Our adoption of the four-factor model depended on the results of the principal factor analysis, including the total-variance-explained table and the scree plot (see Figure 2 below). There was little difference between the four-factor Varimax and Oblimin solutions, thus both solutions were examined in subsequent analyses before deciding to use a Varimax rotation for the final solution. According to this solution, the four factors explained 58.724% of the variance in the democracy scores.

### Validity and reliability analysis

Validity and reliability analyses were performed for the four factors. To ensure validity, the first-version of the questionnaire was presented to experts in mathematics education or in the social aspect of learning to analyze it and thus verify its validity for data collection. After this analysis, the necessary corrections were made to the scale in accordance with their comments, which gave the present 18-item 5-point Likert type rating scale. To ensure reliability, Cronbach's Alpha was computed for each of the four democratic factors. This computation gave .81 for Freedom, .82 for Engagement, .78 for Equality, and .54 for Justice. These reliability results indicate good reliability for the constructs: freedom, engagement, and equality (Field, 2009) because these reliabilities are around .80. However, the reliability of justice is not sufficient, and we suggest the need to add additional items to the questionnaire in order to improve the reliability of this construct (Field, 2009). The Cronbach Alpha computation for the whole questionnaire is .88 which indicates high reliability.

### Level of democratic practices in Palestinian middle schools

To assess the level of democratic practices in the Palestinian mathematics classrooms, we computed means and standard deviations for the four factors: freedom, engagement, equality, justice s. We also conducted a one-sample t test to assess the statistical significance of the variation of each factor with a low, normal and good level of democratic practice (see Table 4).

Component	M (SD)	T value		
		Low	Normal	Good
Freedom	2.64 (1.01)	16.60**	0.87	
Engagement	2.42 (1.00)	12.34**	-3.58**	
Equality	2.81 (2.04)		3.97**	-11.40**
Justice	2.45 (0.91)	14.22**	-3.26**	
General democracy	2.59 (0.77)	20.54**	-.135	

**Table 4: Level of democratic practices in the Palestinian mathematics classrooms (N=398), \*\* p<.000**

### Discussion and conclusions

Empirical research regarding democratic practices in the mathematics classroom is still in its infancy. One way to develop such empirical research is to develop quantitative tools, such as questionnaires, to assess the level of democratic practice in mathematics classroom. The present research offers a questionnaire that assesses four democratic factors: freedom, engagement, equality and justice. These four constructs/factors explain 58.72% of the variance in the overall democracy score across our sample. Previous research, using questionnaires to assess democratic practice has suggested one scale consisting of only one factor that explains 47.701% of the variance of an overall democratic score. I argue that a scale with four factors addresses the concerns regarding scales with only one or two factors, which may not provide an accurate representation of the construct (Pett, Lackey & Sullivan, 2003). Also, further democracy constructs, such as autonomy and decision making, could also be assessed in future research.

The questionnaire suggested in the present research may help researchers study the level of democratic practice in mathematics classrooms. Here, I used the suggested questionnaire to examine the democratic practices in Palestinian ninth grade mathematics classrooms. The results indicate that the level of democratic practice in this context is less than good. There may be various reasons that explain this level of democratic practice, such as authoritarian styles of teaching by teachers (Ramahi, 2015). These authoritarian styles cannot foster critical or independent thinking, which may impact negatively the future functioning of students. In addition, the ‘less than good’ level of democratic practice may be a result of students’ and teachers’ limited awareness of the student’s right to a democratic space in the mathematics classroom.

The present research indicates the need to improve the level of democratic practice in the Palestinian mathematics classroom. This could be done by different means. First, by holding workshops for mathematics teachers with the goal to increase their awareness of democracy factors and discuss with them ways to increase democracy in their classrooms. These workshops need to be based on pedagogic approaches that enhance student agency and voice, foster creative and critical thinking, and enable students to collaborate, share their mathematical ideas, and negotiate their decisions regarding their mathematical learning (Daher, 2017; Ramahi, 2015). Moreover, these workshops need to be supported by the ministry of education as it calls for inclusive education in the schools (Ministry of Education & Higher Education, 2015). Second, special emphasis needs to be put on enhancing students’ awareness of their democratic rights. These workshops to advance democratic practices in the Palestinian context could benefit from similar attempts around the world (see, e.g., Varnham, Evers, Booth, & Avgoustinos, 2014).

*Diversity raises different questions such as how an adequate education of student teachers can be organized in this context. Against the background of a potential-related view, this paper outlines an exemplary concept of an interdisciplinary seminar and an evaluation study about possible impacts reflected by student teachers as barriers in inclusive mathematics teaching. Qualitative data were generated by learning maps in a pre-post-design and analyzed by a reconstructive pedagogic- iconological interpretation. The results indicate that the foundation of the seminar leads to a more complex reflection of student teachers' individual educational paths.*

*Keywords: Diversity, inclusive mathematics education, teacher education.*

## Introduction

According to Ainscow (2007), inclusion is seen “as a reform that supports and welcomes diversity amongst all learners” (p. 3). Its aim is to analyze barriers to participation and learning experienced by students within school systems. In some countries, inclusive education is seen as teaching children with disabilities within general education, traditionally by special educators. Slee and Allan (2001), who express their skepticism about inclusion as co-location of pupils, criticized this understanding earlier. There is a similar discourse in Germany: Hinz (2013) states that inclusion moved from ignorance to being unrecognizable, reminding us that inclusion had been ignored by educational science and politics, and now the scientific discourse shifts its attention from inclusion to de-segregation: Instead of focusing on barriers, the individual problems of pupils with special needs and their location in regular schools are discussed. This causes consequences for teacher education: Mathematics teacher education for inclusion is often realized by implementing elements of special education (Werner, 2017), or inclusive mathematics education is reduced to the question of how pupils with special needs learn and what can be done to compensate for their deficits (Krause, 2017). Three problems can be found in this approach: Empirical research showed that marking pupils with special needs is highly influenced by socio-economic status or migration, leading to negative consequences for further schooling and to the potential danger of stigmatization (Sturm, 2016). Secondly, a focus on categories might neglect other children who do not belong in a predetermined category and, therefore, become marginalized (Messiou, 2017). Finally, concentrating on pupils' individual deficits ignores the role of the social and political environment in mathematics education and individualizes failure (Veber & Fischer, 2016). An alternative approach and the framework of this paper is given by viewing inclusion not limited to deficits or categories like gender or social class, but by perceiving individuals' differences as an advantage. We will outline that addressing pupils' differences in this sense of diversity, which we call potential-related, understanding inclusion as a

concept welcoming diversity, and a focus on barriers to participation are suitable frames for mathematics teachers' education (Benölken, Berlinger, & Veber, 2018). In this paper, we address the learning and reflection of student teachers in the context of inclusive mathematics education. Therefore, we do not only describe our attempts on inclusive teacher education but focus on the students attending these courses. The following questions will be investigated: *How can a seminar for student teachers be conceptualized into inclusive mathematics education from a potential-related perspective? How do student teachers reflect on barriers in inclusive mathematics teaching before and after taking part in the seminar?* First, brief overviews of the theoretical frameworks will be given. On these bases, the seminar concept will be outlined. Finally, the design and results of an exploratory study analyzing learning-maps in a pre-post-comparison by applying methods of pedagogic-iconological image interpretation will be subsumed and discussed.

### **Theoretical framework: A brief overview**

*Inclusive* education demands a positioning in the understanding of 'inclusive'. While most of German mathematics education research regards the concept in the sense of special education, an alternative approach is a potential-related view. Benölken, Berlinger and Veber (2018) identified three axioms of inclusion: (1) The rejection of labels such as 'disabled' or 'dyscalculia' for pedagogical actions is an inherent part of inclusive approaches. It means that differences are produced in contexts and not determined in a static way. Most pedagogical categories emphasize negative aspects and, therefore, reduce people to one dimension of their individuality. Vice versa, a potential-related view focuses on the resources of learners. (2) The traditional German school-system is based on homogeneity, assuming pupils learn better if they visit schools for their specific needs. For example, the *Gymnasium* for supposedly 'intelligent' children or the *Förderschule* for 'disabled' children. Inherent is the assumption that heterogeneity poses an obstacle for successful learning. In contrast, a potential-related view demands to accept and to appreciate differences, which is represented in the term *diversity*. (3) Inclusion has a political approach. It is based on human rights, and it demands for changes in society (Slee & Allan, 2001). The research status on inclusion in German mathematics education is characterized by proposals for inclusive lessons (Häsel-Weide & Nührenbörger, 2017), often using the concept of natural differentiation. There are few concepts that include other aspects such as co-teaching, diagnostics and beliefs (Käpnick, 2016). There tends to be a lack of a theoretical discussion about the principles of inclusive mathematics education. Often, the needs of pupils with difficulties in learning mathematics are discussed to design learning environments; the role of mathematics education itself as a producer of inequality is hereby neglected. The international research on inequality and exclusion has given useful suggestions on reflecting discriminating structures and the influence of mathematics education and its teachers (e.g., Bishop, Tan, & Barkatsas, 2015). Consequently, we think that it is not sufficient to add special needs courses to mathematics teacher education. We suggest *reflexive inclusion* as a promising theoretical construct (Budde & Hummrich, 2013). Reflexive inclusion means both to perceive differences when it is needed and to make discrimination visible, but at the same time a rejection of implicit norms and institutional categorization. In this understanding, reflexive inclusion is an interdisciplinary task of mathematics education, special education and pedagogy. In contrast to other concepts, it is not reduced to the dimension of disability, but framed intersectionally, that is, several dimensions of

diversity act in combination. This understanding meets our axioms and provides the theoretical background of a potential-related view. Thus, it is relevant for student teachers to learn that differences need to be deconstructed when possible, and to recognize discrimination. Furthermore, specific knowledge about pedagogical diagnostics and categories of social inequality such as disability, gender, milieu and such is necessary. Therefore, it is of interest to scrutinize seminar designs, and to explore the development of student teachers' reflection, knowledge or perhaps beliefs on, for example, ex- and including factors.

## **Survey of a seminar conception**

We will outline an exemplary teaching concept (for further details see Benölken, Berlinger, & Veber, 2018). It has proven itself in implementations at the Universities of Münster, Osnabrück, Halle and Kassel as well as at the Pedagogical University Tyrol. It aims at students who have already acquired their first subject-didactic and subject-scientific knowledge. Thus, it requires a level of ambition that enables students to expand and network knowledge already acquired with a focus on the organization of inclusive mathematics lessons. Against the background of interdisciplinary networks, the aim of the seminar is to enable students to plan, reflect and analyze inclusive mathematics lessons. The overarching questions of the seminar sessions can be identified as follows: Which influencing factors must be considered in the design of inclusive mathematics lessons? How can concrete mathematics didactic implementations be identified, and, conversely, do they meet the requirements of inclusive education? The seminar concept approaches these questions with a potential-related understanding of inclusive education. Consequently, various facets that are discussed in the relevant literature concerning the realization of lessons for all children without exclusion are taken into account: Attitudes and experiences, professional competencies in relation to various diversity facets (including facets relevant to special education), diagnostic and methodical spectra, educational framework conditions, social relationships as well as cooperative forms of teaching. In summary, the complex of all presented aspects mirrors a holistic approach to student teachers' education, and they explore single facets of the complex as well as interrelated patterns by research-based learning, that is, by raising relevant questions, developing corresponding concepts and sometimes examining them in greater depth in bachelor and master theses. The organization of the seminar combines usual demands of higher education didactic such as different methods and both traditional and digital media, multifaceted combinations of theoretical contents and authentic practical examples. Additionally, there are supplements of expert lectures (often as 'best practice' information), school visits and workshops, in which student teachers can network and deepen their knowledge. A recurring highlight are discussions about both potentials and possibilities of implementing developed ideas, concepts and findings in inclusive mathematics teaching. In each case it is scrutinized whether work products meet both mathematics educational and inclusive pedagogical postulates of organizing teaching-learning processes.

## **The study**

The study focuses on the *question* how student teachers reflect on barriers in inclusive mathematics teaching before and after taking part in the seminar. The sample consisted of 124 *participants* (101 f., 23 m.), who were primary and secondary student teachers and took part in the study during the

semester in which they attended the seminar. The data originated from implementations of the seminar concept in Münster (between the winter semester 2015/2016 and the summer semester 2017), Osnabrück, and Innsbruck (each in the summer semester 2018). Mostly, the participants were in their first year of undergraduate studies. The study has an explorative character, that is, generalizations were not intended, but existential propositions (Lamnek, 2010). Thus, a qualitative *design* was advisable. As to the *method*, qualitative data were generated by applying learning maps in a pre-post-comparison, which were anonymized by codes to ensure unbiased interpretations. In the maps' header, the student teachers were given the impulse to craft their way between their current status and their future work at schools: "Inclusive education is currently considered as the greatest challenge for teachers. The question arises as to how teachers can structure their specialized instruction in such a way that (really) all children can learn together in order to reach their respective zone of proximal development. This joint learning of all children without exclusion might arise opportunities, challenges, stumbling obstacles and much more. What does this mean to you personally? Which way have you covered or which way will you have to cover in the future? Please lay out your way" (translated from German). All participants designed the maps for the first time, and the maps were created at the beginning of a semester and its end. As to the *analysis*, the pre- and post-maps were compared by a reconstructive pedagogic-iconological image interpretation, following its characteristic steps: (1) Discussion of previous history and selection of key motives, (2) image description and analysis (with regard to the factual, expressive and form-related sense), (3) context analysis, and (4) comparative analysis (Schulze, 2013). The evaluation procedure was piloted in a research workshop with student teachers in the summer semester 2016; afterwards, the analyses were conducted in a research group.

Figure 1: Example of a pre-map

Figure 2: Corresponding post-map to Figure 1

## Results

As to the map's *previous history*, the reflections' interpretations must be seen in the context of the seminar, which attempts to combine school requirements in dealing with diversity and university teaching. For example, led by theory, the student teachers develop concrete task formats in the seminar, which provides one of the topics in the context of methodical spectra. This framing implies that the student teachers receive a view of school practice from the university perspective between the pre- and post-drawings, which produces impacts on the post-maps' design. Additionally, the seminar's evaluation was conducted in a mixed-method design, where the maps provide one constituent. Regarding *key motives* and their *description*, main types were drawing both (1) paths (or a systems of paths), and (2) obstacles. Subsequently, we focus on spotlights of the reconstructions of one example shown by the Figures 1 and 2, which reflect typical features (the figures show facsimiles with translations from German; the original data can be requested from us).

As to the factual sense of the pre-map (Figure 1), the most important symbols are a path and a mountain. With regard to the sense of form, the path begins and ends relatively narrow, and it winds directly before the finish. The mountain is on the path. Additionally, some persons at the end of the path smile and stretch their arms into the air. As to the sense of expression, another noteworthy detail is that the remarks are often written in questions. The expression is rather sober. As to the factual sense of the post-map (Figure 2), the spotlights are basically repeated. Additionally, at the beginning of the path is a large suitcase, which is taken along: Small suitcases are carried by a person walking on the path. With regard to the sense of form, the path is not winding, but it leads straight to the destination without detours. The suitcase is swung back and forth by the person. The mountains stand beside the path in the background. As to the sense of expression, most of the remarks do not represent

questions, but statements. The bigger person smiles and stretches the arms upwards. Colors are used to highlight single aspects.

As to a *context analysis* of the pair of maps, the feet drawn in the pre-map (Figure 1) seem to indicate that the creator of the map reflects that he or she has started the journey to inclusive teaching, but there are several aspects showing ambiguity like the real starting line is not reached yet or the annotations are phrased as questions. The creator still seems to expect to gain experience, knowledge and the like as shown by both the words on the path and the envelopes, especially the big one with the question mark, but his or her bases are “empathy” and “experience” (which is not explained in detail here). With regard to the central symbol ‘mountain’, an ambivalence must be noted: On the one hand, mountains can block the view, can be a hurdle. On the other hand, mountains represent challenges that require effort but offer opportunities in relation to the goal being achieved, and both the ‘path is the goal’ and the ‘goal is the goal’; climbing and reaching the summit can cause a ‘flow’. The latter can justify the previous effort. Mountaineering can also be influenced by different weather conditions and the like, that is, different conditions that require special equipment. Thus, the symbol ‘mountain’ can stand for different chances but also challenges and dangers (on the part of the teachers, but not only there) and this requires a specific preparation. As indicated, in the pre-map, the mountain is drawn on the path, which seems to reflect that the creator can imagine to cope with inclusive teaching at school in principle (which is also indicated by the cheerful group of people at the school), but he or she still perceives barriers that will be difficult and challenging to overcome. This interpretation is confirmed by the fact that a curve is drawn between the mountain and the school. The comparison with the post-map (Figure 2) suggests that the creator now reflects to perceive a direct access to inclusive teaching: The big suitcase seems to indicate that he or she can classify own experiences in a more differentiated way. Experiences and likeness are reflected to be more comprehensive than it was the case in the pre-map. The potential-related perspective can be assumed as an essential impulse for this fundamental change (e.g., “knowledge about different children and their diverse needs”). Questions posed in the pre-map (e.g., “who?”, “how?”, “what?”) turned to concrete intentions and planning steps (as expressed by the phrasings on the path or the “wishes” of the bigger person on the right). Especially, as to the central symbol ‘mountain’, in the pre-post comparison two aspects appear central: the position of the mountains in relation to the path and their number. As to the position of the mountains, it should be noted that, at the beginning, the mountain stands in the way as a hurdle and it makes it necessary to overcome it. Those who want to walk the path cannot avoid overcoming the mountain. In the end, the position of the mountains has shifted significantly, as the path now leads less curvy in front of the mountains: climbing changes from a compulsory to an optional experience. In connection with the altered position, the increasing number of mountains indicates that in the end the ambivalence of mountains is perceived to a much greater and more intensive extent. However, these opportunities and risks no longer appear to be hurdles that cannot be circumvented. Thus, the symbol ‘mountain’ allows exemplary illustrations of a deeper interpretation of the observable changes considering the previous history of the maps: The student teacher experiences a paradoxical situation, since a synchronization of university theory and school practice provokes numerous difficulties (mountain peaks) within the framework of inclusion. However, the mountains are no longer obstacles (i.e., a key motive was reinterpreted). This interpretation is confirmed by the facts that the path is drawn continuously and no longer winding.

Furthermore, there are different impressions reflecting a higher level of confidence like the swinging of the small suitcases, the use of colors (e.g., the ‘sun’ on the right) or the big person, whom one may assume to be the creator him- or herself. The synthesis of his or her size and his or her cheerful expression might be interpreted as a symbol of prospective knowledge and experience, that is, he or she can now well imagine coping with diversity at school and experiences him- or herself better equipped for the journey (e.g., by the suitcases).

Based on these typical examples, a *comparative analysis* of all pre- and post-maps suggests that both the paths of student teachers and their experience of walking on the paths, thus, the reflections of barriers in inclusive mathematics teaching, changed to more confident characteristics. In sum, these changes can be described by three reflexively connected levels: key motives, lines of development, and their antitheses or contrasts. For example, the symbol ‘mountains’ clearly shows that the student teachers change their image of inclusive mathematics teaching in the course of the seminar. On the one hand, it becomes more differentiated and extensive, since in their opinion it is no longer sufficient to simply overcome a hurdle and the goal is already in front of their eyes. It rather seems that inclusion in mathematics teaching offers numerous challenges. These offer opportunities, but also dangers for teachers. The given pre-post-map-example represents a main type of all pairs of maps, the ‘expectant expert’. A feature of this type is that knowledge about inclusion increases and the person develops confidence in inclusive teaching. Another type shows similar characteristics, but in a lower level of contrast, which we named the ‘optimistic novice’. In both cases, we reconstructed an increase of knowledge and reflection, so we assumed deeper understanding of – or at least insight in – the possibilities and challenges of inclusive education. Finally, the type ‘interested layman’ was reconstructed showing much lower levels of confidence’s increase (forming the subtypes ‘positively stagnating’ and ‘no process’), but it was rarely found.

## Discussion

The results indicate that participating in a seminar which takes a potential-related perspective on inclusive education and which considers the idea of research-based learning as well as intertwining theory and practice in a university context contributes sustainably to student teachers’ reflections of removing barriers in inclusive mathematics teaching. Thus, beyond the context of mathematics education, the results suggest the hypothesis that the seminar’s foundation provides an appropriate approach to student teachers’ education in the field of diversity, which is, for example, reflected by the main type ‘expectant expert’. Of course, the study’s character is explorative and it has obvious limitations, for example, the reconstructions were conducted within a group of researchers, but it remains uncertain if a consensus view is the right one (Lamnek, 2010). The interpretations reported in this article focus on the most important spotlights, especially regarding the characterization of the previous history of the images’ geneses, the connection between motives emerging from the previous history and the central symbols applied in the maps’ drawings, or the introduction of different types. As to the sample, all data collected between 2015 and 2018 were included in the analyses in order to get both various and sustainable impressions, although single conceptual improvements were conducted during this period because of feedbacks from the single evaluations. However, the basic principle of a potential-related perspective always remained the same. Subsequent research might focus on a deeper clarification of the evaluation of the seminar’s theoretical framework in the context

of both mathematics education and education in different subjects. Another step could be adapting contents of the seminar to different types of learners we found in the comparative analysis.

# A farewell to mathematics: A personal choice or social exclusion?

Oğuzhan Doğan

Yeditepe University, Faculty of Education, İstanbul, Turkey; [oguzhan.dogan@yeditepe.edu.tr](mailto:oguzhan.dogan@yeditepe.edu.tr)

*One of the dimensions that the socio-political understanding of mathematics education brings to mathematics education research is the study of how students are excluded from mathematics education. Social media could be a fruitful site to examine students' exclusion from mathematics. Therefore, the purpose of this study is to analyze how some social media users describe the moments of their farewell to mathematics and discuss what these moments imply to mathematics education researchers, specifically to the critical ones. Content analysis was utilized to analyze social media users' description of their own farewell moments to mathematics. From the analysis of these descriptions, it was concluded that almost all stages of the formal education system from the beginning of elementary school to the very last day of university, and almost all mathematics topics from multiplication to differential equations could be the moments of farewell to mathematics.*

*Keywords: Mathematics education, farewell to mathematics, exclusion, social media, ekşisözlük.*

## Introduction

Understanding mathematics education as socio-political construct has been finding increasingly more place in the mathematics education research community in the last 20 years. Straehler-Pohl, Pais, and Bohlmann (2017) portrayed this increase prominently:

Established conferences like ICME and CERME now incorporate in their programmes working groups exclusively dedicated to sociopolitical studies; the “Mathematics Education and Society” conference series has become an inherent part of the field; on a regular basis, themes like “equity”, “diversity”, “social justice” and “critical education” are problematized in edited collections and special issues of the most renowned journals; and one of the four sections that compound the very recent Third International Handbook of Mathematics Education is dedicated to “Social, Political and Cultural Dimensions in Mathematics Education”. (p. 2)

Although educational conferences, journals, edited collections or handbooks provide particular spaces for the social and political dimension of mathematics education, it is questionable whether or not such understanding reflects on educational policies and public opinion. For example, for the case of Turkey, ‘equity’ is still only a mathematics topic but not a policy identifier (Doğan & Haser, 2014).

One of the dimensions that this socio-political understanding of mathematics education brings to mathematics education research is the study of how students are excluded from mathematics education. The social, cultural, class-, gender- and race-based explanations of this exclusion are clearly presented in critical mathematics education literature (Jablonka, Wagner, & Walshaw, 2013; Jorgensen, Gates, & Roper, 2014; Kolloosche, 2017). However, we still have limited knowledge of how this exclusion is explained by the excluded themselves.

In the last decade social media has become one of the important places that individuals use to communicate with each other, explain their point of view, share their ideas, discuss different perspectives and so help the construction of public opinion. With the awareness of the common

popularity of social media and its growing potential, it could be fruitful to examine social media shares to understand their relations with mathematics. Considering this potential, this paper will examine a popular social media site ([eksisozluk.com/sourtimes.org](http://eksisozluk.com/sourtimes.org)) in Turkey in terms of how social media users describe their exclusion from mathematics education.

## **Exclusion in Mathematics Education**

Similar to what Marx and Engels (1848) indicated about the written history of mankind, “the history of all hitherto existing society is the history of class struggles” (p. 14), it could be argued that the history of all hitherto existing mathematics classrooms is the history of exclusion. In the first handbook of research on mathematics teaching and learning, Secada (1992) highlighted this history as such:

For over 40 years, we have been confronted with an ever-growing body of research documenting that the American educational system is differentially effective for students depending on their social class, race, ethnicity, language background, gender and other demographic characteristics. This differential effectiveness has been found in mathematics as well as in many other academic subjects. (p. 623)

Following comprehensive reviews on mathematics education research (Jablonka, Wagner & Walshaw, 2013; Bishop & Forgasz, 2007) also emphasized that a wide range of students (from different racial, ethnic and religious minorities, working-class students, female students and students with disabilities) had suffered from conflicts with mainstream mathematics education. It can be concluded from this consistent body of literature that disadvantaged groups of students are excluded from mathematics education on both micro level (in mathematics classrooms) and macro level (national tests, higher education entrance, job preference etc.). Mathematics has an important role in the intellectual selection, preparation and guidance of students to enter higher education studies and has used to help select those who will occupy different social positions. Thereby it serves as a critical filter. Understanding these exclusion processes can help us to understand the role of mathematics education in the reproduction of social inequalities.

These exclusion processes or moments are investigated under the roof of different theoretical frameworks. Within a traditional Marxist perspective, it can be argued that working class children have fewer resources (economic opportunities, family support etc.) to be successful in mathematics and are subjected to be a member of future working-class thorough education/schools (Bowles & Gintis, 1976). With a Žižekian contribution to this perspective, it can be argued that failure or exclusion in mathematics education is not an observed singularity that can be solved through better mathematics classrooms with hard-working mathematics teachers, but a necessary feature of existing schooling and mathematics education (Pais, 2012; Straehler-Pohl & Pais, 2014). As Pais (2012) influentially stated “the ‘slogan’ or ‘motto’ ‘mathematics for all’ is used as an exemplary case for the social fantasy that is concealing the crude reality that, as any mathematics teacher knows, mathematics is not for all” (p. 58).

In addition, in a Bourdieusian sense, it can be argued that working class students or students with limited cultural baggage do not have the necessary cultural capital to ‘play the game’ that is involved in the learning of mathematics and are less likely to understand the mechanisms required to succeed

in mathematics (Lareau & Horvat, 1999; Doğan and Haser, 2014). Similarly, based on Bernstein's theory of the language and codes used in educational settings, it could be argued that some context or language use in mathematics lessons can result in mathematical exclusion (Helenius, Johansson, Lange, Meaney, & Wernberg, 2015).

Moreover, from a Foucauldian perspective, the concept of 'power' can be an expressive tool to understand moments of exclusion. For example, Valero (2007, p. 226) indicated that viewing power as a "capacity to participate by taking and defining the positions and conditions for engaging in social practice" offers investigation of the microphysics of power in mathematics education practices. According to her, such an analysis clarifies the mechanisms through which different actors get positioned as more or less influential participants and thereby get included and excluded.

These perspectives can provide mathematics education researchers a supplementary toolbox for understanding and portraying the processes and moments of exclusion. On the other hand, how these processes and moments were interpreted by the excluded themselves needs to be clarified. Therefore, the purpose of this study is to analyze how some social media users describe the moments of their farewell to (or exclusion from) mathematics and discuss what these moments imply to mathematics education researchers, specifically to the critical ones.

## Methodology

In line with the purpose of the study, the research questions are: (i) How do social media users describe the moments of their farewell to mathematics? (ii) What are the themes that emerge as a portrayal of these farewell moments? and (iii) What are the implications of these farewell moments for mathematics education researchers?

To answer these questions, one of the most popular social media sites in Turkey, Ekşisözlük (Sour Dictionary) was analyzed. Ekşisözlük can be considered a unique website, somewhat similar to Wikipedia, in which each member of the dictionary writes their own definition/description of a specific concept, people, event etc. For example, you can find users' own definitions of lasagna, Deep Purple, Utrecht or the latest comments of political figures. In 2018, there are almost 500.000 active members writing in Ekşisözlük and it ([www.eksisozluk.com](http://www.eksisozluk.com)) is the 15th most visited website in Turkey.

The research methodology was content analysis. The content of the users' definitions (entries) of 'the moments of farewell to mathematics' was investigated in this study. There were 945 different entries under this heading (<https://eksisozluk.com/matematige-veda-edilen-an--4614088>), which means that 945 different users describe their own farewell moments to mathematics. As an example, the last entry was "In the second year of university, when I passed the differential equations. I got rid of mathematics, but then I faced more terrible things".

The 945 entries under the heading 'the moments of farewell to mathematics' were retrieved from the website in June 2018 with the help of NVivo 11 (NCapture for NVivo 11). Each entry was read in the beginning of data analysis. 236 of the entries were not related with the title and did not include any meaningful definition, so they were omitted in the further analysis. After this first reading, the possible themes for the farewell moments were constructed, such as the year of the farewell and the

specific reason of the farewell. Each entry was coded according to these initial themes with the help of NVivo 11, and through the analysis the themes were combined, separated or re-constructed. Finally, the data (709 entries) were re-coded with the final version of themes, sub-themes and codes.

## Findings

To clarify how I examined Ekşisözlük users' description of their farewell moments, I will present some of the representative entries and try to explain how I interpreted these entries. One of the entries under the heading 'the moments of farewell to mathematics' was this:

Entry 1: I think, for everyone, there is a moment when they say goodbye to mathematics. Some go away when they see 'x' or 'y', some wait for the derivatives. The moment that I feel I did not understand mathematics at all was the first grade where we saw the multiplication with 7. I am still mad at this multiplication table.

As it can be seen, the user pointed out the first grade of primary school and multiplication table as the moment of farewell. S/he did not identify any specific reason for the farewell but only indicated the mathematics topic (multiplication with 7). There were a lot of similar entries indicating specific mathematics topics and grade levels, for example:

Entry 2: Math was my favorite lesson in primary school. However, when the letters came into stage I fell out of love with mathematics.

Entry 3: My body was fumbling with functions, and the last blow was trigonometry.

The writer of Entry 2 pointed out the 'letters' as the farewell moments, so it can be inferred that the mathematics topic was algebra and the time was elementary school (although there is no specific grade level, algebra is one of the main mathematical concepts of elementary schools (5<sup>th</sup> to 8<sup>th</sup> grade) in Turkey). Entry 3 pointed out two mathematics concepts (functions and trigonometry) from high school as the farewell moments.

In addition, some of the entries gave further reference to the users' reasons of farewell. For instance:

Entry 4: With the start of limit-derivative-integral and because of the teachers who cannot explain what these topics mean.

While the user specifically indicated the topic (calculus) and so also the grade level (High school, 12<sup>th</sup> grade), s/he also pointed out the teachers and their lack of explanation as the reason of farewell.

On the other hand, some of the entries did not specify any mathematics topics or reasons of farewell but indicated a national exam. As an example:

Entry 5: It is the moment that you give up hope from KPSS (Exam for Civil Servant Selection).

Five main themes have emerged as a result of content analysis of the farewell moments; the grade level of the farewell, the specific mathematics topic of the farewell, the specific national exam of the farewell, the reasons of the farewell and no farewell. The number of entries that have specific reference to these main themes is presented in Table 1.

Theme	Code	# of entries
Grade Level		<b>232</b>
	High School (Grade 9-12)	70
	University	53
	Primary School (Grade 1-4)	41
	Elementary School (Grade 5-8)	40
	Passing the University Entrance Exam	19
	Graduation	9
Mathematics Topic		<b>167</b>
	Calculus	43
	Algebra	31
	Trigonometry	20
	Functions	15
	Advanced Calculus/Mathematics	11
	Multiplication Table	11
	Equations	5
	Negative Numbers	5
	Others (Sets, Logic, Fractions, etc.)	26
Reasons		<b>64</b>
	Teachers	42
	Poor grades	20
	Friends	2
National Exams		<b>24</b>
	ÖSS (University Entrance Exam)	17
	ALES (Exam for Graduate Study)	4
	KPSS (Exam for Civil Servant Selection)	3
No Farewell		47

**Table 1. The number of entries that have specific reference to main themes**

When the grade level theme was examined, it can be seen that the users identify all stages of education from elementary school to university graduation as a farewell moment. While high school and university grades were the most referenced grades, a significant number of users emphasizes the

farewell moments almost at the start of their education career, primary school (41; 18% of grade level references).

In addition, when the mathematics topic theme is examined, it is understood that the users have highlighted a variety of mathematics topics from multiplication table to calculus as a farewell moment. Calculus (43; 26% of mathematics topic references) and algebra (31; 18% of mathematics topic references) were the most referenced mathematics topics.

Moreover, when the reasons of the farewell are examined, two main reasons emerge: the teacher and poor grades. In addition, it should be noticed that most of the entries did not include any specific reason of farewell: only 64 entries (9%) of 709 entries pointed out a specific reason.

Lastly, 47 (7%) of the entries indicated that it is not possible to say goodbye to mathematics and so there can be no such farewell moment. Two examples were these:

Entry 6: I think there is no such moment, math is life.

Entry 7: Only death can separate us.

To sum up the findings of this content analysis, it can be argued that Ekşisözlük users portrayed their moments of farewell by drawing mostly on specific mathematics topics and grade level but do not identify socio-political reasons of these farewells. When they indicated a specific reason, it was either the teacher or their poor grades.

## Conclusion and Discussion

From the analysis of the Ekşisözlük users' description, it can be concluded that almost all stages of the formal education system from the beginning of elementary school to the very last day of university, and almost all mathematics topics from multiplication to differential equations could be the moments of farewell to mathematics. It could be re-stated after these findings that the history of all hitherto existing mathematics classrooms is the history of exclusion. Additionally, when the grade level and mathematics topics are considered together, it can be concluded that multiplication table in primary school, algebra in elementary school, functions and trigonometry in high school and calculus in university emerged as the key moments of farewell to mathematics.

Furthermore, another conclusion can be drawn from what was absent in these descriptions. Although Ekşisözlük users identified (i) mathematics itself (they mostly identify specific mathematics topics as the farewell moments), or (ii) the difficulty of mathematics (poor grades as the farewell moments), or (iii) teachers as the reasons their farewell, they did not give any reference to social, cultural, political, gender- or class-based reasons for their farewell. While identifying the reasons of their farewell, social media users did not cross the wall of mathematics classrooms, therefore they oscillated between their teachers and themselves.

From this absence of socio-political reasons among the reasons of farewell, it can be inferred that although understanding mathematics education as socio-political construct finds increasingly more space in the mathematics education research community, it seems that this understanding could not get across through the walls of mathematics education research to reach public opinion. While we, as (critical) researchers in mathematics education, examine and emphasize that one of the most

important variables affecting mathematics education is socio-economic status, that gender is both a factor in achieving mathematics and in selecting mathematics-based studies/jobs, that cultural capital is responsible for mathematics scores, our students mostly emphasize the individual or mathematics-specific factors as the reason of their farewell to mathematics.

Following these conclusions, the implications for mathematics educators and researchers are two-fold; firstly, there are strong personal reasons for farewell to mathematics, such as mathematics being perceived as difficult and unachievable (reference to poor grades), complex and meaningless (referenced the specific mathematics concepts). Therefore, the inside of the classroom should be organized to make mathematics more meaningful and achievable for students. Additionally, as Kollosche (2017) emphasized “auto-exclusion is not merely the result of psychological dispositions of the individual, which could then be changed by pedagogical intervention, but that auto-exclusion is created in the interplay of the individual and the social environment” (p. 2). So, counter-acting auto-exclusion from mathematics is as much an issue of changing the social environment outside the classroom as it is an issue of changing the mathematics classroom itself.

Secondly, social, cultural, political and gender- and class-based factors that divorce students from mathematics need to get more reference in the public sphere. In spite of the socio-political turn within mathematics education, specific working groups in educational conferences and special issues in high stake journals, it could be argued that the social, cultural, political and class-based exclusion in mathematics education is not publicly echoed adequately. Therefore, as critical mathematics educators, it would be better to demand more to get more public spaces so as to not confine ourselves to special issues or handbook chapters.

# A call for nuancing the debate on gender, education and mathematics in Norway

Trine Foyn

OsloMet – Oslo Metropolitan University, Norway; [trine.foyn@oslo.met.no](mailto:trine.foyn@oslo.met.no)

*This paper aims to scratch beneath the surface of a domestic concern with boys' 'underperformance' in school in Norway. Focusing on mathematics, I argue that there is more to the ongoing debate on gender and education than meets the eye. Exploring the unexpected emergence of a gendered context in a 10th grade mathematics class, I show the need for revisiting the gender and mathematics debate. Characterising the current debate in Norway as a binary concern with boys struggling in the educational system versus successful girls, I argue that the current moral panic is detrimental for girls in mathematics, where challenges remain for those choosing to study at a level which enables access to further studies in the STEM field. The Norwegian debate in this field needs to be more complex and nuanced than first impressions and assumptions about gender equality suggest.*

*Keywords: Gender, mathematics, discursive challenges, Norway.*

## Introduction: Presenting two discussions in the education debate in Norway

Current debate in Norway addresses how boys are outperformed by their female peers, from the early school years onwards. Led by Camilla Stoltenberg, Director General of the Norwegian Institute of Public Health, a National Commission on Gender Equity in Education was convened to explore gender differences in school and make recommendations to address inequities. Their report, published in February 2019, concludes that there are differences in girls' favour in the Norwegian educational system (NOU, 2019). The Commission's work has gained a lot of media attention, leading to headlines such as "Girls continue to storm ahead of boys in school"<sup>1</sup> (Solvang, 2017). While Camilla Stoltenberg has strongly expressed her worries about boys, academics such as Harriet Bjerrum Nielsen (2017) and Kristoffer Chelsom Vogt (2018) have challenged this view in public debate, arguing that it over-simplifies complex gender relationships in current Norwegian society.

Mathematics is not a central focus in this domestic discussion, apparently because differences in test results between boys and girls are small. Girls are performing slightly better than boys in mathematics, but the gap is less noticeable in comparison with other subjects and reading (Backe-Hansen, Walhovd, Huang, 2014; Nordtvedt, 2013; Statistisk Sentralbyrå [SSB], 2017). However, Norwegian students' overall level of performance in mathematics has caused school authorities a headache since the "PISA-shock" of 2000, in which Norway did not perform well in comparison to other countries, triggering major policy-level attention on the improvement of mathematics teaching, including the introduction of National Tests in reading, English and numeracy in grades 5, 8 and 9<sup>2</sup>.

---

<sup>1</sup> Translated from «Jentene fortsetter å rase fra guttene på skolen»

<sup>2</sup> These are distinct from national level examinations in mathematics in grade 10, at the end of lower secondary school.

My experience as a secondary school mathematics teacher has meant that I have frequently seen students who seem to give up on mathematics during the years in upper secondary school, or on the other hand begin to connect to mathematics. Reflecting on the issue of Norwegian students' poor results in mathematics, I have wondered why some students seem to change their attitude towards mathematics during these crucial years of early adolescence. Hence, I embarked on a longitudinal study of students in a lower secondary school mathematics class, aiming to understand their developing relationships with mathematics, whether in a positive or negative direction.

Having tracked a class for one and a half years from 8<sup>th</sup> to 10<sup>th</sup> grade, I noticed gender dimensions in the 10<sup>th</sup> grade which are not captured by the general discussion of gender and education in Norway. This unexpected emergence of gender patterns led me to look more closely at the current debate. In this paper, I describe how a longitudinal analysis of individual students' trajectories in this class provides a very different account of gender in comparison to basic test statistics. I will argue that the ongoing debate on gender, education and mathematics has to be both more nuanced and given more attention, in order to be fair to all the students in the Norwegian educational system.

### Setting the scene: “Class A”

“Class A” is a 10<sup>th</sup> grade class (age 15) in a lower secondary school in Norway, just outside Oslo. The school is situated in a high income socio-economic area with a largely well-educated population, of whom the majority are ethnic Norwegians. I have been tracking “Class A” since midterm in the 8<sup>th</sup> grade (age 13), observing classes and holding focus group interviews. These data are supplemented with information on students' test<sup>3</sup> performance and teacher assessments. “Class A” is in general a high-achieving class with results remarkably better than the national level in mathematics, even those one grade above. The average grade in their 9<sup>th</sup> grade final test was 4,65, in comparison with national results in 10<sup>th</sup> grade examinations of between 2,9 and 3,6 in recent years<sup>4</sup> (SSB, 2017).

	Average grade in 8 <sup>th</sup> grade	Average grade in 9 <sup>th</sup> grade
Boys	5,0	5,2
Girls	4,25	4,4

**Table 1: Average grades for boys and girls in 8<sup>th</sup> and 9<sup>th</sup> grade**

Table 1 illustrates the picture gained from the basic statistics for boys and girls in 8<sup>th</sup> and 9<sup>th</sup> grade. These give the impression that boys are performing remarkably better than girls in this class. If we go beyond average grades a more nuanced picture appears. As we can see in Table 2, at the end of 9<sup>th</sup> grade, all boys are labelled as high achievers in the terminology used in the Norwegian assessment system (students achieving grade 5 or 6). Their grades are largely stable or improving, and only one boy is an exception to this pattern. The girls not only lag behind the boys in terms of basic grades, but, as a group, their grades seem to be more unstable, either remaining static or declining. Just one

<sup>3</sup> These are school-level tests, designed by the teachers.

