quickly that it would be two lots of 47 plus 3 for each end. Within one minute

they had expressed the rule of  $2n+3+3$ . The articulation of  $2 \times 47 + 3 + 3$  rather than the single number of 100, which would be the result of carrying out the arithmetic of that expression, meant that the structured way in which they viewed the tiles was contained within that expression. The stressing of the structure allowed them to see the generality that, however long the rectangle was, they needed two lots of that length plus another two sets of three tiles. A significant aspect of this anecdote is that the rectangle was long enough so that they would not attempt to build this and count the number of tiles. As Radford (2010b) noted, it is important to work with a case where the numbers involved are too big for a learner to carry out arithmetic or to count. This forces the need to seek structure. Indeed I go further and say that in order to head towards algebra in such situations, all arithmetic should be avoided.

**Figure 5: Chairs round tables**

Chimoni, Pitta-Pantazi & Christou (2018) give an indicative answer from a group of 10-13 year olds who were successful in solving all the tasks given to them. In this case they were asked to find how many children could be seated around a group of 10 trapezoidal tables (see Figure 5 for the first two cases). The answer was presented similar to  $N_{10} = 5 + (9 \times 3) = 32$ . The number 32 may be seen as the answer to the question but it is the expression  $5 + (9 \times 3)$  which reveals the structural way of seeing the situation. It is this expression, not the 32, which offers the insight to go on to express a general rule of  $5 + ((n-1) \times 3)$ , which may be written in the conventional form of  $5 + 3(n-1)$ . I argue that in order to head towards general algebraic statements *learners should never do any arithmetic, just write down the arithmetic they would do*. This is another reason why a table of values is often not as helpful as it might initially be considered to be; arithmetic is carried out in order to enter each value into the table. This means that any structural insights obtained are lost. Ferrara and Sinclair (2016) describe a teacher who worked with a class of grade 3 learners to see if they could work out the position number of 26 in the sequence 2, 4, 6, ... The teacher stressed that this was not to be done by counting. After a while several children were clear that doubling was involved. The teacher asked what number would be in position 99. One learner answered “Hum, I don’t know the double of 99” (p. 13). For algebra, I argue that you do not need to know the double of 99, you just need to express the arithmetic you would do (i.e.  $2 \times 99$ ). This then leads towards an articulation of  $2 \times n$ , or  $2n$ . In some ways a learner might struggle to carry out some arithmetic whilst just writing down what arithmetic they would do can feel easier. In that sense expressing an algebraic structure in written form can feel easier than having to carry out any arithmetic involved.

## Summary and implications

The research literature has shown a frequent practice of presenting learners with figural diagrams and encouraging them to construct a table of values for the first few terms. This results in learners’ attention being focused on to numbers rather than the context from which those numbers arose. The activity for learners then becomes number pattern spotting and there are examples of students

finding patterns in the numbers which can be detached from the contextual situation. The nature of a table of values is such that recursive rules are likely to be found and students do not always find it easy to translate such rules into a general functional rule. The argument I have made is that it may be preferable to stay with the contextual situation and encourage learners to find ‘structural ways of seeing’. This is supported by Strømskag (2015), who identified staying with the context as important for a successful pattern-based approach to algebra. Indeed, learners who stayed focused on the original figures were more likely to take a functional approach (El Mouhayar & Jurdak, 2016) and find several important *connected* features (El Mouhayar, 2018), whereas those who focused on numbers were more likely to take a recursive approach and noticed features which were *disconnected* with each other.

The principle of *never carrying out any arithmetic but just writing down what arithmetic you would do* can allow the structured way of seeing to be expressed within a written expression. Such expressions, and their associated ways of seeing, are a step towards seeing generality through a particular example (Mason, 1987). To aid this process of not carrying out any arithmetic and stressing structure instead, it is worth teachers considering offering just one example for learners to work on. This example should be one which is sufficiently complex so that learners are not able to count and are unlikely to be able to do any necessary arithmetic (Radford, 2000). This will increase the likelihood of learners expressing the structure they observe and writing it in a form which preserves that structure. Since a large number will be involved, this acts as a quasi-variable (Fujii & Stephens, 2001) in which the number acts as if it were a variable as learners have a sense that this could be any other number and the expression would still be true.

# Algebraic thinking in the shadow of programming

Cecilia Kilhamn and Kajsa Bråting

Uppsala University, Sweden; [cecilia.kilhamn@edu.uu.se](mailto:cecilia.kilhamn@edu.uu.se); [kajsa.brating@edu.uu.se](mailto:kajsa.brating@edu.uu.se)

*This paper calls attention to how the recent introduction of programming in schools interacts with the teaching and learning of algebra. The intersection between definitions of computational thinking and algebraic thinking is examined, and an example of a program activity suggested for school mathematics is discussed in detail. We argue that students who are taught computer programming with the aim of developing computational thinking will approach algebra with preconceptions about algebraic concepts and symbols that could both afford and constrain the learning of algebra.*

**Keywords:** Algebra, algebraic thinking, programming, computational thinking.

## Introduction and background

In the wake of introducing programming into school mathematics curricula (Mannila et al., 2014) we have identified the intersection of algebraic thinking and computational thinking as an important area to explore (Figure 1). Specifically, this intersection has come to the fore in Sweden, where programming has been inserted into the national mathematics curriculum as part of the core content of algebra. Computational thinking (CT) is a fairly new concept in educational research, first introduced by Papert in 1996. The term involves the kind of thinking skills needed to understand and capitalize on computers. Since Wing launched CT as a didactical term in 2006, researchers in computational science as well as mathematics education have attempted to define it. For example, Hoyles and Noss (2015) describe CT as incorporating four central thinking skills: decomposition, pattern recognition, abstraction and algorithmic thinking. Programming, on the other hand, can be seen as a problem-solving activity that can be used to address the different aspects of CT (Mannila et al., 2014). Although CT is generally considered to encompass more than programming, teaching programming requires the use of CT (Hickmott, 2017). Moreover, programming is a feature of CT that does not necessarily involve writing code in any particular computer language (Bocconi, Chioccarello & Earp, 2018). Programming is thus a more inclusive term than coding, and seen as an activity in which students develop computational thinking. In this paper, we limit the discussion to aspects of CT that can be developed through programming. The aim of this paper is to raise the question of how programming in schools, with the goal of developing CT skills, may potentially interact with, afford or constrain students' development of algebraic thinking.

**Figure 1: The intersection of CT and AT**

A contemporary international movement in school development is to implement programming in the curriculum. This has been done in various ways (Mannila et al., 2014). For instance, in England, “Computing” was introduced as a new subject in the curriculum, while Finland and Sweden adopted a blend of cross-curriculum and single subject integration with the strongest link to mathematics (Bocconi et al., 2018). Unlike other countries, Sweden included programming in the mathematics

curriculum in close connection to algebra through all grade levels. The curriculum change was released in August 2017 and was taken in effect throughout the country by August 2018. There is extensive literature from the last three decades tackling issues of teaching and learning programming at university level (Grover & Pea, 2013), but except for the early work on LOGO programming there are few studies of teaching programming in the early school years (Blikstein, 2018; Hickmott, Prieto-Rodriguez & Holmes, 2018). Furthermore, most educational research about programming concerns the learning of programming per se, rather than learning mathematical ideas through programming. One exception is the ScratchMaths research program, which in light of the recent curriculum changes in England, set out to explore the relationship between computational thinking and mathematical thinking in general, identifying mathematical ideas such as place value, proportional relationships, coordinate systems, symmetry and negative numbers in ScratchMath activities (Benton, Hoyles, Kalas, & Noss, 2017). We wish to broaden the discussion about “learning to program” or “programming to learn” by raising questions about how learning (and knowing) programming influences the learning of algebraic thinking. Until now, research on computational thinking and algebraic thinking has run on separate tracks, but the Swedish case offers a great opportunity to investigate the intersection of these two research domains in the wake of programming activities.