<sup>4</sup> The Norwegian grading scale in grades 8-10 runs from 1 to 6, with 6 as the best possible grade to achieve.

girl improved her results from 8<sup>th</sup> to 9<sup>th</sup> grade. No girls achieved the top grade in either 8<sup>th</sup> or 9<sup>th</sup> grade, although four boys did so in 8<sup>th</sup> grade and three boys in 9<sup>th</sup> grade.

Test Grade	Number of boys achieving each grade		Number of girls achieving each grade	
	8 <sup>th</sup> grade	9 <sup>th</sup> grade	8 <sup>th</sup> grade	9 <sup>th</sup> grade
6	4	3	-	-
5	3	5	6	5
4	2	1	3	4
3	1*	-	3 (2*)	1

**Table 2: Overall patterns of attainment by gender (\*Moved to a group for struggling students)**

Given the current debate on education, gender and mathematics, this emergent gender pattern was unexpected. The apparently more unstable situation of girls in “Class A” led me to question whether gender matters or not in Norwegian mathematics classrooms. Could “Class A” be just an exception from the norm in Norway? Thinking further on this question, a contrary question presented itself: “Could it be that the binary gender debate in Norway needs further nuancing in order to bring genuine equity for both boys and girls in Norwegian mathematics classrooms?” Could it be time for a discussion of the challenges for girls as mathematics students in the Norwegian context where gender is ostensibly not an issue? The importance of scratching beneath the surface of the debate on gender, education and mathematics in Norway thus became difficult to ignore and is my aim in this paper.

### **The context of gender, education and mathematics in general in Norway**

The current debate on education and gender in Norway emphasizes that girls outperform boys. When it comes to school results, data from the Norwegian Central Bureau of Statistics (SSB) show that girls perform better than boys in almost every subject except gymnastics. The gender gap is most significant in Norwegian and English, and least in mathematics (SSB, 2017). The high school drop-out rate is higher for boys, and the general picture in higher education is that girls are in the majority in universities and colleges (Hollås, 2007). With this established reality of gender patterns in education, there is little room for worrying about girls, while ensuring boys’ success is at stake.

However, although women may be in the overall majority in higher education, this is not the case in the STEM area, where in Norway they are in a minority (Hollås, 2007; Olofsson, 2016). International studies of this situation in the Netherlands and the Nordic countries have labelled this phenomenon “the gender-equality-paradox” (Stoet & Geary, 2018), noting the contradiction between high rates of women’s emancipation and hence gender equality in these countries and their underrepresentation in STEM higher education. Even though this pattern is also known in Norwegian statistics and has gained attention in the past (Tønnessen, 2018), it seems that it has been forgotten in the current debate.

Consideration of why women are a minority in the STEM area in Norway suggests that the years before students make their choices for higher education must be influential. It makes sense to look for traces of this pattern in the field of mathematics in the secondary school years, since mathematics

is a key subject for all students who intend to continue with study in the STEM area. Girls' situation in mathematics is in danger of becoming a blind spot in this domestic debate on gender and education.

### **Digging beneath the surface of gender equality issues in Norway**

To move beyond a binary picture of gender in the Norwegian education context, we need to draw on different data from that provided by the SSB analysis of test results. PISA 2012 (Kjærnsli & Olsen, 2013) not only presented data on test results, but also on students' relationships with mathematics. Nordtvedt's (2013) analysis of PISA 2012 was that although girls performed slightly better than boys, there were no significant gender differences in mathematics performance in Norway; differences were more prominent in reading and in English. However, when it comes to students' relationships with mathematics, another perspective on gender and mathematics appears. Jensen and Nordtvedt (2013) reported that boys scored more positively on intrinsic motivation, stamina, assessment of their own capacity in problem solving, self-perception and self-efficacy. Focusing on extrinsic motivation and anxiety, while there were no differences in the former, girls scored more highly on the latter.

Turning to national test data from the 5<sup>th</sup>, 8<sup>th</sup> and 9<sup>th</sup> grades, 2017 data show that girls achieve better results in reading, while boys have better results in numeracy (UDIR 2017a, 2017b). These results are in line with those of previous years. Even though boys seem to be ahead of girls according to these national tests, statistics show that when it comes to the 10<sup>th</sup> grade examination in mathematics, they do not gain better grades, suggesting a decline in the last year of high school. As the SSB (2017) notes, the tests differ in terms of both form and content, but they nevertheless raise issues regarding gender which suggest that we need to understand more about students' experience of mathematics.

At the end of lower secondary school, students choose different education pathways. Bjørkeng (2011) reports that girls' participation in the more theoretical mathematical pathway for science drops from 48% in 11<sup>th</sup> grade to 40% in 13<sup>th</sup> grade, even though they perform better than boys on the same pathway. Bjørkeng (2011) argues that girls have a need for better grades than their male peers do, in order to choose this mathematics pathway. She concludes that although girls often have equally good results as boys, they have less motivation and poorer perception of their skills, corresponding to the conclusions of PISA 2012 and drawing attention to the impact of girls' relationships with mathematics on their participation in post-compulsory mathematics, in spite of their better grades.

### **Discursive issues in gender and mathematics in international and Scandinavian contexts**

“Whether the issue is gender difference or gender equity, in the Nordic countries the underlying issue will always be equal opportunity” (Wedegge, 2007, p. 252). If equality of opportunity is the pathway towards gender equity, it is difficult to see why women are still in a minority in STEM and the mathematics pathway for science in egalitarian Norway. However, international studies have shown the impact of discursive challenges for girls who study mathematics, where mathematics is inscribed as a male domain (Mendick, 2005; Rodd & Bartholomew, 2006). In the Scandinavian context, Brandell and Staberg's (2008) research in Sweden finds that despite the country's “fairly good record concerning gender equity” (p. 495), female participation in intensive mathematics programmes is 38% in upper secondary school, dropping to 30% at undergraduate and 26% at graduate levels. They found that even in the egalitarian context of Sweden, mathematics was more likely to be perceived as

a male domain among high school students. Boys had more positive relationships towards mathematics, and while both boys and girls conceived of mathematics as difficult and unattainable, these negative qualities were seen as more applicable to girls. Szabo (2017) similarly reports that boys and girls in accelerated mathematics classes in Sweden differ in their experience of mathematics.

Foyn, Solomon and Braathe's (2018) study of high-performing 10<sup>th</sup> grade girls in Norway also reports on the discursive challenges for girls in mathematics. They document the social cost of being a "clever girl" and its effect on the dynamics between students in this group. In line with these findings, With and Solomon (2014) found that the dominant Norwegian discourse of gender equality seemed to have little impact on upper secondary school students' attitudes towards mathematics. They found that girls positioned themselves as "just" hard workers and as lacking natural ability for mathematics. These studies suggest that there are challenges for high-performing girls when making choices to study mathematics, even in the Norwegian context.

## Returning to "Class A"

The importance of understanding more about students' relationships with mathematics than basic statistics can tell us is illustrated further by looking at "Class A" from another perspective. Looking beyond the impression given by the students' overall results, and instead exploring individual trajectories in mathematics in the period from the second half of 8<sup>th</sup> grade and throughout 9<sup>th</sup> grade, suggests a complex picture of gender in mathematics.

Figures 1 and 2 show individual students' trajectories in mathematics as they move through grades 8 and 9. Close inspection shows a pattern of gender differences which appear to be important. As we can see, boys show a more stable development than girls. Focusing on Figure 1, five of the boys gained better results at the end of 9<sup>th</sup> grade than at the beginning of 8<sup>th</sup> grade. One shows a drop at the beginning of 9<sup>th</sup> grade, but is back on track at the end of 9<sup>th</sup> grade. Another has lost his top mark, but he is still achieving very good results and these could be interpreted as stable with a slight dip. Turning to the girls, their individual trajectories show a more unstable situation. Figure 2 shows that there is only one girl whose results improve. The rest of the girls are in a more unstable situation, either declining or showing a dip before getting back on track. The girls' unstable situation is a potential indicator in terms of their future as mathematics students.

**Figure 1: Boys' grades from grade 8 to 9, based on written tests and teacher assessment combined**

**Figure 2: Girls' grades from grade 8 to 9, based on written tests and teacher assessment combined**

Data from focus group interviews adds a further interesting perspective. Those girls who described themselves as enjoying working with mathematics in 8<sup>th</sup> grade did not maintain their positive attitude during 9<sup>th</sup> grade. None said that they still enjoyed working with mathematics. On the other hand, boys who expressed positive attitudes toward mathematics in 8<sup>th</sup> grade maintained this view in grade 9. The most stable higher achieving girl in the group expressed a very negative attitude towards mathematics, using expressions such as “I really don’t see the point”. A final comment worth mentioning is that, in 8<sup>th</sup> grade, the teacher named just one girl among the best students in mathematics. She was not on the teacher’s top list in 9<sup>th</sup> grade.

### **A need for expanding the debate of mathematics and in Norway**

Having argued that the debate on gender, education and mathematics is more complex than the impression given by basic statistics and average grades, my claim is that we need to take a more nuanced view of the role of gender in mathematics. Including data on students’ attitudes and relationships to mathematics, the course of individual trajectories and the role of popular discourse and peer cultures in student choice underlines the complexity of the issue. Knowing that women are underrepresented in the STEM area, combined with knowledge of discursive challenges for girls as students in mathematics in the educational system, my conclusion is that there is a gender dimension in mathematics in Norway which we need to be aware of. Maintaining the binary picture of boys struggling while girls effortlessly succeed in school will not be fair to either boys or girls.

The problem of girls being in a minority in mathematics for science is not being treated as in need of attention in the Norwegian context. Quoting Harriet Bjerrum Nielsen (2017a), it seems as if the alarm is louder when there is a problem for boys rather than for girls. From an economic point of view, failing to give this situation further attention means that Norway will suffer from the lack of women with important skills in mathematics in the STEM area. More theoretically, there is little basis for such a binary conception of boys and girls, and it does disservice to both (Francis, 2012).

The case of Class A shows the importance of conducting longitudinal, qualitative studies of students in Norwegian schools in mathematics. Important knowledge about the situation in mathematics will get lost if we continue to rely only on basic statistics and ignore issues of relationships towards mathematics and the dynamics of the mathematics classroom. My preliminary analysis raises issues which cannot be captured by the ongoing debate, and the emerging gender pattern shows the

importance of scratching beneath the surface. Finally, these words from Harriet Bjerrum Nielsen (2017a) will highlight my conclusion: “Those who think that boys are being neglected in schools nowadays have most probably not been in a classroom for a long time”.

# The relevance of mathematics and students' identities

Andualem Tamiru Gebremichael

Universitetet i Agder, Norway; [andualemtam@yahoo.com](mailto:andualemtam@yahoo.com)

*This paper reports on a project, which explores the relevance of mathematics to students in an Ethiopian school. The data collection, which involved group interviews, was undertaken in 2010-2011. The analysis process identified themes that captured diverse perceptions of relevance and students' identities. The focus of this paper is on diverse aspects of students' identities and their relationship with students' perceptions of the relevance of mathematics. The analytic framework is cultural historical activity theory. The results indicate that the students' perceptions of relevance and identity are dialectically related.*

*Keywords: relevance, identity, mathematics curriculum, dialectical relation.*

## Introduction

This paper reports on data collected in 2010–2011. It is part of a research project, which was launched in 2009, and had two phases: a pilot study and a main study. The participants were students of a *preparatory* school (equivalent to an upper secondary school) in Ethiopia. The study examined students' perceptions of the relevance of mathematics to their future goals, their everyday life and society. Previous studies have investigated perceptions of mathematics' relevance focusing on upper secondary school (e.g. Sealy & Noyes, 2010; Black et al., 2010) and middle school (e.g., Masingila, 2002). Sealy and Noyes (2010) identified three different categories regarding the perceived relevance of mathematics to students' future goals: usefulness, exchange value and transferable skills. They note how students' perceptions are varied across different schools, and argue that such variations are linked to differences in the social and cultural situations of students as well as differences in the social context of the schools. They assert that the mathematics curriculum and its pedagogy should be framed in accordance with these varied perceptions of relevance.

Black et al. (2010) relate students' identities to the exchange value and use value of mathematics focusing on students' aspirations to study mathematically demanding subjects and their future career plans. They argue that the exchange value and use value of mathematics frames students' motives for studying mathematics. Use value relates to how mathematics enables one to pursue a vocation, and exchange value refers to what mathematics offers, e.g. it may enable one to join the university or obtain an academic degree. Black and colleagues suggest that identity develops alongside the motive, students' identities influence their perceptions of the use value and exchange value of mathematics.

Students' perceptions of the relevance of mathematics to their everyday life has also been examined previously (Masingila, 2002). Masingila's study is about students in Kenya. Her aim is to close the gap between students' experiences of mathematics in the classroom and its use in out-of-school contexts. She identifies six mathematical categories which are consistent with Bishop (1988): counting; measuring; explaining; playing; locating; and designing. Furthermore, some studies relate mathematical identities and perceptions of relevance to students' cultural backgrounds (e.g., Nasir, 2002; Nasir & Saxe, 2003). Nasir's (2002) study highlighted how students establish a sense of identity as learners in relation to their African-American cultural backgrounds. She argued they learn better when tasks

relate to their sociocultural backgrounds, such as playing dominoes and basketball. A similar study by Nasir and Saxe (2003) reported that students experience tensions between how they are situated in school and in out-of-school cultural practices (Nasir & Saxe, 2003). This body of work highlights how identity relates to race, and its influence on power (Nasir & de Royston, 2013) supporting Gutiérrez (2013) who also calls for the sociopolitical turn in exploring racial identity in mathematics education.

The Ethiopian sociocultural context has peculiar features and its schooling has a peculiar history. Before the introduction of modern education in Ethiopia, there have been traditional education associated with Islam and Orthodox Christianity. Modern education was introduced in Ethiopia around the beginning of the 20<sup>th</sup> century (Wagaw, 1979). In 1908, a modern school was opened in Addis Ababa (Hoot, Szente, & Mebratu, 2004). It was named after the Emperor, Minilik II, who ruled the country in that period. Modern education was not in line with the country's needs in some ways, where many of the subjects were languages such as Arabic, English and French (Wagaw, 1979). Wagaw asserts that though local languages such as Amharic and Ge'ez were taught as subjects, the language of instruction was not any of the local vernaculars (the language of instruction for the participants in the current study is also English). Although education was considered as a gateway to getting a job, some parents were sceptical about 'modern education' fearing it would not maintain cultural values (Wagaw, 1979). According to Wagaw, the clerics also expressed concern about maintaining Ethiopian values, a worry shared by some scholars.

Participants of the current study were 16 to 18 years old, yet distinguished from the rest of their age group as they are considered as elites (high ability). Because they joined the preparatory school based on their success in the second of the three national examinations in the Ethiopian school system. They expect to join university after sitting the third and final national examination.

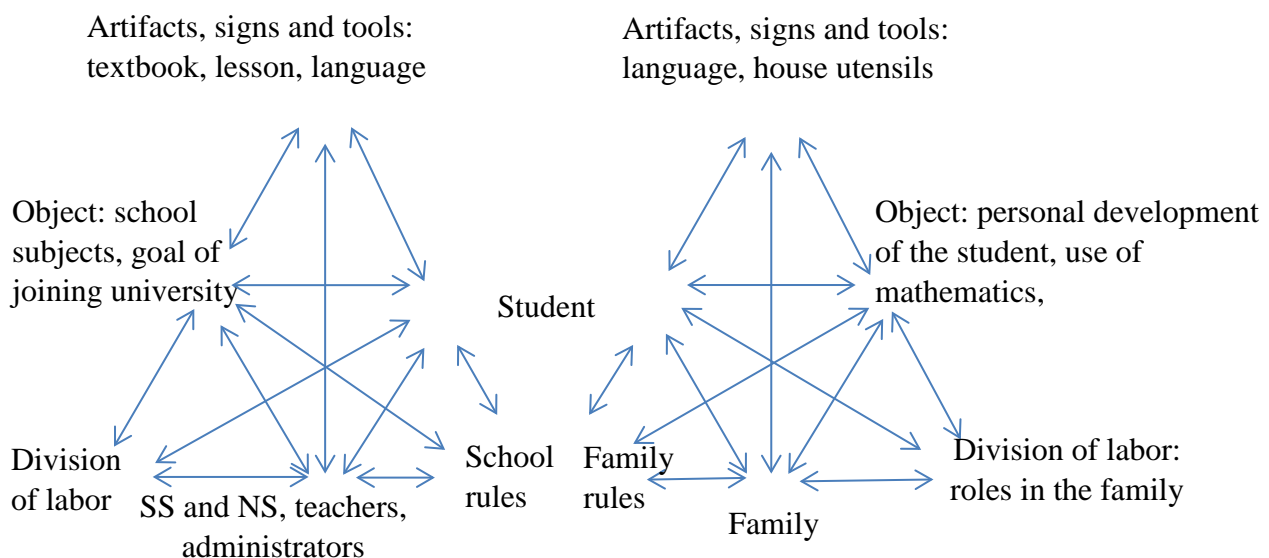

It is important to examine if students perceive that mathematics is relevant to their everyday life, society and future studies, and how students perceive the reason for learning and engaging with mathematics. Preliminary results of this study were reported earlier (Gebremichael, 2013). The purpose of the current paper is to show the relationship between perceptions of mathematics' relevance and students' mathematical identities. This introduction provides background information, which can help the reader to understand the results. In the following sections, I provide the theoretical and methodological issues before presenting the data and its analysis. I finalize the paper with my concluding remarks.

## **Theoretical issues**

Cultural historical activity theory (CHAT) is adopted as the theoretical perspective in this study. I employed Engeström's mediational triangle (Engeström, 2001) to understand how the students spend their time at home and at school. In the current study, the school and the family-life are considered as two different activity systems (see Figure 1). In the school, students experience and use artifacts, signs and tools such as textbook, lessons, etc. while undertaking actions towards the goals of learning mathematics and the other school subjects. The students are subjects of the schooling activity, and interact with the object (Roth et al., 2004). The object of an activity system consists of material objects, the motive, and the goals (Roth, 2007). The object of the school activity system consists of the motive and the goals, including students' future goals. The school's motive could be producing students who can succeed in the national examination to attend university and become capable of

solving problems of everyday life and society. The school's goals could be providing adequate knowledge for realizing the motive.

The artifacts, rules, community and division of labor mediate this interaction (Roth, 2007). There are rules, which govern members of the community. According to the rules, students should follow the classroom norms, attend to specific topics and sit examinations. Students are members of the school community, which also interacts with the object. These relationships are also mediated by the division of labor among members of the school community; the students and the teacher have different roles. There could also be differences in the roles of students. There are authorities, who have roles in deciding who will go to preparatory school and university. These authorities are represented by the school administrators, who enforce the rules set by these authorities and form part of the community. The students are divided into social science (SS) and natural science (NS) streams. These are also communities. The mathematics teacher also classifies them in terms of achievement level. The teachers of the various school subjects are members of the school community. According to the school rules, the students are operating in a school, which implements a nationally designed curriculum. Mathematics teachers are required to follow the nationally produced textbook (Federal Democratic Republic of Ethiopia Ministry of Education, 2010). This artifact influences another school artifact, the lesson. It is from this textbook that teachers give classwork and homework.

**Figure 1: Network of activity systems adopted from Engeström (2001)**

Figure 1 shows that the components of the activity systems are related to each other, and the double arrows represent the dialectical relationship between them. The figure represents two activity systems: school and family-life. As in the school activity, the student is subject of family-life activity, and interacts with the two objects as an actor. The object of the family-life activity system consists of material objects, home tasks, motive and goals. The motive of the family-life activity could be survival of the family, and one goal of this activity is a student's personal development. As part of this goal, the student engages in school tasks and family members provide support. Participants experience contradictions between the components of activity systems, and contradictions are considered as sources of development (Roth et al., 2004). Students may experience contradictions

between objects of the school and out-of-school activities. For example, as we will see in the data presentation, preparatory mathematics is hardly seen as useful in everyday life and society. These contradictions can be sources of development of particular perceptions of relevance and identity.

As long as there is activity, there is an acting individual, and the individual's identity is integral to the activity (Roth, 2007). Roth et al. (2004) distinguish between social and personal identity. In my study, the students seem to form aspects of identity as they participate in the school and out-of-school activities. Personal identity is where the individual student recognizes her/himself as such, and the student can also have a social identity where other members of the community recognize her/him as such (Roth et al. 2004). For example, a student is recognized by others as a high achiever. Roth and Lee (2007) suggest a third aspect of identity, collective identity, which an individual holds as a member of a group. Students are recognized as members of SS or NS streams. Collective identity is associated with the structure, which includes the components of activity systems (Roth & Lee, 2007). The national curriculum and the instruction language (which is foreign to them) are parts of the structure.

Artifacts, rules, community and division of labor mediate students' identities (Roth et al., 2004). For example, the teacher recognizes students as such based on their roles in the classroom. The division of labor also mediates the perceptions of relevance as the teacher directs students' attention to what might be of value for future studies in both the SS and NS communities. The school rules, which enforce the significance of success in examinations, can mediate the students' personal as well as social identities. The rules direct the students' attention to the importance of examinations scores for recognizing themselves or others. The teacher's recognition of students as such is also based on examination scores. In addition to the rules, which enforce the adopted curriculum, the school and out-of-school artifacts mediate students' identities as Ethiopians and perceptions of mathematics' usefulness. The contradictions, which they experience between the objects of the school and out-of-school activities, can be sources of development both in relation to their national identities and in addressing doubt about mathematics' usefulness in everyday life and society.

## **Methodological issues**

Group interviews were undertaken where each group had three students of the same sex and same class. Each group had high, medium and low achieving students. The intention of the grouping is to make students feel comfortable and remind each other of their respective experiences. Following Miles and Huberman (1994), I conducted data reduction through listening to the video-recorded interviews. This was done to simplify the data and obtain focus by deciding on which pieces of data provided the best idea of what each participant is saying. This data reduction process was influenced by the research questions and aimed to expose the students' perceptions of the relevance of mathematics. I made a table indicating the time and a description of what the interviewer and interviewees said. I transcribed the utterances of students that possibly exposed their perceptions of the relevance of mathematics and related issues. Then, I followed Miles and Huberman, and undertook coding. Miles and Huberman (1994) explain that coding of written transcripts can be undertaken based on the research questions and can employ concepts that are often used in certain theoretical perspective. The excerpts reported in the data presentation and analysis are students'

responses to the interview questions about the relevance of mathematics. After coding was completed, the next step was to examine the coded text to obtain themes (e.g., Miles & Huberman, 1994). I grouped the data segments with the same recurring topic into a particular theme.

## **Data presentation and analysis**

This section presents examples and analysis of the interview data under two subsections as follows.

### **Students' personal and social identities and the relevance of mathematics to future goals**

Students tell stories which relate to their identities and mathematics' relevance to future goals.

- Andualem: What do you want to study in the future? Is mathematics useful for what you want to study? How do you come to know about its use?
- Milkias: I want to study law. I ... do not think that it has mathematics ... Some teachers say to us, you [SS students] are not serious about mathematics because you think you do not need it in the future. [12<sup>th</sup> grade, SS, male]
- Andualem: Why do you learn and engage in mathematics?
- Beliyu: Primarily, to get a higher rank in the class. I derive pleasure from it [getting a higher rank] .... to get some knowledge because I have a target to meet.... The reason for coming to school is that I have a target that I hope to meet. In order to meet that target, I have to work now.... My target is to learn well and become someone in a field of study I like. ... I want to study medicine. [11<sup>th</sup> grade, NS, female]
- Sofia: It is joyful answering about something you know. .... It tells who you are. Let us say I graduated [from the university] and someone asked for help, how could I explain to him, if I do not know about it? However, if I know it, I can explain it without feeling ashamed. Therefore, I enjoy knowing it, even though I do not benefit from it.
- Andualem: Do you have such experience of helping others in mathematics?
- Sofia: I have little brothers and sisters and I help them ... My brother used to help me and advise me using his own experiences. Now, he is studying at the university. [11<sup>th</sup> grade, SS, female]

Identities and perceptions of relevance seem to emerge as students participate in school and out-of-school activities (e.g., Sofia's story). They emerge in the interactions between the subject, the communities and the objects of the activities (Milkias's story). The rules and the division of labor mediate students' identities as well as their perceptions of relevance (Beliyu and Milkias's stories). The school rules, which enforce that students should master certain mathematics topics and are ranked in the class based on examination scores, direct their attention to the relevance of mathematics to their future goals and to recognize themselves as such (see Beliyu's story). The division of labor also mediates their identities; for instance, their teachers recognize Beliyu and Sofia as high-achieving students. In the family-life activity, there is interaction between the community and the object, in which members of the family have roles in the student's personal development (e.g., Sofia's story).

The rules in family-life activity enforce that students should follow what their elders tell them to do and that elders should care for the younger. Members of the family recognize each other as such. The rules and the division of labor in family-life activity direct students' attention to recognize themselves as such in connection with mathematics. The division of labor also determines their perceptions of relevance as the teacher directs the students' attention to the relevance of mathematics with respect to their current community and their future study (Milkias's story). The students also perceive that mathematics has exchange value (e.g., Beliyu's story). The school rules, which mediate the students' identity, mediate this perception of relevance.

Other members of the community such as the mathematics teacher, recognizes the individual student as such (e.g., Beliyu and Sofia). This could be their social identities (e.g., Roth et al., 2004). There is a distinction between the areas of study, which students of SS and NS streams can progress to at university. There is also evidence of a collective identity (e.g., Roth & Lee, 2007). Based on their membership of either SS or NS streams, students recognize themselves or others recognize them as members of these communities, particularly, in connection with the implications this membership has for the use of mathematics in future studies (e.g., Milkias's story).

### **Students' national identities and the relevance of mathematics to the nation**

Students tell stories relating to national identity and mathematics' use in everyday life and society.

Andualem: Is preparatory mathematics useful in everyday life? In the society?

Akalu: I think that is the difference between the others [other countries/ societies] and us. They are more practical, but we grasp the theory and we get confused where to apply it. That is the problem. [11<sup>th</sup> grade, NS, male]

Haleluya: We learn to change our situations in a scientific way. Therefore, what we learn has to be related to our everyday life ... After consuming two or three pages, you get ... numbers. ..., what is its importance in my life? .... Or something related to ... society. Our country might not have a need for mathematics. However, in economics, many people want to know ..., and about business, about alleviating unemployment ... How we can use our resources. [12<sup>th</sup> grade, SS, male]

The students perceive that preparatory mathematics is hardly useful in everyday life and society. The lessons and the textbooks mediate the perceptions of relevance by offering mathematics topics with hardly any usefulness in everyday life and in Ethiopian society (e.g., Haleluya's story). These artifacts direct students' attention to recognize themselves in connection with their attending of a national mathematics curriculum. The rules and artifacts, which enforce the content of school subjects for SS and NS communities, mediate students' identities by directing the students' attentions to the available gaps (e.g., Haleluya's story). The division of labor, which gives students the role of grasping the theory and does not allow students to have a clear idea of where to apply it, directs students' attention to recognition of themselves as such (e.g., Akalu's story). In addition, participants experience contradiction between the objects of the school and out-of-school activities in Ethiopian society (e.g., Akalu's story). The experiencing of this conflicting situation can be a source of the development of national identity. The students belong to a society, which uses artifacts and has a cultural heritage that

are Ethiopian, though diverse. They operate in an Ethiopian school system, which enforces Ethiopian education policy. Students are experiencing a national mathematics curriculum, which hardly embraces the situation in Ethiopian society (e.g., Haleluya's story). They learn in a foreign language. These national features form the structure in which national identity emerges.

## Concluding remarks

The different aspects of students' identities and their perceptions of relevance are dialectically related (one presupposes the other). They recognize themselves as preparatory students, who have a future goal of joining university. Then, they perceive that preparatory mathematics has an exchange value in giving access to this future goal. Thus, an exposition of students' perceptions of relevance presupposes their identities. In addition, students' expositions of identities presupposes their perceptions of mathematics' relevance as having exchange value in giving access to university study, as well as in being ranked high in examinations. The teacher's recognition of students as SS and NS students presupposes the relevance of mathematics to these students' future study, which influences their perceptions of relevance. The students' perceptions of relevance also presupposes their identities as SS and NS students as well as their identities as future students of certain disciplines. The exposition of perceptions of mathematics' relevance to everyday life and society appears to presuppose who they are as mathematics learners in this Ethiopian situation. On the other hand, their expositions of national identities are based on perceptions of mathematics' relevance to Ethiopian society and everyday life.

The current study exposed national identity, which is different from ethnic or racial identity (e.g., Gutiérrez, 2013; Nasir, 2002; Nasir & de Royston, 2013; Nasir & Saxe, 2003). These works attempt to examine identity of particular minority groups within a larger national culture (e.g., American culture, American school system where school rules enforce the American curriculum). But each national context has peculiar features. The sociocultural situations, including out-of-school activities, and the artifacts students experience in the school and outside of the school are likely to be different in various national contexts. National identity is a collective identity, and consistent with Roth and Lee (2007) the focus is on the structure. It is important to examine this identity in national contexts with peculiar features of the structure including adopted curriculum, use of language foreign to them, etc.

Therefore, mathematics education in Ethiopia must consider the sociocultural situation in which it sits. The situations that separated parents from students, in the introduction of modern education, still appear to prevail in the students' learning of mathematics. Students feel detached from their society with respect to the usefulness of mathematics. Further investigations need to be undertaken in this direction.

# Social inequalities in mathematics from a socialization theoretical point of view – Analysis of problem-solving processes of students

Belgüzar Kara<sup>1</sup>, Bärbel Barzel<sup>2</sup>

<sup>1</sup>University of Duisburg-Essen, Germany; [belguezar.kara@uni-due.de](mailto:belguezar.kara@uni-due.de)

<sup>2</sup>University of Duisburg-Essen, Germany; [baerbel.barzel@uni-due.de](mailto:baerbel.barzel@uni-due.de)

*Keywords: Problem-solving, diversity, inequality, habitus*

## Theoretical background

In the recent German school curriculum, mathematical problem solving is anchored obligatorily as an important competence for mathematics learning. Since 2008, competence expectations for problem solving have explicitly indicated what the pupils are supposed to have acquired at the end of grade 4 (Ministerium für Schule und Weiterbildung des Landes Nordrhein-Westfalen, 2008). But empirical research results indicate that the demands can generate inequalities with regard to social origin (Cooper & Dunne, 2000; Lubienski, 2000). Achievement studies confirm the impact of socio-economic status on mathematic achievement (Stubbe, Schwippert, & Wendt, 2016). Research in mathematics education on social inequalities in the acquisition of mathematical competences observes different achievement in dealing with problem solving tasks specific to social class (Cooper & Dunne, 2000; Piel & Schuchart 2014). The study by Lubienski (2000) shows differences between students with different socioeconomic status (SES) dealing with problem-centered materials. The analyses show, for example, that,

In general, lower-SES students focused more on giving the right answer to a question (...), whereas higher-SES students were more inclined to discuss a method or an idea. (...) lower-SES students were more likely to use language in “common-sense” reasoning that was closely tied to the context of the problems. (...) Higher-SES students were more likely to contribute in relation to abstract, strictly mathematical contexts and to use generalized language and reasoning. (p. 369)

Based on the theories of Bourdieu (1987) and the research work of Lareau (2011), in the study presented here, the problem-solving process is analyzed from a perspective of socialization. The theory of habitus (Bourdieu, 1987) is used as an analytical tool for the mediation between the individual problem-solving process and the structural conditions of the social background. Lareau (2011) identified two milieu-specific child-rearing approaches and characteristic practices associated with the two educational styles: Middle-class families concerted child rearing on cultivation, working-class families concerted child rearing on accomplishment of natural growth. In particular, Lareau (2011) describes the two approaches as differently beneficial learning environments and socialization conditions for school practice. For example, while the discussion and argumentation between child and parents is an essential feature in the child-rearing approach of concerted cultivation of the middle classes, the child-rearing approach of accomplishment of natural growth of the working class is characterized by direct instructions. If the characteristics of child-rearing approaches are considered in competence expectations and the inherent structure of problem-solving, origin-related differences in competence development can be expected through habitual dispositions. The danger

that mathematical competence expectations have undesired impacts for less privileged students, which in turn can have the consequence that accessibility to mathematical contexts and the intended learning processes become more difficult or blocked, is subject of this investigation.

## Design and methods of the study

The praxeological approach theory establishes dialectical relationship between objective structures and structured dispositions of the acting actors and serves as the epistemological fundamentals for the investigation. A mathematics performance test and student and parent questionnaires were used to select and classify pupils according to mathematical achievement level and social background. Data was then collected within the framework of individual clinical interviews during the processing of a total of three mathematical problem-solving tasks to get an insight into possible differences in the process.

## Results

The preliminary analysis according to the phases model of Schoenfeld (1985) gives an indication of milieu-specific ways of acting through the phenomenon of the abridged analysis and exploration of mathematical problem-solving tasks of students from families of less privileged origin. The focus on a direct approach like one-word-answers without complete comprehension of the task has so far only been observed in students of less privileged origin. The correct answer seems to be more important than the understanding or discussion of the task which is unfavorably supported by the abridged analysis and exploration.

# **Towards guidelines for the analysis of teaching materials in linguistically and culturally diverse mathematics classrooms**

David Kollosche

Pädagogische Hochschule Vorarlberg, Austria; [david.kollosche@ph-vorarlberg.ac.at](mailto:david.kollosche@ph-vorarlberg.ac.at)

*An ongoing research project aims at analysing and improving materials for teaching mathematics at German community colleges to non-native speakers of German. This paper first gives details on the circumstances of the study. Because of a lack of empirical research on the analysis and design of appropriate teaching materials for multilingual mathematics classrooms, this paper then discusses research findings from socio-political, linguistic and socio-linguistic perspectives and theoretically deduces guidelines for the analysis and improvement of the teaching materials.*

*Keywords: Multilingualism, learning problems, instructional materials, sociolinguistics, community colleges.*

## **Analysing teaching materials for multilingual mathematics teaching in Germany**

As a basis for teaching elementary mathematics to adults who experienced difficulties with mathematics, the German Community College Association had both a curriculum and teaching materials developed for corresponding courses (Deutscher Volkshochschul-Verband, 2017). Course contents are organised in three different entry levels, beginning with a therapeutic approach to dyscalculia, covering basic arithmetic operations with bigger numbers, and arriving at secondary school mathematics contents which are considered useful in private and vocational environments. The development was pursued on the basis of empirically founded theories of learning mathematics but the materials were not themselves tested in practice. In a follow-up project, which is headed by the author of this paper, the practical usefulness of the materials is to be evaluated theoretically and empirically with the aim to guide and implement improvements. It is paramount to understand that the teaching materials constitute the central manifestation of the idea of the course, for teachers in German community colleges, even those teaching mathematics, are usually laypersons in mathematics who orient their teaching by the materials available. Apart from the questions in how far the available materials mirror the educational philosophy of the curriculum and whether they are practical to use with students who experienced difficulties with mathematics, the evaluation project lays a special focus on the suitability of the materials for learners whose first language is not German. Irrespective of the other goals of the project, this paper will illuminate *how teaching materials in mathematics can be analysed for their suitability for non-native speakers of German*.

Despite a substantial increase in research publications on multilingual mathematics classrooms during the last two decades (e.g., see the edited volumes of Barwell, 2009; Barwell et al., 2016; Halai & Clarkson, 2016; or, for the German case, Prediger & Özdiil, 2011), insights on suitable material is still scarce. In her recent meta-study of all 51 anglophone journal articles on mathematics education in multilingual classrooms published between 1970 and 2012, Setati Phakeng (2016) found only six articles that explicitly discuss didactical and methodological aspects of teaching in such environments, whereas the majority of the publications focusses on linguistic explanations for critical moments in the learning process. As Prediger and Wessel (2011) argue, the same is the case for the German

research community, “for up to now there are relatively few empirically founded insights on the question what constitutes special linguistic and subject-related obstacles for multilingual learners of mathematics and with which support (of empirically tested efficacy) such obstacles can be overcome” (p. 163, my translation). Clearly, the question of material-use in multilingual mathematics classrooms has yet to be studied, a task that cannot be achieved in this project. As the goal of this project is to analyse available teaching materials from the perspectives of multilingual learners, *the following discussion sets out to synthesise the results from previous studies on multilingual mathematics classrooms and to deduce guidelines for the analysis of teaching materials*. Accordingly, it can be understood as an early theorisation of material use in multilingual classrooms.

### **The specific situation of Germany and its community colleges**

As this project is located at community colleges in Germany, some information on the local circumstances is required to interpret the following discussion from an international perspective. Although Germany knows some autochthonous languages other than German, some of which are accepted as official languages in small regions of Germany (e.g., Danish and Sorbian), plus some regional languages (e.g., Low Saxon) and a large variety of regional dialects of High German, Germany constructs its national identity as a monolingual country. Immigrants are expected to learn German and school education is almost exclusively organised in German. In most cases, multilingualism is based on immigration. Nearly every fourth German citizen has an immigration background (i.e. at least one parent born with a nationality other than German). Many immigrants, mostly but not exclusively of Turkish descent, were invited to West Germany in the 50s and 60s as so-called guest workers, stayed and founded families. In addition, people with German ancestors resettled to Germany in the last decades, mostly from the former Soviet Union. Germany has also welcomed a large variety of refugees with an especially large population from Syria, Iraq and Afghanistan arriving in the last years. Consequently, education in Germany faces a wide variety of cultural backgrounds and proficiency in the German language, with many students of immigrant background being born and educated in Germany, some speaking mostly German with their parents, and some having been learning German for a few years only. Nevertheless, the German situation differs a lot from the situations in bilingual communities (as on Malte, in French Canada or in Spanish-speaking communities in the USA), in classrooms with different regional languages (as in South Africa or India), and in classrooms with revitalised a language (as in Ireland). Therefore, it has to be checked carefully in how far research results from these socio-cultural settings can be transferred to the German situation.

The German educational system appears to be ill-equipped to face the challenges of multilingual classrooms, given that, irrespective of intellectual capability, an immigration background is highly correlated with under-average achievement in national assessment (OECD, 2007). As a lack of proficiency in the German language has been shown to influence learning negatively, the perceived achievement gap is mainly being associated with language deficits (Herwartz-Emden, 2003). Indeed, a recent study with 766 pupils of Turkish descent attending a German primary school labelled about a half of this population as not competent in German, seeing their chances to participate in the German-speaking classroom substantially limited (Dollmann & Kristen, 2010). All in all, estimates assume the proportion of students who did not learn German as a first language to lie around 20%,

thus identifying a large proportion of the student population in risk of being disadvantaged by the German school system (Chlosta & Ostermann, 2008). In regard to mathematics education, studies suggest that the under-achievement of multilingual learners can partly or even totally be explained by language deficits (e.g., Heinze, Herwartz-Emden, Braun, & Reiss, 2011). For example, differences in achievement between first and second language speakers of German disappeared when problems were presented symbolically instead of verbally (Heinze et al., 2011). Some authors go as far as claiming that “subject learning can essentially be understood as language learning”, thereby accentuating the focus on linguistic obstacles towards the learning of mathematics (Gellert, 2011, p. 98, my translation). Consequently, research in the last two decades has aimed at explaining how multilingual students in German mathematics classrooms are systematically disadvantaged and at exploring how education can create a supportive and inclusive environment for such students.

However, the situation of students in German community colleges differs from the situation of students in regular schools and has not yet been studied in relation to mathematics education: Students in mathematics courses at community college attend these courses voluntarily, as adults they have more extensive life and work experiences, and they assume to have problems with mathematics. As a consequence, different to the situation in the regular school system, mathematics courses at community college are first and foremost concerned with learning mathematics in a supportive environment rather than with simultaneously improving the mastery of German.

### **On the politics of multilingualism in mathematics classrooms**

Discourses on language use in public education are usually ideologically biased as they closely interfere with national language, minority and immigration policies. Such bias has also been found in research. For example, Leung, Harris and Rampton (1997) revealed that the anglophone discourse on multilingual classrooms implicitly assumed that multilingual students do not use English at home, primarily learn English in school and thereby face comparable problems, altogether assumptions that do not withstand any closer analysis. Nevertheless, they constitute the group of those whose first language is not the language of instruction as a distinct group of others, sharing specific problems and needing the same kind of support. It is in such ways that the multilingual student is constructed as a deficient learner in spite of the fact that multilingual students differ a lot in their abilities and needs (Halai, Muzaffar, & Valero, 2016). As will be explained later, an alternative explanation resting on the distinction of certain language registers allows to analyse a wide range of linguistic difficulties of first and second language speakers simultaneously, leading the focus away from first language status and towards language proficiency in general.

Linguistic obstacles for multilingual learners are partly created by the classroom policy of promoting German as the only language of communication in school (except in foreign language classes). This limitation means that often students cannot use all of their language resources, not even when they work in pairs or groups with their language peers, thus denying them options of participation that have proven highly beneficial (Meyer, 2016). Instead, students learn not to use their first language for their learning endeavours, a process that leads to a devaluation of immigrant languages (which, in an act of resistance, might be used as a solidary signs of a specific ethnic affiliation) and to the installation of German as the hegemonic language in science and politics (Setati, 2005). This

attribution of social status to the different languages spoken by the students leaves its traces in the micro-structure of education. For example, Schütte (2009) revealed that mathematics teachers communicate the meaning of mathematical language almost exclusively in an implicit form, thereby systematically leaving behind many multilingual learners who rather require explicit explanations (Tshabalala & Clarkson, 2016, provide similar results from English-speaking classrooms).

In an attempt to discuss the situation of multilingual mathematics learners from a perspective that does not construct under-average achievements as an issue of individual deficits, recent studies have promoted the ideas to valorise multilingualism as a resource (Barwell, 2018). Indeed, several studies prove that competent multilingualism is closely related to achievement in mathematics, probably because of meta-cognitive abilities either pre-existent or acquired by the learning of multiple languages (e.g., Clarkson, 1992). In German mathematics classrooms with students of Turkish background and a policy of free language use, code-switching between German and Turkish has proven beneficial for the understanding of mathematics (Meyer, 2016; Özdil, 2011). However, Swain und Cummins (1979) found that positive effects of the use of multiple languages in class depend on a language-friendly atmosphere where the learners' first languages share the same privileges as the language of instruction. In this respect, Meyer (2016) reports that he needed to have students teach him how to count in Turkish before they would feel comfortable to use Turkish in classroom conversation.

### **The impact of differences in language proficiency**

Instead of focussing solely on the traditional categories of lexicon and grammar, a considerable part of differences in languages proficiency can more appropriately be explained by the analysis of different language registers. Already in the 50s, Bernstein (1996) started to analyse how the English language is used rather differently in different discursive situations and among different groups of society. He found that speakers of the working class often use a “horizontal code” which uses a particular set of vocabulary, rather easy grammatical constructs, and organises knowledge along personal stories and shared experience, while middle class speakers rather use a “vertical code” which uses more loanwords and nominalisations, more complex grammatical structures and an organisation of knowledge along universal logics. Above all, Bernstein also showed that students often lack the means to recognise the structure of the meaning-making process in the code they are not used to. This phenomenon results in substantial disadvantages for the participation of horizontal speakers in the primarily vertically organised discourse of school and mathematics education (Cooper & Dunne, 2000). In an adaption to the German situation, Gogolin (1988) differentiated between everyday language (*Alltagssprache*), erudite language (*Bildungssprache*) and subject-specific language (*Fachsprache*, in our case mathematical language), with each of them differing in their use of vocabulary, grammar and knowledge-organisation. For example, “if and only if” is a phrase that is typical for mathematical language but hardly used in everyday and erudite language.

While proficiency in everyday language can be obtained in about two years (Cummins, 2010), erudite and subject-specific German language takes four to eight years to learn for second language learners (August & Shanahan, 2006), creating a barrier for understanding and participation in the mathematics classroom (Gellert, 2011; Özdil, 2011). Vertical discourses in German can be extraordinarily difficult to decipher because of its synthetic grammar and extensive use of nominalisations, compounds,

dependent clauses, prepositional phrases and participial attributes – at times even causing German native speakers to pose linguistically problematic tasks as teachers (Rösch & Paetsch, 2011). Deseniss (2015) could show that students in Germany can much more easily describe the characteristics of erudite and mathematical language if their first language is German instead of any other language. However, proficiency in the vertical registers of the first language has been shown to support the acquisition of the vertical registers in the language of instruction (Celedón-Pattichis, 2004). It becomes clear that language-related learning barriers are not only a matter of immigrant background but to a large extent a question of a learner's socio-economic background. *En passant*, the same holds true for the learners' familiarity with situational context which might differ tremendously between learners of different socio-economic conditions, for example when it comes to planning a bicycle trip or reading the bicycle's speedometer (Rösch & Paetsch, 2011). So, while it is true that everyday vocabulary might pose a barrier for non-native speakers of German, for example when words such as "to remove", "to spend" or "to disappear" are used to explain subtraction, large parts of the mathematical language are equally unknown to speakers of the language of instruction, starting already with the quantity-based conception of words such as "more" and "less" (Walkerdine, 1988). The same is certainly true for the understanding and use of register-specific grammar. Consequently, a language-sensitive teaching of mathematics education should explicitly address the characteristics of the vocabulary, phrases and grammatical structures involved in erudite and mathematical language, for the sake of both non-native and native speakers of German (Gellert, 2011).

Finally, another problem arises from linguistic interferences, that is from the confusion of seemingly similar but functionally different linguistic structures in two languages. Confusion begins at the pre-verbal level, for example with different number symbols or with differences in marking bundles of thousands and the beginning of decimals (for "3,835.4" Germans write "3.825,4"), and extend to verbal constructions of numbers (Germans literally say "seven-and-fifty" instead of "fifty-seven") and other mathematical objects ("three-fifth" literally translates to "in five three" in Turkish) (Frenzel, 2017).

### **Consequences for the analysis and design of teaching materials**

Instead of a summary of the ideas discussed above, the last section of this paper will deduce guiding questions for the analysis and design of teaching materials in multilingual mathematics classrooms. The underlying assumption is that, especially in educational environments where teachers are usually laypersons in mathematics, materials and the comments provided on them can provoke or hinder certain activities in the classroom and thus influence teaching substantially. In this sense, the question is in how far materials can constitute or induce new barriers for multilingual learners and in how far materials can be designed to include and support multilingual learners. The guiding questions are:

(1) *Does the text of the material include everyday language words of German which are used to clarify the meaning of mathematical content but might be unfamiliar to some learners?* Research in language-sensitive education proposes to collect and discuss the relevant vocabulary, to illustrate it in labelled pictures, to document it in various forms of word lists and to train its use by filling word puzzles or writing mathematics-related texts (Leisen, 2011).

(2) *Does the text of the material feature unnecessarily complex grammatical forms?* While such grammatical features can be understood as attempts to introduce learners to vertical registers of the

language of instruction, they pose a barrier for the understanding of mathematics for many students. Often such text can be reformulated into more comprehensible versions (see, e.g., Griebhaber, 2011).

(3) *Does the material allow or provoke an explicit discussion of the new mathematical vocabulary and phrases that come with the covered mathematical content?* If not, materials such as mind-maps with appropriate words and phrases or building sets with chunks of mathematical phrases can help (Leisen, 2011). Mathematical writing appears to be an activity that strongly supports learners in building up competence in vertical registers (Morgan, 1998), probably because it grants students more time and chances for revisions for the struggle with the language than verbal communication does. Reports from an unexpectedly successful Latino classroom in the United States, where a culture of mathematical writing was cultivated, support this assumption (Chval & Licón Khisty, 2009).

(4) *Does the material encourage learners to compare German formulations and notations with other languages in order to identify possible misunderstandings based on linguistic interference?* Even monolingual students may profit from an explicit comparison of different possibilities of expressing mathematical ideas. Such a comparison may be introduced by easy prompts: “If you speak any other language than German, do you know how to say this in the other language? Which way do you prefer?”

(5) *Does the material allow or provoke the use of other languages in the learning process?* As Meyer (2016) discovered that students have often internalised the German-only policy of the classroom and are inhibited from the use of other languages, more or less detailed prompts to provoke the use of other languages seem necessary if the resources of other languages are to be used in the classroom.

(6) *Does the material build on situational contexts which might not be well-known to some students, especially because of cultural and socio-economic differences?* If it does, it would be worth to check if the context can be changed to one all students are familiar with, or if the situational contexts can be clarified before proceeding with the mathematical analysis of the situation.

These theoretically deduced guidelines do only constitute a first approach towards the research-based analysis and design of teaching materials for multilingual mathematics classrooms. They refer more closely to the situation in German community colleges than to other localities of mathematics education. Its usefulness will be tested when the available teaching materials of the German Community College Association are analysed first on-the-paper and then in practice. For reasons of word limitations, this paper could not include a closer discussion of ethno-cultural obstacles towards the learning of mathematics, which Setati Phakeng (2016) sees in danger of being neglected in the mostly language-focussed discourse in academia. For example, Deseniss (2015) could identify different beliefs about the usefulness of mathematics and mathematics education between native and non-native speakers of German and even between different groups of non-native speakers. More research will be needed to apply the insights from cultural, linguistic, sociolinguistic and socio-political perspectives on multilingual classrooms to the analysis and design of appropriate teaching materials.

# How do we teach mathematics to refugee students? A qualitative study of the teaching and learning of mathematics in International Preparatory Classes

Maike Lüssenhop<sup>1</sup> and Gabriele Kaiser<sup>2</sup>

<sup>1</sup>University of Hamburg, Germany; [maike.luessenhop@uni-hamburg.de](mailto:maike.luessenhop@uni-hamburg.de)

<sup>2</sup>University of Hamburg, Germany, [gabriele.kaiser@uni-hamburg.de](mailto:gabriele.kaiser@uni-hamburg.de)

*Although migration itself is not a new phenomenon, the rising numbers of refugees in Germany and Europe are influencing the population composition leading to greater diversity within our society. This particularly affects school systems, as a great number of refugees are of school age and have to be provided with adequate schooling. In this paper, we discuss how the German education system, in particular in the city of Hamburg, deals with the schooling and integration of refugee students in what are called International Preparatory Classes. We describe a research study, which is examining what aspects influence teaching practices in mathematics lessons in these classes for refugees. The study investigates how teachers in these classes design their lessons from a mathematical and a linguistic perspective, how they deal with the task of providing refugee students with adequate instruction and how students experience mathematics.*

*Keywords: Refugee students, teaching practices, mathematics classroom, diversity, mathematics education and language.*

## Introduction

[H]ow school systems respond to migration has an enormous impact on the economic and social well-being of all members of the communities they serve, whether they have an immigrant background or not. Some systems need to integrate large numbers of school-age migrants and asylum seekers quickly; some need to accommodate students whose mother tongue is different from the language spoken in the host community or whose families are socio-economically disadvantaged; some systems are confronted with all three challenges at once. (OECD, 2015a, p.1)

Indeed, it is a major challenge for the German school system to teach refugee students with limited knowledge of the German language and to provide them with adequate support. Refugee children and young adults are perceived as a vulnerable group with a diverse range of special needs. In Hamburg, refugees and other immigrant students attend International Preparatory Classes (IPCs). IPCs prepare them for admission into German mainstream classes. Currently, scarcely any research studies how mathematics teachers work with students in these particular IPCs. Moreover, little is known about how they design lessons while they are confronted with linguistic, cultural and performance-related heterogeneity (Benholz, Magnus, & Niederhaus, 2016). Supporting refugee students' development in general, and specifically in mathematics, is crucial for their participation in society and their ability to contribute to the society as a whole. Our study aims at contributing to close the existing gap in research but will also allow others (e.g., authorities) to use the knowledge gained for educational changes on several levels (Cornely Harboe, Mainzer-Murrenhoff, & Heine, 2016). In this paper, we present two case studies from two different mathematics classrooms. Sharing ideas and best practice examples in order to improve the schooling of refugees in the European Union and worldwide is of great importance for the international community as recognized by the OECD report (OECD, 2015b).

In the following, we introduce the current state of research on IPCs from a German perspective and present first results of our ongoing research.

## **National frameworks for IPCs**

Although German federal states implement different school-organizational models of teaching children and adolescents from refugee families, three basic models can be recognized:

- Integrative model: In this model, the students of refugee families are taught in regular classes with additional language support in German.
- Parallel model: In this model, children and adolescents from refugee families are taught in separate classes that are set up for them. The greatest amount of teaching is dedicated to the acquisition of the German language.
- Semi-integrative models constitute a transition between these two models: Students who are taught in IPCs can already take part in regular classes, depending on the level of subject-specific competences in individual subjects (Massumi & Dewitz, 2015).

The three models outlined here are also prevalent internationally (OECD, 2015a). Countries deal very differently with the schooling of refugee students. Some countries such as Iceland and Norway follow the integrative model (Ragnarsdóttir, Berman, & Hansen, 2017), others such as Spain follow the parallel model (Gorgorió & Planas, 2001).

The framework for IPCs of the local education authorities in Hamburg provides insight into the current situation of schooling of refugees in Hamburg and Germany, since each year school-aged refugee children and adolescents move to Hamburg with little to no knowledge of the German language. According to the Geneva Convention, all children are guaranteed the right to education. The Geneva Refugee Conventions (Article 21), the UN Universal Declaration on Human Rights (Article 26) and the UN Convention on the Rights of the Child (Article 28) as well as the German Basic Law (Article 3) explicitly encourage compliance with this right (El-Mafaalani & Kemper, 2017). In IPCs at different types of schools (primary/middle/high school etc.), refugee students are prepared for entry into mainstream classes.<sup>1</sup> The objective of IPCs is to enable children and adolescents to learn the German language and thus to facilitate their integration into the German-speaking environment as smoothly as possible. Students that are able to write in the Latin script, start in IPCs that focus on learning the German language and basic knowledge of other subjects. Students who are illiterate<sup>2</sup> or literate in a different script – such as Arabic – gain German reading and writing skills in literacy classes. These classes focus on reading and writing in the Latin script and on basic German skills. IPCs aim at providing a quick transition to an age-appropriate class, suiting students' individual education level at general or vocational schools (mainstream classes). Refugee students can be admitted into IPCs at any time of the year and stay in them for a period of twelve months. The number of students in each class is around 15. The language learning process in all different forms of IPCs is divided into two phases in the first year of schooling. In the first phase (basic level), students acquire basic knowledge in German and receive guidance in dealing with, and acting within, the

---

<sup>1</sup> Immigrant students from EU-countries or other countries are also schooled in IPCs. In our study, however, we focus on refugee students who recently and forcibly fled from their country of origin.

<sup>2</sup> By illiterate, we mean that these students can neither read nor write.

German-speaking world. This first phase should not be longer than 6 months. At the end of this phase, the parents receive information about the performance and learning development of their children in learning development talks organized by the teachers. These meetings advise parents on further schooling and acts as an exchange on how best to support the development of their children.

The second phase (advanced level) focuses on the preparation of the students for classroom communication and the use of subject-specific language in different subjects. After six months, students receive a transition certificate. At the end of the second phase, students transfer into mainstream classes and receive additional language tutoring for another year.

The basis for teaching in IPCs are the frameworks and curricula of German as a Second Language in IPCs at each school level, in which minimum requirements and assessment for performance are set. The level of difficulty of teaching is oriented towards the Common European Framework of Reference for Languages. Subject-specific instruction, such as mathematics, is based on the minimum requirements laid down in the curricula offered in each grade. The framework for IPCs in Hamburg focuses more on the macro level of the regulation of the schooling process than on the micro level of actually teaching the subject. It recommends, however, that teachers orient themselves towards the minimal requirements of the mathematics curricula for mainstream classes.

### **Current state of research on IPCs**

In empirical educational research (in general), there are numerous and comprehensive analyses of the educational opportunities of various groups of refugees. In particular, the research field covers studies on participation in education, educational transitions, acquisition of competencies, and school success. In-depth analyses focus especially on social background, gender and ethnic background and/or migration background. Despite this highly differentiated field of research, the long history and increased presence of refugees, it is surprising that the educational opportunities and conditions of refugee students have not been steadily researched (El-Mafaalani & Kemper, 2017). Unsurprisingly, however, since Germany had a high influx of refugees in 2015, interest in education policy and research into the education of refugees has increased. This interest is also reflected in the literature and more recent research publications (Kleist, 2017).

Nevertheless, a paucity of research is still especially obvious when the focus turns to subject-specific instruction in IPCs, including mathematics education. Some studies use ‘wordless methods’ of teaching mathematics to circumvent possible language barriers. In his study, (Oswald, 2017) used ‘wordless methods’ with adolescent refugees and found that it had a positive impact on the motivation of the students and the teachers. Furthermore, Mink & Sauerwein (2017) conducted a teaching project in one IPC on figured numbers and proofs without words. They found that only after intensive study of the material the mathematics could be understood, and it remained questionable whether students who see a visualization for the first time can use this to carry out complex proofs, since they are still unfamiliar with elementary mathematical activities. Despite the intention of these ‘wordless methods’, it is not possible to avoid oral explanations, which were difficult for participating students to understand. Most of the respective research projects implemented so far focus on language and mathematics (Prediger & Schüler-Meyer, 2018), or mathematics in the context of migration (Deseniss, 2015). In other words, this research does not consider mathematics lessons with refugee students and their teachers. Exceptions are the studies by Oswald (2017) and Mink and Sauerwein

(2017), which focus on new teaching methods for IPCs. However, there currently exists no research on the actual classroom practices of teachers in IPCs. Although an increasing number of textbooks and teaching materials for refugee students are published by publishers all over Germany, there is clearly a gap in scientific research concerning the needs and challenges of teachers and students in IPCs.

Apart from the German state of research, there exists an extensive discussion on the teaching and learning of mathematics in multilingual classrooms that highlights social, cultural and linguistic aspects of mathematics teaching and learning (Gorgorió & Planas, 2001; Moschkovich, Wagner, Bose, Rodrigues Mendes, & Schütte, 2018). As most of these studies focus bilingual or multilingual classrooms and not classrooms with only refugee or immigrant students, we can only draw partially on these studies. For example, Barwell et al. (2016) stress that situations of language diversity have been extensively examined, such as bilingual and multilingual context. They underline that there is a need in researching trilingual contexts where learners are exposed to home languages, a national and an official language. However, they do not focus on students that are second languages learners (sometimes referred to as minority learners, immigrant students) with different native languages. Furthermore, refugee students might come from countries with multiple national languages, which equals bilingual students, but most of them have no knowledge of the academic language, in this case German, at all, when they enter IPCs. However, Barwell et al. focus partly on second language learners. Gorgorió & Planas (2001) conducted research on language and socio-cultural aspects of mathematics education in a classroom with a high percentage of immigrant students and they are particularly convinced of the importance of continuing to study the teaching and learning of mathematics in multiethnic and multilingual situations. Moreover, they emphasize the need for continuing studies not only in terms of equity and social justice, but also in terms of the richness of the research ground.

Overall, these studies and the above-mentioned gaps in the research highlight the need for a deeper understanding of what is happening in the IPC mathematics classrooms, what affects the (teaching) practices of teachers and the challenges they face when it comes to teaching materials, previous knowledge of refugee students etc. This research project aims at narrowing this research gap.

## **Research questions and aims of the study**

Overall, it can be stated that the framework for IPCs does not offer advice for teachers on how to teach mathematics to refugee students except to focus on the minimum requirements of the same or similar grade of general schools. Furthermore, the analysis of the current state of research on IPCs in the previous section shows that there is a research gap in the field of mathematics in the context of IPCs relating to best practices, teaching materials and theoretical approaches. Hence, our study highlights findings from research that explores mathematical teaching practices and aims at researching mathematical teaching approaches and mathematical practices within the IPC mathematics classrooms.

Our research project investigates the following research questions:

How do teachers deal with the task of designing and implementing mathematics lessons for refugee students? What kind of practices and which materials do they use, and how do social, cultural and linguistic aspects influence the learning and teaching of mathematics in IPCs?

Overall, the aim of this study is to generate knowledge about how teachers design lessons, which theories from other subjects their lessons are based on, and whether these fit the needs of the students they teach. More insight is necessary on the challenges mathematics teachers are encountering in IPCs, and how they deal with them within the mathematics lessons in order to develop supportive learning environments for refugee students.

## **Design of the study**

The study is embedded in the project “Mathematics and refugees” at the University of Hamburg, a subproject of the state-funded research network “Everyday Mathematics as Part of Basic Adult Education”, the so-called “Hamburg Numeracy Project”. The research network focuses on (adult) numeracy practices and their use of everyday mathematics, focusing on particularly vulnerable groups, for example refugees and asylum seekers, over-indebted, and disabled persons. The presented study is qualitatively oriented and focuses on the IPC mathematics classroom and the practices of mathematics teacher and their students. The sample of the study consists of teachers and students from three comprehensive schools at lower and higher secondary level in Hamburg. For the data collection, we use different methods such as classroom observation, guideline-based interviews with the mathematics teachers and narrative interviews with 3-4 students from each class.

The study has been conducted in the last 6 months of 2018 and this paper emerges from a larger research project which we described above. At first, informal talks to gain a first impression of the research field have been carried out with teachers outside of the classroom. After that, participatory observations of four lessons each lasting 45 minutes have been conducted. From these observations and the literature we draw on, we generated questions for the guideline-based interviews. Each IPC-teacher has been interviewed for approximately one hour. The interviews focused on the question how teachers design mathematics lessons in IPCs, for example how they deal with the particular heterogeneity of the learning group, how they proceed methodically and didactically, which challenges occur and how they deal with them, and so forth. Moreover, we conducted narrative interviews with refugee students from each class. The interviews focused on the experiences of the students inside the mathematics classroom of their country of origin and in their new school in Germany. The data collection and analysis has been based the coding paradigm of Grounded Theory (Corbin & Strauss, 2015). All interviews conducted have been recorded and transcribed. Furthermore, the data collected has been or will be evaluated with MAXQDA.

## **Preliminary results**

In the following, we focus on two IPCs at two different comprehensive schools in Hamburg, which were selected as paradigmatic cases reflecting general characteristics of the whole database. We summarize selected aspects of the observation of four lessons in the mathematics classroom and informal conversations with teachers and students. In this paper, we name these classes IPC A and IPC B to distinguish certain aspects of the observation. Both IPCs are linked to grade 7/8 teaching groups (inter-year groups) situated in parts of Hamburg with a low social index.

Both classes consisted of approximately 12-15 students at the age of 12-16 years. The majority of the students came from Syria, Afghanistan and Iraq. According to both mathematics teachers, the students were very heterogeneous in terms of their mathematical competences and educational biography. Some students from Afghanistan had never gone to school before having fled to Germany,

others had finished primary or secondary school in Syria and directly joined the German system, and again others had not gone to school for many years. In addition, both classes had students from Eastern European countries, for example from Bulgaria, or students from countries such as Thailand, Turkey, Ghana and Togo.

### **Teachers' mathematics and teaching experiences**

The mathematics teachers of both IPCs had a very different educational biography but both were class teachers of the observed classes, meaning that they taught most of the subjects and lessons of their IPC. The teacher of IPC A completed her teacher education, worked and researched abroad, had a PhD and worked as a lecturer at university level in educational science, particular in multilingualism, migration and education. It was her first year teaching an IPC and the first time teaching mathematics to students. She emphasized that she did not study mathematics as a subject in her studies, but she had a very good knowledge of the didactics of German and German as a Second Language and carried out extensive research in the field of migration. The teacher of IPC B has completed his teacher education and taught mathematics in IPCs for seven years. He did not study mathematics as a subject at university but completed an additional course in mathematics some years ago. At that time, there was no specific teacher education program for IPC classes. Since the increase of new immigrant students in recent years, many teachers who have been employed for the newly created school classes have completed a German as a Second Language degree. Often these teachers have to teach mathematics lessons in their IPCs, also due to the existing lack of teachers of mathematics. This means that many teachers lack the didactic and mathematical knowledge of mathematics. In some cases, underqualified teachers were also recruited because the positions in the IPCs could not be filled otherwise. This highlights the fact that apparently many teachers have very different experience with IPCs and teaching mathematics as a subject.

### **Linguistic aspects**

Teacher A paid significant attention to the native languages of the students, which is in line with the accepted research results. A table with important German sentences hang on one of the walls of the classroom, such as "What does that mean in German?", "Good Morning", "Can you help me?". Students added a translation of these sentences in their own mother tongue. Throughout the school year, the teacher studied all sentences of the languages of her students herself. At the beginning of each week, students were allowed to test her language skills. Apart from this, language comparisons between German and the native language of the students were an integral part of the lessons. In addition, two of the weekly lessons in mathematics focused on subject specific vocabulary. With teacher B the picture was contrary. Even if some posters with German grammar were hanging on the walls of the classroom and some dictionaries were available, a set of rules was attached to the teachers table forbidding or avoiding the usage of native languages of students. This seemed to be a general rule for the IPCs of this school. This handling of the native language of the students contradicts findings from language teaching research and general pedagogy, and yet seems to be widespread.

### **Mathematical Aspects**

In IPC A, students were taught in cross-class teaching two hours per week in homogenous groups regarding their performance in mathematics, and the other two-hour classes on subject-based mathematical language in their original classes. Some students sat in groups according to mother

tongue, topics or performance. There were chalk-and-talk phases within the lesson and reflections on mathematical vocabulary. Work sheets with topics such as addition, subtraction, multiplication of fractions and subtraction of fractions with different denominators, text problems etc. mainly focused on basic mathematics. Students were working on different worksheets with diverse topics. After each lesson, the teacher collected the sheets, corrected them and handed them back during the next lesson. Furthermore, the teacher offered some enactive materials such as wooden fraction models. In IPC B, each student worked on his/her own work plan. The teacher talked to each student for 5-10 minutes and gave personal support, no chalk and talk phases occurred. Topics were similar to IPC A and focused on basic mathematics such as subtraction, addition, fractions and so on. In both classes, some students worked with the mathematics textbook that was being used in the mainstream classes they are supposed to transfer to after completing IPC.

## Discussion and looking ahead

The two case studies presented here emphasize the great diversity of the design of the lessons in IPCs and the learning opportunities provided by the two teachers based on the heterogeneous group that they were teaching. Socio-cultural aspects played a crucial role, as students seem to have very different backgrounds according to their previous educational development and different linguistic background (and possibly experiences with flight, conflict and/or war). The role of the linguistic aspects in the observed lessons was handled very differently by the two teachers and led to different learning environments. Drawing on the research results of Prediger and Schüler-Meyer (2017) and other scholars, who emphasize that the appreciation of the students' native language has positive effects on students' motivation and confidence, we find it a concern that only one of the two teachers was drawing on these findings. This might indicate that there is a need of further education in terms of the inclusion of the native language of the students.

Furthermore, the initial results of the study point out that the two teachers design their mathematics lessons very differently. Nevertheless, both of them tried to adapt their classes to the need of the students, in a way that they think is best for them. Earlier on, we demonstrated that there is no official curriculum for mathematics in IPCs and few adequate teaching materials that have been developed in the last years. This is also reflected in the initial results, as both teachers' lessons are mostly based on self-developed materials. Overall the two case study presented in this paper provide first insights into how teachers deal with the task of carrying out mathematics lessons to refugee students. The research seems to suggest that the educational background of the teachers influences the way in which they carry out this task, especially concerning lingual aspects and the role of mathematical content and the kind of its inclusion, but also how external factors influence the learning and teaching of mathematics, such as socio-political and socio-cultural aspects.

# Using photo-elicitation in early years mathematics research

Dorota Lembrér

Western Norway University of Applied Sciences, Bergen, Norway, [dorota.lembrier@hvl.no](mailto:dorota.lembrier@hvl.no)

*In this paper, I examined the use of photo elicitation interviews as a method for gathering data from parents, whose views are not often investigated in research in early childhood mathematics education. The parents shared and discussed photos of their children engaged in mathematics. This method for gathering parents' views is investigated using Bourdieu's theoretical lens of the field. The findings suggest both advantages and disadvantages that established rules of the field which could interfere with or enhance relationships. Photo-elicited interviews can provide insights into parents' knowledge, experiences and views, revealing broader perspectives on mathematics activities at home. However, the choice of photos influenced the interview, limiting or silencing parents if they were unable to recognise any mathematics in what the children were doing in a photo.*

*Keywords: Home environment, parents, photo elicitation interview, research methodology*

## Introduction

In this paper, I discuss the advantages and disadvantages of using photo elicitation focus group interviews to gain insights from nine parents, who have children in preschools in Norway, about mathematics education at home. In a photo elicitation interview (PEI), a single photo or a set of photos are used as stimuli during a research interview (Hurworth, 2004).

Vasilyeva, Laski, Veraksa, Weber, and Bukhalenkova (2018) concluded that parents' involvement in school and preschool practices has a significant impact on children's development and learning. Studies have shown that there is generally a positive association between parents' engagement in their children's education and students' academic outcomes (e.g., Galindo & Sheldon, 2012). These studies concluded that parents and family members have a role in children's achievement in preschool and school. Therefore, it is not surprising to find that parents' funds of knowledge when interacting with children at home have been recognised by researchers (Björklund & Pramling, 2017), with parents and families being acknowledged as children's first educators (Phillipson, Gervasoni, & Sullivan, 2017). The relationships between parents, teachers and children has consequences for children's engagement with mathematics.

Nevertheless, issues remain about the kind of role parents are expected to have. Most research focuses on parents' limited ability to support their children's mathematics learning at home. Although parents might feel welcome at preschool (Hujala, Turja, Gaspar, Veisson, & Waniganayake, 2009), Whyte and Karabon (2016) suggested the communication is typically one-way, from preschool to home. Although parents, such as immigrant parents, can have different views (Civil, Bratton, & Quintos, 2005), their views about mathematics done at home are often marginalized or absent in mathematics education research (Milner-Bolotin & Marotto, 2018). It is the teachers' expertise which is expected to enhance parents' awareness of their children's learning of mathematics (Streit-Lehmann, 2017). Consequently, some researchers, such as Anderson and Anderson (2018), have stressed the need for more understanding of the mathematical experiences of young children that adults mediate at home. To conduct research which values parents' views about mathematics education for young children at home there is a need for an appropriate methodology.

To better understand the views of parents about the mathematics that their children engage with at home, I wanted to use photo elicitation interviews. PEIs are considered more effective in gaining insider views than information gained through exclusively verbal methods (Hurworth, 2004). In PEI, participants are asked to take photos on a topic (Epstein, Stevens, McKeever, & Baruchel, 2006). Using the photos as stimuli in interviews supports participants to reflect on a moment or an action (Torre & Murphy, 2015). Frith and Harcourt (2007) stated, “We saw the photographs as a reference point to be used in conversation rather than an objective representation of reality that has a meaning independent of these conversations” (p. 1342). Conversations around photos of everyday life can provide understandings how both the photographer and the viewer construct meaning. Thus, PEI are considered to facilitate dialogues that participants find enjoyable (Pain, 2012) and which enhance collaborative and participatory forms of data collecting.

In early childhood studies, photo elicitation has been used in several ways to try to gain participants’ views on particular issues. Clarke and Robbins (2004) stated that discussions between parents and teachers when sharing photos taken by the parents created opportunities for a better understanding of aspects of activities captured in these photos: “The nature of these and the parents’ ability to articulate them was a surprise to many of the teachers in the project” (p. 181).

In this paper, I examine photo elicitation interviews as a methodology for gathering data from parents about their views on mathematics. The paper is divided into three further sections. First, I outline Bourdieu’s notion of a field as the theoretical framework for identifying the advantages and disadvantages for gathering data in this way. Secondly, I describe my study of parents’ views, before, finally, I use examples from my study to discuss PEI’s advantages and disadvantages.

## **Theoretical framework**

Parents’ involvement in and preparations for PEI occur within power relationships, as they are influenced by the knowledge they have about the subject of mathematics and how this knowledge is then described by the researcher. As well, within a social situation such as the group interview, there is a negotiation of power and this determines which parents’ views are heard. Thus, I have used Bourdieu’s notion of a *field* to consider how parents and their social positions are located (Bourdieu & Wacquant, 1992). Social positions refer to the knowledge, skills, resources and dispositions that parents take into their discussions with other parents and myself as the researcher. These inform the types of relationships that parents have in society and with the institution of preschool.

Key aspects of Bourdieu’s notion of a field are production and the material resources of power and capital. Capital refers to the variety of resources, noticeable and hidden, through which agents can further their aspirations and achieve “success” in the field (Bourdieu, 1975). A social position arises from an interaction between the rules of the field, the parent’s habitus and the parents’ capital (social, cultural and economic). The field is the social arena in which positions are available for agents, each with a different habitus (behaviour, dispositions to act in the social world), and which are constructed by relations between agents in this field. These relations are bound by rules, which are dynamic in that they can differ within the field and be changed and adjusted by circumstances. Additionally, understanding the impact of capital can help to unpack and explain what is hidden, for example, in the parents’ photos as it determines what is valued as mathematics activity. Identifying the capital

that parents make use of within PEIs provides an opportunity to see how this affects their sharing of views.

Habitus can also help to unpack the set of dispositions parents use to identify the mathematics in their children's activities, as these are rooted in their experiences of schooling (Grenfell & James, 1998). Habitus includes a sense of parents' place in a social situation and the status they bring, such as how comfortable they feel in an interview and their views about what is expected of them to say or do.

### **The data in my study**

Using Bourdieu's notions, I discuss the advantages and disadvantages of photo elicitation interviews by using examples from my study of nine Norwegian parents' (4 males, 5 females) views on mathematics activities their children engage in at home. This is a typical sample size for photo-elicited research involving both the production of visual data (photos) and participants' discussions and reflections of the photos (e.g., Clark-Ibáñez, 2004; Miller, 2015). Participants received guidelines in a letter about what to photograph (children engaged in mathematics), how many photos to take (10), time to complete this task (one week) and where to send the photos after completing the task. No data that could identify participants, such as income, education and family structure, and demographic details, were collected. The parents were asked to attend focus group interviews in which some of the photographs were used as stimuli. In group one, there were four parents, in group two five. During the interviews, the parents used their photo and those of others as a basis for sharing their views about children's mathematics activities.

In reflecting on my use of PEI, I was able to identify both advantages and disadvantages associated with gaining an insider view on parents' understanding about their children's mathematics activities. In the reflection, I also need to consider how my position as the researcher and facilitator of PEI may have affected my understanding. I come from a working-class background, was a preschool teacher in a low-income household area, and am a mother of two children. My research focuses on mathematics education in preschool and at home. These personal characteristics and experiences influence my position in the field and affect my habitus and doxa (organising the rules of PEI in the field of social situation to discuss photos). Reflecting on PEI supports me to understand how my own background can hinder or support me making sense of parents' views.

### **Discussion**

Reflecting on PEI contributed to identifying advantages and disadvantages in generating data from it. In particular, the parents' cultural capital seemed to affect their sharing of views about their children engaging with mathematics.

#### **Disadvantages of PEI**

Drawing on Bourdieu's theoretical notion of the field, I could identify some of the parents' available positions which were affected by parents' habitus and dispositions to discuss mathematics activities and the status they brought to the situation. Although earlier research suggested that PEI is an effective strategy to gather data for investigating parents' views, it has some challenges.

PEI requires participants to be provided with more or less detailed instructions about what to photograph. However, the field in which these instructions are given in my study is that of research, a field in which not all participants can determine the implicit rules. For example, the participants

needed to understand how the photos would be used, including ethical, privacy and sampling issues, but this information was not provided. It was clear that their interpretation of these issues shaped how and what they took photos of in their home environments. This sometimes resulted in the parents not being able to describe their views on the mathematics young children could engage in. For example, a parent stated, “I think he shows fingers too, but I did not manage to take a picture to capture that”. For a researcher, knowing the context of the discussion stimuli is important. However, like this parent, it did not always occur to the participants to take notes about the circumstances of a photo. This lack of knowledge about the research field affected how much each photo contributed to the discussions. If the parent who had taken the photo could not remember why they had taken it, then it was often difficult to provoke a discussion amongst the other participants. Thus, it seems that I needed to be more aware of the habitus and dispositions that the participants brought to the task.

Although it is stated that PEI offers insights that might not be achieved through verbal-only methods, the usefulness of the data is still dependent on the interviewing skills of the researcher. Within the field of research, the researcher is accepted as being more knowledgeable about how to do the research than participants are. This power dynamic can affect participants’ willingness to discuss the topic if I, as the researcher, impose my own view, as occurred in the following example:

- Researcher: Is Yahtzee a game that you play a lot in Norway?
- Parent 1: It is a (holiday) cottage phenomenon.
- Parent 2: Yes, yes, yes!
- Researcher: Okay.
- Parent 1: Yes, everybody plays Yahtzee.
- Parent 2: All Norwegians that have respect for themselves have Yahtzee in their (holiday) cottages.
- Researcher: So, you can claim that all children know Yahtzee in Norway?
- Parent 2: Yes, I think so. They probably have the same in preschool too.
- Researcher: But I mean, do you have it at home?
- Parent 2: Yes, it’s quite common to have it at home.
- Parent 3: Yes, it’s a regular game to have at home. Yes!

The rules of PEI used by myself, as the researcher to construct or, as Bourdieu stated, to produce, circulate and exchange knowledge, pushed the conversation in a particular direction through my follow-up questions. Although I was seeking clarification, the parents’ responses suggest that the conversation was somewhat awkward as they are not entirely sure what was being clarified and why. The parents’ answers suggest that they assumed that I as the researcher would have the same knowledge (cultural capital) about what would occur in holiday cottages, and as this was an experience shared by all Norwegians, it appeared not need elaboration. They seemed confused as to why I continued to question them about the presence of Yahtzee in Norwegian homes. The status they brought was not embedded in my habitus for understanding parents’ embodied views.

In the Yahtzee, example parents were placed in a position of having to convince me, which could affect their behaviour in later discussions, hence limiting their possibilities to develop a sense of trust in how I would make sense of the information they were providing. In another example, the angle of the photo of the outdoor game “stone skipping” did not provide an immediately recognisable mathematical situation for myself or other parents.

Parent 4: I think of distance, but I am unsure if this is correct.

Researcher: What are you doing?

Parent 4: My son will throw stones in the lake and has two stones, one in each hand. I do not know if you see here (pointing on the photo). No, you cannot see his hands!

Researcher: What you are thinking about this situation?

Parent 4: I think distance, but he does not. I do not know, maybe how far he should throw the stone?

The lack of response by other parents suggests that they perhaps did not share the social capital hidden in Parent 4’s photo, and thus did not “see” the potential mathematics that the child was engaging with. Whereas Parent 4’s habitus could be explained as a disposition to act in this activity, for the researcher to see a possible identification of mathematics in “stone skipping” to some degree was uncertain.

As well, differences in social capital between parents and the researcher can interfere with providing recollections about the content of the photo and its social context. For example, after a father spoke about playing an app on a tablet, a mother asked me, as a researcher, for an opinion about children playing apps. That parent seemed to consider that I had a form of cultural capital that gave me the possibility to evaluate the value of another parent’s point of view.

In summary, PEIs have some disadvantages, related to how parents’ positions are located in the field. As the facilitator of the PEIs, I, as the researcher, had more status and the social capital that I brought with me seemed to be considered more relevant for this research field. This unacknowledged valuing could limit the possibilities for parents’ views to be valued appropriately in the discussions. As a researcher, I needed to be aware of how I could overcome these disadvantages.

### **Advantages of PEI**

Bourdieu’s notion of field situates parents’ positions (knowledge, skills and relationships) in interactions in which their habitus (behaviours and dispositions) is evident. From this notion, I could identify opportunities for gaining insights into parent’s views about mathematics activities at home for young children in the PEIs. In my project, 23 coloured photos were used to stimulate discussions. Parents used the photographs to discuss the mathematics they considered their children engaged with. Parents’ positions were constituted by the system of the relationships they had to each other as parents and having an interest in discussing and presenting their views on children’s mathematics activities at home.

Sharing photos engaged parents in discussions about their children engaging in a variety of mathematics situations at home (e.g., gaming, cooking, playing, building etc.). Some situations, such as playing the board games Ludo or Yahtzee, were recognized in the photos by many parents, suggesting that they shared social capital that allowed them to relate to these activities. This then

allowed them to share their understanding about their family resources to describe different strategies the family used to play these games with children. Within the social field of the group interview context, there were possibilities to uncover what parents had in common as the first educators of young children. The similar strategies for supporting children in the games, such as manipulating the game so that younger siblings had a chance to win or participate, suggested that the parents could “read” each other’s habitus and confirmed each other’s views on these situations being mathematical. The parents supported each other in a confident manner when discussing their children’s actions, for example, when they were using dice. In the field, there are different positions available for persons with different habitus, and they are equipped with different capitals. Their capitals can be valued differently and also in different ways (Bourdieu, 1975). Bourdieu stated that what is valued is important as what it is, and different ways of being engaged in mathematics at home may also be given different values. This is an example of a condition for being qualified as a capital.

For some parents, the sharing provided them with new ways to think about everyday activities. For example, a parent stated:

In a busy day at home, it is a bit difficult to think about mathematics, it’s not easy at all. You are not thinking about it. But once you are aware of it, you are going to find it, you’ll find it all over the place.

From the everyday activities, these parents could identify and discuss mathematics and its possible relevance in home environments. As considered with cultural capital, parents’ views about mathematics activities can be gained through PEI and it becomes relevant to reflect on mathematics from their point of view.

The photos taken in environments well known by the parents supported them to express their point of view. The parents’ photos had been taken because the parents believed that they showed their children engaging with mathematics, based on their knowledge of what could be labelled mathematical. As parents’ participation in PEI includes a system of power relations between positions, the parents seemed to share cultural capital by recognising that they also engaged in similar situations, which meant they were able to take powerful positions as experts within the research field. This was in contrast to situations where PEI did not support the sharing of views – a result of one person, often me as the researcher, being seen as having more valuable knowledge or by acting as though that was the case.