## **Programming activities in Swedish schools**

The description of programming in the Swedish revised curricula and on-line material provided by the government,<sup>1</sup> focuses in grades 1-3 on the use of symbols to construct and follow stepwise instructions either without computers (unplugged) or with simple robots such as Bee Bots or screen equivalents such as Lightbot.<sup>2</sup> In grades 4-6 algorithms are created in visual programming environments such as Scratch.<sup>3</sup> and in grades 7–9 other programming languages are introduced. In the visual environments, an algorithm is often described as a “recipe” or a “function”, and if variables are introduced, they are mostly non-numerical. While a function is described as a correspondence between two sets in abstract algebra, a function in school algebra is commonly interpreted as a co-variation of numerical values possible to represent in a graph (Usiskin, 1988). If students in the early grades meet functions as a correspondence between non-numerical input and output variables in programming activities, they will have experiences that may challenge the school algebra conception of function where one quantity is said to vary depending on another quantity, represented in a cartesian graph. Due to the limited space of this paper, we leave to the side further investigations of early programming activities in relation to algebra and focus our discussion on programming in text-based environments commonly included in later grades.

## **Algebraic thinking and programming**

As algebraic thinking (AT) slowly made its way to the early school years during the last decades, the definition of what algebra is and what comprises algebraic teaching has become wider and more inclusive (Kieran, 2018). A broad definition of AT based on work with young children is suggested by Radford (2018) who describes AT as analytically dealing with indeterminate quantities using

<sup>1</sup> <https://larportalen.skolverket.se/#/moduler/1-matematik/Grundskola/Lärare%20i%20matematik>

<sup>2</sup> <https://www.bee-bot.us>; <http://lightbot.com>

<sup>3</sup> <http://scratched.gse.harvard.edu>

culturally and historically evolved modes of symbolizing. Although this definition excludes operating on specific numbers, it includes generalized arithmetic such as analyzing properties of addition and multiplication or analyzing the structure of an algorithm (for example using the distributive property to work out the partial products in a multiplication algorithm). We set out to investigate if this definition of algebraic thinking excludes or includes aspects of computational thinking that are at the heart of programming. We note that in a contemporary state-of-the-art publication written by members of an ICME topic study group on the teaching and learning of early algebra at ICME 13 (Kieran, 2018) there is no discussion at all about the connections between the learning of algebra and computer programming. The word “programming” is never mentioned and “computer” appears only in one paragraph (out of 17 chapters), where Mason claims that computer languages have emerged from algebra, and that these “expressive and manipulable languages [...] invoke algebraic thinking and algebraic awareness” (Mason, 2018, p. 335). Kaput (2008) describes early algebra in terms of three content strands including: i) the study of structures; ii) the study of functions; and iii) the application of a cluster of modelling languages both inside and outside of mathematics. In addition, symbolizing is described as core aspects of algebra (ibid). We find that all three content strands could also be aspects of computer programming. As an example, constructing code to generate all odd numbers presupposes reflection on what an odd number is and how it could be described and represented. Such an exercise is a study of structure, modelled in a specific programming language. Although the study of structure in algebra (e.g. generalized arithmetic) is emphasized in more recent work (e.g. Kieran, 2018), such structures have not been related to structures that becomes visible when breaking down complex calculations into small steps in a computer program. Although structure seems to be fundamental in both domains, little has been said in previous research literature about the study of structures embedded in computer algorithms in relation to the study of structure described as an aspect of algebraic thinking.

### **Investigating the intersection between computational and algebraic thinking.**

For the purpose of comparison, we have tried to illustrate similarities between two definitions of CT and two definitions of AT by aligning them in Table 1. The definitions are chosen as examples of contemporary definitions in the respective areas, proposed by researchers often cited in the literature. We see that both CT and AT deal with structure, generalization and symbolization in various ways, describing culturally developed organized symbol system where structures can be studied and generalizations made. Questions that arise are if structure, symbolization and generalization represent the same thing in the two domains, and if the syntax and semantics of programming languages are aligned with or divert from corresponding algebraic symbolism. Surprisingly, the definitions of CT do not explicitly mention functions or variables, which are fundamental concepts for AT (see Table 1). In programming activities, these concepts appear up front, where an algorithm in a program is often described as a function, and variables are omnipresent. Perhaps they are simply taken for granted in CT. Algorithmic thinking is not mentioned as part of AT, although it involves features that are fundamental in algebra, such as the ability to analyze a problem, specify it precisely, and find adequate basic actions (Futschek, 2006). Further, Futschek mentions the ability to construct a correct algorithm using the basic actions, to think about possible special and normal cases, and to improve the efficiency of an algorithm. We see such abilities as prominent when algebra is used as a problem-

solving tool where the basic actions are for example rules of equation solving or symbolic manipulation. Finally, according to Futschek, “algorithmic thinking has a strong creative aspect”, which undoubtedly should be true for algebraic thinking as well. Can we assume that students who develop their algorithmic thinking skills through programming also develop their algebraic thinking skills? Could algebra teaching explicitly relate to and build on algorithmic thinking? Note that algorithmic thinking in CT concerns the how and why of algorithms, as opposed to what Hiebert (2003) calls algorithmic reasoning, which is to recall a solution algorithm based on “rote thinking”.

**Table 1: Some features of contemporary definitions of CT and AT that are found in the intersection**

Features in the intersection	Computational thinking (CT)		Algebraic thinking (AT)	
	Grover & Pea 2013	Hoyles & Noss 2015	Radford 2018	Kaput 2008
Structure	Structured problem decomposition (modularizing)	Decomposition. Pattern recognition.	Deals with indeterminate quantities in an analytical manner	The study of structures
Symbolization	Symbol systems and representations		Using idiosyncratic or specific culturally and historically evolved modes of symbolizing	Acting on symbols within an organized symbol system through an established syntax
Generalization and abstraction	Abstractions and pattern generalizations. Conditional logic.	Entailing abstraction	Deals with indeterminate quantities in an analytical manner	Systematically symbolizing generalizations
Functions and variables	*	*		The study of functions, relations and joint variation

\* there is no mention of functions or variables in these definitions of CT

\*\* there is no mention of algorithms in these definitions of AT

Next, we give an example of a programming activity in order to highlight some points of intersection with AT, in particular the issue of symbolization, taken from government-provided teaching materials available on line in connection to the revised curriculum in Sweden (Rolandsson, 2018).

### **An example of differences in syntax and semantics in algebra and programming**

In this activity, the students are going to write a short computer program inspired by the algorithm of “Sieve of Erasthones”, i.e., an algorithm for finding prime numbers. Examples are given in two programming languages: Python and Javascript. The latter is given in Figure 2 below. By using this algorithm, one can find out if a given integer is a prime number or not. We have highlighted six places in the code that illustrate some crucial passages regarding syntax and semantics. These places are circled and marked from 1-6 in Figure 2 and will be discussed next.