## **Conclusion**

Drawing on Bourdieu’s notion of the field to reflect on the impact of using PEIs in early years mathematics research, habitus was a tool for understanding parents’ dispositions and had to do with conditions that are set up in the field. The way in which the parents understood the structure of PEI and how this knowledge was incorporated in their habitus was influenced by the new experiences of discussing photos with others. The condition of PEI was structured internally in terms of power relations between parents and researcher and had an impact on gaining insights into parents’ views about mathematics activities of young children. Parents views are embedded between structure, their habitus and capitals and are representations of implicit relations that affect what is considered as mathematics activities. In the field of research, parents struggle over the unequal distribution of and

definition of what are the most valued views. Therefore, it is a matter of distinguishing the most worthwhile efforts and methodology where parents' views can be carried out.

A field can be considered as a social arena of the positions available for persons, each person with a different habitus. In a certain field different capitals are valued (Bourdieu, 1975). As a method for gathering data, PEI includes certain kinds of rules which made a limited set of positions available for those who participated in a study. PEIs are described as enabling participants to record and reflect on their own perspectives and concerns, by promoting dialogue about issues and views through discussions about photos (Miller, 2015). When initiating PEI, I had no doubt that parents' dispositions to take an active position in discussion required me to be reflective. As the parents had already identified mathematics activities at home when they decided to take specific photographs, they came into the interviews situated as experts. In the parts of the interviews in which they could situate themselves as experts, parents were able to discuss the different photographs by talking about the mathematics that they saw their children engaged with at home.

However, there were challenges in using PEIs which hindered the parents in retaining the position of expert in those interviews. As a researcher, I was located within the research field, where I organized the rules and guidelines for PEI. Although the formal rules were sent out with the information letter, there were invisible rules connected to the field of research that the parents were unaware of such as keeping notes about the photos they had taken, which affected the data which was produced.

The PEI methodology is a social activity, where parents could contribute with a certain kind of knowledge, based on their capitals and habitus. Parents suggested that taking photos gave them new views on the activities their children engage in at home. They also found the task to be of interest and helpful to unpack their own views about mathematics education for young children at home. As a researcher, reflecting on the use of PEI to gather data has helped me understand how my actions can support or limit parents providing their views about the mathematics that their children engaged with at home. This is important if I am to be able to evaluate my own research questions as well as give information back to the preschool sector about the expertise that parents could have about mathematics activities that could be used as a basis for activities in preschool.

*When it comes to appreciating school mathematics, there is a strong tendency to turn to the work of professional mathematicians as a reference. Although we see good reasons to do so, in this paper we question that reference to professional mathematicians as a “standard” for school mathematics and pay more attention to what the practice of mathematics in school itself has to offer. This raises significant political and cultural issues for school and research practices. The concept of doing/mathematics is discussed for this purpose, along with that of proffering.*

*Keywords: School mathematics, mathematicians’ practices, reference, doing/mathematics.*

### Introduction

Historically and culturally, learning mathematics has often, if not always, been closely associated with the work of professional mathematicians. Evidence of this, for example, can be found in ancient Babylonian and Egyptian traditions, where training seems to mingle formal education and apprenticeship (Karp & Schubring, 2014). Closer to us, when the French decided to establish widespread public education after the 1789 Revolution, they naturally turned to mathematicians like Monge, Laplace, Lagrange, and Carnot to design and teach mathematical curricula to young people. One also thinks of Klein, who supervised the publication in Germany of many volumes on teaching mathematics at all levels. This turn toward mathematicians appears quite natural, because, after all, professional mathematicians are said to be the experts of the discipline: They spend their days doing mathematics and so they probably know better than anybody what mathematics is really about and what one needs to do in order to know about mathematics and practice it (Hersh, 1997).

Hence, we could say we have good reasons to refer to what mathematicians do to think about what is going on in schools. For one, paying attention to how mathematicians work helps us see the difference between doing mathematics and learning about mathematics (Papert, 1972). We also realize how much asking questions and trying out ideas is central to this practice (e.g., Brown & Walter, 2005; Lockhart, 2009). Also, we understand why problem-solving or mathematical modeling cannot be reduced to linear 4- or 5-steps procedures (Schoenfeld, 1985). Looking at what it means to do mathematics for a professional mathematician thus provides us with good grounds to challenge the simplistic idea of direct instruction and the possible overemphasis on the procedural part of school mathematics. Attending actual professional mathematicians’ work is also important to humanize the discipline: mathematics is often seen as cold, uncreative, abstracted from real-life, homogeneous, and indubitable: all aspects that a close account of professional struggles and enjoyment of mathematicians can help transform (Burton, 2004).

This being said, we are, however, also familiar with the disastrous political upshot of the “new math” movement started in the 1960s, when governments tried to include “up to date” topics such

as modular arithmetic, matrices, symbolic logic, and Boolean and abstract algebra in elementary and secondary school. This was also the case in the vivid discussions we know as the 1990 “math wars” in the US and elsewhere. The political role that mathematicians played in school mathematics was then talked about in relation to so-called traditional and reform mathematics philosophy and curricula; these ideas were often criticized as being conceived in an isolated way and disconnected with the everyday reality of the classroom. Nevertheless, it is still common today to hear mathematicians comment on how school mathematics “should” be: One thinks of Wolfram (2010) in the US, of Liu (2000) in Canada, and of Villani and Torossian (2018) in France.

Mathematicians undoubtedly have something to contribute to school systems, but the nature of that contribution might be interesting to discuss and not left unquestioned. Thus, in this paper, we raise a number of these questions, and in turn raise cultural and political issues, by reflecting on the issue of *referring* to mathematicians’ practices. Through drawing on the concept of *doing/mathematics* (Maheux & Proulx, 2015, 2018), we consider what the practice of mathematics in schools offers, and even *proffers*, as we call it, to mathematics itself as a discipline.

### **Referring to mathematicians’ practices**

One way of examining how mathematicians’ work relates to school mathematics is to think about how we use this work to talk about what is, or needs to be, happening in schools. As mentioned above, it is quite common to refer to mathematics as practiced by professional mathematicians to express or orient what students ought to be doing in a mathematics classroom. Schoenfeld (1994), for example, describes true mathematics as the science of patterns and thus suggests that curricula be organized in the form of mathematical inquiry resembling what mathematicians do. The idea of being “authentic” to what mathematics is really about is also often used to critique didactical approaches to teaching mathematics in schools in order to promote a variety of practices that are said to be better aligned with what mathematicians really do: for example, problem solving (Borasi, 1992; Lampert, 1990), modeling-driven curricula (English & Gainsburg, 2016; Lesh & Zawojewsky, 2007), and classroom culture (Bauersfeld, 1998; Papert, 1996).

This notion of referent, when considered in relation to mathematicians’ practices for school practice, is multifaceted. One of the facets consists of referring to mathematicians’ practice as what ought to be happening in the classrooms. This would entail tailoring students’ mathematical experiences to what doing mathematics represents for a mathematician and try to have them experience this. So, if much of what mathematicians do is read papers, ask questions, try to find answers to these, and eventually change the questions based on the answers they find, this is also what students ought to be doing in classrooms. Of course, we do not see this often, but *some* parts of it are easily selected from what mathematicians do as we decide what to ask of students.

A second facet is referring to mathematicians’ practices as considering them as an objective to attain, that is, as the finality of school mathematics work, and the end goal to achieve. In that sense, students are not expected to reproduce the mathematicians’ activity, but to prepare themselves to perform it. From this perspective, one could say that although students might need to start learning how to ask good mathematical questions, they might mostly need to “learn the basis” (or the basics) so they can later engage in mathematicians’ practices. This is a common view, especially in undergraduate mathematics. However, there is no easy agreement on what exactly students most

need as preparation to become mathematicians. For some, the answer to this question might be exactly what is suggested in the first facet.

A third facet is related to referring to mathematicians' practices as a means of devising classroom practices. In analyzing what mathematicians do, we can identify key elements around which educational practices or activities can exist. For example, one could draw on mathematicians' ways of discussing during conferences to organize classroom debates or boil down peer-review processes to students through checking one another's work in writing, or again transform mathematicians' lab interactions as small-group talk. Hence the activities considered are not necessarily direct examples of mathematicians' practices, nor are they done to prepare students to be mathematicians, but are mostly inspirations from which to guide the design of specific activities. That is, the starting point could even be any given school practice (like testing, lecturing, note-taking, homework) into which some of the "essence" of mathematicians' practices has been injected.

A fourth way of referring, more at a meta-level, is for mathematicians' practices to be used, referred to, as a source of justification of practices attempted in schools. For example, the idea of changing a mathematics classroom's ethos to make it more engaging for girls because we do not see enough of them in the professional community would be one example. Arguing in favor of introducing the history of mathematics because of its importance to the discipline itself could be another. Here, it is about mathematics as a practice, but more as an authority for justifying actions. Obviously, the three facets mentioned above can also be seen as a way of doing just that.

Although all these make sense for taking the mathematicians' practice as a referent, one can wonder if they are legitimate for thinking of school mathematics. Hence, aside from the habits of doing things like this culturally, aside from political agendas related to curriculum aimed at reproducing societies' current goals, one can wonder: is this reference to mathematicians' practices, in all their possible facets well aligned with school mathematics' practices?

### **Questioning professional mathematics as a referent**

If only to make more transparent the choices we make, the reference to mathematicians' practices is something to be examined. Indeed, a number of possible questions could be raised in relation to this reference. For example, who are the mathematicians to whom we are referring? Squalli (2010) answers this question, first by wishing to include all people who have a university mathematical background, but then arguing that we should be more inclusive and consider any person who uses or produces mathematics. This would include not only engineers, economists and many artists, for example, but also teachers of mathematics and even students who do mathematics every day. For Squalli, all these persons can be considered mathematicians because they are all engaged in activities that produce<sup>1</sup> mathematics at various levels, for diverse uses and needs. From this angle, the concept of mathematicians' practices as a referent no longer makes much sense: If everybody engaged with mathematics is a mathematician, then everybody acts as its own referent! Albeit lightly, this raises questions about the relevance of mathematicians' practices for school purposes. And many other questions can be raised on the matter, each leading to different viewpoints on the

---

<sup>1</sup> In the sense of making mathematics happen, causing it to take place, to come into existence. It thus includes both the invention of some "new" mathematics and realization of any mathematical work, since both are based on the occurrence of some mathematical activity, or, again, as one mathematician in Burton's (2004) study argues, re/creation for oneself.

use of professional mathematics as a referent for the classroom. We offer here a sample of these questions, as a range of reflections frequently heard of when discussing mathematics education matters. This list is obviously not exhaustive, nor does it raise all possible matters on the issue.

- It is said that mathematics is everywhere around us, that we use it all the time. Would it not be more relevant to use everyday life mathematics skills as a referent?
- Mathematics is an evolving domain, as are mathematicians' practices. How can we use mathematicians' practices as a referent for school if they are not fixed and established?
- Most teachers have not been trained as mathematicians. Is it reasonable to expect teachers to have mathematicians' practice as a referent if they have not experienced it themselves?
- For many, school mathematics should prepare for citizenship, for example, by reproducing values that society deems relevant. How is mathematicians' practice of any help for this, especially if mathematicians' work is seen as lodged in a space where relevance to society is rarely desired, or even cumbersome?
- We often assert that mathematicians have a tendency to conceive mathematics as a platonist/absolutist domain. Is this a reference aimed at for school mathematics?
- Mathematicians are not homogeneous and are widely oriented (topologists, algebraist, logicians, etc.) by diverse (kinds of) problems, expectations, goals, and so forth. When we refer to mathematicians' practices, to whom are we referring?
- Mathematicians engage in the solving and posing of problems never solved or encountered before. How is this a valid referent for school when most problems, if not all, already have the answers at the end of the textbook?
- Mathematicians do not gather in a room to solve, in a given time frame, problems imposed by someone else. How close can school be to professional mathematicians' context?
- We might generously estimate the number of mathematicians on earth at 100 000. This contrasts with millions of kids doing mathematics in schools. Is it fair to impose the view of a few on the many?
- Most (previous and current) mathematicians are white occidental males living in privileged countries. How equitable is it to aim at reproducing their practices in schools?
- We know that pure and applied mathematicians, as well as engineers and other professionals, do not use the same mathematics and do not do mathematics in the same way. How is this to be taken into account as a referent for school practices?
- Almost all mathematicians learned their mathematics in school and use that knowledge to create new mathematics. Would not professional mathematics then be considered as a form of applied school mathematics? Which would be the referent of which?
- Studies have shown that even in the university, classes taught by mathematicians do not align with mathematicians' practices. Hence, how is this "project" doable for schools if it cannot even be achieved in the university by the mathematicians themselves?

Each one of these questions could also be examined closely as a way to clarify why and how we think or not about mathematicians' practices as a reference for schools. These questions highlight how using mathematicians' practices as a referent for school mathematics is not trivial and hides diverse interpretations or outcomes, as well as agendas. But, while we see how the reference to mathematicians can be questioned, the notion of "referent" in itself can also be scrutinized.

### **Doing away with the referent? From referring to proffering**

Desiring a referent for school mathematics comes with a prescriptive attitude. Why do we wish to look at the classroom mathematical activity from the outside, if not to "judge" it, one way or another, in relation to something else? A question we might ask is: what does it mean to *refer* to something? The verb *refer* comes from the Latin *referre* meaning "carry back", from *re-* "back" + *ferre* "bring". We refer to professional mathematicians' work when we turn back to it in order to appreciate what is going on in school, to describe either what it is, what it is not, or what it can be.

Reference is a relation in which one object designates another. As such, it suggests the defined, rather static existence of these objects in themselves. Searle (1983) explains that descriptive content of the sentence "Aristotle was a philosopher" does not define the name (what is "Aristotle") but establish the name's reference. There is something called "a philosopher", there was someone called "Aristotle", and by saying "Aristotle was a philosopher" we do not at all fix or change who Aristotle was and what a philosopher is: we simply state an assignation relationship. This view on language is challenged by other linguists (e.g., Bakhtin, Wittgenstein) for that very reason: thinking that a word can actually represent something is too restricting in regard to how words live in actual languaging (where their signification changes with the intonation, the context, the intention, the response, and so on), and the continually evolving nature of meanings (across time or cultures, for example). "Carrying back" school mathematics to professional mathematicians' work can certainly be unsatisfactory in this sense. What we mean by being a mathematician or doing mathematics is something open, fluid, and so is school mathematics. The designation relationship is problematic once we accept the dynamic, irreducible complexity *evoked* by the words "school mathematics" or "professional mathematician's practices".

One way to go around this tension is to think in terms of self-reference: an approach developed in many fields of studies, such as language, biology, philosophy and others. In mathematics, for example, self-reference is fundamental to the notion of fractals: mathematical objects exhibiting similar patterns at various scales. The specific nature of a given fractal is expressed in how it recursively reproduces its structure. Looking at coherence and similarity at various scales of mathematical activity (in and out of school) could be one way to further examine and develop it without having to make continual comparison with some externally posited entity. We offered elsewhere such conceptualization of mathematical activity (Roth & Maheux, 2015), contrasting the idea of defining mathematics "in itself" (i.e., as a fixed, independent, objective thing) with a dynamical approach in which mathematics is a way of making difference "in its own terms". Coherently, these terms are themselves observer-dependent and evolve under their own movement.

We have explicitly discussed this idea through the use of the dialectical expression *doing/mathematics* (Maheux & Proulx, 2015, 2018). *Doing/mathematics* is both *doing* something (some thing) recognizable as *mathematics*, but also producing *mathematics* as this thing that we

are *doing* when what we do is mathematics. The Sheffer stroke between “doing” and “mathematics” serves here to emphasize the dialectical relationship between the two terms. *Doing/mathematics*, as an activity that produces mathematics in its production, represents as much the activity of mathematics than the mathematics produced: it is an act of meaning-making, where meaning is made through it. Thus, in this view, it is *doing/mathematics*, its activity and its product, which constitutes the landscape that we call Mathematics. That landscape is a “reference” for any mathematical idea or activity, but it is also something to which all contribute by nourishing, complexifying, defining and developing this very landscape of “reference”. The two processes are inherently tied, dynamically: As we contribute to the mathematics landscape, this landscape influences us, and as it influences us, we contribute back to it. This also means that students, university professors, statisticians, teachers, and so on, in their ways and time, all indirectly but inescapably influence one another through this evolving landscape.

What is suggested here is *also* to consider school mathematics more like a *response*, a dialogue with mathematicians’ professional activity, and not merely something that exists *in reference* to it. In this sense, school mathematics as an instance of *doing/mathematics*, is an act of *proffering*: offering itself as an answer to what it means to do mathematics. If mathematicians are seen as producers of mathematics, it is precisely because they engage in an activity that we identify as mathematics. They do mathematics in order to produce what we recognize as mathematical, while that very product of their activity also affects how we conceive of mathematics. It is the same for mathematics in schools, or in any other places where mathematics happens: workplace, street, institutes, etc. Mathematics in schools affects itself and contributes to itself while being influenced by the mathematical landscape with/in which it occurs and evolves. From such perspective, school mathematics legitimately has a life of its own (something often called for, see Hart & Johnson, 1984; Watson, 2008). But like just any other living entity, it is in constant interaction with other life forms (as non-living material).

Focusing on school, we could say that classroom mathematics dialogues with professional mathematician’s practices; not to see what ought to be, but in terms of possibilities that they both embody. Thinking about what might happen is very different from setting something as an objective. Enabling students to further engage in mathematics can mean many things. Similarly, if school mathematics is seen as contributing in its own terms to the landscape, that is, to understandings of what it means to do mathematics, thinking of how students might experience things similar or different to what mathematician do is not merely justifying or reducing the later to the former, but exploring the very nature of those experiences. Considering how similar or different mathematical experiences might occur outside school or professional practices simply adds to these possibilities and enriches their very nature and essence. To some extent, this is at the core of ethnomathematical research (e.g., Powell & Frankenstein 1997), leading to wonder what really are “mainstream” mathematics practices. These are, of course, only very general orientations: something to be discussed, worked on, and engaged with more deeply.

### **Coda: On mathematics education research**

The term *proffering* is provocative. It suggests turning the tables and thinking about what school mathematics actually offers to our understandings of mathematics as a practice. The idea that professional mathematicians could learn from schoolchildren does have a revolutionary twist.

Taken more generally, the proposition is less aggressive: we can learn about what is mathematics and mathematical activity from both lay and professional mathematicians. Following such an assertion, one might ask: what is the role of mathematics education research in relation to this?

Evolutionary epistemology (Campbell, 1974) teaches us that by paying attention and studying a concept (or phenomenon) in order to understand it, that very concept (or phenomenon) is transformed. Studying professionals' or schools' mathematical practices also has this effect. By reifying, deconstructing and explicating them, we affect those practices. Analyzing a phenomenon renders some elements (more) salient; it imposes an interpretation that changes how we view things (regardless of how we acted on them or not). Observing always disturbs the observed, and discourse always shape how we do things. From this perspective, we can see mathematics education research as also contributing to the development of mathematics in a broad sense. If research investigates mathematical practices in schools and elsewhere, it not only makes these mathematical practices available to one another, but it also contributes in its own ways to them, affecting them in the process, and thereby also contributing to the mathematical landscape through it. So, coherently, whatever comes out of mathematics education research is not to be taken as *the* reference for mathematical activity. Proffering is also something mathematics education research does.

*This paper builds on Ernest's five ideologies for mathematics education in order to explore the socio-cultural buy-in of mathematical problem solving tasks within the context of private schools that are governed by the Egyptian national mathematics curriculum. The research contributes to the contextual understanding of teacher beliefs and school power dynamics that affect the adoption or rejection of a culturally foreign teaching ideology of problem solving. Findings from one teacher focus group revealed that the teachers had a good understanding of the features that align with a literature-based classification of problem solving tasks. Yet, a disparity was found between desired and existing best practices for classroom implementation of problem solving tasks. This disparity is argued to be a function of power tensions between inner and outer circles of contextual influence.*

*Keywords: problem solving, socio-cultural power tensions, educational ideologies, teacher beliefs*

## Introduction

Literature argues against school education being viewed as a neutral enterprise (Apple, 2004). The skill and knowledge dissimilation process in schools is arguably better understood when viewed from the perspective of the schools' position in a dynamic and turbulent context that incorporates complex social and cultural power relations (Bernstein, 1971). This study explores the specific context of mathematics instruction at Egyptian private schools that teach the national curriculum. As will be elaborated further in the upcoming sections, this context is particularly interesting as it embodies – at the private school level – a teaching culture that appreciates an inquiry-based enactment (Apple, 2004) of the mathematics curriculum. This culture is however situated and controlled by an imposed national curriculum agenda that is rather stagnant and one-sided in nature (Hargreaves, 1997; Naguib, 2006). The study aims to unravel the mentioned inner and outer circles of influence and how these play a role in shaping mathematics teachers' beliefs and practices, particularly in relation to their teaching of mathematical problem solving.

## Literature Review

Literature claims that social and cultural configurations govern the outcome of schooling in order to ensure the reproduction of an existing culture of stratified social class relations (Apple, 2004). In line with that view, Alexander (2000) unpacks the term 'education' and focuses on three particular aspects, namely curriculum, assessment and inspection. He claims that the formation of those is bound by different forms of policy and power. Our study focuses on the first element and argues that, since education cannot be viewed as a neutral enterprise, similarly curriculum design and knowledge distribution schemes cannot be viewed as neutral. According to Apple (2004), curriculum design and enactment which govern the process of skills formation and cultural capital distribution (Bourdieu, 1986) are controlled by power dynamics that relate to a given context's social class hierarchy.

Particularly in relation to science and mathematics curricula, literature suggests that the general tendency to move towards a curriculum design where students are taught to become independent inquirers is often quenched by a culturally selective curriculum enactment tradition where educators may choose to teach certain skills or forms of knowledge in order to re-enforce certain configurations of social power. This selective tradition, which in turn is governed by social and cultural power dynamics, can be better understood when considering the historical roots that led to its formation (Apple, 2004; Bourdieu, 1986).

Scholars (e.g., Alexander, 2000; Apple, 2004) have added to the discussion about forces affecting curriculum design and enactment the dimension of political control. In his comparative study on primary education in five different cultures, Alexander (2000) claims that the national constitutional identity plays a vital role in prescribing curriculum outlines and elevating certain forms of knowledge and skill transfer over others. According to scholarship, to better understand the question of political control, the question of centralizing (or de-centralizing) systems of curriculum design and enactment is crucial to consider (Alexander, 2000).

In light of that understanding, we intend to map the situation of primary stage mathematics curriculum enactment and design in Egypt. A wider study from which this work is derived has elaborately addressed, drawing on relevant literature (Heyworth-Dunne, 1968; Sika, 2010), the historical evolution of education in modern Egypt. It sought to map out social and cultural configurations and power tensions against educational outcomes of skills and cultural capital distribution. While it is beyond the scope of this work to elaborately address the overall historical mapping of education in modern Egypt, we consider it as important to use sections of that mapping, particularly to better understand political and social control forces governing the purpose and identity of curriculum enactment and formation. In light of Alexander's (2000) views about political control, it is worth mentioning that, since the republic of Egypt was formed in 1953, curriculum design and enactment agendas have been standardized. A centralized system that is governed and tightly controlled by the Ministry of Education (MOE) strategically selects the forms of knowledge acquisition and skill transfer that are to be enacted by the national curriculum to all schools of Egypt. Literature (Naguib, 2006) shows that for the case of the mathematics curriculum the focus is on factual knowledge and the transmission of a one-sided set of facts that are not to be questioned or debated. Mathematics instruction is meant to take on the form of a procedural, teacher-led, exam-oriented structure (Sika, 2010). The national curriculum in Egypt is taught in all public schools and also in the so-called 'national curriculum private schools'. Both forms of schooling stem from different social, cultural and historical roots (Heyworth-Dunne, 1968). The historical plotting, referred to earlier, indicates a so-called cultural migration (Alexander, 2000) of educational values which governed the original institution of foreign private schooling, even before the republic of Egypt was formed. Those values are centered around a more multi-façade, student-centered scheme for curriculum enactment. Nevertheless, being under the governance of the MOE, a centralized system ensures that the curriculum enactment follows the same format across all types of national schools in Egypt (Hargreaves, 1997; Naguib, 2006; Sika, 2010).

Alexander (2000) claims that schools are micro-cultures mediating imposed curricula in such a way that reflects some of the school's own flavor. It is true that, despite the fact that the same mathematics

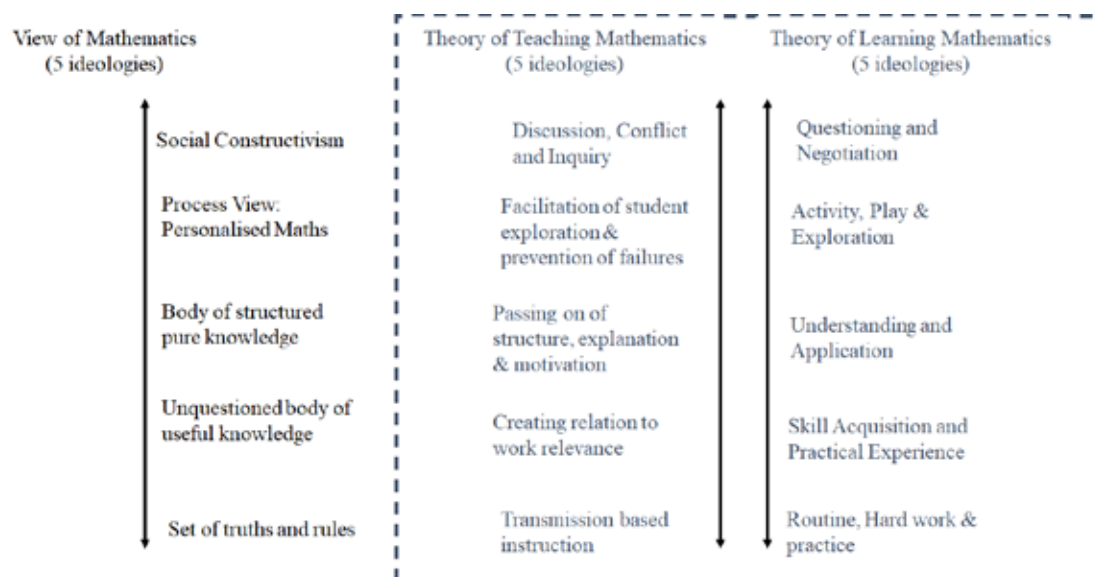

curriculum is meant to be applied across the mentioned wide base of schooling, curriculum enactment remains quite a complex process (Remillard & Heck, 2014). This paper presents a case study that addresses the interplay between a centrally governed curriculum and its contextual enactment in the culture of a private school. More specifically, we will focus on how the factual nature of the national mathematics curriculum translates into the formation of teacher beliefs about problem solving and how in turn these beliefs affect, according to the teachers, their curriculum enactment decisions in the classroom. The research questions to be addressed are the following:

- (1) Within the context of a private school in Egypt that is bound to follow the national curriculum, how do school mathematics teachers perceive features of problem solving tasks?
- (2) Within this same context, how do school mathematics teachers view the contextual suitability of adopting their perceived problem solving tasks into their local teaching setting?

### Theoretical Framework

In his model of educational ideology for mathematics, Ernest (1995) situates the wider aims of mathematics education along with the specific function of school mathematics teaching, learning and assessment within a context that is bound by the theory of society, the theory of the child and the moral ideologies attached to a given society. Ernest (1995) differentiates between five educational ideologies in viewing teaching and learning mathematics and maps those out against cultural power configurations in society. He views these ideologies from various social and pedagogical perspectives. Three of those perspectives form the theoretical grounding of this paper (Figure 1).

**Figure 1: Mathematical ideologies: Three perspectives (adapted from Ernest, 1995)**

As illustrated in Figure 1, it is not possible to dissociate a teacher's perception of mathematics, which in turn translates into a teaching and learning theory, from the student's experience when learning mathematics and from the wider nature of viewing and experiencing mathematics both by the teacher and by the student. Figure 1 shows how five different mathematical ideologies manifest themselves in the experience of the teacher and the learner. These ideologies extend all the way from viewing mathematics as a set of fixed truths and teaching it in a rather authoritarian and transmission-based

mechanism all the way to viewing mathematics as a subject of constructive nature and the teaching of it as being rather more inquiry- and discussion-based. In turn, the learning of mathematics is viewed as lying on a spectrum that extends from the mastery of formulas and procedures on the one end to the learning of inquiry skills and negotiation on the other end. Ernest's (1995) discussion of the latter features align broadly with our understanding of problem solving skills as discussed in the literature (Schoenfeld, 1992; Stein, Smith, Henningsen, & Silver, 2000).

Various scholars (Polya, 1945; Schoenfeld, 1992) have sought to conceptualize mathematical problem solving as a construct and apply that understanding in the formulation of mathematical tasks. As an extension of the scholarly view that perceives mathematics as ranging from the pure application of rules on the one side of the spectrum to problem solving on the other (Schoenfeld, 1992), Stein et al. (2000) identified four types of mathematical tasks: memorisation tasks, procedures without connections tasks, procedures with connections tasks, and doing mathematics tasks. While we acknowledge that the term "problem solving" has been used in different ways in the literature (Schoenfeld, 1992; Reiss & Törner, 2007), for the purpose of this work we have adopted Stein et al.'s (2000) perspective on problem solving which, at the task level, has been conceptualized by the authors as "doing mathematics tasks" (p. 16). According to the authors, doing mathematics (or problem solving) tasks are unique in that they invoke student analysis based on conceptual understanding of the underlying mathematical principles, their solution process has an unpredictable nature and a high level of ambiguity, they place on the solvers high cognitive demands and they require solvers to self-regulate their thought process. The broad understanding of the ideologies that formulate a teacher's and a learner's view of mathematics along with the specific unfolding of that view in the form of mathematical tasks constitute the foundation to conceptualizing the upcoming analysis.

## Methodology

As part of the larger project exploring contextual power dynamics in relation to framing teacher perceptions of mathematical problem solving, this research adopts the methodology of a multiple case study, conducting various focus groups across a wide range of private schools in Egypt. It is worth mentioning that, in Egypt, private schools annually serve a wide base of students (approximately two million) from various sociocultural family backgrounds (CAPMAS Yearly Report, 2017). The case studies have been carefully selected to represent the high end, the low end, and the middle of the socio-cultural map of private schooling. Each case study represents findings of two focus groups conducted at different schools that are both classified within the same socio-cultural cluster of schooling. In the following, we present findings from one focus group that has been classified by local partners as lying on the high end of the private schooling spectrum. This classification has been also confirmed based on an assessment of the school location, the school fee and the selection criteria of both students and teachers. The sample comprised a group of six mathematics teachers.

Being a contextual study, it was important that the method selected was locally fitting. Researchers have investigated the suitability of using focus groups as a research method in the Arab context and have argued that focus groups are well received by participants (Thomas, 2008). Being a collective culture (Thomas, 2008), teachers' choices and practices are governed and influenced by each other's perceptions making it unlikely for a teacher to adopt a practice in their classroom if it is not

collectively perceived as best practice by most other teachers. Hence group power dynamics represented a cultural reality that needed to be taken into consideration.

The data collection protocol was framed around prompts of a Task Sorting Activity (Friedrichsen & Dana, 2003) followed by a more holistic focus group discussion. For the Task Sorting Activity, eight tasks were put together ranging across Stein et al.'s (2000) mathematical task spectrum. The tasks showed an interesting variation in terms of their presentation, including numerical tasks, word problems, and visual integration tasks. The participating teachers were unaware of the existing task pre-classification and were prompted to classify the eight tasks according to (a) which tasks they considered to be problem solving tasks (cf. RQ1) and (b) which tasks they would be more likely to use in their classrooms (cf. RQ2). Each of the sorting prompts was followed by a more elaborate focus group discussion about teachers' task sorting choices.

The data analysis followed an inductive data-driven approach. Incidents in the data demonstrating task features that were associated by teachers to problem solving tasks (cf. RQ1) were grouped together to form codes and clusters. Based on the constant comparative method (Glaser, 1965), the coding scheme was developed over three levels of analysis. First, incidents in the data were compared to each other. More specifically, three different focus group transcripts were chosen representing low, high and middle socio-cultural levels. Incidents in those three transcripts were cross-compared and clustered to create a preliminary coding scheme representative of all three sets of data. Secondly, the created code was compared to another set of incidents, represented by three other focus group transcripts also varying across socio-cultural standings. Resulting from that was a more elaborate coding scheme. Finally, created codes were compared against each other, yielding a saturated format of codes and clusters. This saturated code was then utilized for the frequency count analysis of all focus group transcripts. Occurrences in the transcripts that aligned with the codes in the saturated coding scheme were counted in order to trace the popularity of certain task features. Following the same method, a separate set of codes was created to represent task features that teachers perceived to be suitable for their local classroom practices (cf. RQ2) given the constraints of the national curriculum framework. Contrasting the findings obtained from these two sets of codes cast some light on the power tensions between teacher perceptions and the contextual reality.

## Findings

Results of the analysis revealed the following task features to be most popularly associated by teachers with problem solving tasks:

*Nature of the task:* The task layout has to be relevant to students' everyday lives. Also, the task needs to be approachable by a range of different methods, thereby giving space for a wide audience of learners to address the task, each in their own way.

*Teaching the task:* Students need to independently tackle the task, thereby exploring new and often unfamiliar territories. However, the teacher needs to be in tight control of that exploration process.

*Learning from the task:* In order to solve the task, students would need to go through an inductive process, to develop a yet unknown formula or solution procedure, that can then be adopted to find the solution to the problem. This creative process of invention was said to be cognitively demanding and was argued to naturally trigger student enjoyment.

These results show a high degree of alignment of teacher perceptions of problem solving task features with Stein et al.'s (2000) conceptualization of problem solving tasks (referred to as “doing mathematics tasks” in their classification). Indeed, teachers seem to agree with the literature about the knowledge creation process that ought to be triggered in students’ minds as they engage in problem solving tasks.

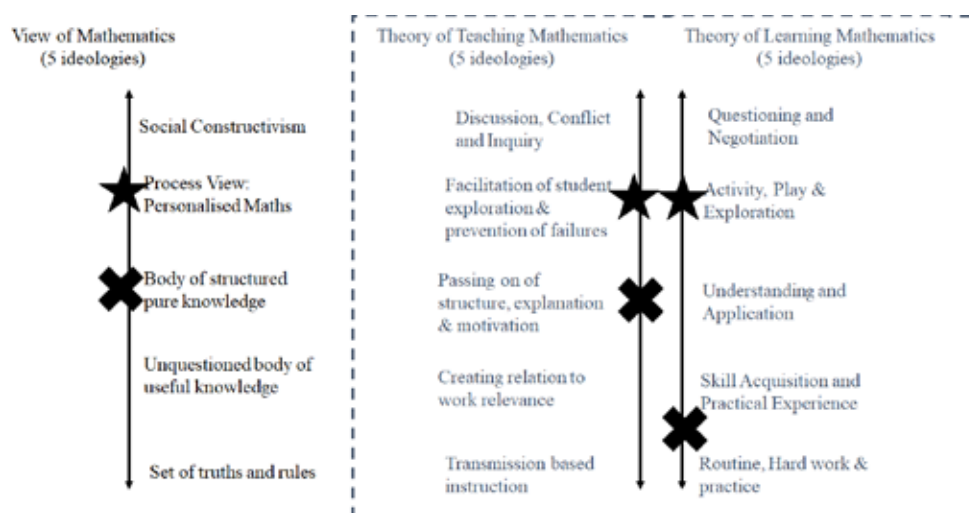

When asked about the suitability of adopting such tasks in the classroom, teachers admitted that these tasks would not naturally align with the national curriculum agenda. Yet, they also made it clear that they would favor adopting this type of tasks over the tasks that fulfil the national curriculum textbook requirements. The teachers described the latter kind of tasks as follows:

*Nature of the task:* The task layout has to be tangible and relevant to students’ everyday lives. Its formulation needs to be straightforward and needs to align with the formulation of expected examination questions.

*Teaching the task:* The teacher presents to the students the task solution process. This is often coupled with a more elaborate explanation of the concepts that relate to that solution process. Students are encouraged to follow teacher explanations and ask questions.

*Learning from the task:* The task needs to be quickly and easily solvable by an average student.

When contrasting the two descriptions of task features, we see a gap between (1) the kind of tasks that align with the curriculum requirements and that the teachers perceived to be suitable for local adoption and (2) the kind of tasks that the teachers perceived to be problem solving tasks and would rather enact in their classrooms if they were given the choice. Figure 2 maps our classification of the two aforementioned task types on to the framework developed in Figure 1. The symbols (x) and (\*) have been used to mark the position of the first and second kind of tasks, respectively.

**Figure 2. Mapping of findings**

As illustrated in Figure 2, there seems to be a variation between the ideology that the curriculum dictates and the mathematical ideology that would rather be implemented by the teachers and that in their view relates to problem solving. In their focus groups, teachers commented about them being governed by a one-size-fits-all curriculum model that does not align with their own views about mathematics. They also argued to be bound by a narrow time schedule that is dictated by the national

curriculum requirements which results in them mostly having to enact a rather more procedure-based (Stein et al., 2000) mathematics view in their teaching.

Nevertheless, the discussion still revealed traces of teachers attempting to enact their own mathematical ideology in the classroom despite being bound by a different curriculum ideology. Teachers expressed their belief in the importance and relevance of integrating into their teaching the tasks that they defined to be problem solving tasks. Being foreign to the national curriculum, it would be difficult to integrate this type of tasks as a student-led activity. Nevertheless, teachers claimed that those tasks could still be useful as a pedagogical tool to introduce students to new mathematical concepts and to involve them in the development of formulae and procedures in relation to those. In that way, the teachers' definition of a problem solving task experience would be partially fulfilled. The task would trigger knowledge construction, yet it would only serve as a teacher explanation tool.

## Discussion

In response to the research questions about teacher perception and enactment of problem solving within the context of the mathematics national curriculum, the following can be stated:

- (1) Teacher perceptions about mathematical problem solving seem to align more with the ideology that is found in literature (Stein et al., 2000) rather than with the ideology that is dictated by the curriculum (Naguib, 2006; Sika, 2010).
- (2) In view of curriculum enactment, the ideology dictated by the national curriculum seems to have superiority on classroom enactment choices when compared to teachers' ideological preferences. Nevertheless, there is some evidence of a partial realization of problem solving task integration in the classroom, which aligns more with teachers' preferred ideology.

These results re-emphasize the indicated gap between the inner and outer circles of culture and contextual influence. In line with the plotting at the onset of this paper, the historical roots of cultural migration that led to the formation of a different cultural footprint of foreign private schooling in Egypt seem to still have an impact on teacher belief formation and desired curriculum enactment practices. As the results indicate, teachers seem to be more oriented towards inquiry-orientated curriculum enactment practices. Despite the fact that the mathematics curriculum in Egypt is meant to be centralized around schemes dictated by the MOE and that its enactment is meant to be unified across all national Egyptian schooling types, the investigation of the actual enactment seems to offer more variety and complexity. Findings of this study indicate some traces that re-emphasize Alexander's (2000) views of schools being microcultures transferring their own cultural flavor. As the findings indicate, teachers seem to find it important to integrate problem solving tasks into their daily instruction, even if those do not align with requirements of the national curriculum. Results also indicate an apparent power dynamic that gives superiority to the influence of the national curriculum ideology, resulting in teachers' mathematical ideologies being trapped and only being partially realized in terms of practical enactment in the classroom. This superiority seems to only influence the practical enactment, yet it seems not to affect the formation of teacher beliefs about mathematical problem solving. Findings reported in Figure 2 also indicate a disparity between the national curriculum's views of teaching and those of learning mathematics. While teaching mathematics seems to be associated with the teaching of structures, the learning of mathematics was associated by

teachers as a routine process of recalling knowledge. According to Ernest's (1995) framework there seems to be a mismatch between both views that is worth investigating in future research.

# Discourse of otherness in a Universally Designed undergraduate mathematics course

Juuso Henrik Nieminen

University of Helsinki, Finland; [juuso.h.nieminen@helsinki.fi](mailto:juuso.h.nieminen@helsinki.fi)

*To meet the needs of student diversity, universities have often implemented the principles of Universal Design in their instruction. However, previous literature knows little about the effectivity of these practices. In this study, two students with special needs are given a voice to share their experiences about a Universally Designed undergraduate mathematics course. The study uses the view of a Foucauldian discourse analysis in order to investigate how these students construct discourses on their position in the context of the course. According to the results, the students positioned themselves as the Others, constructing a discourse of “different learners”. The study implicates that there is a need to shift the existing discourses to open up alternative subjectivities.*

*Keywords: Discourse analysis, otherness, special needs, university mathematics, Universal Design.*

Little is known about disabled students' perceptions of their studies in the field of postsecondary mathematics. Indeed, disabled students are often marginalized in mathematics educational research. These students are rarely seen as mathematical thinkers and doers rather than focusing on cognitive deficits (for a review see Tan & Kastberg, 2017). What is known about disabled mathematics students is that they are not encouraged in their studies (Feigenbaum, 2000) and that university staff might also be reluctant to change their teaching methods in order to take these students into account (Thurston, Shuman, Middendorf, & Johnson, 2017). It is also known that especially dyslexic students are shown to struggle in studying tertiary mathematics because of environmental barriers for learning (Perkin & Croft, 2007). In general, it is known that disabled students often struggle while participating in higher education. These students are less likely than others to persist until completing their educational program (Mamiseishvili & Koch, 2012). According to Weeber (2004) students might see their disability status as an undesirable factor in how they perceive themselves as the campus environment does not provide enough support. In a Finnish report, it was found that accessibility was rarely thought about when learning environments were designed (Laaksonen, 2005). However, in this study it was the staff who assessed the level of accessibility, and the disabled students themselves were never given a voice. I argue that there is a critical silence, in terms of Seale (2014), when it comes to researching disabled students in the field of postsecondary mathematics.

In this study, an undergraduate mathematics course was designed to be more accessible. By using Foucauldian discourse analysis on power, the voices of the students with special needs themselves were heard. The aim of this study is to examine how these students positioned themselves in this course that tried to promote inclusion for all through the framework of Universal Design.

## Background of the study

### Discourse and power as theoretical frameworks

This article draws on Foucauldian discourse analysis. Discourse analysis is not used simply as a research method; it serves as a broad theoretical framework for understanding discourse and its

importance in social life. According to Foucault, discourses are “practices that systematically form the objects of which they speak ... [they] are not about objects, they constitute them and in the practice of doing so conceal their own invention” (Foucault, 1977, p. 49). Discourses, therefore, produce normality by constructing what can be taken as granted. By studying discourse, we can gather information on social organizations and identities, since they are constructed by rules about what is *normal*. The way language is used shapes reality. Observing the ways in which social constructions form our world are the core of discourse analysis and form the theoretical base for this study.

Discourses produce meaning and knowledge, and these Foucault (1977) connected with power. Foucault (1977) proposed that in modern societies, we must move forward from analyzing dyadic relations of a ruler and a subject, and instead focus on finding these power relations in institutions that are so often labeled as ‘humane’. He defined the concept of disciplinary power, a form of power that is understood to be the body of knowledge and those discourses takes as the ‘truth’. According to Foucault (1982), personal identities are only produced through institutional or societal power and knowledge. In other words, subjectivity is constructed through the productive power of discursive practices. Various scholars have also emphasized the socially constructed nature of mathematical identity – how discourses construct mathematical identities and agency (Alderton & Gifford, 2018). Because discourses truly produce our social reality, they are all about power. Some voices are heard as meaningful and authoritative, while some others are not. When power and knowledge are combined, *hegemonic discourses* are constructed (Dant, 1991). By this, Dant means that certain socially constructed discourses are considered as facts.

### Universal Design

Inclusive pedagogy has often been introduced as a way to promote positive discourses of students with special needs by promoting a view of disability as a social construction. While the traditional, medical model views disability as an abnormality that has to be cured and assisted, the social model emphasizes the idea that disability is constructed when the environment cannot account to the needs of the disabled (Seale, 2014). The social model is often fostered in higher education by using Universal Design (UD), an environmental design that is accessible for everyone (Burgstahler, 2015). According to Burgstahler, the learning environments create barriers for learning, and UD aims to reduce these by taking into account the needs of the diversity of students. Often, UD is fostered by using the guidelines by the Center for Applied Special Technology: 1) engagement 2) representation 3) action & expression (CAST, 2018). These guidelines are tied to brain research on how people learn. Another common and practical way to enhance inclusion in higher education is to implement the Principles of UD of Instruction (UDI) into learning environments: 1) equitable use 2) flexibility in use 3) simple and intuitive 4) perceptible information 5) tolerance for error 6) low physical effort 7) size and space for approach and use (Burgstahler, 2015). Often, two additional principles are used: 8) community of learners and 9) instructional climate (Shaw, Scott, & McGuire, 2001).

Although UD has been used as a base for legislation (e.g., the USA; Higher Education Opportunity Act 2008), we know surprisingly little about whether it works in higher education (for a review, see Roberts, Park, Brown, & Cook, 2011). The warm-hearted idea of supporting inclusion through UD is not to be judged, but there is a need for more research-based evidence. Also, the voice of disabled

students themselves is usually not heard in the research on UD in higher education (Seale, 2014; Griful-Freixenet, Struyven, Verstichele, & Andries, 2017). Griful-Freixenet and colleagues underline the fact that it is impossible to “tackle the need of all learners” and calls for a need of responsiveness. I argue that there is need for studies that would, at the same time, break the silence surrounding UD and also examine the power structures surrounding it. This study examines whether the framework of UD, aimed to promote the socially constructed view of disability, was able to promote discourses that would see students with special needs as an equal part of the learning community.

### **Aims of the study**

In this study, the power relations in a Universally Designed university mathematics course are brought into light through students’ own voices. The objective of this study is to examine the subjective positions that the students with special needs have constructed during the course.

### **Methodology**

#### **Context of the study**

The study was conducted on a proof-based undergraduate mathematics course with over 400 participants that lasted for 7 weeks. The course arrangements reflected the principles of UD: All of the three principles of CAST (2018) and the nine principles of Burgstahler (2015) and Shaw, Scott and McGuire (2001) were implemented in the course examined in this study. Each week, students were given a set of problems to solve, both pen-and-paper and digital. After that, they received various feedback on the tasks (peer feedback, automatic feedback, feedback from the teacher and the teacher assistants) and participated in mathematical conversation during active lectures. There was no exam, and the final course grade was self-assessed. Table 1 shows an overview of the course components.

<b>Engagement</b>	<b>Representation</b>	<b>Action and learning</b>
Applied tasks relevant to different majors	Course material been developed for years to be simple and intuitive <sup>2</sup>	Various options for returning the tasks (LaTex, drawing...) <sup>2</sup>
Accepting and supportive classroom climate <sup>8, 9</sup>	Materials in Finnish and in Swedish <sup>2</sup>	Digital WhatsApp groups for group discussion <sup>8, 9</sup>
Active lectures based on discussion; minimizing the social demands <sup>7, 8</sup>	Mathematical discussion was one of the learning objectives <sup>8, 9</sup>	Anonymous discussion forum <sup>8, 9</sup>
Learning objective matrix	Concept maps about the relationship of concepts	Digital GeoGebra tasks
Formative assessment used to value process and effort <sup>5</sup>	A guide for producing clear mathematical text was provided <sup>3</sup>	Digital polls during lectures <sup>8</sup>
An open learning space with tutor students offering support when needed <sup>2, 4, 6, 7</sup>		Digital Moodle environment as a “base” for the course <sup>1, 3</sup>
		Social interaction in the open learning space; students are guided to tutor each others <sup>5, 8, 9</sup>

Peer-assessment <sup>5</sup>	Dynamic geometry	Personal goal-setting through
Formative and summative	(GeoGebra) offering multiple	formative self-assessment
self-assessment <sup>5</sup>	representations	Various kinds of digital feedback;
Flipped learning approach <sup>5, 8</sup>	Progressive information	automatic, from tutors <sup>5, 8, 9</sup>
	releasing; first simple, then	Octave software for computing
	more advanced tasks	

**Table 1: The course components through the lense of the principles of UD (CAST, 2018), linked with the elements of UDI (with superscript; Burgstahler, 2015; Shaw, Scott, & McGuire, 2001)**

## Participants

All of the participants of the course were emailed an advertisement about the study. Six students, self-reporting as having some kinds of special needs during the course, were interviewed. Because of the page limit, only two of these six interviews were used in this study, the ones of Jesse and Nico; these two interviews were chosen as representative examples of the phenomenon. Jesse, aged 20, had been studying for two years and self-reported having difficulties with dyslexia. Nico, aged 23, was also studying in their second year and stated to have been diagnosed with ADHD. Both of the participants could explain as much about their diagnosis as they wanted to, and their choice was respected. Self-report about the diagnosis was needed; no diagnostic documents were collected for this study. Jesse and Nico were both majoring in mathematics or related science. Both of the names are gender-neutral pseudonyms – gender of the participants is not reported in order to provide anonymization. Gender neutral pronouns *they/them* are used throughout the text. “Special needs” is the term used in this study to describe the participants. The purpose is not to label these students as one group and contribute in constructing a discourse of “students with special needs” as one subject. Instead, this label is used to underline that the students, usually neglected in studies, are given a voice here (Seale, 2014), even though mediated by the researcher.

## Data collection and analytical process

Data was collected after the course using semi-structured interviews, with the questions concerning perceptions of the course components. The students were able to give feedback on the course arrangements and therefore participate in the development process of the course.

The first cycle of analysis consisted of careful familiarization with the data. The transcripts of the interviews were read through multiple times to gather a general understanding of the discourses of the students. The focus on the first cycle was on the position that the students created for themselves. Foucauldian concepts of discourse and power were used in order to unpack the ways students described themselves as participants of the course. This first part of the analysis was led by the question “Do the students position themselves as included or excluded in the learning community, and how is that inclusion or exclusion created?”. The analysis was guided by identifying hegemonic discourses.

The second analysis changed the view towards examining *how* the students constructed the discourses on their subjective position and *how* they contributed in building hegemonic discourses. The data was read through the lens on *simplifications*: When did the students choose to rely on simplifications over

complexity and contradictions? How were these simplifications made seem convincing (Dant, 1991)? The concept of *naturalization* (Fairclough, 1989) was used in the analysis as an ultimate form of simplification; this kind of a process happens when socially constructed discourses and practices are taken as natural and are even connected to the nature itself. The analysis of simplifications reconstituted as follows: when do the students see social orders arranged by nature and not by people, and how are these discourses justified? During the analysis it was noted that there is a need for an analytical tool that would frame the asymmetrical power constructed through naturalization. This is why the theory of otherness was implemented; as a part of the reliability of this study, I describe this process as it chronologically happened in my findings.

## Findings

### The first analysis cycle: The discourse of ‘a different kind of a learner’

The first notice, after getting familiar with the data, was that both of the students described a very lonely learning process. This loneliness was connected with the difficulties the students faced in this course. An evident part of this loneliness was that throughout the data, the students spoke almost entirely in the first-person point of view as is evident through all the citations used in this article. In the entire data, there were no references to *us*.

Jesse: When I am doing an exercise, the exercise number one. Everyone else has started that exercise at the same time as me but they are already doing the task number five when I’m moving forward to task number two. I just progress so much slower. – – I realized a long time ago that for me it is better to work on my own.

The clear, choiceless segregations made between *me* and *them* were seen as building blocks of the discourse about *difference*. The discourse was named by the researcher as ‘the discourse of a different kind of a learner’ after Nico’s feedback on the course:

Nico: I think it is good if there is a will to map out the needs of different kinds of learners.

One way of constructing difference between these students and the others was the *discourse of different kinds of study methods*. The students did not want to lean on to the ready-made methods, built for them by the teacher. On the contrary, they created their own study strategies by themselves, because they could not make use of the *normal* ways of studying. This smaller discourse was seen as a legitimator for the stronger discourse of difference. Even these kinds of *helper discourses* might have some serious real life consequences.

Jesse: Well. I have been to small groups or so. Where you need to do group work with other people. These kinds of situations have always been very bad for me since. I mean, goodness. You have to write very fast, just whatever comes to your head. And the answers to the tasks, they are what they are.

Nico: I tried to study in a way everyone else is studying and. In the end of the year I realized that I wasn’t even getting grades from my courses. Now then, I built this learning strategy. So, maybe I don’t learn like other people, so I’ll just have to learn completely in my own way. – – I was using a timer with these exercises. For example, I decided that at 5 pm I’ll start doing these exercises.

The discourse of difference was also identified when the students gave feedback on the course. This was most clear with Nico, who told that they almost did not use any of the social course components, yet still they praised the existence of these arrangements. They told that they did not attend the lectures nor the open learning space, and neither wanted to take part on the digital discussion groups of the course. According to Nico, there was nothing wrong with the course components, designed with the principles of UD; they were just meant for someone else.

Nico: I would say that compared to last year. Well, this is. A hundred times better arranged, this course. So, keep going like this and it'll be very good.

As shown, there was a hegemonic discourse of 'a different kind of a learner', a strong discourse that was obviously constructed way before attending this course. But how was this kind of a hegemony legitimised? For further analysis, a new tool was needed: the concept of *otherness*.

### **A plunge back to the theory: Otherness and power**

Individual subjects construct their reality and identity under the supervisory of normalizing practices that impose homogeneity and build discourses on *norms* (Foucault, 1977). This leads to monitoring one's behavior, a process that is constantly judged. Fenwick (2003) uses the concept of *internalisation* to describe the process where identities are produced through following norms, thus leading to being dependent on the disciplinary power the subjects have directed on themselves.

When norms produce inclusion and exclusion through disciplinary power, they produce *otherness*. Staszak (2008) conceptualizes otherness as a discursive process which is produced by a dominant group by stigmatizing a difference. The creation of otherness thus constructs two different group: *them* and *us*. Asymmetry of power is the key feature in constructing otherness: Only the more powerful group of *them* and *us* is able to maintain hegemonies and construct their own identity, while the identity of *the other* is only constructed in a relation to these powerful discourses. Discipline power is found when the others define themselves in relation to the dominant group, not having equal power to define themselves by their own means. When otherness is seen in a negative way through dominant discourse, the results tend to be very real and reflect the power structures (Okolie, 2003).

### **The second analysis cycle: The discourse of otherness**

Because of the asymmetrical power structure that was found at the first cycle of analysis, the 'discourse of a different kind of a learner' was renamed as the 'discourse of otherness'. It was kept up with simplifications; strong discourses that left no room for seeing things from different angles. Internalisation of norms created otherness when the students saw their differences as something that could not be taken account by the course or the university staff. The students positioned themselves as the others that cannot and therefore should not be *helped* by the course. This is a strong hegemonic discourse: This learning environment of university mathematics is not meant for *them*, even if it is constructed with the principles of UD. This is an obvious simplification, since the learning environments could, of course, be adjusted for these students too.

Jesse: It would have been nice if I would have bought the physical copy. And not just read the material from the screen of my computer, since there is that backlight. I always become so confused about the line I'm reading. -- It costs money. So no thank you.

Nico: I would say that if you are a different kind of a learner, then the most important thing you should do immediately after you start your university studies is to find out how you learn.

Naturalization was the key element in constructing otherness. This kind of a process was most evident in Nico's interview. Nico referred to themselves as an 'ADHD person' and constructed otherness through neurology. Also, Jesse made references of dyslexia as a biological state that prevented them of studying in a *normal* way. These kinds of discourses can be seen as ultimate ways of asymmetrical power between *them* and *me*.

Jesse: Well. Always, it would be nice to get. Some kind of an assistance. When it comes to dyslexia. Which means more hours to a day, but that just isn't possible.

## Discussion

This study examined how students with special needs position themselves in a Universally Designed undergraduate mathematics course. Even though the theories of UD and UDI were reflected in the course design, it was found that the two students interviewed constructed a discourse of otherness (Staszak, 2008; Okolie, 2003). Asymmetrical power structures were found in the way they distanced themselves from the *other* students.

Mathematical identities are known to be formed through institutional power. As educators and researchers, we need to see our responsibility in how we create discourses – or silence. There is a growing need to admit there are students with special needs in undergraduate mathematics, both in research and practice. What we can do is to transform the experiences and possibilities of students with special needs (Alderton, & Gifford, 2018). This study showed how naturalization helped to build the discourse of otherness. If we normalize this kind of inequity, we are constructing a hegemonic discourse that legitimizes subordination through asymmetrical disciplinary power.

UD offers a way to change our view towards more equal mathematics teaching in higher education by challenging the medical model of disability. However, implementing the principles of UD into a course is not enough if discourses of otherness in mathematics are not shifted. The study suggests that that designing inclusive environments *for* disabled students is not enough, since, in the end, that would reflect the medical model of disability and not social. Seale (2014) sees participation, both in research and practice, as a way to truly foster inclusion. Maybe this would be a way to shift the discourse of otherness and truly include disabled students in the mathematical learning environments. In university mathematics, the first thing to do would be to *listen* to these students.

*Keywords: Lávvu, ethnomathematics, sámi and indigenous education.*

### **Introduction**

*Sápmi* is the Sámi term for the Sámi homeland and society, the land area extends from Central Norway, Sweden and Finland to the Kola Peninsula in Russia. In Norway, the Sámi as a population has status as an indigenous people, which means that the Sámi have the right to develop their own culture and language on their own premises. Traditionally the Sámi people has lived as hunters and gatherers and in connection with this, they lived a nomadic life. The *lávvu* is a temporary dwelling, and the design of it reflects the Sámi culture as a community. Families travel in small groups, and the *lávvu* is designed so that even one person could quickly set it up with little effort.

Teachers at a Sámi school in northern part of *Sápmi* in Norway have for several years developed teaching units for all grades in lower secondary school with *lávvu* as an overall theme. When students attend their last year at lower secondary school, they develop their own teaching unit in mathematics with the *lávvu*. This study builds on research by Fyhn et al. (2016), Fyhn, Meaney, Nystad, and Jannok Nutti (2017), and Jannok Nutti et al. (2015), where the Sámi culture founds basis for mathematics in school. The research question investigated here is: How do students use the *lávvu* in mathematics teaching?

### **Theoretical framework**

The Sámi pedagogy reflects the Sámi culture, and the culture has a holistic conception of knowledge (Balto, 2005; Keskitalo & Määttä, 2011; Siri & Hermansen, 2018). The holistic view is also central in the upbringing of the Sámi children. Culturally-responsive teaching is about teaching that founds basis in cultural knowledge and insight (Gay, 2013). It is essential that this teaching must not take cultural phenomena out of its context, because the student can experience that the teacher and the school simplify the students own culture (Fyhn et al., 2017).

### **Method**

The analysis of the data in this study can be characterized as abductive, and the data material has been analyzed towards Sámi pedagogy and culturally-responsive teaching. The data is based on observation, audio recordings of the teaching activity and conversation between authors. Ole Einar was the teaching students' supervisor in the development and performance of the teaching. Siv participated in the teaching as a participating observer following one group of learners.

## Findings

There were five *lávvue*s in the schoolyard. Each of them had different themes in which it was taught. These topics were cooking in the *lávvu*, building a traditional *lávvu*, storytelling and *luohti* (Sámi traditional song), the history of the *lávvu* and mathematics in *lávvu*. In addition, each lesson in the *lávvu* lasted for approximately 30 minutes. The students who were taught were divided into four groups, and each group of learners were visiting all *lávvue*s. In Sámi pedagogy the place where teaching happens does not necessarily need to be situated in the traditional classroom (Keskitalo & Määttä, 2011). This teaching is literally situated outside the classroom. It takes place in *lávvue*s in the schoolyard. The teaching combines the Sámi culture and the Norwegian upper primary school level curriculum. Four of the *lávvue*s addressed phenomena and activities in relation to the Sámi culture. The fifth *lávvu*, where mathematics was taught, stands out in such a way that it was based on *lávvu*, but it related to geometry. All the *lávvue*s had to be included in the teaching because this gave a holistic perspective and cultural-responsive teaching, even though the mathematics teaching could be characterized as deductive.

# Interdisciplinarity, culturally sustaining pedagogies, and the problem of pandisability as culture: Co-creating diverse mathematics learning contexts

Alexis Padilla<sup>1</sup> and Paulo Tan<sup>2</sup>

<sup>1</sup>University of New Mexico, Department of Language Literacy and Sociocultural Studies, Albuquerque, United States; [m3689@unm.edu](mailto:m3689@unm.edu)

<sup>2</sup>University of Hawaii, Mānoa, Institute for Teacher Education, Honolulu, United States; [paulotan@hawaii.edu](mailto:paulotan@hawaii.edu)

*We argue for the need to reframe interdisciplinarity to encompass pandisability. Such reframing enhances cultural experiences and genuine diversity through collaborative creation of mathematics learning contexts and culturally sustaining pedagogies. We explore ways to undo vertical hierarchy patterns of relationality that hinder exchanges across differences. In these equity-driven pedagogical interventions, we call for conflating multiple disciplinary fields within and around mathematics as well as diverse layers of practice, namely in research, teaching, teacher education, disability advocacy, parenting, youth self-determination, rehabilitative sciences, and so forth. We recognize that these practices relate to multiple disability experiences and identity formation trajectories that enrich mathematics as a collaborative space for all and of all within and outside schooling.*

*Keywords: Mathematics education, disability culture, radical interdisciplinarity, pandisability.*

## Introduction

The present paper highlights the need to reframe interdisciplinarity in conjunction to pandisability cultural experiences to enhance genuine diversity in the collaborative creation of mathematics learning contexts inside and outside schooling. Pandisability refers to the full scope of disability categories, including disability modes of identity not yet labeled as such by system actors or not fully accepted by recipients of disability labels. The unique knowledges afforded by this sense of difference must be deliberately incorporated into mathematics learning pedagogical interventions, competency assessment, and process standards in meaningful ways. Doing so enriches not only the collective experiences of students with disabilities but most especially those imbued with privileged status as expressions of embodied normalcy (Davis, 1995, 2002, 2013; Goodley, 2003; Hughes, 2007). In this introductory section we touch on interdisciplinary knowledges as typically conceived in ways that marginalize experiential spaces such as those afforded by pandisability culture. In the next section, we tackle the link between pandisability cultural knowledges and mathematics learning. The section that follows dives into the theoretical and practical implications of using culturally sustaining pedagogies (CSP) in conjunction with interdisciplinarity. We conclude by drawing a few critical notes on ways to enhance CSP as it becomes part of the everyday practices of disability studies in mathematics education (DSME). To this end, we use the example of the braille literacy crisis, showing how expansive views on pandisability culture can help CSP and mathematics education practices transcend typical interdisciplinary boundaries and knowledge creation pre-conceptions. Importantly, the reader should note that DSME's pedagogical and learner-centered practices are radically distinct from special and mathematics education approaches that rest on medical and

behaviorist models with their fixing, deficit-driven attitude toward students with disabilities (see, for example, the DSME-centered meta-analysis of recent mathematics education empirical work carried out by Tan, Lambert, Padilla, & Wieman, 2018).

Interdisciplinarity is portrayed as a set of practices designed to bridge multiple knowledges. Unfortunately, by its very definition, the implementation of interdisciplinarity privileges disciplinary knowledges (Bhasker & Danermark, 2006). Therefore, the experiential wealth of knowledges such as those afforded by disability identity and alterity tends to be neglected and/or marginalized as external to the making of interdisciplinarity. Likewise, parallel knowledges of interdependence actors, for example, families or friends of learners with disabilities tend to be discarded as insignificant or completely ignored.

We are appealing to an international audience. Our positionality is grounded in DSME research and practice contextually based in the United States. As such, through the present paper we aspire to engender an invitational dialogue which revolves around the need to explore ways to articulate a new, much more embracing conceptualization of interdisciplinarity that transforms the way everyday mathematics education practices inside and outside the classroom are conceived and enacted. The aim is to incorporate disability difference and the knowledges it affords into why and how things are approached and learned by students with and without disabilities. Our purpose is to capture the multiple layers of diversity associated with disability knowledges and ways of knowing in the making of mathematics as their equity-centered learning space for belonging and reciprocal interactions of collaborative creativity. Such creativity is nurtured by special modes of disability-centered multicultural difference and parallel spheres of intersectionality with identity areas such as gender, class, race/ethnicity, multi-lingual richness, and so on.

### **Why pandisability?**

Disability is a social category of culture in action. It flows in reciprocal interaction with institutionalized settings (Blanton, Pugach, & Bóveda, 2018; Kupperts, 2011). Each disability category constitutes a sub-cultural sphere. Disability's unique difference-based sense of richness can enhance collective contexts for mathematics learning in special ways. Take for example the meaning of musical silences as a mathematical unit susceptible to rhythmic and trans-melodic embodiments. How many of our readers have ever wondered if or how deaf learners and their interdependence partners would contribute to enriching our understanding of the mathematical depth of musical silences? The absence of questions such as these in mathematics learning circles is quite telling. Yet, answering these questions is only viable by unleashing the power of true belonging in co-learning spaces for sharing. Those knowledges are already brewing within the vitality of deaf learner experiences and those of their interdependent partners. Excluding them, we are also depriving the contextual whole from one of its core learning parts.

Now consider visual mathematics dimensions as they get experienced by blind and/or visually impaired individuals and their interdependent partners. To what extent do stereotypical conceptions of visuality prevent us from dialoguing with these kinds of learners?

An example outside mathematics may help us appreciate the power of non-visual knowledges and ways of knowing in terms of their intuitional relationality. We allude to an essay by critical

anthropologist Michael Taussig (1991) who builds on Walter Benjamin's (1969) suggestion that one should place the sense of sight under the guidance of tactility for the sake of aesthetic interpretation. From this idea, Taussig implies that tactility can guide everyday interpretations to an extent non-realized by actors. Taussig (1991) states:

Surely this sense includes much that is not sense so much as sensuousness, an embodied and somewhat automatic 'knowledge' that functions like peripheral vision, not studied contemplation, a knowledge that is imageric and sensate rather than ideational and as such not only challenges practically all critical practice across the board of academic disciplines but is a knowledge that lies as much in the objects and spaces of observation as in the body and mind of the observer. What's more, this sense has an activist, constructivist, bent; not so much contemplative as it is caught in *media res* working on, making anew, amalgamating, acting and reacting. We are thus mindful of Nietzsche's notion of the senses as bound to their object as much as their organs of reception, a fluid bond to be sure in which ... 'seeing becomes seeing *something*'. (pp. 147-148)

Taussig is talking here about the interpretative processes and intuitional knowledges experienced and created by sighted individuals. If he had developed statements like these in relation to experiences of blind students or scholars, the depth of what he was saying would immediately vanish. This vanishing is the byproduct of ableist readings of blindness as mere impairment or as an incapacitating/paralyzing state.

What if pedagogically one takes Taussig's idea of tactility and asks blind students to become teachers of sighted students and perhaps prospective teachers on how they enact and embody tactility as students of disciplines like mathematics and the arts? In doing so, one should be prepared for all kinds of outcomes. For instance, thinkers with visual impairments such as David Bolt (2014) criticize the over-representation of haptic constructions in relation to the blind. In Bolt's view, this haptic over-emphasis is an expression of ocularcentrism, that is, the belief that knowledge is only possible under sighted guidance, under the "light" of wisdom and proper directionality, which contrasts with the frightening darkness and vacillation inherently associated with tactility. What if there is a culture of resistance toward tactility among these teaching blind students? What if there is more cultural plurality among them than initially anticipated by non-blind audiences? Ultimately, only these teaching individuals could show us the lights and shadows of tactility as a dynamic knowledge-creating tool and as a multifaceted expression of cultures of blindness.

### **Exploring interdisciplinarity along with culturally sustaining pedagogies and dialogicality**

A great part of the problem with narrow conceptualizations of interdisciplinarity stems from a dualist split between thinking and doing, and knowing and experiencing. Disciplinary knowledges, if they do something, the doing is conceptually framed as encapsulated within abstract thinking. This is a Cartesian legacy. Our mind is always "in interaction with others, that is, with individuals, groups, institutions, cultures, and with the past, present and future" (Marková, 2016, p. 91).

It is precisely with our mind's interaction with, within and beyond the boundaries of disability cultures that we are concerned with as we reframe the dialogical enactment of interdisciplinarity to encompass experiential knowledges typically excluded from its purview. Our invitation engages the

special implications of these culturally contextualized interactions for the making and re-making of mathematics as a learning space for all and of all. Therefore, the value of CSP as a core component of this process becomes paramount.

Paris (2012) suggests the use of CSP terminology as a much more accurate conceptualization of the dynamics pursued as one engages with cultural contexts of diversity that are threatened by their systematic marginalization within learning spaces. It does not suffice to keep talking of culturally relevant or culturally responsive pedagogies (as has been done in United States educational contexts of critical multiculturalism for at least three decades, but especially with the publication of Ladon-Billings, 1995; along with this terminology there are other less diffused similar terms that have been used in the literature such as culturally congruent pedagogy, Au & Kawakami, 1994, culturally compatible pedagogy, Jacob & Jordan, 1987, engaged pedagogy, hooks, 1994, everyday pedagogies, Nasir, 2008, and critical care praxis, Rolón-Dow, 2005)

The next logical step is to grapple with another core question: What are the concrete areas of cultural practice one is trying to sustain and why? Paris and Alim (2014) interrogate this dimension. They argue that important as it is to employ asset-based pedagogies, it is paramount to dynamize their applicability to keep up with the evolving transformations of youth cultural processes at the local level and throughout the globe, as well as counteract the myriad of institutionalizing practices that aim at stifling this relational learning dynamicity. The latter is of crucial significance for youth and adults with disabilities in their mathematics of all experiences inside and outside schooling contexts. Paris and Alim (2014) point out their own sense of responsibility in the areas of practice they criticize:

[S]ome of our own research and teaching has uncritically taken up and built on previous notions of asset pedagogies, has at times reified traditional relationships between race/ ethnicity and cultural practice, and has not directly and generatively enough taken up problematic elements of youth culture. ... we live, research, and write with the understanding that our languages, literacies, histories, and cultural ways of being as people of color are not pathological. Beginning with this understanding ... allows us to see the fallacy of measuring ourselves and the young people in our communities solely against the White middle-class norms of knowing and being that continue to dominate notions of educational achievement. Du Bois ... of course, theorized this over a century ago with his conceptualization of double consciousness... (p. 86)<sup>1</sup>.

Double consciousness means a state in which people of color, students with disabilities, gendered and lower-class subaltern individuals reject their own selves, adopting a stance that favors dominant cultural patterns. For students with disabilities this might entail rejecting sign language, in the case of deaf youths, or, in the case of blind individuals, rejecting braille or wanting to continue driving motor vehicles at the onset of visual impairments to deny any pandisability linkages. All of these self-isolation and self-rejecting behaviors are likely to impact negatively the enactment of edifying mathematics learning habits as well as collaborative learning prospects grounded on pandisability culture and interdependence.

---

<sup>1</sup> see also, Du Bois (1965).

Let us transpose this to the field of DSME. In terms of teaching and research practices, the plight of students with intellectual disabilities illustrates quite well what happens. There is a dualism that tries to transform deficit-centered scenarios but falls into rather ritualistic mathematics learning attempts. Many modalities of direct teaching with their repetitious behaviorist exercises guided by deficit-centered conceptions of intellectual disabilities seldom involve youth with disabilities themselves as drivers of their own transformational mathematics learning as well as that of the institutional environments where their education takes place. Our own review of the specialized mathematics education literature for the past decade (Tan, Lambert, Padilla, & Wieman, 2018) makes evident a minoritarian status for those instances of research where DSME principles are explored. Sadly, this exploration is often timid and, in none of the studies we found are students with disability involved as co-designers of their learning or the mathematics education research that pertains to them. Of course, we know that this very prospect would alarm many mathematics education researchers. For whom the very configuration of research studies is a continuous exercise that corroborates their self-fulfilling prophecy: that these students are not capable of complex operations. Thus, it would be temerity to leave their learning destiny in their disabled hands or pretend that one can have a meaningful collaboration toward pedagogical ends and processes with them as responsive agents. Double consciousness acquires an internalized status in the lives of these students with disabilities. Learned helplessness, learned hopelessness are not an unlikely outcome for them. After all, the symbolic exposure to exclusion messages in classroom settings for years at times is taken to heart (Ayres, Lowrey, Douglas, & Sievers, 2011; Baglieri, 2017; Connor, 2008a, 2008b; Connor & Ferri, 2007; Connor, Ferri & Annamma, 2016; Duckworth, 1995; Erevelles, 2000, 2005; Gallagher, 2004; Graham & Slee, 2008; Paris & Alim, 2017).

### **Concluding Remarks**

One example of possible interdisciplinary applications of CSP and disability-centered double consciousness examinations is the so-called braille literacy crisis faced by students with visual impairments in the United States. This is a crisis that indirectly impacts mathematical inclusivity practices. It involves youth self-advocates, families and blind membership organizations. Teaching institutions and researchers could design collaborative research models aimed at tackling culturally sustaining ways to approach the crisis and transform it creatively into a broad, long-term co-learning opportunity. This collaborative research approach would build momentum. It would allow multiple layers of collaborating partners to discover, discuss critically and undo from the inside out those youth cultural practices collectively identified as detrimental and alienating, instead of assuming a priori things about which researchers only have very tenuous knowledge. Most significantly, it would avoid blaming the victim and perpetuating the very top-down systemic practices that originated the braille literacy crisis in the first place (teacher certification requirements, limited incorporation of blind teachers, distancing from youth needs, downplaying of braille, special mathematics coding tools developed with and for the blind, etc.), letting it deepen as years went by.

There are many other innovative paths of interdisciplinary applications of CSP and disability-centered double consciousness examinations which are in their own right interdisciplinary and desperately needed in order to change the lives of individuals with disabilities in and out of mathematics classrooms. Yet, one problem in tackling these explorations is that CSP in its original design has

ignored disability issues. Waitoller and Thorius (2016) suggest remedying this by combining CSP with Universal Design for Learning (UDL) techniques. This solution only addresses the problem in part. Both UDL and CSP lack a genuinely global/international approach for dealing with educational contingencies and are too circumscribed to narrowly conceived schooling dynamics. Therefore, we hope that our CERME discussions will help elucidate innovative ways to correct these deficiencies particularly in relation to how disability studies and mathematics education can embody a true sense of interdisciplinary collaboration.

# **The teaching of higher education mathematics by pre-service mathematics teacher educators: How might this contribute to social justice? A consideration of a possible approach**

Hilary Povey

Sheffield Hallam University, England, [h.povey@shu.ac.uk](mailto:h.povey@shu.ac.uk)

*This paper considers the teaching of higher education mathematics as part of pre-service teacher education and the potential for it to contribute to social justice. In it I ask and seek to offer one possible answer to the following question: By enacting within their own higher education mathematics teaching an enquiry-based pedagogy informed by considerations of fairness and equality, can mathematics education tutors open up possibilities for their students to engage more deeply with such practices and the attendant commitment to social justice? A set of exemplar practices drawn from my own teaching is briefly described and discussed and responses from a cohort of students considered.*

*Keywords: Neo-liberalism, mathematics education, pre-service teacher education, activism.*

## **Introduction**

Socio-political researchers in mathematics education have connected active, engaged, meaning-making pedagogies with the possibilities for social justice in school mathematics classrooms (Skovsmose, 1994; Gutstein, 2006; Boaler, 2008). Although there is a rich literature about innovative and critical approaches to other aspects of pre-service teaching (for example, Cochran-Smith, 1991; Nolan, 2012), there has been comparatively little written about the impact of such pedagogies on those teacher education students who study academic mathematics as an undergraduate subject in its own right. We know that talking about and recommending practices that go against the grain (Cochran-Smith, 1991), whilst essential, have, in themselves, comparatively little effect in teacher education (Nolan, 2012) – but that, in other educational contexts, *enacting* recommended practice may do so (Alexander, 2008).

In England, over the last three decades, neo-liberalism has been successful in colonising educational discourse to such an extent that we are left with just “the rubble of words” (Berger, 2016, p. 7)<sup>1</sup>. It becomes almost impossible to think outside neo-liberalism’s world view and, therefore, to think how things could be otherwise (Llewellyn, 2017): Our human priorities have been “systematically sprayed, not with pesticides, but with ethicides – agents that kill ethics and therefore any notion of ... justice” (Berger, 2016, p. 83). Education has been marketised as a consumer good and no longer understood as a moral enterprise, leading to relentless managerial auditing ruthlessly imposed and internalised by practitioners who have to constantly remake themselves as neo-liberal individuals (Povey, Adams, & Everley, 2017). I argue that offering the experience of countervailing ways of being in the world (often momentarily) can open up other ways of *thinking about* and *acting in* the

---

<sup>1</sup> Space allows for only a brief statement of these ideas here and in the next paragraph. See Povey & Adams (2018) for a fuller argument.

world: “Revolutions are about little things. Little things which happen to you all the time, every day, wherever you go, all your life” (Rowbotham, 2000, p. 211). Routine preservice classroom practices are part of this everydayness.

In this study, I largely bracket, for the time being, whilst accepting them as always already essential for critique, a set of difficulties and dilemmas present in any critical engagement in socio-political mathematics education research. In capitalist societies, inequity and exclusion are consubstantial with the acts of teaching and learning mathematics (Pais, 2017). Mathematics itself creates pernicious collateral damage (summarised in Povey & Adams, 2018, and developed in some detail in Ernest, 2016, and Skovsmose, 2016). Nevertheless, as well as critiquing existing patterns of inequality, I intend my research and writing to contribute to the struggle for a more just, democratic and socialist mathematics education, to enable us to act in the world, however necessarily unstable and temporary that positioning and analysis may be. My project is an activist one, not functioning as we are supposed to do as researchers (Straehler-Pohl, Pais, & Bohlmann, 2017, p. 13) but otherwise and utopian in seeking to catch an occasional, penumbrian glimpse of “the speculative could” (p. 3).

This paper asks: *Can teacher educators, by enacting the approach considered here, open up possibilities for their students to engage more deeply with (and therefore perhaps adopt) such practices and the attendant commitment to social justice?* Neo-liberal discourses regulate practices (Nolan, 2012), reproduce existing class relations and valorising being “strong and selfish” (p. 210). Can we enable our students to reassert in education a moral landscape of autonomy and trust (Stronach, Corbin, McNamara, Stark, & Warne, 2002, p. 130), an interpersonal enterprise contributing to understanding how we should live and challenging hegemonic neo-liberalism?

## My practice

There is a categorical difficulty in trying to represent practice given its “dense, continuous, expressive nature” (Coldron, 2013, np.). Practice, a set of “socially produced, culturally constructed activities” (Holland, Lachicotte, Skinner, & Cain, 1998, p. 41), can probably only be properly conveyed by the practice itself. Nevertheless, it is expressed and mediated by spoken discourse, materiality and embodied practices: It is opened by and entered through *artefacts* (Holland et al., 1998, p. 251) which assume and express *intentionality*. In this case, the mediating artefacts include:

- *my language and the implicit and explicit rules I set up for classroom talk* – for example, discussing and disallowing talk about people as ‘clever’ or ‘able’ or, including about oneself, as ‘useless’, ‘thick’ or ‘stupid’, encouraging talk which is collective, supportive and reciprocal; welcoming mistakes and queries as prompts for thinking rather than worrying about being wrong;
- *the physical space for studying* – for example, preparing the room with mathematical posters and frequently taking in eye catching and intriguing objects to promote inter-cultural respect and the awareness of possibilities of communicating mathematics outside a common vernacular; arranging tables in groups of about six;
- *promoting collaboration across the whole class* – for example, putting students in heterogeneous groups chosen by me; restructuring each time a new topic is introduced; discussing my research-

evidenced conviction that this supports building a learning community; requiring that everybody in a table group must understand before the group moves on;

- *questions or other responses where answers might be expected* - for example, developing a sense of themselves as being sources of authoritative knowing when they look to me for conventional 'help' and it is not forthcoming and offering instead, say, 'Can you apply that reasoning to this one?', 'How does what he is saying connect with what we were discussing last week?', 'You two don't agree - excellent - an opportunity for mathematical argument!'
- *the tasks set* - for example, ensuring that they are group-worthy; adapting the curriculum according to students' responses;
- *the pattern of attendance* - for example, making some sessions explicitly optional and others justified as essential, required for honouring and contributing to the learning community; allowing extended periods for an enquiry;
- *the physical objects used* - large, colourful physical models, shared task recording sheets, cards to be flexibly sorted and organised rather than static texts, erasable short-term responses to group questions;
- *characteristics of the final assessment* - for example, open book where students can take in anything except things that connect with the internet; more marks available than needed so that any work submitted can be rewarded.<sup>2</sup>

For almost all of the students, the effect of these mediating practices in mathematics education is “a totally new experience” (interview data).

## The study

This action research case study offers a “serious example” (Skovsmose, 1994, p. 9) of practice, that bundling together of “co-dependent (mutually constitutive) sayings, doings, understandings, physical arrangements, purposes, feelings, roles and identities” (Coldron, 2013, np.). It is framed within my “living education theory” (Whitehead, 1989, p.41), undertaking research as thoughtful practice. I have been teaching very similar mathematical content with very similar intentions to very similar students for many years and the theory which guides my practice has become embodied and enacted with increasing complexity over time. McNiff and Whitehead (2010) describe the process thus:

Because you are a living person, you are changing every day; and because you are reflecting consciously on what you are doing, and making adjustments as you go, your theory is also developing with you. Your theory is part of your thinking and living, which is continuously transforming. So your theory, as part of your own thinking, is living... In living educational theories the explanations are produced ... in the practice of enquiries of the kind, ‘How do I improve what I am doing?’. (pp. 252–253)

---

<sup>2</sup> For much greater detail and exemplars see Povey (2017).

I used interview data from students to explore their experience of and reaction to my practice. The participants were from a class of 40 who were following an undergraduate pure mathematics module comprising a third of their final year study taught within a mathematics education centre by staff who had been school teachers (Povey & Angier, 2007).