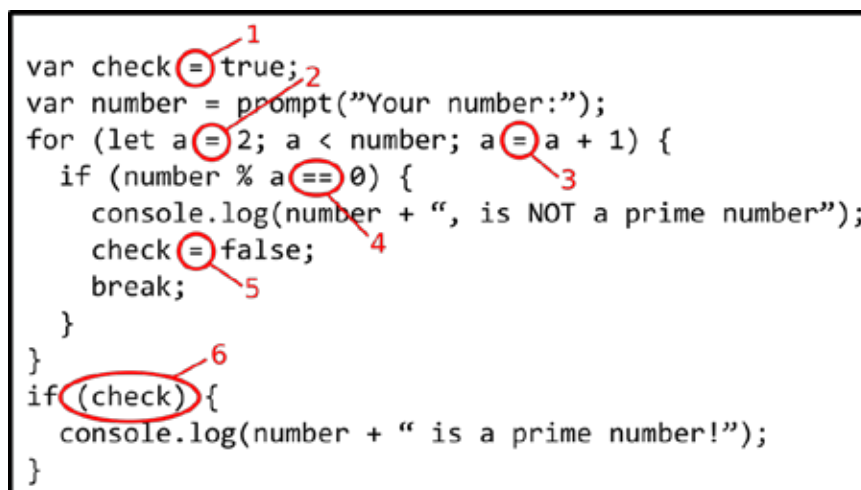

Let us begin to consider the equal sign. At the places 1, 2, 3 and 5 in Figure 2 the equal signs all represent *assignments* of different values to variables. For instance, at place 2 the program declares the variable *a* and assigns it the value 2, i.e., gives the variable the value 2. This usage of the equal sign differs from how it is normally used in algebra, where the equal sign is a symbol for an equivalence *relation*, and different from arithmetic, where pupils tend to interpret the equal sign as an *operator* symbol ( $5 + 3$  equals 8) rather than a relation (Kieran, 1981).

In algebra, it would be meaningless to write  $a = a + 1$ , since it is not true for any value of  $a$ . However, in programming the expression  $a = a + 1$  makes sense since the equal sign is understood as the assignment “add 1 to the value  $a$ ” (see place 3 in Figure 2). This is often used when a program needs to loop through a range of consecutive integers, as in Figure 2 when the program loops from 2 to the input value stored in the variable “number”.

Let us now consider place 4 in Figure 2, where we have two consecutive equal signs ( $==$ ). This is the only place in this code where the equal sign is not used as an assignment. Instead,  $==$  is used as a relational operator that tests if two entities are equal. In our example the program tests if the result of the modulo operation “number % a” is equal to 0, i.e. if the remainder is equal to 0 after dividing the input value “number” with the loop variable  $a$ . Here, the double equal sign is used in a similar way as the relational equal sign in algebra.

Many instructions in programming, such as `for` and `if`, have built-in checks for truthfulness that closely corresponds to the algebraic equality without including an equal sign in the syntax. An example of this can be seen at place 6 in Figure 2 where the instruction `if(check)` should be understood as ‘if the variable *check* is equal to “true”, then...’. Perhaps one might argue that in programming the relational equality sometimes is applied although it is invisible in the code, similar to the convention in algebra where we write  $4 \cdot a$  as  $4a$  (Hewitt, 2012).

```

var check = true;
var number = prompt("Your number:");
for (let a = 2; a < number; a = a + 1) {
  if (number % a == 0) {
    console.log(number + ", is NOT a prime number");
    check = false;
    break;
  }
}
if (check) {
  console.log(number + " is a prime number!");
}

```

**Figure 2: An algorithm for deciding if a given integer is a prime number**

Let us now demonstrate some differences regarding the meaning of the variable concept in programming and algebra. First, in programming variables can be used to *hold non-numbers* such as in places 1 and 5 where the variable *check* holds the Boolean value “true” and then “false”. Second, in programming a variable can *change value* during the execution of the program. This is illustrated at the places 1, 3 and 5 in Figure 2. As already mentioned, at place 3 the variable  $a$  increases with 1 for every execution ( $a = a + 1$ ). This means that if, for instance,  $a$  is equal to 3, the computer calculates the value  $3+1$  and then  $a$  is assigned the new value 4, i.e.  $a$  *changes value* from 3 to 4. As we are about to see this differs from the algebraic context. In algebra, the concept of a variable is broad and has been further categorized as *unknown*, *variable* (in a more nuanced meaning) and *placeholder* (Ely & Adams, 2012). The term unknown corresponds to a determinate quantity in an equation that remains to be solved. Clearly, an unknown cannot change its value as it is predetermined

from the equation. The term variable is meant to correspond to a varying quantity, typically  $x$  and  $y$  in the equation  $y = x^2 + 1$ . It can be perceived that the variables in this equation can change value, but the change is related to different cases of the problem. E.g. “Case 1: we assume  $x$  is 1, then  $y$  will be 2”, and then “Case 2: we assume  $x$  is 2, then  $y$  will be 5”. Within each of these cases we allow the variable  $x$  to have a determinate value which will make  $y$  into an unknown (that can be easily resolved). Observe that we cannot assign  $x$  the value 1 and later derive another value for  $x$  within the same case, that would constitute a contradiction ( $x = 1$  and  $x = 2$  imply  $1 = 2$ ) and force us to eliminate this case. The same argument can be applied for the term placeholder. This is different from programming where instructions are executed in order, one after the other. When an instruction assigns a new value to a variable  $x$  it does not constitute a new case, instead we are just changing the value recorded in a specific place in the memory of the machine (referred to by the variable).

## Discussion

We have shown above how programming activities can interact with students’ development of algebraic thinking in different ways. One of these concerns symbolization. In algebraic thinking, the use of culturally and historically evolved modes of symbolizing (Radford, 2018) is described as a prominent feature. Notice the plural, indicating that algebraic thinking is not exclusively bound to alphanumerical symbols and conventional algebraic syntax, and could thus hypothetically incorporate also programming languages. While many programming languages use similar, but not equivalent, symbol systems, there is no common syntax. For example, in some languages the short hand notation  $a++$  (the increment operator) is used instead of  $a = a + 1$ . Nevertheless, the differences between the established algebraic symbol system and new programming languages could potentially entail difficulties for students learning algebra.

In order to clarify some of these differences we have, from the example in Figure 2, compiled three categories regarding the meaning of some operations (the semantics) and the symbolic representations of these operations (the syntax) that appear in algebra and programming: 1) Different symbols represent the same meaning: e.g., the *modulus operation*, represented by *mod* in algebra and % in programming; 2) The same symbol represents different meanings: e.g., the equal sign (=) representing *relational equality* in algebra and *assignment* in programming; 3) Symbols with no corresponding meaning in the two domains: e.g., *approximately equals* ( $\approx$ ) in algebra and *increment with one* (++) in programming. These differences could afford the development of algebraic thinking through contrasting examples and awareness of accuracy, or constrain it if the teacher is unaware of the different experiences students have. In particular, the equal sign in algebra is already a cause for much didactical effort in helping students switch from an operational to a relational meaning (Kieran, 1981, 2018). When programming introduces yet another meaning, this could cause more confusion. In contrast, the use of different symbols to represent the same meaning could help students understand that the meaning of a mathematical concept does not depend on the symbol used to represent it.

The meaning of variable is another issue found in the intersection of CT and AT. The use of non-numerical variables (such as true/false) in programming affords a wider understanding of the concept of variable than the traditional use of variables as quantities, and does not correspond to the school algebra idea that letters always represent numbers.

The focus on algorithms and operational execution of instructions in programming may interact with the focus on structure in algebra. As shown in Table 1, both CT and AT value the study of structure, decomposition and pattern recognition. Approaching questions about structure from two perspectives could serve as an affordance for developing AT if differences in structure are noticed, contrasted and discussed. Algorithms are important in programming but absent in descriptions of AT. In school mathematics, the idea and use of algorithms have changed greatly since the introduction of digital tools in the 1980's when traditional algorithms were replaced by an increased emphasis on number sense and conceptual understanding. The fact that the term algorithm was removed from the description of arithmetic in the Swedish national curriculum in 2011 and re-inserted in 2017 as an aspect of the core content of algebra in connection to programming, implies a shift of emphasis from a procedural use of algorithms, to a conceptual understanding in terms of “algorithmic thinking” (Futschek, 2006). An open question for further empirical research is, if this newly awoken interest in algorithms will induce a study of the structures embedded in algorithms, and as such afford the development of algebraic thinking in terms of increased focus on structure and generalizations, or if it will tip over towards a more procedural approach to mathematics as a whole, thus working as a constraint to AT.

We argue that future algebra students who are taught programming in school, will encounter working with variables, structure and patterns, and engage in simplifying, generalizing and symbolizing in computer related contexts. We therefore urge for an awareness of what these experiences might do to how algebra is conceptualized and talked about in school, and what preconceptions teachers need to be aware of. We trust that empirical research into the intersection of AT and CT, as programming evolves in school practices, will highlight possible pitfalls and supply algebra teaching with new input.

# Linear figural patterns as a teaching tool for preservice elementary teachers – the role of symbolic expressions

Iveta Kohanová<sup>1</sup> and Trygve Solstad<sup>2</sup>

<sup>1</sup>NTNU, Department of Teacher Education, Trondheim, Norway; [iveta.kohanova@ntnu.no](mailto:iveta.kohanova@ntnu.no)

<sup>2</sup>NTNU, Department of Teacher Education, Trondheim, Norway; [trygve.solstad@ntnu.no](mailto:trygve.solstad@ntnu.no)

*Figural patterns connect several aspects of mathematical activity central to the work of teaching mathematics. In this pilot study, we investigated the solutions of 16 preservice elementary teachers to linear figural patterns of different levels of complexity after the completion of a series of six teaching sessions of a course in mathematics education. We found that a) most students were able to generalize and find the figural number of an arbitrary figure in the sequence; b) about half of the students produced mathematically imprecise formulas when translating from an arbitrary number into a general algebraic expression; c) the formulas students produced frequently lacked structural correspondence with the figural patterns and d) students had difficulties in interpreting figural patterns that are more complex. These results indicate that although the course successfully trains students to generalize with linear figural patterns, more attention to precisely formulating mathematical ideas and to interpretation of more difficult patterns can further improve the training of preservice elementary teachers.*

*Keywords: generalization, prospective elementary teachers, algebraic thinking, figural patterns.*

## Introduction

Research on students' algebraic thinking has drawn considerable interest over the past decades. For Blanton and Kaput (2011), experiences in building, expressing and justifying mathematical generalizations constitute the heart of algebra and algebraic thinking. Mason, Burton & Stacey (2010) highlight the importance of the generalization process in mathematics when stating that “generalizations are the life-blood of mathematics. Whereas specific results may in themselves be useful, the characteristically mathematical result is the general one” (p.8). The placement of algebraic content within the mathematics curriculum has received considerable attention. For example, documents from the National Council of Teachers of Mathematics (2000) in the United States, the Department for Education (2014) in England and The Norwegian Directorate for Education and Training (2013) recommend the development of algebraic ideas at elementary and middle school levels through activities such as generalizing number and figural patterns. Several authors have researched algebraic generalizations, but in most cases the target group were pupils in primary or middle school (e.g. Carpenter, Franke & Franke, 2003; Becker & Rivera, 2005; Rivera & Becker, 2009; Rivera, 2010). There is less research on generalization of pre-service elementary teachers (PSETs). A study by Yeüilderea & Akkoç (2010) indicated that PSETs, when trying to find the general term of number patterns, described number pattern rules in relation to differences between terms and used visual models without a purpose. The study of Rivera & Becker (2003) suggests that PSETs who used figural reasoning acquired a better understanding of the generalizations they constructed than PSETs who reasoned numerically, even if relationships among numerical values had

greater contribution to similarity between the compared entities than the figural patterns. Måsøval (2011) studied the factors that constrain PSETs' establishment and justification of formulae and mathematical statements that represent generality in different quadratic shape patterns. Her findings indicate three such constraints: The first constraint is related to a limited feedback potential in situations where the students are supposed to solve the mathematical tasks without teacher intervention. The second constraint is related to obstacles the students face when they transform informal mathematical statements expressed in natural language into formal algebraic notation. The third constraint is related to challenges with justification of formulae and mathematical statements that the students have proposed. Hallagan, Rule & Carlson (2009) found that after a problem solving-based teaching intervention, PSETs improved in their ability to generalize, however, they encountered more difficulty with determining the algebraic generalization for items arranged in squares with additional single items as exemplified by  $x^2+1$ , than with multiple sets of items, as exemplified by  $4x$ . Callejo & Zapatera (2016) characterised profiles of the teaching competence "noticing students' mathematical thinking" in the context of pattern generalization. PSETs named various mathematical elements to describe the students' answers but did not always use them to interpret the understanding of pattern generalization of each student. Their findings allow one to generate descriptors of the development of this teaching competence and provide information for the design of interventions in teacher education addressed to support the recognition of evidence of students' mathematical understanding.

To meet the goals of teaching in the elementary school curriculum, we need to understand more about how to better prepare PSETs for this undertaking. As part of a formative evaluation of the mathematics education course design, we set out to identify aspects within the course module about generalization that require increased attention and emphasis. Specifically, we asked: Which are the most common challenges that PSETs still face when solving problems with generalizations of linear figural patterns after completing our six-session course module about algebraic generalization?

## Theoretical framework

According to Radford (1996), the goal of generalizing spatial or numerical patterns is to find an expression representing the conclusion derived from the observed facts (concrete numbers). Radford claims that the obtained expression is in fact a formula, which is constructed on the basis, not of the concrete numbers in the sequence, but on the idea of a general number. Radford asserts that "general number" appears as precepts to the concept of variable. Hence, he claims that the notion of letter as variable is consistent with a generalizing approach to algebra, aiming at establishment of relations between numbers. The point is constructing formulae where the symbols represent generalized numbers (Radford, 1996). He highlights that one of the most significant characteristics of generalization is its logical nature, which makes the conclusion possible. This means that the process of generalization is closely connected to that of justification and proof. The underlying logic of generalization can be of various types, depending on the student's mathematical thinking. Radford (2008) distinguish between arithmetic and algebraic generalization of the pattern. While in both domains some generalizations do certainly occur, in algebra, a generalization will lead to results that cannot be reached within the arithmetic domain. Algebraic pattern generalization involves the

students in (1) grasping a commonality, (2) generalizing this commonality to all the terms of the sequence, and (3) providing a rule that allows them to directly determine any term of the sequence (Figure 1; Radford, 2008).

**Figure 1: Radford's (2008) architecture of algebraic pattern generalizations**

Rivera and Becker (2009) extended Radford's definition by including the necessity of justification at the middle school level. "Students have to provide some kind of explanation that their algebraic generalization is valid by a visual demonstration that provides insights into why they think their generalization is true." (p.213-214) Rivera (2010) claims that meaningful pattern generalization involves the coordination of two interdependent actions, as follows: (1) abductive-inductive action on objects, which involves employing different ways of counting and structuring discrete objects or parts in a pattern in an algebraically useful manner; and (2) symbolic action, which involves translating (1) in the form of an algebraic generalization.

## Methodological approach

After a six-session module on algebraic generalization as part of a course in mathematics education, 16 PSETs completed a digital survey with six tasks about generalization of figural patterns. Before data collection, the background of the study and research questions were presented to the PSETs. Participation was voluntary and anonymous. Answers were in the form of multimodal digital texts including text and freehand drawings. Subsequent to data collection, PSETs' responses were downloaded from the server and sorted according to task. A content analysis was performed independently by both authors in order to identify categories of common challenges in the PSETs' algebraic pattern generalization process.

## Course content

The Mathematics 2 course is an optional course which integrates mathematics and didactics. The content of the course previous to data collection was: Rich mathematics conversations, Argumentation and proof, Representations, Algebraic thinking, Generalization, Figural numbers, Equality, Relational thinking, Models for negative numbers, Realistic Mathematics Education, Fractions – multiplication and division, Decimal numbers, Percent, Difficulties in Mathematics.