The group interviews, each of which lasted about an hour, were conducted by a researcher unknown to the participants using a very open, semi-structured protocol. I explained the purpose of the enquiry in writing, making it clear that they were under no obligation to take part and could withdraw from the study at any time. I assured them that all data would be reported anonymously unless they specifically requested otherwise. I guaranteed that the data would not be viewed by me until I had finished teaching and assessing them, hoping in this way to address the ethical issues involved. Everyone in the class agreed to be interviewed but logistical constraints during a pressurised time of year meant that only eighteen ended up being able to participate. Overall, the groups were heterogeneous and not composed of friendship subgroups from the class.

The interviews were all transcribed by an independent transcriber (with occasional editing for clarity and brevity). The initial analysis, despite being careful and systematic, was iterative and somewhat ‘messy’. I worked with the transcription texts, reading and re-reading them many times, tentatively extracting what seemed to me to be interesting and coherent passages of dialogue. I printed each of these onto a separate sheet of paper and physically grouped, de-grouped and re-grouped the sheets, searching them and annotating emergent themes. I did not identify the individual participants in the transcripts at this stage in order to gain a little distance from the texts. I then listened to all the tape recordings more than twice, attempting “radical listening” (Clough & Nutbrown, 2012, p. 99), immersing myself in the full data set to gain a sense of how the emerging themes were, or were not, grounded in the data. I then repeated the initial process of working with the transcripts, checking out and supplementing the existing themes and looking for new ones. No new themes emerged but some were modified and/or enriched. Finally, I referred to my record of which students had participated in which group interview and listened carefully to the tapes for a final time in order to identify the participants in the extracted passages.

## Analysis

The interviews were cultural spaces where the students, through improvisation, articulated an understanding of their experiences of the module. In analysing them, I asked to what extent and in what way (i) my “living theory” was visible to them and (ii) they were willing to experiment with embracing aspects of it in their sense of who they were becoming. All but one suggested some such identification. After interrogating the data, I identified a number of themes which there is no space here to discuss. Rather, I present extracts from the data which link to just one aspect of working for social justice in and through mathematics education, that of experiencing solidarity.

Solidarity involves *challenging the discourse of ‘ability’* (Marks, 2013) and destabilising attendant hierarchies, offering equal value and equal respect towards each other.

Anna: I think we’re all on kind of a level as well. Like we all have obviously our strengths and weaknesses in certain areas, but they’re all different so we can actually get that collaborative kind of thing that everyone’s talking about.

Matt: There's one example where the vast majority of all the groups thought one particular answer was correct and then one person disagreed and that person was the one that got it right... that's kind of a bit of an indicator... It's not the fact that 95% have got it wrong. It's the fact that one person got it... it's almost like reverse psychology... instead of feeling left out because you're the one that hasn't got it right, it's like everybody else thought 'we can do it as well' ...Does anyone know what I'm trying to say there?

Rach: ... Because you've got a group mentality you sort of think 'One of us has got it so between us we've managed it and with a little bit of work it's not out of reach for us all'.

Developing links *in a learning community* expressed metaphorically as being a family (comp. Angier & Povey, 1999) becomes a shared preference and brings *pleasure*:

Anna: It encourages a different way of working... you don't get the chance to work in a group very often normally for maths. It's seen as a very solitary subject, but I think it makes it a lot more interesting and a lot more enjoyable when you can sit and work with people on a subject and on a problem particularly.

Will: I do like it a lot better ...It's more like a little family, ain't it?

Rach: There's a lot of us who will come into uni when we haven't got set lectures... because we want to sit and work as a group of us rather than sitting at home doing the work...

Int: Would you have done that before?

Rs: [*several*] No, no never.

They appreciated that the nature of their tasks supported this. These group-worthy tasks and the discourse of collaboration are used by the students to position themselves as agentic in the face of doubt or difficulty. Such a sense of *agency and authority* has been found to be a central characteristic of those mathematics teachers who were able to interrogate taken-for-granted practices in schooling and work for progressive change (Povey, 1997). The approach to answers plays a part in developing their shared conviction and authority.

Dora: I think a lot of the tasks though because they're quite open-ended, it's not stuff you can do individually. You have to do it with other people's inputs, so you're using other people's ability... at first it got us kind of gelling together and then we just naturally did it afterwards.

Sally: I think it's a lot more open to ask questions...

Beth: Yeah, I think it definitely encouraged me to keep going with problems when I've been stuck... when you're in a group and you see that other people have understood it, you know that it is possible and it just pushes you to keep going that bit further.

Julia: She asks us to convince each other what the right answer is... she rarely actually gives us answers. You know, we have to work to the answers between us until we're all happy that we have got the answer...

Dora: I feel it almost takes away that kind of elitist side of maths where somebody'll be like 'I have the answer. You don't have the answer', because it doesn't particularly work like that because we've all been discussing. Nobody really knows who's got what, but we've all gained.

Working together and supporting each other is expressed through *an ethic of caring* (Collins, 2000) where the experience of being left behind is turned around to be an opportunity to demonstrate solidarity with each other.

Sue: I think maybe if everyone on the table understands it and... [you're the one] left behind... I'm not always the one [*laughter and cross talking*]... times like that it's not fantastic, but it's very rare that actually happens anyway because everyone tends to help everyone in our group.

Sally: ... there's always somebody in the group... they'll go through it again and again if need be and I've been in the situation where I've understood something and somebody else hasn't and they've been getting a bit stressed out and I've been able to explain to them, like taking it back a step and going through things.

Rach: Yeah, people are very good at giving you the time if they can see something's bothering you... helping you through... getting everybody to the same level before everyone moves on.

## Conclusion

In order for hegemony to be questioned, students have to be able to gain a critical and reflective distance from the taken-for-granted. This cannot be accomplished without theoretical engagement with the workings of power and our own complicity in perpetuating and reproducing hegemonic discursive practices (Nolan, 2012). Here, however, I have foregrounded the significance also of *experience* in shaping our understanding of what it is possible to be and to do, of who we are and who we might become and of how we might act in and on the world. This springs from a conviction that inhabiting “potentiary” (Holland et al., 1998, p. 250) imaginative spaces defies the corruption of the capacity for hope that neo-liberalism engenders (Berger, 2007).

The interview data suggest that the students distanced themselves from neo-liberal discourses and experimented with other ways of constructing themselves and others, enacting new selves-in-practice, engaged, confident, authoritative, agentic and participatory selves, selves which allow for a commitment to social justice. Mathematics is *par excellence* the discipline that is used to separate learners from each other, to valorise individuals, to rank them and to place them in hierarchies in order to justify fundamental inequalities as appropriate and merited. In addition, it epitomises a separated, de-personalised, moral-free epistemology. Combatting these ways of using and understanding mathematics with the experience of solidarity – challenging ‘ability’ hierarchies, experiencing pleasure and caring within a learning community and developing agency and both

personal and shared epistemological authority – has the potential to support the fight for social justice in mathematics education.

# The student's perspective on school mathematics – a case study

Ann-Sofi Røj-Lindberg<sup>1</sup> and Kirsti Hemmi<sup>1,2</sup>

<sup>1</sup>Åbo Akademi University, Vasa, Finland; [aroj@abo.fi](mailto:aroj@abo.fi)

<sup>2</sup>Uppsala University, Sweden; [khemmi@abo.fi](mailto:khemmi@abo.fi)

*This paper is based on a long-term case study of students' experiences of reform mathematics classrooms in Finland. Specifically, it focuses on emerging school mathematical actions and activities experienced by three committed and engaged students. Students described their experiences in interviews during and ten years after lower secondary school. The paper asks why taking part in certain practices makes some students learn to like and others to dislike school mathematics, despite high attainment concerning reform-related objectives on achievement and responsibility. The case study showed the importance of making classrooms places where all students belong to communities in which mathematical knowledge is negotiated.*

*Keywords: Habits of the mathematics classroom, long-term case study, spaces for participation, student perspective.*

## Introduction

In mathematics education, it is challenging to develop classroom cultures in which students maintain positive relationships towards mathematics after their first school years (Sullivan, Tobias, & McDonough, 2006). Although Finnish students have performed well in mathematics in international comparisons, especially in the Programme for International Student Assessment (PISA), many Finnish students' attitudes, self-confidence and engagement are poor in comparison to other countries. Based on PISA 2003, Viking Brunell (2007) found that only one third of the students in Swedish-speaking classrooms in Finland looked forward to mathematics lessons, and one half did not express any interest in mathematics whatsoever. Later, the 2015 Trends in International Mathematics and Science Study showed that Grade 4 Finnish students had a less positive attitude towards school mathematics than those in other European countries (Mullis, Martin, Foy, & Hooper, 2016). This was especially the case with girls, who chose to invest in subjects other than mathematics quite early on (Metsämuuronen, 2017). While much research has confirmed some students' negative relationship with mathematics (cf. Brunell, 2007; Lewis, 2016), very few studies have focused on why engaged and committed students develop negative attitudes and abandon mathematics by neglecting to study advanced courses in the subject at upper secondary level. The aim of this paper was to contribute to our understanding of the reasons behind these choices.

For some decades, attempts have been made in many countries to improve/reform school mathematics to make it more meaningful for all students (Fennema & Scott Nelson, 1997). This has also been the case in Finland. This paper was situated in a reform context in a Swedish-speaking lower secondary school in Finland. The reform emerged in connection with a three-year action research project that focused on learning processes and assessment, especially those involving problem-solving and investigative project work. The national core curriculum declared that solving problems and attending to the internal logic of mathematics were the two most important principles for mathematics teaching (Finnish National Board of Education, 1994). By probing and assessing the mathematical thinking of

students, teachers wanted to encourage the discovery of useful and viable mathematical ideas that they described as ‘active’ knowledge and to support individual students’ emerging sense of control over and responsibility for learning to a greater degree than was possible through ‘ordinary’ classroom practices.

Few studies have investigated school mathematics from students’ perspectives, and we have not come across any studies that involved students as legitimate participants in an interpretive research methodology that relates to teachers’ reform work during lower secondary school and beyond. In the doctoral study on which this paper was based (Røj-Lindberg, 2017), participating students were interviewed several times from the age of 13 to approximately 25. In this paper, we aimed to answer the following question, “Why do some committed and engaged students develop a negative identity concerning mathematics during lower secondary school?”

### **School mathematics from the student’s perspective**

About thirty years ago, Alan Schoenfeld (1988) argued that school mathematics might unintentionally produce “disasters” even though most actions and activities in mathematics classrooms proceed as envisaged by teachers in terms of the curriculum and teaching practices. As a result of his inquiry, Schoenfeld called for broad research agendas that should aim “to understand the world from the student’s point of view” (p. 165). His message was that if learning could be perceived as much more than what can be inferred from observing students in classrooms, including their mathematical performance, different forms of assessments, and so on, then the voices of students really should start to matter in school mathematics and educational research. Since then, the same type of request has been formulated repeatedly both outside and within mathematics education (Berinderjeet, Anthony, Ohtani, & Clarke, 2013).

Jo Boaler (2003) defined classroom practices as the recurrent activities and norms that develop in classrooms over time. We argue here that even if researchers are strongly focused on changing classroom practices, they have tended to apply a top-down perspective, looking at students and processes of learning from the outside. Classroom practices have been studied in isolation from students themselves, though they have been conceptualized as methods of teaching<sup>1</sup> that provide a social context that influences and allows the experiences and expectations of students. From an observer’s perspective in a classroom, it may be possible to describe and conceptualize regularities within observable actions and activities. But such a stance does not take into account the notion that activities and actions in the classroom are complex when seen from the perspectives of students who are the immediate participants.

Here, we have taken reflexivity as a premise of the research and argue that students’ accounts of what happens or is expected to happen in mathematics classrooms are socio-cultural in their very nature. We have accepted that social situatedness should be taken as a premise when students’ perspectives are the focus of interest. Whatever else might be innate, students’ expectations concerning school

---

<sup>1</sup> In the literature, teaching methods have been described in different ways, for instance, as open, progressive, traditional, constructivist and discussion oriented.

mathematics are not; these are formed over the years, largely through students' interactions with their parents, peer group and teachers. Based on such a premise, we interpreted the experiential accounts given by students in interviews as having a social and cultural origin. Interpretations can be created through "zooming in" (Lerman, 1998) on the complex territory of classroom practices through accounts given by students and by looking at classroom actions and activities through students' 'eyes'. On the other hand, one must "zoom out" to view individual students' experiential accounts without losing contact with the actions and activities that constitute school mathematics in their individual classrooms.

The study was embedded in social practice theory and focused specifically on students' alignment and their development of identities and imagination in relation to classroom practices in which they took part. Learning was defined as increasing participation in classroom practices, which were understood as social processes where meanings are negotiated and students become or avoid becoming persons for whom mathematics is important (Wenger, 1998).

## Methodology

This paper was based on a case study (Røj-Lindberg, 2017) within the context of teacher-initiated action research and reform work. The main case record material (see Bassey, 1999) was semi-structured interviews with four to five students from each reform classroom, in total 120 interviews with 27 students. Four to five interviews were done with each of them during the three lower secondary school years. Students were asked to describe and comment on their experiences of school mathematics, including their wishes and expectations, for instance, in relation to recent mathematics lessons. Students were also probed about their views on problem-solving activities and other reform-related activities, for instance, on being asked to explain one's thinking publicly. Interviews with three committed and engaged classmates, Joakim (male), Kristina and Nette (females), were selected for further analysis for the case study. These three students, who had experienced the same classroom context, were also invited to look back on their experiences as adults. Adult interviews were conducted when the three students had finished university and focused not only on lower secondary school classroom practices but also on mathematical practices more widely. The first author's preliminary interpretations of the lower secondary school interviews were used as inputs in the adult interviews, which were conducted to deepen the researcher's understanding of school mathematics from a student's point of view, not for fact-finding.

The analysis of the interviews, which were conducted in Swedish, was first inductive and then deepened through holistic interpretations of each interview (see Merriam & Tisdell, 2016). The researcher's responsiveness to emic issues appearing in students' accounts was high. Important emic issues were *structure and closure* emerging from the lower secondary school interviews and experiences of *identity work* from the adult interviews (see Røj-Lindberg, 2011, 2015). Emic issues were theoretically connected to Wenger's social practice theories. In the final analysis, they were connected to other theoretical constructs from this theory, such as communities of practice (applied to school mathematics), negotiation of meaning, modes of belonging and students' trajectories within a specific practice. These were applied during the interpretation of interview accounts. It is beyond the scope of this paper to give a thorough explanation of the use of these constructs. It is also

impossible to give an exhaustive account of the extent to which the reform influenced activities in the classrooms (for detailed information, see R  j-Lindberg, 2017). Yet, when presenting the results we connected the issues brought forth by students to relevant classroom events. The quotes have been translated into English by the first author. Results presented here do not intend to generalise but to understand school mathematics as it emerged in one reform classroom from students' perspectives.

## Results

In the following section, we have introduced the students, Joakim, Kristina and Nette, and their trajectories (Wenger, 1998) in mathematical practices. Next, we have reported two reasons that we claim to be of crucial importance to students who make negative choices concerning the role of mathematics in their lives. These reasons are neither mutually exclusive nor exhaustive. They are more like what can be seen in a kaleidoscope; each turn gives a new view of school mathematics from the student's perspective.

### Student trajectories

As newcomers in the seventh grade, Joakim, Kristina and Nette were highly engaged students. Nette's engagement clearly related to an imagined future as a veterinarian, while Joakim and Kristina were generally confident about the significance of learning mathematics. During lower secondary school, they were responsible students who were evaluated by the teacher as skilful/capable in different types of assessment. They wanted to take part in actions and activities in school mathematics communities, and they appreciated the problem-solving activities that were introduced within the reform. In short, we can describe them as successful students who expressed strong alignments in relation to reform objectives. Nevertheless, their trajectories and identifications related to school mathematics were constituted very differently over the following school years, which strongly affected their futures. Joakim's trajectory continued to be structured by positive choices concerning mathematics. He passed the advanced mathematics courses he had selected in upper secondary school<sup>2</sup> with success and chose a mathematics-intensive university program to obtain a MSc in engineering. The trajectories of Kristina and Nette differed significantly from Joakim's. Both of them chose basic mathematics courses at secondary level and neither of them chose university programs that included mathematics. Nette's dream of becoming a veterinarian turned into a claim that mathematics was not for her, and she chose a university program in psychology. Kristina described school mathematics as a more or less alienating experience, but in contrast to Nette, she continued to be very accepting. However, she dropped her plan of studying science, because she did not want to align with the workings of the mathematics classrooms she had experienced in school. Instead, she chose a university program in pedagogy.

### The dominant habits of the mathematics classroom

From a student perspective, the actions and activities in a mathematics classroom are complex. A characteristic that supports participation in the case of a student at one moment in time might not be

---

<sup>2</sup> The upper secondary mathematics curriculum is divided into basic and advanced level courses. Only students who select advanced courses must take mathematics in the matriculation examination.

supportive for all students and might not continue to be supportive for that student over time. However, our analysis of students' interview accounts showed recurrent patterns in mathematics classrooms that we described as dominant habits. As the space of the paper does not allow us to thoroughly account for all habits, we have chosen those that most likely led to the development of non-participation (Wenger, 1998) of Kristina and Nette in the long run. Two dominant habits that appeared in all student interviews in the case study were as follows:

(1) The “all-look-alike” structure of lessons, which contributed to the sense that mathematics was a monotonous subject and led to a kind of meaninglessness for students who did not accept non-participation as an adventure (see the work of imagination, Wenger, 1998, pp. 185–186):

All lessons look alike, we have theory and write down the things we are doing. The teacher asks different things. Then, we may count at our own pace from the book. The last lesson we did  $x$  times  $x$  and such. (Nette, Grade 7)

I don't think there have been any changes. It just continues from year seven to year eight and then, to year nine. In my opinion, nothing has changed. It has been fairly similar all the time. Of course, they follow and teach by the book. (Nette, Grade 9)

(2) The general mode of working individually during lessons, which meant that students were mostly left by themselves to struggle for coherence regarding mathematical structures. Hence, there were limited opportunities to develop a sense of belonging to any community where mathematical knowledge was negotiated in the classroom:

We do work alone all of us. It is like that anyhow, the teacher has to come to everybody, so it is the fastest way to ask the one you sit next to, so you talk to everybody. (Kristina, Grade 9)

Joakim continued to take part in communities that included the teacher and students he described as “smart”. Moreover, the support he received from his teacher reminded him repeatedly of his membership in communities of mathematically-able people.

The textbook continued to be the main pedagogical artefact during the reform, and teachers continued to structure the tempo of student learning with the textbook. The habit of working alone with textbook tasks may have added to some students' sense of enjoyment. But as Kristina stated, the positive effect emerged only “when you succeed and keep up with new things”. In the long run, both Kristina and Nette expressed a sense of not keeping up with the tempo. Hence, the way the textbook was used in the classroom may have contributed to their developing identities of non-participation.

All students who took part in the case study welcomed reform-related activities, such as investigative project work, which “did show a little what mathematics can be”, as Joakim stated as an adult. However, some students considered investigative project work to have a marginal role in their learning of mathematics even if their accounts clearly described the opposite:

You learn things that don't have so much to do with mathematics. I did learn about unemployment rates in Finland. But this has nothing to do with mathematics. I think that I haven't learned anything that has to do with mathematics. I mean, like what we are doing in the book for (math) theory. I don't learn in that way when I do investigative work. (Kristina, Grade 9)

In general, reform-related activities had the potential to increase participation for all students. Yet, as the extract above shows, students did not always see the connection between these activities and their development of mathematical knowledge. Therefore, the activities did not necessarily enhance students' participation.

### **The character of spaces for participation in classroom practices**

We defined learning as increasing participation in classroom practices. Thus, it is natural to consider the character of mathematical spaces where meanings were negotiated in the classroom (Wenger, 1998). We have attended here to the most obvious characteristics that seem to have contributed to some students becoming persons for whom mathematics was not important.

The most important aspect was that “right or wrong” classroom practices limited the possibilities for constructing mathematical knowledge for all students. Nette succinctly captured this aspect and her perspective on one of its side effects, which was that questioning might be interpreted by the teacher as a lack of responsibility for learning and not as comments from students striving for understanding:

You cannot dispute lower secondary school mathematics, because it is right-or-wrong mathematics. If you start questioning it, the teacher thinks you are trying to escape. (Nette, adult)

Within “right-or-wrong” practices, there was little room for social, playful and investigative mathematics. Aligning to the practice meant individually struggling for coherence and understanding by listening to the teacher. The struggle for understanding was accompanied by feelings of insecurity, because the act of giving a wrong answer in public was shameful.

When students are supposed to answer in public, I get fairly nervous. I think what if I give the wrong answer. (Nette, Grade 7)

You have to listen all the time to what the teacher is saying and you get so tired. As soon as you talk just a little bit with your friend then it goes, oh, now I do not understand anything again. It is rather strenuous. You should have a better ability to concentrate. (Kristina, Grade 9)

Reaching the right answers rapidly was, from the students' perspective, a sign of understanding and often meant immediate rewards, such as praise from the teacher or not being constrained by homework. The case study showed that tentativeness, wrong answers, misinterpretations or extended interpretations of textbook tasks were not considered by students to be characteristics of a space where every student could belong and participate. For some students such as Nette and Kristina, this situation contributed to the development of negative identifications towards mathematics, which strongly affected their futures.

### **Discussion**

We argue that a main concern for reforms in mathematics education should be a critical focus on the reality of the classroom, which from students' perspectives is even more complex than interviews can reveal (see Berinderjeet et al., 2013). Also, dimensions that extend the classroom level had an impact on students' relationship to mathematics. According to Gregg (1995), reformers should encourage teachers to think in new ways by implementing new ‘idioms’ into their stories and explanations. This is, however, exactly what teachers who were involved in this case study did; they were supported by

the scholarly community to integrate new idioms based on constructivism (see, for example, Black & Atkins, 1996) into their talk about classroom practices. Idioms such as active learning, discovery processes and responsibility for knowledge construction were strongly present when teachers talked about reforming their practice. Yet, they did not oppose the epistemological hegemony of academe by asking, “What if we lift our gaze from the student as a ‘constructing individual’ to zoom out and include the ‘socio-cultural whole of the student and ourselves?’” They attended to the practice-in-individual but not to the individual-in-practice (Lerman, 1998). The latter perspective confronts us with the question “What is the nature of school mathematics practices in which all students should become qualified in order to develop positive identifications and to enhance the role of mathematics in their lives?” This question must be the starting point whenever we want new curriculum ideas to change classroom culture in a direction that makes participation an inclusive experience for as many students as possible. This is an issue to which hardly any research attends.

Several factors interacting in a complex manner influence students’ choices and relationships to mathematics, and, therefore, it is valuable to explore some cases deeply to understand them. In this study, Wenger’s (1998) theoretical constructs proved fruitful for revealing hidden regularities behind the development of students’ negative identifications concerning mathematics. According to Wenger, learning is so much more than gaining skills and knowledge, it is a process of becoming that transforms both who the learner is and what the learner can do (p. 215). Concerning the results presented here, this a very strong statement. When students, regardless of gender or school mathematical practices, learn disengagement (e.g., Sullivan, Tobias, & McDonough, 2006) or explicitly refuse mathematics in school (e.g., Chronaki & Kolloosche, 2019), their lives as adults, and especially their possibilities to partake in the working life, might be diminished.

# Agency and identity of female Arab students entering a technological university

Soryna Sabbah<sup>1</sup> and Einat Heyd-Metzuyanim<sup>2</sup>

<sup>1</sup>Technion, Israel Institute of Technology, Israel; [sorynas86@gmail.com](mailto:sorynas86@gmail.com)

<sup>2</sup>Technion, Israel Institute of Technology, Israel; [einat.metz@gmail.com](mailto:einat.metz@gmail.com)

*This report studies the progression of cultural and mathematical identities of female Arab students during their first semester of engineering studies in a technological university in Israel. The report focuses on the cases of two students, Mira and Lena, who demonstrated remarkably different trajectories of identity development. Data was analyzed by closely examining narratives in students' Space of Authorship related to gender and ethnicity. Findings show that Mira's Space of Authorship included multiple narratives relating to ethnic and religious conflicts, upon which Mira enacted agency by debating and choosing specific courses of action both in social life and in mathematics learning. In contrast, Lena's Space of Authorship drew upon psychological discourse to explain her difficulties in ways that did not afford her agency to act back on the challenges she was facing.*

*Keywords: Agency, identity, gender, Arab students, undergraduate education*

## Introduction and theoretical framework

The Arab minority in Israel is an involuntary minority (dependent on their collective identities in relation to the dominant group) (Flum & Kaplan, 2016) which consist of 20.5% of the general population. There are long standing tensions between the Jewish majority and the Arab minority in Israel, which have encouraged geographical, political and social separation between them (Flum & Kaplan, 2016; Kaplan, Abu-Sa'ad, & Yonah, 2001). This separation also exists in the education system, where the K-12 education systems of the two populations are completely separated. Thus, universities are usually the first multicultural encounter between Arab and Jewish students. University courses are taught in Hebrew, while in school Arab students study mostly in Arabic. In addition, Arab students have multiple challenges connected with their minority status and the political and ethnic conflicts it entails. For female students, these are compounded by difficulties relating to changing gender roles in this relatively traditional society (Arar & Masry-Herzalah, 2014). As female students enter the predominantly Jewish university, they are exposed to social narratives that question their ability to succeed (similar to Jewish female students). Yet, for Arab females, university studies are often the first occasion to leave their home-village and be exposed to Western, secular culture. This is a transition that often causes "culture shock" (Arar & Haj-Yahia, 2016).

The report is a part of a large study whose goal was to explore the process that Arab female students' identities undergo through their entry into a predominantly Jewish university, both in relation to these students' academic and mathematical learning, and in relation to their sense of ethnic and cultural belonging. Data shows high rates of failure of this particular minority on entry-level mathematics courses at the Technion. We employ a socio-cultural lens on the activity of mathematics learning to study the relation between cultural transitions and the development of a student's mathematical and learning identity (Sfard & Prusak, 2005; Wenger, 1998). In particular, we rely on a sociocultural view of learning as becoming a participant in a certain community (Lave & Wenger, 1991; Sfard & Prusak,

2005). Communities are characterized by shared values, forms of action and interpretative schemes. These have been defined by Holland, Lachicotte, Skinner, and Cane (1998) as “figured worlds”, where a figured world is defined as “a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued by others” (p. 52). In the case of Arab students, the home, family and village figured world is extremely different from the predominantly Jewish, technological and western figured world of the university.

In our work, we rely on Holland and colleagues’ (1998) concept of “space of authorship”, which links between figured worlds and the identity participants author for themselves within these figured worlds. Holland et al. point out that the space of authoring, in which people figure their identity, is always a contested space. We link these ideas with Sfard & Prusak’s (2005) definition of identity as a set of reifying, significant and endorsable narratives about a person. Space of authorship, for us, is the realm of narratives from which identity narratives are picked up, contested against and negotiated. Agency, defined by Holland and colleagues (1998) as “the realized capacity of people to act upon their world” (p. 42), is enacted through the orchestration “arranging the identifiable social discourses/practices that are one’s resources” and form his/her space of authorship (p. 272). Thus, the question of this study is: How do cultural and mathematical identities of female Arab students develop during the initial phase of their college level mathematics studies and in what ways do these students enact agency in relation to the narratives regarding ethnicity and gender in their space of authorship?

## Method

The cases of Mira and Lena were taken from a larger study in which we followed 13 female Israeli Arab undergraduate students during their first semester at the Technion, a technological university in Israel. All of the participants were studying in either the Computer Science faculty or the Electrical Engineering faculty, where 40-50% of the courses taken in the first semester are mathematics courses (usually Calculus I and Algebra I), both of which are among the most coveted faculties in this institute and have very high entrance qualifications. The students’ ages ranged between 18 and 19.5 years. They were recruited voluntarily, during the first week of the semester, through an institutional mentoring project for Arab students in which senior students mentor the incoming students. Students were promised complete confidentiality and signed informed consent forms. The study was approved by the Institutional Review Board of the Technion.

All the students were interviewed at the beginning and at the end of their first semester. Interviews were semi-structured and conducted by the first author in Arabic. They lasted between 30 and 90 minutes. Students also completed two midterm diaries, which included answers to questions sent to them by email. The final interview consisted of questions eliciting reflections about the past semester. In addition, students were requested to reflect upon and answer some of the questions from their final calculus exam. Data was analyzed using a combination of inductive and deductive codes (Saldana, 2016). Inductive coding searched for recurring themes in students’ interviews. For example, a common conflict described by the students regarded social encounters, whether to “hang out” with certain people and with whom to study. Deductive codes were based on the theoretical orientation of figured worlds. In particular, we searched in the interviews’ transcripts for valued actions, valued

outcomes, significant actors and roles in the home vs. Technion figured worlds. The main themes arising in all the interviews in relation to conflicts between the home figured world and the Technion figured world related to narratives about ethnicity and gender. In relation to these conflicts, we searched for indications of agency both in the actions described by participants (e.g., “I try to study hard”), or lack thereof (“I feel I am not focused” – with no mention of possible action to become focus). We also searched for agency in the manner in which interviewees spoke about the conflicts – as a given situation or as something that can be acted upon.

## Findings

Mira and Lena were chosen for this report since they exemplified very different trajectories of acclimation to the figured world of the Technion. While Mira ended the first semester with passing grades and relative success, Lena failed several courses and was quite discontented with herself at the end of the semester. The different trajectories afforded opportunities to view and contrast different processes of change in identity narratives and the ways in which these changes drew upon certain spaces of authorship. We first explore the figured world of Mira and Lena, as seen through the collective narratives told by them. We pay attention here to what they say about gender/ethnicity and their positioning with relation to the conflicts they talk about.

Mira's stories about her family and village drew a figured world that is mono-ethnic and mono-religious. She reported in her first interview that she was having trouble living in a multi-cultural environment. She also identified herself as a “non-social person by nature”, perhaps to minimize the potential conflicts that could arise as result of the multi-cultural environment at the Technion. Mira also reported being the first in her family to attend university and that she felt pressure from her family to succeed:

I'm the first one [from my family] to ever attend a high academic institution. Everyone at home has expectations (from me) and that's a bit stressful. (Mira, 1st interview)

Positioning her academic skills in relation to her family seemed to be important to her:

I have four older brothers and they were not strong at school, and a sister (who is) a year older than me. I'm better than her academically. She has not yet begun her academic studies. (Mira, 1st interview)

Although Mira authored herself as “strong” academically, she confessed in her first interview that mathematics was not a subject she preferred: “to tell (you) the truth, I do not like mathematics”. Her goal was to study computer science and mathematics was seen only as a means towards that cause.

Unlike her academic identity, which included narratives of relative strength and did not include many conflicts in its space of authorship, regarding her ethnic identity as an Arab student Mira's space of authorship was much more conflictual. In the initial interview, Mira reported that she had not encountered people from other religions before she started studying at the Technion. Her first close encounter with someone of a different religion occurred when she entered the dorms:

I live with a Christian student in the dorms; she is from a different religion. At first, I worried about the idea of living with her, because I am a Muslim and she is Christian. I was worried I would feel restricted and not able to behave freely. (Mira, 1st interview)

Mira's justification of her worries as based on the fact that the student was "Christian" while she was "a Muslim" indicated that, in her space of authorship, the mere religious identity of a person could cause problems while living together and "not behaving freely". Notably, the fact that the Christian student was also Arab was not mentioned but taken for granted, and the possibility of living with a Jewish student was not mentioned at all. Yet, like in many other instances, where Mira only reported about conflicts in retrospect, this encounter was already authored as resolved. She ended the story by:

Later I discovered that if I give her the space to behave according to her beliefs and religion, she will give me back the same space I need. (Mira, 1st interview)

Her agency in relation to this conflict could be seen in the actions she described ("give her space") that resulted in what she needed ("the same space I need"). As the semester progressed, Mira repeatedly recounted encounters with students of other religions and gave them significance. Although Mira expressed an acceptance of students from different religions, her diary entries clarified that she was engaged with conflictual narratives around ethnicity and religion and that these were entering her space of authorship:

Every day and all the time, I face differences. First, the atmosphere at the Technion is not like the atmosphere at home at all. Here everyone is independent and each person is responsible for himself and his own decisions. There are people from different places, different religion[s], different thoughts and different values and cultures. For example, I came from a village where everyone is Arab and we all belong to the same religion, whereas at the institute I meet people from all over the world and from different religions. I see people behaving in a way that goes against my values and that is a new atmosphere for me, I am constantly trying to stay on the side and not get involved with anyone. (Mira, 1st diary)

Several issues relating to this excerpt are worth mentioning. First, Mira is explicitly talking about "differences" between the "Technion" and "home". In other words, it is clear that she is constructing the two locations as different figured worlds. The differences mainly point to differences in relations between the individual and the social community ("here everyone is independent"), hinting that in her home figured world, people are interdependent and not responsible for their own decisions. The interdependence is linked in Mira's words to the Arab ethnicity and to the religious homogeneity of her home village. Thus, it is clear from Mira's words that she is able to locate the conflict, the values that are at stake, and her positionality with relation to this conflict. Notably, there are signs of agency in this story too. Mira writes about the conflict and immediately states her actions in relation to it ("I try to stay on the side and not get involved"). Later in the semester, this action of "staying on the side" seems to mature into a more nuanced positioning and identification of herself with relation to the "others":

I came from a traditional and relatively conservative family, where I grew up with values that I believe are correct. However, at the Technion, I encounter many people who behave against my beliefs, and it makes me feel that I am an extreme person or something like that. Yet I continue to believe in my tradition as they continue to believe in theirs. (Mira, 2nd diary)

This excerpt hints at several processes that Mira underwent during the semester. First, there are beginnings of separation from "her beliefs". Whereas these beliefs were stated in the first diary as

simply “her values” (“I see people behave against *my* values”), here, these beliefs are located in time and space (“I came from a traditional ... family”, “I *grew up* with values”). Moreover, the statement about values “that I believe are correct” shows hints of voices that position these beliefs as “incorrect”. These voices are later located in people “who behave against my beliefs” and that, whether directly or indirectly, make Mira feel she is “an extreme person”. The taken-for-granted “beliefs” and “values” have thus been questioned and contested for Mira, and this has raised a conflict with regard to identity narratives concerning religion and ethnicity. In the face of these conflicts, Mira enacts agency in choosing to adhere to her home values.

With relation to her mathematical identity, Mira reported finding her mathematics studies to be surprisingly satisfying. In her first diary, she wrote:

The most interesting lecture in my weekly schedule is a Calculus lecture, because I learn mathematics differently... I learn how to learn mathematics, how to think outside the box and how to find ideas or solutions for different mathematics problems. It is a hard course but the lecturer is a wonderful person and he makes it an enjoyable course. (Mira, 1st diary)

Her satisfaction with her mathematical studies continued throughout the semester despite hurdles and setbacks. In the last interview Mira reported failing in the first take of the calculus exam because of being “unprepared unlike I should have been”, then studying better and passing the second take with a satisfying result.

To summarize, Mira retold her identity at the end of the semester as stronger in mathematics than at the beginning, despite recounting many stories of conflicts with relation to her ethnic and religious identity in a foreign figured world. With relation to almost all the descriptions of conflict, Mira’s talk was full of agency, whether it was related to decisions she made to adhere to her religious values, or with regard to changing her methods of study. Along with that, some changes in the space of authorship of her ethnic and religious identity occurred. These could be detected mainly in how she narrated her “values” and “beliefs” – from being inherently “hers” to being a result of her “upbringing” and her home figured world. In addition, the space of authorship came to include also third person narratives about her being identified as an “extreme” person by others, something which forced Mira to reexamine her beliefs and values and to make choices regarding them.

Unlike Mira, who was hesitant about her connection with mathematics in the first interview, Lena’s first person mathematical identity was authored in the interview as highly successful. To signify her success, she narrated the following story:

I don’t know if you know the Elkasmi competitions? (Interviewer nods.) I participated in this competition from fourth till ninth grade, almost I won the first place, once I won second place and once third place... that means it (mathematics) was for me. (Lena, 1st interview)

Elkasmi is a competition for gifted students in mathematics in the Arab community. Lena was signifying her strength in mathematics by drawing on the significance that participating and winning these competitions has in her community, a significance she made sure was shared by her interviewer.

Apart of the Elkasmi story, Lena relied, similarly to Mira, on her family’s narratives when authoring her first person academic and mathematical identity. She reported that her family thought of her as a

strong student, who could achieve anything she wanted. These expectations were talked about both as a reassuring element and as a stress factor:

They (parents and family) always remind you that you have potential. So I somehow try to turn this potential (to reality) ... So that's my parents' expectations in particular, and my sisters think that I'm 'Rambo'. That I could do anything and get along. Most people expect so. (Lena, 1st interview)

Unlike Mira, Lena was not a first generation university student in her family. Her parents both had academic degrees. Yet similarly to Mira, she also reported feeling stress from her family's high expectations. Again, it was clear from her talk that she was highly accountable to her family and community with relation to her academic choices and achievements. Yet unlike Mira, Lena's talk about her studies was mostly devoid of agency. Her authoring of herself as successful was based on the diagnosis that "math is for me", justified by her winning math competitions during her childhood. Also in revoicing the voices of parents and significant narrators ("they always remind you"), these voices narrated her as "having potential" and "turning this potential into reality". This diagnostical discourse was most noticeable in the main conflict Lena talked about from her first interview – that relating to her gender:

I will not begin now by saying that boys are smarter than girls, but I believe that boys have more self-confidence in the science field than girls. They (boys) always think that the science field is for them, and girls think that they are less ... that is what I read and see around me. Here I see the difference between boys and girls, but that does not mean anything about the final results because sometimes the way the girl thinks help her beat all her competitors. (Lena, 1st interview)

Notably, already at this initial phase of her studies, Lena was contesting voices that were saying "boys are smarter than girls". She was negating them, yet endorsing the narrative that "boys have more self-confidence than girls", which she justified based on what she "read and saw around her". Again, there were no signs of agency in Lena's talk. Her talk was diagnostic ("here I see the difference between boys and girls"), but there was no mention of her own actions in relation to this conflict.

As the semester progressed, the gender related narratives turned into first person identity narratives. In her first diary, she wrote:

Despite all the faith I have in myself, I feel that I'm not confident enough, in comparison with boys, at least with a boy who I study with. I think it comes from old stereotypes about the composition of the boy's brain versus the girl's brain. Sometimes I fear that these stereotypes are true and that my mental ability is not enough. (Lena, 1st diary)

Again, Lena's authoring of the narratives about gender and mathematics/technological studies was solely diagnostic and devoid of agentic descriptions. She was examining her "beliefs in herself" and her "self-confidence" against "old stereotypes", indicating at least a partial endorsement ("sometimes I fear these stereotypes are true") of these narratives about "the composition of the boy's brain versus the girl's brain". Importantly, these "stereotypes" were about "brains" of males and females, something that was clearly beyond Lena's agency to change. Lena was examining and identifying herself within this figured world of fixed-ability gender-related narratives, without any indication that

she had a choice to accept or reject them. The gender-related narratives evolved in the second diary into a mini-theory of the relation between her “self-confidence” and her actions:

When a person is less confident, I don't know how (to explain this) ... But sometimes you do not believe in yourself, sometimes you do not want to meet anyone. That (decision), not wanting to meet anyone, is not the best decision in the world. You have to be with people who you see every day and share with them what you solved, and what you did not (solve). So that it helps you keep going. Sometimes it made me stop or slow down. (Lena, 2nd diary)

This quote exemplifies well the psychological discourse that Lena drew upon to explain her perceived failure during the first semester. Explanations about her failure (which is not mentioned here explicitly, only hinted at) use psychological keywords (“self-confidence”, “belief in oneself”) to justify her decision “not to meet anyone”. The self-diagnostic statements are written about as pre-given and beyond Lena's control. Further, these psychological states have led Lena, according to her narrative, to certain decisions that she regrets (“you have to be with people”), yet there is no indication that Lena had a choice regarding these decisions. They were a direct result of her low “self-confidence”. In the final interview at the end of the semester, Lena's discourse was full of such regrets:

I started the semester as a little girl, I was not focused ... I was very nervous about people around me so I did not study in the library and stayed at the dorms. Everyone asks you ‘what's going on?’, ‘Did you solve the homework?’ Why should they ask me? I felt pressure. (Lena, 2nd interview)

Again, this quote is full of psychological terms relating to maturity, cognitive and emotional functioning (“a little girl”, “not focused”, “very nervous”). As was common in all her interviews and diary entries, there is no mention of any difficulties relating to her ethnic or cultural status.

The final interview also had indications that Lena was re-authoring her identity as a high-school student (at least to the audience of the interviewer). She said: “I have never been in a place like this, even in high school there were difficulties but it isn't like here.” This narrative was different than those authored in the first interview, where Lena talked about herself as successful and being “made for” mathematics. She now talked about her high-school career as containing difficulties too, yet not as extreme as in the Technion. The lack of agency with relation to these difficulties was consistent. Lena talked about wrong decisions that she made during the semester (such as not asking for help) but always in retrospect, and always with relation to how these decisions were unhelpful.