A module with six sessions of 180 minutes was devoted to these topics: algebraic thinking, generalization, figural numbers, equality and relational thinking. These six sessions were taught in English and gave the PSETs the opportunity to discuss several tasks about generalization (not only with figural patterns), their different solutions, and challenges for pupils. PSETs also discussed several research papers on generalization, equality and relational thinking (e.g. Carpenter, Franke & Franke, 2003; Kaput & Blanton, 2005; Becker & Rivera, 2006; Mason, 1996) under the guidance of the course instructor.

Prior to the Mathematics 2 course, in 2016, the PSETs had completed a two-semester compulsory Mathematics 1 course whose main content was: Numbers and the number line; Counting; The position system; Addition and subtraction; Multiplication and division; Fractions – models, comparison, estimation, addition, subtraction; Probability and statistics in primary school.

## Survey

The survey consisted of six tasks; for the purpose of this paper we focus only on three of them (Figures 2, 3, 4).

1. Monika began designing the pattern with short sticks. Each day she continues the pattern.

- Describe how she would proceed to make her design on 5th day.
- How many sticks will she need to make her design on 8th day?
- How do you calculate how many sticks she will need to make her design on day number 100? Write down the corresponding formula.
- Write down the general formula for total number of sticks she will need to make her design on day number  $n$ . Explain how you got the formula and how do you know that it is correct.

Figure 2: Task 1

2. Having the sequence of figures composed of blue and red squares,

- how many blue squares there would be in Figure 4?

Explain how you got the result.

- consider Figure 7. How many more blue squares than red squares will there be in Figure 7? Explain how you got the result.

- consider Figure number  $n$ . What is the relationship between number of blue and red squares in Figure  $n$ ? Explain how you got the result.

Figure 3: Task 2

4. Jan circled (and coloured) pieces of the figures to illustrate a particular decomposition of the pattern. Describe verbally the pattern in terms of given decomposition. Based on given decomposition, what is the corresponding general formula expressing number of all dots in Figure  $n$ ? Explain what all the numbers and variables in your formula stand for. (Hawthorne, 2016)

Figure 4: Task 4

## Participants

PSETs were in their third year of a 4-year undergraduate teacher education program for Grades 1-7 at Department of Teacher Education, NTNU in Trondheim, Norway. The whole group consisted of 67 students, but only 20 were present in the last session. For technical reasons we only received answers from 16 students. In the third teaching session, PSETs were given a figural pattern task to

solve on their own. Most PSETs did not complete an answer to the first question about near generalization, and all of them gave up answering any of the following questions. All PSETs who answered the survey were present at almost all teaching sessions and the majority of them was participating quite actively during the course. Hence, the subjects in this study were likely among the most highly motivated students in the class.

## Findings

### Pattern generalization

The majority of students gave satisfactory answers to most of the figural pattern questions, requiring both finding the first few figural numbers (near generalization), as well as generalizing to figure number 50 or 100 (far generalization). This requires successful abductive-inductive action and shows that the PSETs in the study had learned to generalize the figural patterns. This is indeed an encouraging result considering that none of the PSETs could solve figural pattern tasks at the beginning of the course. At the same time, it is likely that the sixteen PSETs who participated in the survey were also among the highest attaining students in the class.

### Imprecise symbolic action

For items involving the construction of formulas, typically around half of the subjects formed symbolic expressions containing mathematical imprecisions, indicating a potential for improvement in symbolic action.

Answers from task 1 illustrate this point well. While in task 1 (Figure 2) 75 % of PSETs provided valid generalizations to pattern number 100, only 50 % of PSETs wrote accurate algebraic formulas. Answers from the subjects who did not provide mathematically precise formulas fell into two categories: a) inaccurate use of variables, and b) improper use of the equal sign.

Although the problem text specified that the letter  $n$  denotes the figure number, 4 PSETs chose to use the letter  $x$  for their formula without defining what  $x$  denotes. As for subject 3:

S3: General formula:  $N=3*x+1$ ; Because we always want to start with 3 since this is the "bush" [that makes up the base of the continuing pattern], then we have to multiply this "bush" with  $x$  since we do not know which day we want to find. Finally we must add 1 since all these shapes have only one "stem".

The notation  $F(n)$  could be used to denote the figural number while the letter  $x$  was used instead of  $n$  to denote the figure number. Subject 11:

S11:  $100*3 + 1$  Corresponding formula:  $fn = x*3 + 1$

These inaccuracies indicate an inflexibility in the students' appropriation of variables, which might be rooted in an experience with solving equations where  $x$  stands for the unknown.

In some answers, PSETs gave the same variable name to the figural number and the figure number, as for subjects 5 and 10 below:

S5: General formula:  $N = (N*3)+1$ ; This expression is correct because figure number  $N$  will have  $N$  number of triangles. These triangles have to be multiplied by 3, since

each triangle consists of three sticks. Then one has to add 1, which corresponds to the stick at the bottom.

S10: General formula:  $n = n \times 3 + 1$ ; Because in each triangle one needs 3 matches, so to make 4 triangles one needs  $4 \times 3$  (12) matches, and to make 100 triangles one needs  $100 \times 3$  (300) matches. Therefore  $n \times 3$ . In the end one needs to add the one match which stands, and then it finally becomes  $+1$ .

These responses indicate a lack of attention to equality and the meaning of the equal sign. It appeared not only in solutions of task 1, but also in task 4, as shown in the example below for subject 15 (task 4c, Figure 4).

S15 Here he divides into parts where he circles the same dot twice.  $n = n + ((n + 1) \times 4) - 2$ . Have to subtract 2 since this is counted twice.

### **Lack of structural correspondence with figural pattern**

Finally, both for correct and incorrect answers, the structure of the formulas given by the PSETs often did not correspond to the figural pattern.

For instance, subjects 5 and 13 responded with the same formula for all three different decompositions of the figure in task 4 (Figure 4):

S13:  $N = n + 2 + (n \times 4)$ ;  $n + 2$  is the body;  $n \times 4$  is the arms

Decomposition c) in task 4 contained overlapping regions that were to be subtracted. Still, subject 7 provided the formula in reduced form, reinterpreting the figure from the second decomposition of the same figure:

S7:  $n \times 5 + 2$ ;  $n$  is the figural number, 5 is the number that it increases by for each figure,  $+ 2$  are the circles that are overlapping encircled, that are constant

While all students wrote some formula for decompositions in task 4a) and 4b), in task 4c) six students wrote “I don’t know”. We could see a similar phenomenon in task 2 (Figure 3). While all students gave adequate answers to tasks 2a) and 2b), five students answered task 2c with “I don’t know”. Slightly more difficult structures of figural patterns (overlapping regions or the two colors, which add a layer of complexity) seem to be challenging for PSETs.

### **Discussion and conclusion**

In this paper we investigated sixteen preservice elementary teachers’ solutions to linear figural pattern generalization tasks. The analysis of these solutions showed that although PSETs typically recognized the underlying structure of linear figural patterns, their algebraic notation and syntax of algebra was often imprecise. This observation corresponds to the second constraining factor identified in Måsøval (2011), related to formalizing mathematical ideas expressed in natural language. Most of the formulas that PSETs provided were meaningful, i.e. the formulas conveyed the underlying structure in the figural patterns. However, several solutions were characterized by imprecise mathematical language. Variable names commonly were not defined or not used consistently, and indicated a lack of attention to equality and to what a variable represented. The fact that it wasn’t an interview, where PSETs were

not asked for further and detailed explanations of their answers, might support the assumption that this is how their notation and argumentation will look like in the classroom.

A meaningful pattern generalization must be accompanied by a symbolic action (Rivera, 2010). In the study of Hill et al. (2008), mathematical errors, including errors in language (conventional notation, technical language, general language for expressing mathematical ideas), proved the most strongly related to teacher knowledge. In further research we will investigate whether increased attention to equivalence, symbolic notation, dependent and independent variables, variable names and the accuracy of the mathematical language during teaching sessions on generalization might benefit the development of PSETs' teacher knowledge and better prepare PSETs for teaching generalization in real classrooms. The recent decision to incorporate programming into the Norwegian mathematics curriculum is also an invitation to investigate the role of programming in developing the concept of variables and symbolic action in pattern generalization.

*Many students have difficulties giving meaning to algebra. In this study, we investigated how graphing formulas by hand can help grade 11 students to give meaning to algebraic formulas, defined as the ability to “read through” an algebraic formula: i.e., to recognize its structure and to link it to graphical features. During five 90-minute lessons, 21 students worked on graphing tasks focusing on recognition and heuristic search. To assess the effects of this intervention, a graphing task, and a card-sorting task were administered to the students. In addition, six students were asked to think aloud during the graphing task. The results of the card-sorting task showed that 14 students used categories similar to the ones experts use, but had trouble in consistently categorizing all formulas. The thinking-aloud protocols showed that the students improved their recognition of basic functions and graph features, and their qualitative reasoning, which allowed them to give meaning to algebraic formulas.*

*Keywords: Algebra, giving meaning to algebraic formulas, graphing formulas.*

## Introduction

Many secondary school students have problems with algebraic formulas, which are very abstract for them (Arcavi, Drijvers, & Stacey, 2017; Kieran, 2006; Thompson, 2013). Students, also those in upper secondary school, have difficulties giving meaning to algebraic formulas: they lack symbol sense. Symbol sense has to do with the ability to read through a formula, to recognize its structure and its characteristics (Arcavi, 1994) and would allow students to give meaning to algebraic formulas. It is insufficiently known how to teach these aspects of symbol sense (Arcavi et al., 2017; Hoch & Dreyfus, 2010). In regular education, teaching for giving meaning often starts with realistic contexts and manipulation of formulas. In the current study, we used graphs to give meaning to formulas and used basic functions as building blocks in reasoning with and about algebraic formulas.

## Theory

### Giving meaning to algebraic formulas

Acquiring meaning is synonymous with assimilating to a cognitive schema, which is a (hierarchical) network of concepts and procedures. Assimilation is the integration of new information into a schema, which results in an adjusted schema (Thompson, 2013). To give meaning to algebraic formulas, different sources are suggested in the literature: for instance, via the problem context, via the algebraic structure of the expression, via multiple representations, and via linguistic activity, gestures, body language, metaphors, etc. (Kieran, 2006). Ernest (1990) used a syntactical analysis to decompose algebraic expressions into meaningful sub-expressions (building blocks). Hoch and

Dreyfus (2010) used structure sense to describe the ability to recognize familiar structures by using compound terms as single entities. Janvier (1987) and many others have shown that functions can be investigated by linking different representations. We chose to link algebraic formulas to graphs, which seem to be more accessible for students than formulas (Leinhardt, Zaslavsky, & Stein, 1990), as they appeal more to the Gestalt aspect of a function and visualize the “story” that an algebraic formula tells. Therefore, graphs can be used to give more meaning to algebraic formulas (Eisenberg & Dreyfus, 1994; Kieran, 2006; Heid, Thomas, & Zbiek, 2013). To link formulas to graphs in order to give meaning to the formulas, graphing tools such as graphic calculators can be used (Heid et al., 2013). Using these tools, it seems easy to make a graph from a formula. However, research has shown that one must know what aspects of graphs to look for (Stylianou & Silver, 2004), and that students establish the connection between formula and graph more effectively when they do graphing by hand than when they only perform computer graphing (Goldenberg, 1988).

The aim of the current study was to improve students’ abilities to give meaning to algebraic formulas by teaching them to graph formulas by hand. We defined giving meaning to algebraic formulas as the ability to “read through” an algebraic formula: that is, to recognize its structure and to link it to graphical features.

### Teaching graphing formulas for giving meaning

In expertise research, it has been established that for effective and efficient problem solving one needs recognition, and heuristics when recognition falls short (Chi, Feltovich, & Glaser, 1981). Based on this idea, a two-dimensional framework to describe strategies for graphing formulas was formulated (Kop, Janssen, Drijvers, Van Driel, & Veenman, 2015). In this framework, one dimension is about levels of recognition: from complete or function family recognition, to no recognition of the graph. The other dimension is about heuristic search, from strong heuristics, which provide information about large parts of the graph (e.g., qualitative reasoning about infinity behaviour and/or symmetry), to weak heuristics, which give only local information (e.g., calculating points). See Figure 1.

		<i>Heuristic search (strong <sup>®</sup> weak)</i>				
<i>Levels of Recognition (low <math>\beta</math> high)</i>	A	A1. Graph is instantly recognized as a whole				
	B	B1. Recognition of family (with characteristics)	B2. Search for ‘parameters’ of the graph	B3. Investigate the family characteristics, for instance via zeroes		
	C	C1. Split formula in sub-formulas	C2. Compose the graphs by qualitative reasoning	C3. Compose the graphs by making a table		
	D	D1. Graph unknown; Characteristic aspect of graph is recognized.				
	E	E1. Graph unknown; strategic exploration of algebraic formula	E2. Qualitative reasoning about domain, or vertical asymptote, or symmetry, or infinity behaviour, ...	E3. Algebraic manipulation	E4. Strategic search, for zeroes or extreme values	E5. Calculate strategically chosen point(s)
	F	F1. No recognition at all	F2. Standard repertoire of research	F3. Make random table		

**Figure 1: Two-dimensional framework for strategies to graph formulas**

For recognition, a repertoire of basic function families and knowledge of attributes to describe graphs are needed (Eisenberg & Dreyfus, 1994; Slavits, 1997). Kop, Janssen, Drijvers, and Van

Driel (2017) found, using a card-sorting task, that experts' repertoires of basic function families resembled the basic function families taught in secondary school, like exponential, logarithmic, and polynomial functions. Experts seem to have linked prototypes of these function families to a set of critical graph attributes. For instance, a prototypical logarithmic graph has a vertical asymptote, only positive  $x$ -values as a domain, and is concave down. They use their repertoire of basic function families as building blocks in working with formulas, for instance, when decomposing complex functions into simpler basic functions and when reasoning about characteristic graph features from formulas (Kop et al., 2015, 2017).

Experts often start with a global perspective that enables high levels of recognition (Even, 1998). With the global perspective the whole function and/or graph is in view, whereas with a local perspective only a part is in view. The global perspective is more powerful and gives a better understanding of the relation between formulas and graphs, but the pointwise approach is needed to monitor naïve and/or immature interpretations (Even, 1998; Slavit, 1997).

The question in the current study was whether we could teach these experts' strategies to students. This led to the following research question: How can graphing formulas based on recognition and heuristic search help pre-university students to develop a knowledge base to give meaning to algebraic formulas?

## Method

The teaching experiment was performed in a grade 11 mathematics B class, a regular class of 21 students who were 16- and 17-years old. Mathematics B is a course that prepares students in the Netherlands for university studies in mathematics, science, and engineering. The intervention took place during five lessons of 90 minutes. The students were obliged to work in pairs or groups of three which required them to exchange ideas. Each day, the lesson started with a short plenary discussion (max. 10 minutes) with general feedback on the students' work, reflection on the tasks, and modelling of expert thinking processes aloud. During the rest of the lesson, the students worked on tasks, related to the levels of recognition of the two-dimensional framework (Figure 1). These tasks were formulated as exploratory whole tasks with help, concluded with a reflection question. After the lesson, each pair and group handed in their work for feedback.