## Summary and Discussion

Multiple studies have discussed the relationship between being part of a minority group and success in school or academic studies (Arar & Haj-Yahia, 2016; Flum & Kaplan, 2016; Nasir & Saxe, 2003). According to these studies, higher education allows minority students to move from the margins of society closer to its centers of power. Yet, at the same time, institutions of higher education pose significant barriers and conflicts for minority students. In the case of the Arab minority in Israel, and in particular, female students, these barriers are only starting to be understood. In this study, we shed light on two contrasting cases of first semester acclimation. These two cases hint that agency may be a crucial aspect of such acclimation, in the face of complex social and political conflicts. Mira's story

demonstrates a case of high agency, along with very explicit positioning of herself in relation to ethnic and religious conflicts. This agency seems to have helped her overcome difficulties in the social, as well as the academic and mathematical aspects of the Technion's figured world. In contrast, Lena's story demonstrates a case of very little agency, along with a total neglect of her positionality with regard to ethnic and religious conflicts. Paradoxically, although Lena seemed to start the semester as better acclimated to the figured world of the Technion, her lack of awareness of the constraints imposed on her by her minority status may have led to lack of agency. The significance of our study lies in turning attention to the importance of Arab female students' awareness of the social and ethnic conflicts they face upon entering a foreign figured world. This awareness may cultivate choice, which is the necessary condition for these students' agency to cope with challenges.

# Students' experiences of learner autonomy in mathematics classes

Shipra Sachdeva

Norwegian University of Science and Technology (NTNU), Norway; [shipra.sachdeva@ntnu.no](mailto:shipra.sachdeva@ntnu.no)

*This paper presents representative excerpts from post-project interviews conducted with 8<sup>th</sup> and 9<sup>th</sup> grade students from a Norwegian countryside school. Interviews attempt to explore students' experiences of learner autonomy in mathematics classes. These students participated in a larger study where they responded to a pre-project questionnaire followed by solving practical group projects using mathematics and science knowledge and post-project interviews. Preliminary interview analysis reveals that students' experiences with learner autonomy in mathematics classes are limited to opportunities provided by their teachers together with an insecurity in perceiving themselves as responsible autonomous learners. However, these learners clearly exhibit a desire to acquire autonomy, the potential to suggest changes, and participate in discussions and decisions concerning their mathematics teaching-learning process, together with their teachers.*

*Keywords: Student experience, learner autonomy, classroom environment and mathematics instruction.*

## Introduction

Developing autonomy in learners has been emphasized as a goal of mathematics education (Ben-Zvi & Sfard, 2007; Yackel & Cobb, 1996). Learner-centered teaching strategies such as mathematics teaching based on real-life contexts, inquiry-based and problem-centered learning (Wheatley, 1992; Yackel & Cobb, 1996) have been discussed to increase learners' autonomy in learning mathematics. However, discussions related to autonomy in mathematics education literature have mostly depicted it as an *intellectual* attribute to be acquired while working with mathematical problems in order to identify, enquire and develop alternative solutions, and/or as the ability to scaffold mathematical algorithms and procedures in a better way (McConney & Perry, 2011; Mueller, Yankelewitz, & Maher, 2014; Wood, 2016; Yackel & Cobb, 1996). Specifically, intellectual autonomy has been defined as, "students' awareness of and willingness to draw on their own intellectual capabilities when making mathematical decisions and judgements" (Cobb & Yackel, 1998, p. 170). However, less researched aspects of autonomy in mathematics classes are the ones in which learners themselves "develop a particular kind of psychological relation to the process and content of [their mathematics] learning" (Little, 1991, p. 4). Developing such a *psychological* relationship with their mathematics learning can help students better understand, intervene and improve the ways *they* learn mathematics.

The first section of chapter one of the Norwegian Education Act (NEA), states that "[through education] students and apprentices must learn to think critically, and act in an ethically and environmentally conscious way. They *must have co-responsibility and the right to influence* [their education]" (Opplæringsloven, 1998/2018, italics added). For pupils to have the responsibility and right to influence their mathematics education, they need to take charge of their own learning in mathematics, that is become autonomous, at least partially. Further, if learners are supposed to apply their mathematical knowledge toolkit effectively in order to solve real-life problems after finishing formal education, they should be autonomous learners. Not only to solve their own real-life problems using mathematics, but also to participate as critical, responsible and active future citizens of society,

learners need to have experience and training in understanding and thinking over their current situations along with taking right decisions and actions to reach desired outcomes. This would require learners to acquire and practice both, the *intellectual* (i.e., the capability to take reasoned decisions), and the *psychological* aspects (i.e., a perception and an experience in exercising) of their autonomy. Although each learner is autonomous and possesses some decision-making skills, these should be nourished by getting an experience of exercising them within their immediate community and own peer-group (in the mathematics class). By learning how to balance power, authority, freedom and co-responsibility among themselves, students would effectively use their autonomy to take charge of their own lives, decisions and their consequences, and benefit society. Consequently, researching psychological aspect of *learner autonomy* in mathematics classes, in addition to its intellectual aspect, is equally significant if learners are to be motivated to succeed in mathematics (George, 2012).

By *learner autonomy* in this paper, I mean learners' ability to develop a psychological relation with, and freedom to take *responsibility* of their own mathematics learning process. This *responsibility* includes learners taking initiatives, participating in discussions, planning and executing self-beneficial mathematics learning activities, making decisions about what one wants to learn, how one likes to learn, at what pace and why together with their teachers, and simultaneously reflecting on these choices. Learner autonomy is a widely researched concept and is considered to be an essential attribute for learners of any second/foreign language because of its positive correlation with language learning (Little, 2003). However, the positive influence of acquiring learner autonomy may not be limited only to second/foreign language learning. Therefore, in this paper, I explore the research question "What can young learners' descriptions communicate about their experiences of learner autonomy in their mathematics classes?" in order to explore young learners' experiences with learner autonomy in mathematics classes as per the aim of NEA.

## Background of the study

This study is a part of a bigger research project called Local Culture for Understanding Mathematics and Science (LOCUMS, 2016). This project explores if using practical activities rooted in *learners' own culture* can benefit them in learning mathematics and science in lower secondary classes. Building on experiences from a former research project where solving practical tasks rooted in students' local culture in discipline design and technology promoted their school engagement (Lysne & Hoveid, 2013), LOCUMS intends to research if similar approach can increase students' interests in learning mathematics and science. While reviewing the literature, I observed that learner-centered intervention studies carried out in mathematics classrooms are often planned either by the researchers or the teachers, and learners' choices remain un(der)stated. For designing practical activities rooted in students' local culture for learning mathematics and science, it was important to get informed about learners' interests. Therefore, I designed a pre-intervention questionnaire consisting open and closed ended questions about themes such as: learner's general views about education, perceptions about mathematics and science education, their activities of interest, what they desire to learn about at the school, their thoughts on culture etc. The purpose of these questionnaires was two-fold – to design a learner-centered teaching approach voicing learners' opinions, choices and interests which acted as an input for designing practical activities; and to explore learners' potential of taking reflected decisions and responsibility of learning mathematics. It was while analyzing students' questionnaire responses such as "I don't know what I want to learn in mathematics", "I do not know what [content]

is useful to learn in mathematics”, “I am not interested in learning mathematics, yet learning mathematics is important”, to open-ended questions concerning mathematics that the notion of *learner autonomy* in mathematics classes emerged as my research interest. Therefore, learners’ autonomy was investigated further through semi-structured interviews. Data gathered for LOCUMS was directed towards both mathematics and science, and consisted of a cycle of pre-project student questionnaires, practical group tasks, followed by individual semi-structured interviews with selected students. Group tasks required knowledge of mathematics and science to be solved. Semi-structured interviews were focused to probe learners’ experiences of autonomy in mathematics classrooms among broader themes such as getting a vision of learners’ experience on project day, their general outlook towards learning mathematics and science, the extent of activities used in the mathematics and science teaching and its relevance etc. Learners’ responses about experiences of learner autonomy in mathematics classes collected in the first ten semi-structured interviews are presented in this paper.

### **Theoretical framework**

Learner autonomy was first defined as “the ability to take charge of one’s own learning” (Holec, 1981). The rationale of fostering autonomy in learners “... is quite simply that a teacher may not always be available to assist. Learners need to be able to learn on their own because they do not always have access to the kind or amount of individual instruction they need ...” (Cotterall, 1995, p. 220). The first definition of learner autonomy was later elaborated by Little (1991) as, “a capacity – for detachment, critical reflection, decision-making, and independent action” (p. 4). Further, Little (2003) mentions that, “... *autonomous learners* understand the purpose of their learning program ..., take initiatives in planning and executing learning activities, and regularly review their learning and evaluate its effectiveness” (p. 4, *italics added*). Therefore, learner autonomy entails more than intellectual autonomy, meaning the learners can “act freely with a sense of volition and choice” (Deci & Flaste, 1996, p. 89) and involves an activating psychological process in order to attain autonomy in relation to one’s learning processes. Little (1991) moreover reminds of the difference between an autonomous learner and an independent learner. Being an autonomous learner does not mean that one is an independent learner and is able to learn without any assistance of the teacher, but it means taking a partial control of one’s own learning process. By having a partial control, the learner should her/himself understand and reflect upon one’s learning curve in order to figure out what strategies work best for her/himself. Resultantly, a learner can comprehend how one learns better and design, plan, execute and analyze self-beneficial mathematics learning strategies.

Students’ intellectual autonomy has been discussed, but, I found fewer studies devoted to promoting learners’ autonomy among students in mathematics education research literature. Research initiatives in directions such as *critical mathematics education* (Skovsmose, 2014), *culturally-responsive mathematics education* (Greer, Mukhopadhyay, Nelson-Barber, & Powell, 2009), *mathematics education for social justice* (Gutstein, 2003), and *sociocultural and sociopolitical awareness* (Sriraman & Knott, 2009) have illuminated social implications of learning mathematics for the learners and our future society. These research areas address concerns to acknowledge learners’ interests, promoting pupils’ critical awareness towards sociocultural and sociopolitical issues involving mathematical calculations, and engage students in struggle for social justice through mathematics education. For learners to become mathematically literate critical citizens of society, they should be able to understand their responsibility of learning mathematics, comprehend the role

mathematics plays in their lives and society, and make decisions involving mathematical calculation. These capabilities require students to understand and take charge of their own learning in mathematics. Skovsmose (2014) mentions that, “It is a preoccupation of critical mathematics education ... to develop a mathematics education that might provide new possibilities for the students” (p. 117). This study tries to enhance research concerning learner autonomy in mathematics education by providing the learners with an opportunity to express their experiences regarding learner autonomy in mathematics classes. The focus is to explore if learners are aware of their responsibility and can suggest changes to improve the quality of mathematics classes, provided they can assume more control of their mathematics teaching-learning process, as NEA expects from them.

## Method and study participants

Qualitative research design using semi-structured interviews with students was adopted as a method to learn about students’ experiences. Since I wanted to know individual opinions, perceptions and thoughts of the learners participating in mathematics classes, interviewing seemed as an optimal way to proceed. Semi-structured interviews provided me with the opportunity to engage the learners in a free conversation with occasional follow-ups, without the restrictions of time limitations and a strict structure. In this way, participants could also, to some extent, control the direction of the interview, so that I avoided being the steering authority in the interview, and could gather authentic and trustworthy information.

Learners of age 13 to 14 years, studying in 8<sup>th</sup> and 9<sup>th</sup> grade in a countryside school located in central Norway were informants of this study. One learner per group was chosen from 4 or 5 groups in each class, based on the level of their activity on the project day. Keeping in mind the principal of representativeness, an attempt was made to select students with different interests, level of activity (high, medium and low), achievement in mathematics (high, moderate and low achievers) etc. so that various experiences could be gathered. Here, I present representative excerpts from interviews with 5 girls (one of them with Sámi background) and 5 boys (one of them with Eritrean background). Most of these students’ parents were working or driving farms, holding an average socio-economic status.

## Results and discussion

The interviews were conducted in Norwegian, translated to English and interview transcripts were analyzed in order to identify learners’ experiences regarding learner autonomy in mathematics classes. Interview questions were designed so that learners had to reflect on their mathematics teaching, make choices, take decisions and suggest changes in it; and were analyzed to find learner responses involving words such as *control*, *decision*, *responsibility* etc. concerning their mathematics education. This section presents selected interview excerpts followed by the *descriptive analysis* of learners’ responses from the first ten informants. In the following transcripts, *I* indicates the interviewer and *L<sub>number</sub>* indicates which of the ten learners is responding. Interviews were conducted after practical group activities and hence in the first extract presented below, the interviewer is asking how in the learners’ experience the learning situation on the day of project was different from the learning situation in their usual mathematics classroom. The following snippet illustrates the learners’ experience:

I: eh... do you think this way to repeat mathematics and science content was different from the usual teaching?

L<sub>3</sub>: yes...

- I: how would you describe that why was it different from usual teaching? ... how would you describe that the situation was different then? what was the difference?
- L<sub>3</sub>: ... we did not sit in the classroom and raised our hands and talked like... we do not calculate like we discuss so much and find it together...
- I: but is it then different form usual teaching or would you say that it's also you who controls there as well?
- L<sub>3</sub>: no... there it's the teacher who has more control
- I: but do you get it [the responsibility] usually like in mathematics and science classes?
- L<sub>6</sub>: or... like we don't get to decide everything on our own because then it's like they have already decided what we should do from beforehand but also...

Both of the learners' responded that the learning situation they experienced on the day of project was different in terms of having control and responsibility. These experiences of learners about usual mathematics classroom exhibit limited experience with self-control and self-decision where the teacher is usually the one who manages the class and everything that is to happen in the classroom is decided beforehand. These classroom experiences, where learners are not exposed to the responsibility of their own learning, may inhibit learners' potential to understand, reflect, analyze and make decisions to improve their own learning processes for their self-benefit. Therefore, only when provoked a bit to assume autonomy, most of the learners suggested probable improvements in mathematics classroom:

- I: are you satisfied with the way teachers teach you?
- L<sub>4</sub>: yes...
- I: why do you think that this way to be taught is alright?
- L<sub>4</sub>: because... eh... I don't know maybe I'm used to having it like that like this so...I have done it all these years so, I think it's a fine way to learn...
- I: but if you had a chance... would you change the teaching in mathematics ...?
- L<sub>4</sub>: no...
- I: nothing?
- L<sub>4</sub>: maybe a bit more activities in mathematics but otherwise I don't think so of anything...
- I: would you have included any other activities like some practical activities in mathematics teaching?
- L<sub>8</sub>: eh... I would have done it because what we've done in the whole 8<sup>th</sup> grade is just to write, write and write and solve the task and then it becomes quite boring and you lose the interest and you sit there just to write and when the class is over so you think "oh yes, finally finished...".

In the first snippet, learner L<sub>4</sub> expresses being *used to have been taught like this* as the reason of being satisfied with the teaching. Consequently, thinking about some other way of being taught or suggesting a change to the *usual* way sounds like a difficult task to him/her. However, when asked

again in a way where she/he could choose, she/he suggested an improvement in the mode of mathematics instruction. Similarly, the frustration of mathematics classes lacking practical activities and a suggestion to include the same if given the opportunity is evident in L<sub>8</sub>'s response. The next excerpt shows that given the possibility to suggest changes and design their mathematics teaching themselves, learners can acquire autonomy in mathematics learning.

- I: hmmm... now when you have a suggestion about that you could have learnt to set up a budget... have you also thought of how would you have liked to learn it? In what way?
- L<sub>5</sub>: eh... if we could have got a realistic situation... and then we could have got a task about it so it would have... for example set up a budget for a whole family for a month and you get different expenses and the teacher and you get the income and you have to pay the tax and you have to pay different and you should have a bit sum as saving if you sometimes get into a trouble and such things... like which are important to learn like you don't need to take a loan and you don't have a lot of debt because you just got into a trouble which you never expected in your budget... so we learn how one should use his money because I mean that mathematics... we use a lot of mathematics in society like money and much is controlled by money and money gives power so... because people should not use up... because of people should have better ... .. like I don't have any concept of... like I don't know what 1 million kroner is... it's a lot and lot but you can't manage to buy a house for one million kroners... so we should learn more about the value like how much 1000 kroner is worth ... and such...

The learner (with Sámi background) not only mentions what he/she desires to learn but also suggests how the lesson could be planned and what kind of tasks they could have worked on. This segment shows that learners have a potential of developing autonomy and co-responsibility in mathematics learning. Further, the extract below presents learners' response to the question of sharing responsibility of their learning with the teacher:

- I: what is the difference between if it's only me [who, as a teacher] decided everything and if you are also with me when I decide?
- L<sub>9</sub>: it becomes more fun if both decide... then... I think it could have happened that people would have liked to come to school more often...
- I: when they are asked...?
- L<sub>9</sub>: yes... when they get to decide a bit what they do at the school...

As indicated in the response of L<sub>9</sub> (Eritrean immigrant, in Norway since three years), the thought of gaining a little bit charge over one's own learning can not only encourage their autonomy but also that they would have liked to come to school more often, exhibiting the importance of listening to student voices.

## Conclusion

Learners' responses concerning autonomy in their mathematics classroom exhibit limited experience with self-control and self-decision. This indicates that decisions regarding what will happen in mathematics classroom are usually made in advance by school authorities and the teachers, which

can act as a constraint for learners' autonomy to emerge and being practiced. Consequently, learners *get used to* mathematics classes, trust decisions of their school and teachers, and consequently see the *traditional way* to be the only way of mathematics education. This can leave learners unfamiliar with assuming autonomy to comprehend their learning processes in depth and limit their creative potential to experiment with better and self-beneficial ways of learning mathematics. Moreover, if concerns for social justice, adopting a critical stance towards mathematics' role in society and learners' personal lives, and raising consciousness towards sociopolitical and socio-economic issues through mathematics education are to be fulfilled; learners need to experience autonomy in their mathematics education. This way they can feel confident to put forward their argument, discuss and design better learning opportunities in mathematics with their teachers and, moreover, get engaged in, discuss and debate about social issues and initiate social changes in wider society.

Moreover, enthusiasm of learners to experience a partnership and co-responsibility of their own mathematics learning is the same regardless of their ethnic background. Interview excerpts from learners L<sub>5</sub> and L<sub>9</sub> depict similar experiences in mathematics classrooms and they desire similar changes (i.e., *a culture of promoting learner autonomy*) in mathematics learning as their Norwegian classmates. Similar responses from learners having diverse backgrounds complemented my focus on *youth culture* instead of ethnic backgrounds in this study.

Observing learners' potential to suggest, design, co-operate and improve teaching-learning strategies in mathematics, I conclude that learners should be *heard*, encouraged to be critical, take responsibility and decisions regarding their mathematics education to make them autonomous, cooperative and responsible mathematics learners fulfilling the aim of NEA, and become mathematically literate critically aware citizens to deal with challenges of our future society. For encouraging learners to be autonomous, they should be provided with time and space to plan and execute their own learning strategies together with their teachers, and approaches promoting autonomous behavior (Deci & Ryan, 1987) should be adopted. Moreover, to make learners think critically, decide, have more control and co-responsibility of their learning with teachers, just asking them simple questions (Croninger & Croninger, 2016) can be the first step of an interaction leading them to assume autonomy. Learner autonomy can make learners aware of their right to social justice by balancing the power relations between students and teachers. Autonomous learners can build a personal relationship with mathematics and gain experience of participation and authority of understanding mathematics' role in his/her personal (i.e., their home, classroom, school etc.) and wider society (as visible in L<sub>5</sub>'s response).

## Acknowledgment

LOCUMS is supported by the Norges forskningsråd (The Research Council of Norway). I wish to extend my gratitude to my supervisor Per-Odd Eggen for his co-operation in data collection and valuable discussions regarding observations derived from data analysis, and to the reviewers' feedback.

# Locally disrupting institutional racism by enacting mathematics in a U. S. laboratory classroom

Sabrina Bobsin Salazar

Universidade Federal de Pelotas, Brazil; University of Michigan, United States;

[sabrina.salazar@ufpel.edu.br](mailto:sabrina.salazar@ufpel.edu.br)

*In this study I investigate whether mathematical knowledge inherently carries fragments of its socio-political-historical development or if mathematics itself is value-free and can only get a political dimension attached to it by how it is used in society. I empirically approached the problem by studying a laboratory classroom collectively solving a problem. This classroom served as a proxy for a community of practicing mathematicians and I particularly investigated how conceptions of mathematics endorsed in this classroom could support (local) disruption of racism. Theories guiding this study include critical realism and critical race theory and analyzed data includes video records of instruction in this laboratory classroom. Results show that creating opportunities for students to engage in more authentic mathematical practices can support (local) disruption of racism.*

*Keywords: Mathematical knowledge, institutional racism, normativity.*

## The problem I am addressing and how I am doing it

Mathematics often enjoys a distinctive status among the sciences. Such highly regard status comes from the idea accepted by most practicing mathematicians that mathematics is universal, objective, and certain (Ernest, 1999), or, in other words, mathematics is an *a priori* knowledge that deals with truths that are true by virtue of necessity, and with objects that are abstract (Linnebo, 2017). These ideas however, are not unanimous, and disagreement about such assumptions can be traced back to the work of Plato and Aristoteles (Machado, 2013). Whereas refined arguments were developed to support one or another claims, the debate is still open. The work of Kitcher (1984) and Ernest (1998) are relatively recent work supporting an *a posteriori* view of mathematics that is intrinsically dependent of human activity in society, but introductory texts on philosophy of mathematics such as George and Velleman (2002) still presuppose that mathematical knowledge can be philosophically investigated disregarding its social and historical construction.

Mathematics education researchers that are concerned with socio-political dimensions of mathematics education have been interested in these philosophical disputes. Such scholars have a long-term commitment in understanding the relationships between mathematics education and society, particularly relationships involved in social inequality and injustice. To these scholars it is important to understand if mathematics inherently carries fragments of its socio-political-historical development or if mathematics itself is value-free and can only get a political dimension attached to it by how it is used in society. It is clear for socio-political researchers that mathematics and mathematics education are deeply connected with our contemporary social structure that privileges a group of people over others. What is not so clear is whether this connection comes from pure mathematical knowledge itself or not.

So far, many philosophers have argued in favor of one option or the other employing a variety of philosophical techniques to support their claims. I am adopting a different strategy. To investigate whether mathematical knowledge is independent of the human activity that produced or discovered it, I study a small community solving a mathematical problem together. This small community is an elementary mathematics laboratory classroom and it serves as a proxy for a broader community of practicing mathematicians. There are striking differences between both communities, and yet many similarities I expect to be helpful in illuminating the problem I am investigating. For example, in this classroom, the teacher functions as a permanent knowledge authority, being responsible for, ultimately, legitimating a mathematical claim in this environment, while in a community of practicing mathematicians, there is an institutionalized peer-reviewing system responsible for legitimating mathematical claims. The discussions the students participate in, however, are very comparable with mathematics seminars run by mathematics departments. There are discussions about whether a mathematical idea is true and arguments are laid out so other participants can be convinced of the validity of mathematical claims.

Moreover, I will look to a specific social dimension, namely institutional racism, so I can investigate it in depth and gather a better understanding of the connection of mathematical knowledge and the (re)production or disruption of racism. A pilot study showed that, in this classroom, there are instructional practices that support local disruption of racism (Salazar, 2018), the question now is if these practices were the only ones responsible for promoting such disruption or if the mathematics itself was also important in promoting local disruption of racism in this classroom. The research question I want to answer in this study is: *What conception of mathematics is endorsed in this laboratory classroom and how can it support (local) disruption of racism?*

## **Conceptual framework**

### **Critical race theory**

Critical race theory (CRT) is a theoretical framework for research that foregrounds race, racism, and racialized experiences. To critical race scholars, race is a complex social construct that goes beyond the color of skin and citizenship (Ladson-Billings, 1999), and brings real consequences to people once they are identified as member of a particular racial group (Bonilla-Silva, 2006). The kind of racism CRT is interested in exposing and challenging is institutionalized racism that permeates daily social interactions as opposed to individual blatant acts of racial prejudice. Finally, CRT posits that people of color experience racial oppression differently based on their individual background and multiple identities and insists in a non-essentialist approach (Delgado & Stefanic, 2001).

### **Critical realism**

Critical realism (CR) is a philosophy of science that starts from a realist conception of the world, and *the real things* that make the world are then structures and mechanisms, or, in other words, causal laws (Bhaskar, 2008). In this perspective, in spite of being socially constructed, race is real because it has causal powers; race brings real consequences for the lives of people (Bonilla-Silva, 2006). In CR phenomena cannot be completely determined by scientific laws, they are only influenced by them. When I say that race causes segregation within schools through tracking, I am describing a tendency of over-representing White and Asian students while under-representing African American and

Latinx students in advanced classes, and over-representing African American and Latinx while under-representing Whites and Asian in lower tracks (Oakes, 1995). Race influences but does not completely determine what is going to be a student placement.

In CR the real things in the world can be combined in a way that, because of their structure and not only its individual properties put together, a new thing emerges in the world. This new thing, also called “entity” or whole, possesses “properties or capabilities that are not possessed by its parts” (Elder-Vass, 2010, p. 4). The whole is then not just the sum of its parts, but something else, with a new causal power that is, of course, derived from the individual properties of its parts. But not only this, the way the parts interact and relate with each other is also responsible for the emergence of the new thing.

The concept of emergence forms the laminated view of the world. A particular whole is said to be in a higher level than its parts. The same whole, however, can be a part of another emergent structure; in this case the whole is in a lower level than the new emergent structure. Individuals are seen as the lowest level of the social world, the whole society as the highest level, with many intermediate levels in between, such as social institutions. The immediate higher level to an individual is, according to Elder-Vass’s (2010) definition, a *norm circle*. The norm circle is defined by the group of individuals who hold a normative belief of *endorsing* a social norm or, in other words, each individual in the norm circle acts to reinforce the norm and discourage behavior that does not conform to the norm. Elder-Vass’s argument is that the norm circle is actually an emergent structure rather than only a group of people because it has a new causal power: to increase conformity to the norm.

### The content within instruction

In this work, I view instruction as defined by Cohen, Raudenbush, and Ball (2003) as “interactions among teachers and students around content, in environments” (p. 122). Figure 1 shows a representation of this definition. I am looking to social normativity as a particular environment, and to classroom interactions as individual actions in light of norms enforced by norm circles when some or most of these norms are oppressive and perpetuate institutional racism. In this study, I am narrowing my gaze to the role of the content in these relationships.

**Figure 1: Representation of instruction from Cohen, Raudenbush, and Ball (2003, p. 124)**

## Methods

### The laboratory setting and collection of data

In this study I analyzed episodes of instruction from a mathematics elementary laboratory classroom. This classroom is the main part of a summer program held each summer at a large research university in the United States. In this program, an experienced White teacher teaches lessons to a group of

rising fifth grade students (students going to start fifth grade at the subsequent fall) in public—that is, while over 70 other educators observe. Because this summer program is a site of research for student learning and teaching practices, different types of data are collected by the research team. The data set includes video records of instruction, video records of pre-brief and de-brief meetings with learning teachers, copies of students' notebooks, pictures of classroom records such as charts, lesson plans, class materials such as handouts for students, etc. The majority are African American and most come from low-income households. Only a few of them are White. The students have different levels of English proficiency and their mathematical performance in school is homogenously low.

### The train problem

At this edition of the summer program, the students worked on collectively solving the train problem (Figure 2) over the span of the entire two weeks of the program. Students worked on this problem every day since the second day of the program at the second half of class that lasted about one hour each day. In this study, I focus on data related with students working on this problem, so video records of classroom, detailed lesson plans for each class, copies of student work (notebooks, homework, and assessments), photos of every collective record produced in classroom (such as charts and white board records). I am focusing on this problem because it is unusual to work in problems of this kind at this level, but some of its characteristics are very common in the field of mathematics, which makes it interesting to investigate practices of doing mathematics in a community. The solution of part 1 is that the SP company can build trains that hold 1 to 15 passengers. Part 2 actually does not have a solution and, in this case, solving the problem means mathematically explaining why it is not possible to find a train that meet all the conditions of the problem.

<p><u>The Train Problem</u></p> <p>The SP Train Company has five different-sized train cars: a 1-passenger car, a 2-passenger car, a 3-passenger car, a 4-passenger car, and a 5-passenger car. These cars can be connected to form trains that hold different numbers of people.</p> <div style="display: flex; align-items: center; margin-top: 10px;"> <div style="margin-right: 10px;"> <div style="width: 15px; height: 15px; border: 1px solid black; margin-bottom: 5px;"></div> <div style="width: 15px; height: 15px; background-color: red; margin-bottom: 5px;"></div> <div style="width: 15px; height: 15px; background-color: green; margin-bottom: 5px;"></div> <div style="width: 15px; height: 15px; background-color: blue; margin-bottom: 5px;"></div> <div style="width: 15px; height: 15px; background-color: yellow; margin-bottom: 5px;"></div> </div> <div> <p>1-passenger car</p> <p>2-passenger car</p> <p>3-passenger car</p> <p>4-passenger car</p> <p>5-passenger car</p> </div> </div>	<p><u>Part 1</u></p> <p>You can use <u>only</u> these five types of cars to build trains, and you can use <u>at most one</u> of each type of car in each train. What are the different numbers of people that the SP Train Company can build trains to hold?</p> <p><u>Part 2</u></p> <p>Ms. McDuff wants to order a special 5-car train that uses exactly one of each of the different-sized cars. Ms. McDuff wants to be able to break apart the 5-car train to form smaller trains that hold exactly each number of people from 1 to 15. The customer wants to be able to build these smaller trains using cars that are next to each other in the 5-car train. Can the SP Train Company build Ms. McDuff's order? Explain how you know.</p>

### Analysis

I watched and wrote fieldnotes from all video records. From the fieldnotes, I wrote a description of how the class solved the train problem. Then I selected episodes from interactions of the teacher and the students that showed students working and discussing pieces of the solution of the train problem. Each episode was then re-watched and a more detailed description was written. In each episode I investigated mathematical normative practices that could illuminate the nature of the knowledge produced in this laboratory classroom. I also look for schooling normative practices that could intersect with mathematical practices. Additional data from student work and detailed lesson plans were used to check and refine hypotheses.

## Enacting math: Collectively solving the train problem

The class worked to find the solution of the train problem. The process started in class 2 and involved individual and small group work, as well as whole class discussions. To solve part 1, the strategy consisted in finding the smallest train that the SP company could build, then the greatest, then find trains “in between”.<sup>1</sup> In this initial discussion, La’Rayne<sup>2</sup> (*La-rain*)<sup>3</sup> said *wr*<sup>4</sup>, which holds 3 passengers, is the smallest possible train because  $w=1$  and  $r=2$ . Other students loudly say “no”, disagreeing. La’Rayne immediately revised her thinking, saying that you could use just the red or the white, unless no train would be made at all. They agreed 1 (or zero) was the smallest train. The class did not reach a consensus about the greatest train as quickly, so they worked independently or in small groups on this question. During this work, the teacher discussed with La’Rayne about the train she was testing. She first thought her train held 19 passengers, but after discussing with the teacher she realized it actually held 15. Then she and the teacher had a very dynamic interaction, with questions and answers being said immediately on top of each other. In this interaction, La’Rayne explained that the biggest train held 15 passengers because it used all the rods, and that it was not possible to build a train for 19 because there would be no rod left to add to the train. The class continued their collective work and concluded that the company could build trains of size 1 to 15 by the end of class 3.

The solution of the part 2 spanned across the remaining 7 classes. They started doing some exploratory work to understand the problem and make sense of the conditions. During this part of the work they build collectively one train that holds 15 passengers, namely *yrpwg*, and broke it apart in different ways, trying to understand how they could break it, how they could not, and what were smaller trains they could build from it. They agreed that this train did not work because they could not build 9, 13, or 14. Then they started testing out other trains of size 15 and begun making records of all the trains they were testing that did not work. In this work, the teacher talked with the pair Layla and Olivia who said they were done, meaning they found a train. As a result of this interaction, teacher and girls realized they “were moving” things around, or, in other words, they were violating the condition that the cars had to be next to each other to form the smaller trains. Many students had

---

<sup>1</sup> I am using the idea of size to talk about the number of passengers a train holds. So, a train of size 7 holds seven passengers, a train of size 7 is smaller than a train of size 11, and the greatest train is a term used to refer to the train who holds the greatest number of passengers.

<sup>2</sup> The research consents and IRB approval permit us to use the children’s real first names. Other identifying information (e.g., last names) are not used.

<sup>3</sup> Names of African Americans in the U. S. often have unusual spellings. Additionally, their names are frequently misspelled or mispronounced. In this work, I am trying to use their first names with correct spelling and pronunciation as a sign of respect. When I cite a name with an unusual spelling and/or pronunciation, I will write the pronunciation in parenthesis with emphasis after the first time I write the name, so La’Rayne is pronounced *La-rain*.

<sup>4</sup> The letters used here are a reference to the first letter of the name of the color of the train cars. So the train *wr* is the train white-red which holds  $1+2=3$  passengers. Similarly, *yrpwg* is the train yellow-red-purple-white-green which holds  $5+2+4+1+3=15$  passengers.

similar confusion and interactions with the teacher. With practice and interactions with the teacher, the students seemed to overcome such difficulty, and also progressed to make more organized records of their attempts. They continued the exploratory work of testing out trains for about three days.

On class 7 they made some important progress with respect to understanding the mathematical work they were doing: they discussed why it is always possible to make trains for 1 to 5 (only one car is needed to build these trains) and for 15 (all cars are needed), how to decide a train did not work (only one number that does not work is enough), and started to think what are the numbers that are difficult to make and why it that so (“big” numbers, such as 11, 12, 13, and 14).

On day 8, the students received the red and white clue: “If there is a train that can be made for Ms. McDuff, it will have to have the red car (2) on one end and the white car (1) on the other end.” This clue contains a logic implication that was not easy for the students to understand. Moreover, the clue was given to the students with the idea that it could be a “wrong” clue, so before they could use it, they would need to find out whether the clue was valid. Students were confused in the beginning, they thought the clue was wrong because they were testing trains with the red and white cars in the ends of the trains and still could not find a train that works. It was only on class 9 that the students agreed the clue was right, meaning that if they were to find a train that works, they needed to build trains for 13 and 14, and that was only possible with red and white in the ends. Then using the clue, they arrived at the conclusion that they only needed to test six trains: wgpyr, wgypr, wpgyr, wpygr, wygpr, and wypgr. On class 10, the students were divided into six groups, so each group were to test one of the six possible trains. After a final discussion in which each group reported their train did not work, the class seemed convinced there was no train that could fulfill Ms. McDuff’s request.

### **When school norms intersect with mathematical norms**

There were often school norms and mathematical norms shaping the interactions observed in this laboratory classroom, and in some instances such norms were conflicting. In other words, in some cases, a school norm assigned a behavior for a particular situation, while a mathematical norm assigned a different behavior for the same situation. For example, this interaction occurred after the brief discussion described above on day 7 about what numbers need to be checked in each train. After talking about not needing to test one to five, the teacher asked if he needed to check 15. He answered:

Kassim: No.

The teacher asked why not, which seemed to be interpreted as a wrong answer, so Kassim changed it:

Kassim: Oh, yes.

Teacher again immediately asked why. Then Kassim presents a full explanation:

Kassim: No, because all of these is equal to fifteen. [Pointing to the rods.]

In this interaction between the teacher and Kassim, the boy tried to guess what would be the answer the teacher was expecting. He answered, waited for the teacher’s response to his question, and quickly changed his first answer after the teacher’s reaction was not confirming. This behavior can support school success given the role teachers have in assigning grades often based in students correct responses to questions. In this classroom, however, the teacher tried to promote mathematical

reasoning. Thus, frequently her responses to students' answers were follow-up questions asking for more explanation. In the end, to answer in a way that aligned with teacher expectations, Kassim would need to do a mathematical explanation, and so did he.

Another issue generated by the conflict between school norms and mathematical norms arises when students are “solving” a problem that has no solution. It is common in school, even more at this grade level, that mathematical problems always have a solution, often a unique one. Problems with no solutions, or with multiple solutions will most likely only appear in algebra in secondary school mathematics. Moreover, even when students deal with this kind of problems in algebra, it is not always discussed how this kind of problems are “solved” by mathematicians. In the field of mathematics, “solving” a problem with no solutions means to prove the problem is unsolvable. In this laboratory class, the students had to negotiate between a school norm, in which they had to find a solution to the problem, and a mathematical norm, in which they had to prove there was no solution to be found. On day 7, Luiz commented when testing one train:

Luiz: I was so close, I needed two more, 13 and 10.

He expressed the frustration of not finding a solution. Later, on day 10, the class received the visit of Ms. McDuff and they had to report how her request cannot be fulfilled. They had discussed before she arrived how they were going to report it to her. They were all sure there was no solution, and they discussed how they were going to talk about the red and white clue, how they tested all the “possible trains” and none works. But when she arrived, they struggled to say it. Even Olivia who had said before very clearly “there is no train” was speaking more quietly, seemed ashamed of not having a train to report, saying “we couldn't figure out a train”. The discussion proceeded and the teacher supported students in reporting what they had actually discovered. Eventually, Miah (*Maya*) said very clearly that her train was impossible, and Chandler spoke loudly, raising her hand to her front with the palm upwards when Ms. McDuff asked what that meant:

Chandler: Your train is impossible, we can't make it.

And Jerone added:

Jerone: So what we're saying is that your train could never be made.

Ms. McDuff replied that she will have to find another company and students responded loudly at the same time “no no no”.

They continued a brief discussion afterwards, and students talked to her about the red and white clue and how they tested all the “possible trains” and none works. They were then able to convince Ms. McDuff her train could not be made and she did not need to keep requesting it from any other company.

## Discussion

In this classroom, students engaged in doing mathematics in similar ways mathematicians do. They explained their reasoning mathematically, why some trains always worked, so they did not need to test them; why they did not need to find all small trains they could not build from the whole train to be sure the whole train did not work; why the red and white clue was right and how to use it to solve the problem. They used strategies to solve problems frequently used in mathematics, such as finding

the small and greatest possible train for part 1, then look for trains “in between”. When engaging in these practices of doing mathematics, the students took an active role in producing mathematical knowledge in their community. The active enactment of mathematics by these students was crucial to support local disruption of racism. When the students described in this report, mostly African Americans, one Latinx, boys and girls, performed mathematics they countered the idea that mathematics intelligence is a function of being White (and male). In this classroom, mathematics is something you do, rather than know, and they could all do it. In spite of the intersection between school normativity and mathematical norms, creating the opportunity for students to engage in more authentic mathematical activity opened up the classroom space for students, specially students in this classroom, to participate in mathematical discussion they usually cannot, and that is disruptive.

# Visible pedagogy and challenging inequity in school mathematics

Pete Wright

UCL Institute of Education, United Kingdom; [pete.wright@ucl.ac.uk](mailto:pete.wright@ucl.ac.uk)

*This paper reports on the initial findings of a research project aiming to explore ways of addressing concerns regarding the persistent gap in mathematics achievement between children from different socio-economic backgrounds and low levels of engagement of significant numbers of students with school mathematics. It argues that such concerns can be addressed without the need to abandon a commitment towards progressive teaching approaches. It highlights the potential of adopting a critical model of participatory action research for challenging existing classroom practices that contribute towards reproducing inequities in mathematics education. It demonstrates how developing strategies for making progressive pedagogies more visible offers students the chance to become more aware of the intentions of the teacher and what they need to do to be successful in school mathematics.*

*Keywords: Inequity, participatory action research, school mathematics, visible pedagogy.*

## Introduction

This paper reports on the initial findings of a research project which aimed to develop strategies to address the large gaps in mathematics achievement existing in schools between children from different socio-economic groups. Evidence suggests that ‘progressive’ teaching approaches, which involve providing opportunities for students to work independently and collaboratively on solving open-ended problems, can lead to higher levels of engagement and more equitable outcomes amongst mathematics students. However, there is also a danger that their relatively unstructured character can further disadvantage children from less wealthy backgrounds who are more likely to misinterpret the intentions of the teacher or to miss the point of the lesson. The project aimed to develop strategies teachers can use to make their pedagogy more visible, so that all students are able to recognise their intentions as teachers, and to identify research processes and methods that enable this to happen.

## Background

Wide gaps in achievement in school mathematics persist worldwide between children from different socio-economic backgrounds. There is evidence of a strong and persistent correlation between students’ attainment and participation in school mathematics and their family income (Boaler, Altendorf, & Kent, 2011). Whilst other differences in achievement (e.g., between boys and girls) have narrowed, socio-economic disadvantage remains the most decisive factor in determining success in school mathematics (Jorgensen, 2016). This is the case in England despite recent government policies aimed at highlighting and reporting differences in attainment and, since the introduction in 2011 of the ‘pupil premium’ (based on eligibility for free school meals), targeting resources at poorer students. Since mathematics qualifications play a critical role in regulating access to higher-paid employment, under-performance in school mathematics restricts the social mobility of disadvantaged children and contributes towards the reproduction of inequality from one generation to the next (Jorgensen, 2016).