To assess the effects of the intervention, we collected students' responses to a written graphing task in a pre-test, post-test, and retention-test (four months after the intervention). Each graph in these graphing tasks was reviewed as correct (score=1) or incorrect (score=0), and a total score was calculated for each student.

Written tests give only limited information about the students' thinking processes. Therefore, six students were asked to think aloud during the graphing task in the pre-test and post-test. These protocols were transcribed and analyzed based on the two-dimensional framework (Figure 1): that is, on the use of recognition (function families, formula decomposed into sub-formulas, and/or graph features), qualitative reasoning, and calculation (points and/or derivatives).

In addition, a card-sorting task was assigned in the post-test to gather information about the students' knowledge base of function families. The students were asked to categorize 40 formulas

according to their rough graph, using as many categories as they wished. In addition, the students were asked to give a description and a prototypical formula for each of their categories. Card-sorting tasks are often used in eliciting structured knowledge (Chi et al., 1981). To analyze the card-sorting task, an expert categorization with 12 main categories, similar to the one found by Kop et al. (2017), was constructed and used as the criterion categorization. For each categorization, the student's categories were compared with those of the criterion categorization and it was established which formulas were not consistently categorized. Each corresponding category was graded with a score of two points and an extra point if a distinction between increasing and decreasing had been made. Then the number of correct formulas (consistent with the category) was graded. This method of analysis has been used by others (Ruiz-Primo & Shavelson, 1996); the total score should be an indication of the correctness of a student's categorization.

## Results

For the card-sorting task, we found that 14 out of the 21 students used categories almost similar to those in the expert categorization, although different names were used for the categories, like "having a horizontal and vertical asymptote" (linear broken functions), or "only a vertical asymptote" (logarithmic function). Many students made mistakes in categorizing distractors like  $y = 8\sqrt{x^3}$ ,  $y = \sqrt{8 - x^2}$ ,  $y = 100 - e^x$ ,  $y = x + 4/x$ , and often no distinction was made between increasing and decreasing log-functions.

To illustrate the results, we report about two students: K (a high-achieving student) and M (an above-average-achieving student). Student K's categorization is shown in the Appendix. S/he distinguished increasing and decreasing exponential, root, and polynomial functions. S/he categorized only a few formulas inconsistently, but s/he did not make a distinction between logarithmic and root functions, which resulted in a total score of only 45 points. Student M's categories also resembled those of the criterion categorization. When categorizing the formulas, student M used predominantly zeroes and max/min with polynomial functions, like in  $y = (x + 3)^4 - 9$ , asymptotes (horizontal and vertical for broken functions, horizontal for exponential functions and vertical for logarithmic functions), and edge points for root-functions. Although, s/he had more inconsistently categorized formulas, her/his categorization had a total score of 44 points.

The thinking-aloud protocols on the graphing tasks showed that, in the pre-test, the students had trouble recognizing (basic) functions, and only high-achieving students were successful now and then because of their reasoning abilities. In the post-test, these students had improved their recognition of basic function families with their characteristics and their qualitative reasoning.

In the pre-test, K scored 9 correct graphs out of 14. As a high-achieving student, s/he was able to compensate for a lack of recognition through qualitative reasoning. However, s/he often had to calculate many points of the graph. We give two citations to illustrate K's strategies in the pre-test. K did not recognize the global shape of a logarithmic function and used calculations and reasoning about the inverse function to sketch the graph of  $y = \ln(x - 3)$  correctly:

“I do not know the ln-graph anymore. When  $x - 3 = 0$ , then ..... When  $x - 3 = 1$ , then  $y = 0$ , so  $x = 4$ . At  $x$ -as the  $x$ -axis is intersected. When  $x$  is increasing then  $y$  increases, so the graph increases. When  $x$  is negative ... (thinking). Because something to the power of  $e$  ( $e^{\dots}$ ) does not give negative  $y$ -values. So,  $x - 3$  cannot be negative; the graph only exists from  $x = 3$ , larger than 3. So, at  $x = 3$  a tangent (asymptote?) and outcomes smaller when  $x$  is in the neighbourhood of 3”.

At first K showed a correct global shape by gesturing, however her calculating of individual points resulted in an incorrect sketch of  $y = \sqrt{6 - 2x}$ :

“...root-functions go like this (makes a correct gesture); the fact that it is  $6 - 2x$  means that the function only exists for negative values of  $x$ , to the point where  $x$  is 3; for  $x$  larger than 3 the argument is negative; when  $x = 3$  then  $y = 0$ ; when  $x = 0$ ,  $y = \sqrt{6}$ , which is about 2.5; when  $x$  is more negative, the argument becomes larger; ...,  $\sqrt{10} \approx 3.3$ ,  $\sqrt{12} \approx 3.5$ , differences become larger (and sketches a graph concave up)”

In the post-test, K's recognition of basic functions had improved and s/he still used her/his abilities of qualitative reasoning, resulting in a score of 13 out of 14. Again, two citations give an illustration.

K sketching  $y = \ln(x - 4)$  correctly: “ln( $x$ ) graph goes like this;  $x - 4$ , so 4 to the right.”

K used qualitative reasoning to compose two graphs while sketching  $y = 2x\sqrt{x + 6}$  correctly:

“ $2x$  goes like this;  $\sqrt{x + 6}$  goes like this (sketch); here it is 0; here negative, here 0, and after this it is steeper”.

In the pre-test student, M had many problems with graphing formulas. S/he did not know basic function family characteristics, and did not recognize graph features like zeroes and turning points. This resulted in a score of only 2 out of 14. Two citations illustrate her/his strategies.

M recognized the parabola-shape but did not know how to proceed while sketching  $y = (x - 3)^4 - 9$  (not finished):

“...at  $x = 3$ ,  $y = -9$ . (After some time) The larger  $x$  is, the larger  $y$ , so it increases. It is a parabola. (S/he stopped talking for a while; after a couple of minutes) I do not know how to proceed.”

M recognized a translation but not the shape of the ln( $x$ )-graph; s/he tried to construct the graph of  $y = \ln(x - 3)$  via the inverse function (not finished):

“...graph of  $\ln(x)$  that is translated 3 to the right (s/he did not use this but writes  $\log_e(x - 3) = \log(e)/\log(x - 3)$ ;  $e^y = x - 3$ ). This is an asymptote;  $x$  cannot be 3; ....; when  $y = 0$ ,  $x - 3 = 1$  (drew point (4,0) and stopped)”.

In the post-test, M's repertoire of basic function families and her/his qualitative reasoning had improved, resulting in a score of 10 out of 14. Two citations illustrate this. In the post-test M recognized more graph features like zeroes and turning points; for instance, while sketching  $y = -2x(x - 2)(x - 5)$  correctly: “...goes downwards; zeroes at 0, 2, 5. At 1 it is negative”.

M in the post-test, sketching  $y = (x^2 + 6)/(x^2 - 4)$  correctly:

“...asymptotes at 2 and -2; zero at  $\sqrt{6}$ ; no, no zeroes, because  $x^2$  cannot be negative; when  $x$  is smaller than 2, then it is positive here, and negative here, so it is negative; when  $x$  is a bit larger than 2, positive here, positive here, so positive; the same for -2”.

Not only had these two students improved their scores in the post-test, but the results of all students showed a significant improvement in scores, with a large effect-size, from a mean score of 3.1 (SD = 2.6) in the pre-test to a mean score of 8.6 (SD = 2.8) in the post-test ( $t(20) = 10.40$ ,  $p < .001$ ,  $d = 2.27$ ). As expected, the scores in the retention-test dropped: a mean score of 6.3 (SD = 3.4). This result is significant when compared with the pre-test scores:  $t(14) = 3.15$ ,  $p = .007$ ,  $d = 0.81$ .

## Conclusion and discussion

The aim of the current study was to enable students to give meaning to algebraic formulas in terms of a graph. A knowledge base of basic function families with their characteristics is needed for this. In the intervention, students learned to graph formulas through recognition and qualitative reasoning. The results of the thinking-aloud protocols showed that in the pre-test students were either unable to link formulas to graphs or needed to use a lot of time-consuming reasoning and error-prone calculations. Therefore, without explicit teaching, students might not link formulas to graphs. The post-test results of the graphing task showed that the students had improved their recognition of basic function families and, in general, their reasoning about formulas. In terms of the two-dimensional framework: in the pre-test the students mostly used recognition level E, whereas in the post-test they often used higher levels of recognition (recognition of function families, decomposition of the formula, and recognition of graph features).

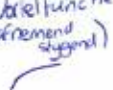

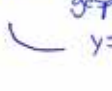

The categorizations gave an impression of the knowledge base and thinking processes of the students. The students' categorizations showed that they used more or less the same categories as experts, but still had problems with categorizing less familiar functions, like  $y = \sqrt{8 - x^2}$ ,  $y = 100 - e^x$ ,  $y = 8\sqrt{x^3}$ ,  $y = x + 4/x$ . Student M used zeroes, asymptotes (horizontal and/or vertical), and edge points as main strategies when categorizing. In the post-test graphing task, s/he often used these same strategies. Student K's categorization was very detailed, although s/he combined root- and log-functions. However, in the post-test graphing task s/he showed that s/he knew the differences well (see sketching  $y = \ln(x - 3)$  and  $y = \sqrt{x + 6}$  in the results section). In the post-test graphing task, K used her/his repertoire of function families often. Both students' categorizations seemed to allow them to recognize function families and use these function families as building blocks in reasoning with and about formulas: these function families are objects that they can use to give meaning to algebraic formulas.

These findings suggest that teaching graphing of formulas based on recognition and heuristic search might enable students to develop a repertoire of basic function families, to identify the structure of formulas, to (qualitatively) reason with and about algebraic formulas, and to link formulas to graphical features. This could allow students to “read through” an algebraic formula, that is, to give meaning to algebraic formulas.

# Relational thinking and operating on unknown quantities. A study with 5 to 10 years old children

Denise Lenz

*The following research design combines relational thinking as an aspect of algebraic thinking with the understanding of variables. In clinical interviews, 5 to 10 years old children were confronted with tasks that required the description of relations between known and unknown quantities. Their answers were examined regarding the ways in which relations are described and thereby variables are seen.*

*Keywords: Algebraic thinking, relational thinking, unknowns, primary school.*

## Introduction

This paper reports parts of a research focused on the abilities of young children to establish relationships between unknown quantities. The aim is to investigate how young children describe relations between known and unknown quantities that are represented with different colored boxes and marbles and how they understand the unknown quantities. First of all, relational thinking as an aspect of algebraic thinking will be described as well as important aspects of variables.

## Theoretical Framework

### Algebraic thinking and relational thinking

It is hard to give a comprehensive description of what algebraic thinking means. However, many researchers (e.g. Kieran, 2011) highlighted that relational thinking is seen as an important part of algebraic thinking.

Relational thinking refers to students' recognition and use of relationships between elements in number sentences and expressions. When using relational thinking, students consider sentences as wholes (instead of a process to be carried out step by step), analyze them, discern some detail and recognize some relations, and finally exploit these relations to construct a solution strategy. (Molina, Ambrose, Castro, & Castro, 2009, p. 122)

In addition to the understanding of relational thinking regarding equations and formal expressions, this can also be extended to the recognition and use of relations between quantities. It enriches the learning of arithmetic and can be a foundation for smoothing the transition to algebra (Carpenter, Levi, Franke, & Koehler Zeringue, 2005).

### Aspects of variables

Radford (2011) described algebraic thinking as dealing with indeterminate quantities conceived of in analytic ways. So dealing with indeterminacy is an important part of algebraic thinking. This indeterminacy leads to different aspects of variables. At least, three different kinds can be distinguished: *unknowns*, *variables*, and *general numbers*. *Unknowns* describe a specific, but undetermined number, whose value can be evaluated, i.e. the  $x$  in the equation  $10 + x = 30$  (e.g. Freudenthal, 1973; Usiskin, 1988). *Variables* describe a range of unspecified values and a relationship between two sets of values, i.e. variables appear in statements about a functional relationship and indicate how one value depends on another value (e.g. Küchemann, 1981; Usiskin, 1988). *General*

*numbers* describe indetermined numbers which appear in generalizations, such as descriptions of properties of a set, i.e. the commutative law of addition can be represented by the equation  $a + b = b + a$ . In contrast to the variable aspect of the unknown, this is not about specifying a value for the letters  $a$  and  $b$ . The meaning of general numbers lies precisely in the general expression of the relationship found (e.g. Freudenthal, 1973; Usiskin 1988). In addition to these three aspects of indeterminacy, empirical data provide further classifications. Children often use *quasi-variables* to express generality before they develop the capability to use algebraic language (e.g. Fujii & Stephens, 2001): general structures are expressed through the use of examples which stand for the general. For example, children use the number sentence  $78 + 49 - 49 = 78$  to express that the number sentence  $a + b - b = a$  is true whatever other number is taken away and added again. In this sense, they have an understanding of indeterminacy and can express a general number without the symbolic algebraic expression.

### Research interest

Studies focused on relational thinking usually refer to relationships in formal representations (e.g. Carpenter, Levi, Franke, & Koehler Zeringue, 2005). In equations with an unknown, students have the opportunity to calculate. If there are two unknowns, this possibility is not given. It can be assumed that the use of several unknowns increases the use of relational thinking. A study by Stephens and Wang (2008) showed that 6<sup>th</sup> and 7<sup>th</sup>-graders use relational thinking in the following task: In each of the sentences below, you can put numbers in Box A and Box B to make each sentence correct. For example:

$$18 + \square = 20 + \square$$

Box A              Box B

Based on students responses to tasks like above, they described three stages of relational thinking: *established relational thinking*, *consolidating relational thinking*, and *emerging relational thinking*. *Established relational thinkers* specify the relationship between the numbers in the two boxes with a clear reference to the numbers, including the magnitude and direction of the difference between them. These characteristics decrease in the other two categories. In terms of task design, they found that tasks with two unknowns served the purpose of moving students beyond computations to more in-depth thinking (Stephens & Wang, 2008). Research by Schliemann, Carraher, and Brizuela (2005) showed that even younger children aged 7 to 11 years old are capable of understanding equivalence and solve linear equations with unknown quantities. In that case, the tasks were represented with concrete objects or told as little stories. In contrast to formal representations, concrete materials have the chance to prompt even younger children such as kindergarteners to show their capabilities of relational thinking while handling unknown quantities. Melzig (2013) tested a task design with boxes and beans with 7<sup>th</sup> graders and found that the boxes can play a meaningful role in developing a viable idea of variables.

The following study addresses the question: *How do young children describe relations between known and unknown quantities that are represented with concrete materials? How do they understand the represented unknown quantities (e.g. as unknowns, as variables...)?*

## Methodology

The following interview-study was performed on 82 children aged from 5 to 10 years old. The sample consisted of 5 to 6 years old kindergarteners ( $n=27$ ), 7 to 8 years old 2<sup>nd</sup> graders ( $n=28$ ) and 9 to 10 years old 4<sup>th</sup> graders ( $n=26$ ). The children did not receive any special algebra lessons or instructions before.