Concerns have also been expressed for a number of years over the quality of mathematics teaching. Traditional teacher-led approaches, based on routine use of repetitive closed tasks, have been blamed

for an alarming decline in students' attitudes towards mathematics as they progress through secondary school, causing them to opt out of further study (Williams & Choudhury, 2016). Learning of mathematics is too often limited to memorising and practising procedures with little understanding of their application, purpose or underlying concepts (OFSTED, 2012; Foster, 2013), resulting in many children (and adults) continuing to exhibit alienation from mathematics (Nardi & Steward, 2003). In contrast, more 'progressive' teaching approaches, characterised by open-ended activities, collaboration between learners and an emphasis on developing problem-solving and reasoning skills, can lead to more equitable outcomes and greater levels of engagement amongst all students (Boaler, 2008; Wright, 2017). There is a growing consensus amongst the mathematics education community that a more relevant and engaging mathematics curriculum is needed, with a greater focus on open-ended tasks, problem-solving and conceptual understanding (ACME, 2011; Hodgen, Foster, Marks, & Brown, 2018; NCETM, 2008; OFSTED, 2012). This is reflected in the renewed focus on reasoning and problem solving in the revised National Curriculum in England (DFE, 2013).

However, some researchers have highlighted a formidable challenge for mathematics teachers concerned with issues of equity who wish to adopt progressive teaching approaches. Barrett (2017) warns of the danger of denying students access to 'powerful knowledge' in an attempt to widen access to school mathematics by emphasising 'everyday knowledge'. In a study in the United States, Lubienski (2004) describes how the relatively unstructured nature of progressive teaching approaches resulted in disadvantaged children being less likely than others to recognise the intentions of the teacher, for example by failing to notice hints and clues and by missing the point of class discussions. Bernstein (2000) argues that children from disadvantaged backgrounds, because of their upbringing, are generally less able to decipher the 'rules of the game', that is the 'recognition rules' (identifying relevant meaning from tasks) and 'realisation rules' (formulating appropriate and legitimate responses). This poses something of a dilemma for mathematics teachers committed to addressing inequity in their classrooms: should they avoid progressive approaches altogether or explore ways to make pedagogical rationale more explicit to learners? Classroom-based studies exploring whether making pedagogies more visible can address issues of inequity have been mostly limited to science education (Morais & Neves, 2017) and literacy (Bourne, 2004). This project focuses on developing strategies for making teachers' pedagogy more visible to learners in mathematics classrooms, to help all students recognise their intentions when adopting progressive approaches to teaching. It seeks ways to enable all students to be successful in mathematics, whilst embracing progressive pedagogies.

## Methodology

The project adopts a Participatory Action Research (PAR) methodology, that is a collaborative approach to research in which academics aim to carry out research 'with', rather than 'on', research participants. PAR recognises how 'academic researchers', with their expertise in conducting research, and 'teacher researchers', with their detailed knowledge of the classroom, each have a distinct, but essential, role to play. It seeks positive social change, through generating knowledge that is of greater relevance to practitioners, whilst developing a deeper understanding of 'theory-in-practice' amongst teachers (Brydon-Miller & Maguire, 2009). In contrast to conventional mathematics educational research, which is often conducted in artificial situations (Skovsmose, 2011), PAR pays closer attention to challenges, constraints and opportunities teachers experience on a day-to-day basis. It can offer a

systematic and critical approach to research based on clearly-defined processes including: reflecting critically on current practice in relation to research literature; articulating an alternative vision; trying out new approaches whilst taking account of realities and practical constraints; analysing outcomes of these trials to evaluate the feasibility of the alternative vision (Andersson & Valero, 2016).

Practitioner-led research is often criticised as lacking rigour and being limited in scale (Myhill, 2015). In a recent review of practitioner-led collaborative research in mathematics education, Robutti et al. (2016) reported how most studies failed to theorise ‘collaboration’, relying instead on theories relating to a ‘community’ in which it is assumed to take place. Much practitioner-led research has been criticised for lacking a critical element, either because it involves general agreement in advance of the intended outcomes, or because the focus is left open for practitioners to decide, without questioning the legitimacy of existing modes of practice (Kemmis, 2009). Critical reflection requires teachers to view their own practice as problematic, and to question the consequences of their actions, in relation to wider historical, cultural and political values and beliefs (Hatton & Smith, 1995; Liu, 2015). It is driven by external support and stimulus, which is seen as essential for challenging existing practice and without which collaborative inquiry is likely to perpetuate existing practice through the process of ‘alignment’ with accepted norms (Jaworski, 2006). Critical action research involves partners working together to “change their social world collectively, by thinking about it differently, acting differently, and relating to one another differently” (Kemmis, 2009, p. 471).

This project aimed to develop, refine and evaluate research processes and methods that facilitate effective collaboration and critical reflection amongst academic and teacher researchers. This is seen as particularly important when applying PAR to the mathematics classroom situation where existing practice has proved otherwise resistant to change. Research methods employed during the project include the joint design of student surveys and interviews (to be implemented by the teachers themselves), carrying out peer observations, and making use of video-stimulated reflection to evaluate lessons (Geiger, Muir, & Lamb, 2016). The project was innovative in that it sought to make the collaborative and critical characteristics of such methods and processes explicit.

## Research design

The research project was situated in a comprehensive secondary (age 11 to 18) school in North London with an above-average proportion of disadvantaged students (approximately 30% of students qualified for the ‘pupil premium grant’ in 2016-17 compared with a national average of 27%). The two-year project was initiated in November 2017. This paper reports on initial findings from the first year of the project. The project was a collaboration between myself, as academic researcher, and two teacher researchers, Tiago and Alba, who shared an interest in developing progressive teaching approaches and exploring issues of equity in mathematics classrooms. (I will refer to the three of us collectively as the ‘research group’.) The school’s mathematics department had recently incorporated a series of problem-solving activities into its scheme of work and was gradually moving away from a rigid setting structure towards mixed attainment grouping in the lower years. There was a whole-school focus on developing ‘oracy’, which in the mathematics department included encouraging students to articulate and communicate their reasoning through ‘think-pair-share’ strategies (thinking about a problem as an individual, before sharing with a partner and then the whole class).

The focus of the study was to explore strategies teacher researchers could use to make their pedagogy more visible, that is to help all pupils recognise their intentions as teachers when adopting progressive approaches to teaching secondary mathematics. In so doing, it was hoped to develop strategies that might be effective in reducing the large gaps in mathematics achievement existing between children from different socio-economic groups within the school. The research questions were:

1. Which teaching strategies are successful in helping students develop their ability to decipher the recognition and realisation rules of the mathematics classroom?
2. What impact do these strategies have on students' mathematical achievement and engagement, particularly for those from disadvantaged backgrounds?
3. What characteristics of PAR enable academic and teacher researchers to work collaboratively to bring about transformations in mathematics classroom practice?

A series of nine research group meetings were held at the school during the first year. At the first meeting, I provided Alba and Tiago with journals in which they were encouraged to reflect on their experiences and write a commentary on the development of their thinking and classroom practice over the course of the project. The initial meetings included jointly agreeing the research design and a focus on critical reflection on existing practice in relation to the research literature. The teacher researchers read and presented for discussion key research papers (identified by me) during these meetings. We decided that Alba and Tiago would work with two similar Year 7 (age 11-12) groups that they taught, making use of teaching materials that already existed within the department. This enabled them to focus on developing strategies to make their pedagogy more visible, alongside the progressive approaches to teaching mathematics already in use. Two 'plan-teach-evaluate' action research cycles were carried out in order to try out strategies devised during meetings. We jointly designed a survey to give students after the first cycle in order to evaluate the impact of these strategies. We also discussed and agreed the questions that were asked and the protocols that were adopted during semi-structured interviews conducted by Alba and Tiago after the second cycle with six disadvantaged students (identified on the basis that they qualified for the 'pupil premium grant').

The focus of the surveys and interviews was on assessing the impact of the strategies on students' success in, and engagement with mathematics, their dispositions towards learning, and their awareness of the pedagogical rationale employed by the teacher. We arranged for four of the lessons (two for each teacher) to be video-recorded and observed by either myself or the other teacher researcher. The observer created a time line of key events during the lesson so that these could be quickly located in the video recording during subsequent meetings. We carried out detailed evaluations of the strategies through reflective discussions during research group meetings. These discussions were prompted by watching back extracts from the video recordings and relating these to survey and interview responses and notes kept by Alba and Tiago in their reflective journals.

Data was collected through making audio-recordings of discussions held during research group meetings and audio-recordings of interviews conducted with the six students. These recordings were transcribed and fully anonymised, with pseudonyms being used throughout the data analysis for students and any third parties mentioned. During the thematic analysis, categories were assigned to extracts of text from the transcripts using a combination of deductive and inductive coding. Since the

project involves applying theory to pedagogical practice, an initial coding structure was derived from the theoretical framework. This structure was developed through a process of repeatedly reading the transcripts to allow familiarization with the data and to interrogate the relevance of the categories. Further amendments and additions were made during the coding process to increase the relevance of the categories to the data. The categories included in the coding structure fell into four broad groups: 1) students' understanding of recognition/realization rules; 2) students' recognition of educational disadvantage and relational equity; 3) teachers' pedagogical strategies; 4) students' dispositions towards learning. NVivo software was used to facilitate the comparison of extracts of text which had been assigned similar categories, and to explore 'commonalities', 'differences' and 'relationships' between these and other categories, enabling themes to emerge from the data (Gibson & Brown, 2009). These themes were then related back to the research questions and underlying theoretical framework in order to generate meaning (Kvale & Brinkmann, 2009).

## **Initial findings**

The findings reported below are based on an initial analysis of the interview and survey data only, from the first year of the project. Further analysis is currently being undertaken of the data from the research group meetings, which will enable a fuller discussion of the research methodology and the collaborative and critical nature of the research design to be reported in due course.

It was noticeable from the responses to the surveys completed at the end of the first cycle that students often did not fully appreciate the intentions of the teacher in adopting progressive teaching pedagogies, resonating with Lubienski's (2004) conclusions described earlier in this paper. Many students misread the rationale behind teaching approaches aimed at enhancing mathematical learning, often perceiving them as being designed to enforce compliance. One example that illustrated this tendency was an open-ended problem given to students that involved calculating the area of different sections of a flag. There were several alternative methods that could have been used to solve this problem. There was nothing remarkable about this open-ended, problem-solving task, or about the 'think-pair-share' approach that was used to introduce it, both of which were employed routinely by Alba and Tiago in their teaching practice prior to their involvement in the project. However, they developed strategies to use alongside the task that had not previously been a focus of their practice. In this case students were asked first to think about the problem on their own, discuss it in pairs, and then to explain their partner's thinking to the rest of the class (rather than explaining their own thinking). The completion of the task was followed by a whole class discussion prompted by teacher researchers asking: "Why do you think I asked you to present your partner's ideas rather than your own?" Students were encouraged to put forward suggestions which were then discussed with the teacher enabling her/him to help students appreciate how the teaching approach adopted was designed to facilitate deeper mathematical understanding. Prompting students to present their partner's ideas and the follow-up discussion of the pedagogical rationale represented a change in teachers' practice.

In the survey administered at the end of the lesson, students were asked the following question: "Why do you think the teacher asked you to explain your partner's thinking and not your own?" The responses of some students suggested they had correctly interpreted the teacher's intentions, for example "So that we understand other's point [of] view", "So you can share everyone's methods", "Because it

helps you to understand different opinions on the maths problems and different paths to the answer”, “Because you can get two different perspective[s] and it may help you finalise your idea”. However, a majority of responses suggested most students misinterpreted the strategy as simply an implicit way of enforcing listening, for example “To make sure you listen”, “To see if you’re listening to your friend.”

The strategy described above was aimed at making pedagogies visible that would otherwise remain implicit (and often not at all transparent) to learners. The intentions of the teacher thus become an explicit focus for discussion and consideration by learners. Another strategy employed during the second cycle was to scribe students’ responses to questions verbatim, that is to write down exactly what they said regardless of whether they were correct or incorrect. This was followed up with a discussion with students around the rationale for doing so, in this case to draw out ambiguity in language used by students and to enable students to identify errors and misconceptions for themselves.

It appeared, from interview responses at the end of the second cycle, that disadvantaged students were developing a greater awareness of some (but not all) of the primary reasons for teachers’ pedagogical choices. Four of the six students interviewed, Marcus, Sophia, Mary and Keira (all pseudonyms), appeared to recognise the primary purpose of identifying and addressing errors and misconceptions when they were asked why they thought the teacher wrote down exactly what students said:

To maybe see like where we go ... because it’s better if you say it out than keep it in because the teacher could help you and try and improve from wrong to right. (Marcus, interview)

Cos then you can compare the correct and incorrect answers together and see, like, where you went wrong, and how you, you know, changed the answer to get the correct one. (Sophia, interview)

It was nice to like write down it, and then look at our mistakes. ... Because of, then we can, like, fix the mistakes. ... But usually people will like ... if we make a mistake, and then they just change it. They just tell you it’s this, but they don’t tell you why ... and then next time they do the same mistake. (Mary, interview)

It will be showing us that you think we’ve gone wrong a little bit. And by writing everything we’ve said, that will help, not just like the person, it will show everyone like where it went wrong. Instead of like you telling us, and that, we can learn from our mistakes. (Keira, interview)

However, Ennis demonstrated only a partial appreciation of the primary purpose, identifying a reason that might be valid in a different situation, whilst Neal was not able to articulate a valid purpose:

So other people can know how to do it. And so everyone could like ... everyone can understand from it, and see what they’ve done wrong, if they’ve got it wrong, and see what they’ve done correct, if they’ve got it correct. (Ennis, interview)

Maybe they never got it right, but then someone worked out the same way but still got it right. And then you will show the person who did it how ... they should do it correctly. (Neal, interview)

There was a similar pattern for other strategies that Alba and Tiago tried out for making pedagogy more visible, with most students recognising at least one purpose identified as primary by the teachers during research group meetings. However, students also articulated other purposes, some considered potentially valid in other situations but not primary for these strategies, and others considered invalid.

## Conclusion

From an initial analysis of the data from the early stages of the research project, it appears that developing strategies for making teachers' pedagogical rationale more visible to learners has the potential to increase students' appreciation of the intentions of the teacher, although some misinterpretation is likely to persist. This offers the promise of eliciting more appropriate responses from a wider range of students, including those from poorer backgrounds, when less-structured teaching approaches are employed. This in turn suggests ways of developing classroom practice that can begin to address issues of inequity in mathematics classrooms without the need to abandon progressive pedagogies. It offers a positive way forward for teachers who are committed towards closing the gap in achievement between advantaged and disadvantaged students and who also believe that adopting collaborative and problem-solving teaching approaches promotes greater mathematical understanding. It highlights the need for further research to explore, refine and disseminate strategies, that can be adopted alongside progressive pedagogies, to help all students recognise the intentions of the teacher and hence to respond appropriately and achieve greater success in mathematics.

# Real-life mathematics: Politicization of natural life and rethinking the sovereign

Ayşe Yolcu

Hacettepe University, Turkey; [ayseyolcu@hacettepe.edu.tr](mailto:ayseyolcu@hacettepe.edu.tr)

*The aim of this paper is to examine the connections made between real life and school mathematics as politics of mathematics education. The analysis focuses on an elective course, “mathematics applications”, offered for middle graders in Turkey. I explore, first, how mathematics education discourses authorize responsabilization, reason and rationality for the administrative needs of a society. Second, my analysis focuses on how the natural lives of humans lie at the center of the political calculations where sovereign decisions are taken. The connection between natural life and life as a citizen offers alternative ways to think about modern sovereignties.*

*Keywords: Discourse analysis, equity, mathematical applications, politics of education*

## Introduction

Mathematics is considered as central to young people’s preparation for life in contemporary societies (e.g., see, OECD, 2013). The will to teach and learn mathematics for better lives, however, has a political dimension where it conceives mathematics as having a positive role to cultivate the new generations into that knowledge and to the related values (Valero, 2004). In these processes, desire for a “better” life in/through mathematics education discourses constitutes particular subjectivities and differences (e.g., Diaz, 2017). Parallel with the aim of preparing youth for “better” lives, an elective course, “mathematics applications”, is offered for middle school students in Turkey to make the school mathematics more real and relevant to life. This course has been the most elected course by students since its initiation (Karagözoğlu, 2015). The course is less about teaching mathematical content (i.e., fractions, triangles or equations); rather, instructional material consists of problems, games and interdisciplinary tasks that include the real life of the child (MNE, 2013). This paper does not treat the “inclusion” of real life in the curricular and instructional materials as natural, but it rather problematizes the processes of associating real life and mathematics as a politicization of natural life. Specifically, I analyze *how* mathematics is associated with “better” life. In doing so, my aim is, first, to explore how connection processes produce administrative tools to govern people at a distance without domination, and second, to examine how these processes make biological life as object of sovereign decisions (i.e., who is allowed to live/die) in today’s politics.

Research has already spent some time examining how school mathematics embodies a set of practices that govern students’ being and acting as future citizens (see, e.g., Diaz, 2017; Valero, 2004; Yolcu & Popkewitz, 2018). These studies provide important insights about the way in which particular subjectivities and their differences are made in/through school mathematics to configure (im)proper modes of life as citizens. For example, it is argued that calculations inscribe a bureaucratic mode of thought among students in modern states where mathematics functions as a technology of trust (Kollosche, 2014). Nevertheless, in today’s societies, calculations are not merely used for bureaucratic-administrative purposes, but become the politics of life itself (Rose, 2001).

That is, the biological existence of humans becomes the object of politics within narratives of security, health or any kind of crisis. Chronaki (2018), in this vein, uses a fictional environmental crisis to argue how a totalitarian mathematical ban may also function as a form of sovereign power that can penetrate the bodies, locate traces of biological lives and decide who is allowed to live. This provides an insight in how life becomes the object of sovereign decisions. In today's societies, nonetheless, connection between mathematics and life is made without domination, but through an inevitable "need" of mathematics for "better" lives. This vanishing point between sovereignty and productive power relations (i.e., relationship between natural life and life as citizen) necessitates further analysis to grasp the nature of contemporary politics.

### **Contemporary Political Paradigms and Life**

For Agamben (1998), there were two different meanings for the word "life" in the classical world. First one is *zoē*, which is the natural life that is common to all living beings. The other one is *bios*, which is the form of life that is proper to a group (i.e., citizens). The distinction between the two had constituted the "city", consisting of people with a proper form of life, until Foucault (1990) makes visible how natural life is included in political calculations. For Foucault, modern power is exercised through different political rationalities and governmental technologies than the sovereign power – those in monarchies, kingdoms or empires. For instance, contemporary government forms administer lives of self and others in the light of conceptions of what is good, healthy, normal, virtuous, efficient or profitable in order to ensure maximal functioning in civil life and to secure the best possible future for its subjects (Rose & Miller, 1992). In this way, power is exercised through a set of practices that make up citizens as a particular kind of human (Hacking, 2007; Rose, 1999). According to Foucault (1990), this has not always been the case. While "sovereignty took life and let live" in societies ruled by monarchs or religious authorities, he points out the emergence of practices that tend to make lives and let them die (p. 247). In the realm of modernization processes, such practices form human life as the object of politics that authorizes particular action and social participation. He calls them "biopolitics of the population" as they focus on human life as species to maximize its well-being, health and security (Rabinow & Rose, 2006).

Nevertheless, according to Agamben (1998), there remain several questions that relate to the original activity of sovereign: If governmental practices are no longer "taking the life" but rather they are "making the life," how can we understand the explosion of numerous and meticulous techniques to control populations at the level of biological/natural life, which are the ones closest to death? If power is exercised at the level of human's biological life, how are its practices and strategies different from domination and repression? To deal with these questions, one should account for the hidden yet converging point between the juridical-institutional and the biopolitical models of power since the inclusion of human's natural life in political strategies points to the original activity of sovereignty:

Placing biological life at the center of its calculations, the modern State therefore does nothing other than bring to light the secret tie uniting power and bare life, thereby reaffirming the bond between the modern power and the most immemorial of the *arcana imperii*. (Agamben, 1998, p. 6, emphasis original)

In those converging points or in the bonds, the body becomes a vital living system where “real” life become molecularized and organized with the gaze of biological and natural sciences, their institutions, procedures, instruments and spaces of operations (Rose, 2001). Health, for example, provides a transactional zone between political concerns of modern states and personal techniques for the care of the self. It is usually offered as a universal human right to protect persons and as a dignity for their living vital bodies. Here, subjects are rendered responsible for their own biological or natural lives, which previously was the duty of sovereign. This does not mean the disappearance of the sovereign, but refers to modification of practices, operating in the horizon of a natural life.

Within the scope of this paper, I take these changes as a historical continuity rather than a threshold of modernity. Following Agamben’s (1998) works and Foucault’s (2007) lectures on biopolitics, my aim is to make visible the modifications of how governmental technologies constitute a complex network of practices that blur the distinctions between sovereign, disciplinary and control relations in the field of school mathematics and in the society as well. Affirmation of bare life offers new and more dreadful rationales and foundations for sovereign decisions (i.e., who is allowed to live), not the sovereign himself, because natural life and its needs become politically decisive facts. Mathematics education is part of those rationalities and technologies since one of the concerns in the field is the inclusion of real or natural lives in order to make mathematics relevant for “all”. The issue, here, is not merely providing equitable access to mathematics because the discourse of “all” is already proven to produce exclusions (see, e.g., Diaz, 2017; Yolcu & Popkewitz, 2018). A fundamental activity of these processes is the production of bare life through the politicization of natural lives in its calculations so that any decision for those “excluded” can be taken. In this way, sovereign logic is normalized and made permanent with notions of security, health, and biological productivity.

This paper offers alternative ways to think about sovereignty in modern societies. Rather than treating natural life and life-as-citizen as separate entities, the examples presented in the paper make visible the indeterminate relationship between the two as the political paradigm of modern sovereignties. In this way, the politics becomes a set of techniques and strategies that legitimize the connection of natural life and life-as-citizen as paradoxes of inclusion and exclusion such as deciding who is going to live and die. I deal with specific ways and techniques of school mathematics that operate at the level of natural lives, the very biological making of humans. To do this, curricular documents and teacher guidebooks of a “mathematics application” course are analyzed. The reason why the focus is on this elective course is to make visible political rationalities and technologies that are far from domination but similar to sovereignty. I have purposefully selected examples from the textbooks that relate biological processes of life. A numerical analysis of the problems indicates that the examples that relate to natural life constitute approximately twenty percent of the total ( $n=132$ ) across the middle school grades (5<sup>th</sup>–8<sup>th</sup>). The rest of the problems are mental games, strategy development tasks, market relations that are concerned with informed shopping or budgeting, and geometry-measurement problems. Analysis of curricular and instructional texts does not assume that they are the same with teacher practice itself. Nonetheless, discourses are results of practices and, at the same time, they produce further practices (Popkewitz, 2013). This reciprocal relation shows possibilities of change without assuming a pre-existing subject (e.g., teacher) as an agent of change.

## **“Adolescent” as an object of school math: Cultivating reason and rationality**

The child in the curricular statements of the mathematics application course is configured as a particular kind of human who is “in transition” and needs math to realize their potentials:

These ages are sensitive transition periods in the life of the students, since the rapid changes are the periods of adolescence. [...] The perceptions of what they get from these ages shape their attitudes towards the course in the coming years and affect their achievements in mathematics [...]. If students challenge the limits of knowledge and skills in mathematics courses in the school, and if they receive the support they need, they will have the best chance of achieving their mathematical potential (MNE, 2013, p. 1, all originally Turkish texts translated by me).

Here, the adolescent is the object of teaching and the target population. Students are configured as “adolescents” who are to learn particular skills to find reasonable and rational solutions to the problems of real life. Adolescent, here, is not merely a label, but a particular kind of human and a fictional construction that comes to being by generating ideas about how one lives or should live (see, e.g., Lesko, 2012). They are to take responsibility in the process so that they would be able to show their agency or “mathematical potentials” in their future lives when they become adults.

The emphasis of the course is not at the end products but the processes of connecting real-life and mathematics in group settings. In this way, students, as future adults, are to learn to find not merely the correct answer but reasonable and rational solutions: “In this course, students need to look for rational and reasonable solutions with their classmates through collaboration rather than finding correct answers” (p. 1). These statements cannot be interpreted as purely domination; rather they are technologies of automation and responsibility that enable the ‘proper’ life as citizens (Rose, 1999).

Let us take one of the problems, connecting the life as citizen and natural lives of humans. It is related to energy saving through using energy-efficient bulbs. Students are expected to learn about the “importance of energy saving” and “calculating the possible saving” for this particular problem (MNE, 2012, p. 45). Energy saving, here, is neither a personal issue nor about saving money for personal interest. Rather, the mathematical task is contextualized around concerns for human life since energy usage is correlated with CO<sub>2</sub> emission that has a negative impact on earth where we, human beings, live. The image in Figure 1 illustrates how the problem is situated in wider world issues with implications on human’s biological lives. Of course, the issue is important and the problem relevant. Nevertheless, the specific questions that are addressed by students through mathematical task assemble with particular processes of making responsible citizens. As stated: “You can also contribute to energy saving. What are your responsibilities for this? In which areas can you save money?” (p. 44).

**Figure 1**

The mathematical part of the problem is the calculation of the energy saving amount if energy-efficient light bulbs are used or if one avoids unnecessary usage of electricity. In this regard, the emphasis of the questions is on everyday habits of people, not on the mathematics itself. Asking questions such as “How many bulbs do you use at home?”, “How many hours are the lights turned on in the living room?” or “How much savings do you get when you turn unused bulbs off?” (p. 44)

bring the everyday life into a calculation practice. However, these are not merely prompting questions that push students into the mathematics, but become specific practices that order (im)proper lives in order to socialize ‘adolescents’ in effective ways. When students denote the correct amount of saving following the calculations, they learn energy-efficient ways of living not just mathematics.

The processes that connect real-life and mathematics do not only regulate human conduct, but also connect with biological lives. The link between the two makes a kind of human who is committed to science, humanity and the world through taking care of nature, life of self and humanity.

There is a release of 1.5 kilograms of CO<sub>2</sub> into the air for 1 kilowatt of energy production from fossil fuels. Calculate how many kilograms of CO<sub>2</sub> emission you prevented with your energy savings. Show the results you find with tables and graphs. (p. 44)

As the above text shows, energy saving is both a personal and social problem, an issue that the whole society should be “accountable” for. Individual efforts are to take care for the natural life, which is a concern for everyone. In addition to this, the ability to “show the results” is not the domination of mathematics but a specific technology that mathematics education offers for taking ownership in the processes of finding reasonable solution for their own lives. In this way, the truth is not imposed upon student’s mind. Individual contribution is valued, but calculations, tables and graphs, simultaneously, create boundaries of rationality in their own solutions and so in their “natural” lives: “All these processes will enable students to take ownership of mathematics and solutions by allowing them to make personal contributions and take responsibility instead of trying to find the “right” solution in the teacher’s mind” (MNE, 2013, p. 7).

Students, aged between eleven and fifteen, are regarded as people-in-transition who are to become future citizens. The real-life application of mathematics is the technology to make them part of the society with a sense of belonging so that there would not be any noise, social disorganization or natural disorder in the unknown future. Practices that make the people responsible are embedded in the connection processes in order to ensure the integration would happen in a harmony neither by force nor through domination. In this way, “freedom” is ensured but it is regulated with reason and rationality for their own well-being and natural lives.

### **Calculations of real life: Irreversible clock time and progressive human nature**

Some problems in the mathematics application textbooks are directly contextualized with biological processes of human beings when making the connection between mathematics and real life. See, for instance, how a problem is introduced in a 5<sup>th</sup> grade teacher guidebook:

The heart is a marvel of biological engineering with its general structure and function. Even the hearts of people who do not do sports are very strong in terms of durability. Our heart, which has a high-density vessel structure, has about 2000 capillaries per square millimeter. This allows oxygen to reach the heart muscle continuously and safely at a sufficient level (MNE, 2012, p. 12).

Here, heart as a vital biological character of living human beings, including its health and durability, is the main context that drives the problem. It is described as a “marvel of biological engineering” and a natural mechanism that allows oxygen circulation throughout the body. The mathematical part of the problem is counting and calculation of the frequency of heart rate at a given time, including a

minute, an hour, a day, a week, a month and a year. At the end, students present their heart rate frequencies with peers or the whole class and discuss results aiming to learn the relationships between second, minute and hour but also between day, week, month and year (p. 13).

Such practices are not simply mathematical tasks but activities that engage students in a process where they learn the irreversible time that provides qualities of growth, development and progress to human nature. That is to say, the linear time is being made and associated with the accumulated heart rate counts, biological productivity and developmental clock-time. This association generates the “nature” of human life as a linear experience similar to the forms of civilization, evolution, development, acculturation, and modernization (Fabian, 2014). The temporal yet accumulated view of human nature is accompanied with the construction of the child as “adolescent” and, thus, it authorizes proper life as a citizen in companion with the processes of making up their natural lives.

As students count heart rates, they are also encouraged to see and discuss different measurements from different groups. Specifically, students evaluate the different results in terms of “physically active bodies”, “other personal characteristics” or “gender” (MNE, 2012, p. 13). Here, numbers become the agents to see and differentiate the modes of life through vital processes of human nature, such as heart rates. However, more is required to secure the best possible future with “healthy” bodies in addition to the comparing different kinds of people in terms of their heart rate measurements. In the 7<sup>th</sup> grade guidebook, for instance, a similar heart rate context is offered. This time, a caution for possible health problems is presented with algebraic equations for the “recommended maximum heart rate” (i.e.,  $y = 208 - (0,7 \times \text{age})$ ): “Due to health problems, people have to obey certain limits when doing sports activities. For example, if a certain heart rate is passed while doing sports, this can cause health problems for people” (MNE, 2017, p. 27).

In this way, students are to calculate the recommended heart rate and how the results change with respect to age. The issue, here, is not simply a matter of comparison. Bodies are calculated with appropriate heart rate at a given age and associated with the kinds of people who do physical activities or who smoke. Techniques of making “normal” bodies also employ rationales to act on those deviate from those normal lines. With numbers revealed from algebraic equations, doing physical activity or quitting smoke become self-authorizations for “adolescents” to “correct” their life, to improve themselves biologically as part of human species and to adapt their bodies in line with the proper modes of life as a citizen. There is no elimination of unhealthy or foreign bodies that are disruptive to progressive human nature; rather, it is a matter of classifying and correcting in the face of death.

### **Politicization of natural life, life as citizen, and school mathematics**

This paper has examined some mathematics education discourses within the scope of contemporary political paradigms. In connecting mathematics and real life, the body is subjugated in a double sense. First, the child is constituted as an object, which is to be made a future citizen, embodying a particular form-of-life through socio-cultural integration. Second, natural life emerges at the center of calculations that make the child a subject who decides for his/her own well-being in that political zone. In other words, biological processes of human life are located at the center of the connections made between mathematics and real life and enabling self-authoritative techniques to maximize health, biological productivity or well-being of their own bodies and also themselves as human

species. In these linked ways, people seek for better, healthier or secure options through a continuous “need” for mathematics since the issue becomes natural life and survival, not only framed in economic but also in biological terms.

The specific case of the “mathematics application” course is important to consider since those students taking the course, in fact, are outside of regular mathematics classes. Taking the elective course is considered as extra mathematics support by themselves or their parents (Çoban & Erdoğan, 2013) or as a mean to reduce mathematics anxiety and to develop positive attitudes towards mathematics (MNE, 2013; Keşan, Coşar & Erkuş, 2016). Although those students are excluded, they are still in the system in paradoxical ways, through an “inclusive exclusion” (Agamben, 1998). The student body for this particular course does not actually fit to the regular classes but is simultaneously engaged with additional mathematics through the “need” for mathematics for their well-being and future survival. This generates topological relations of inclusion/exclusion rather than a polarization.

Instead of immobilizing with the unquestionable need of mathematics to make the individual’s lives better, healthier or more productive, reading mathematics education discourses through contemporary political philosophy makes visible how the logic of sovereignty circulates along the modern life, which is configured as citizen life. That is, as discourses connect natural/biological life and life as citizen, the sovereign decisions become possible. The analysis, here, allows us to rethink the tactics, tools and governmental technologies of modern sovereignties such as affirmation of real-life in mathematics problems. Rethinking makes visible the possibilities as well. We could reconsider questions that seek to discover whose lives are properly represented because the political issue discussed here is less about authentic representation of real life but it is the representation itself. Each of us has a heart rate and we all are exposed to CO<sub>2</sub> emission.

Political potentialities, which need further explorations, could start with contesting the representational paradigms that seeks to emancipate, live or survive with the mathematics. Or more generally, they could challenge and problematize identity politics that “liberate” people within given and historically polarized populational categories. This is partly because exclusions are being generated through inclusion of real life in mathematical practices. Sovereign logic circulates in these processes where life itself becomes the object of politics that organize its survival and death.

# TWG11: Comparative studies in mathematics education

## Thematic working group 11: Comparative studies in mathematics education

Paul Andrews<sup>1</sup>, Eva Jablonka<sup>2</sup>, and Constantinos Xenofontos<sup>3</sup>

### Introduction

As with earlier CERMEs, TWG 11 adopted an eclectic perspective in its interpretation of comparison as referring to any study that documents, analyses, contrasts or juxtaposes cross-cultural or cross-contextual similarities and differences across all aspects and levels of mathematics education. In this way the TWG aimed to encourage critical but supportive discussions around a number of themes, some of which were predetermined by the papers received by the group, while others emerged from them.

A recurrent but very productive aspect of this working group has been the relatively small number of paper presentations, although this has also led to the group being constantly on the verge of extinction. This year, thirteen papers and one poster were received. Unfortunately, for various reasons, two papers were withdrawn, leaving eleven papers and a single poster. This created space not only for colleagues to share their research in detail but for everyone to engage in lengthy and inclusive discussions on the nature of comparative mathematics education research and the means by which it can be meaningfully and rigorously undertaken. In particular, as is discussed in more detail below, the group came to realise that concepts like ‘unit of analysis’ meant different things to different people according to the research traditions from which they derive. The various contributions fell naturally into five themes that framed the different working group sessions.

### Theme 1: Assessment in mathematics education

The first theme drew on two papers with very different foci and methodological conceptualisations focused on assessment in comparative mathematics education research. On the one hand, Cascella and Giberti’s paper, drawing on Italian national test data, highlighted significant gender differences in the ways in which students respond to different presentations of the same arithmetical task. Such findings remind us that the debate concerning gender differences in mathematical understanding are by no means resolved. On the other hand, Simsek, Jones, Xenidou-Dervou and Dowens’ study, framed by the important assertion that if “the same instrument is used in different cultures, no bias should arise from the particular characteristics of an instrument or its administration, focused on children’s understanding of mathematical equivalence. Their use of an extant American scale with English and Turkish students yielded a different factor structure from the original, highlighting the difficulties of assuming the validity of a test developed in one cultural context for use in another.

## **Theme 2: Mathematics teacher education**

The second theme, drawing on three papers, dealt with issues concerning mathematics teacher education. The first of these papers, presented by Clivaz and Miyakawa, reported on how two groups of students, one Swiss and one Japanese, collaborated, both at a distance and face-to-face, on the planning of the same problem-solving lesson. After planning, each group of students taught the lesson repeatedly in their own cultural contexts. Analyses of the two sets of plans and their respective lessons highlighted well the cultural norms that underpin beginning teachers' practices. The second paper, presented by Gorgorió, Albarracín and Laine and written with the aim of evaluating admissions policies, examined the impact of recent changes to the admission requirements for primary teacher education programmes in Barcelona and Helsinki. The study found that such tools are too contextually situated to facilitate genuine comparison and argue for a better theorisation of the expected knowledge of such students and a measure appropriate for cross-cultural application. Finally, in this session, the paper by Zhang and Wray examined similarities and differences in the sequences and patterns of teachers' questioning practices in secondary mathematics classrooms in the UK and China. Drawing on observations of a dozen teachers in each country, the authors' discourse analyses identified clear distinctions between the collectively-focused questioning of the Chinese teachers and the individually-focused questioning of the English.

## **Theme 3: The analysis of mathematics textbooks**

The third theme, based on two papers and a poster, focused on the analysis of mathematics textbooks. The first paper, presented by Hemmi, Lepik, Madej, Bråting and Smedlund, examined the presentation of material focused on expressions, equations, inequalities, and the meaning of the equal sign in textbooks in grades 1-3 in Estonia, Finland and Sweden. They found considerable variation in the presentation of such material, with concomitant opportunities for the later learning of algebra, both between countries and between different language groups within countries. The second paper, presented by Xenofontos, examined the use of the word 'problem' in the state mandated upper primary and lower secondary textbooks of the Republic of Cyprus. He found, with inevitable consequences for the coherence of children's learning of mathematics, that while the word was used frequently and consistently in the primary books, it was used rarely and less consistently in the secondary. Finally, Palm Kaplan presented her poster comparison of the algebra tasks found in year 8 Swedish textbooks and the TIMSS 2003 assessments. Her discourse analytic approach showed considerable differences in the privileged content of the two sets of data.

## **Theme 4: Curriculum**

The fourth theme, comprising two papers, focused on curriculum. The first paper from a multinational group of scholars, Van Steenbrugge, Krzywacki, Remillard, Koljonen, Machalow and Hemmi, examined recent mathematics curriculum reform efforts in the US, Finland, Sweden, and Flanders. Drawing on a range of data sources they showed that curriculum reform that is both region-wide and supported by teachers is a major challenge, not least in systems where teachers enjoy autonomy and textbooks are largely unregulated. Jablonka's study, the second in this theme and initiated by international tests of achievement, found that the mathematics taught in Germany

was intellectually more challenging than that taught in China. However, bringing to the group a concept that provoked much discussion, Chinese teachers experienced greater discretionary space than their German colleagues. That is, they had more adaptive freedom in the planning of their teaching.

### **Theme 5: Methodology**

The final theme, drawing on two papers, differed from the others in its explicit focus on methodology. The first of these, Petersson, Sayers and Andrews, presented an analysis of textbooks based on the use of moving averages to highlight the location and extent of different content emphases. Such an approach, which facilitates comparison between textbooks, offers an important visual support to conventional frequency analyses. The second, Chan and Clarke, alerted group members to the importance, particularly for comparative research, of identifying an appropriate unit of analysis. This particular presentation, despite the issue having been discussed in previous CERMEs, provoked a long discussion, which is revisited below, on how the expression ‘unit of analysis’ is construed differently by different cultural groups.

### **Discussion**

As with previous CERMEs, the variety of topics and methodologies brought to the group highlighted well the diversity of work undertaken within the broader field. All papers offered insights to remind us that comparative research, which includes much mainstream work undertaken in single cultural contexts, is a messy and complex undertaking reliant on strong theoretical foundations and clearly-defined constructs. In this latter respect, the group’s discussion on unit of analysis was particularly interesting as it became increasingly clear that colleagues were not talking about the same thing. On the one hand, colleagues working in a theory-driven tradition tended to construe the unit of analysis as the theoretical framework within which they worked. On the other hand, colleagues working in a problem-driven tradition, typically Anglophone, saw the unit of analysis as the individual piece of data to be analysed. These very different conceptions of the phrase highlighted well the difficulties faced by all researchers and the dangers of assuming a common understanding of what one might typically expect to be unproblematic. Of equal interest, as indicated, was the notion of discretionary space. Here, colleagues were able to see the methodological advantage such a simple yet powerfully evocative concept brings to analyses of curricula and teachers’ engagement with them.

As always, the various contributions brought to the group reflected not only cultural diversity but also methodological pluralism. For example, studies included those that were informed by a priori theoretical assertions and those that were not. There were equal numbers of qualitative and quantitative studies focused on a range of aspects of children’s and teacher education students’ learning of mathematics. All studies confirmed the extent to which mathematics and its teaching and learning are culturally normative.

## Order of factors in multiplying decimal numbers and gender differences: a comparison of tasks

Cascella Clelia<sup>1</sup> and Giberti Chiara<sup>2</sup>

*Differential Item Functioning (DIF) analysis carried out within the framework of the Rasch model has been used to compare scholastic performance in sub-groups of students matched on ability and clustered by some features (such as, for example, gender). In this paper, we use DIF to understand if misconceptions about multiplication with decimal numbers act on boys and girls differently, i.e. if this can lead boys and girls to approach a mathematics item differently and, in some cases, to encounter it not successfully. We present empirical evidences revealed on a sample of 1647 students attending grade 8 of lower intermediate school. Results highlighted that misconception about multiplication of decimal numbers strongly disadvantages girls relative to boys and pose new research questions about mechanisms causing these results.*

*Keywords: Mathematics achievement test, Misconceptions, Gender gap, Rasch model, Differential item functioning.*

### Introduction.

Italian National standardized assessments, called INVALSI test, are administered every year to all Italian students in different grades from primary to secondary school. In recent years the importance given to these tests has increased and researchers in mathematics education are starting to use the INVALSI results.

Results of national and international surveys have highlighted that in many countries there is a strong gender gap in mathematics in favour of males and Italy is one of the countries in which this gap is more remarkable (Mullis et al., 2016; OECD, 2016; INVALSI, 2017). This phenomenon has been deeply studied in mathematics education research. Recent works overcome the idea that the main causes of gender gap are related to biological differences (Hill, Corbett & St Rose, 2010): the main reasons of this gap must be sought considering factors related to the social and cultural context in which the students live, such as the level of gender inequality which is strictly related to the gap in mathematics (Guiso, Monte, Sapienza & Zingales, 2008). Furthermore, the beliefs of teachers and parents on students' ability and differences in metacognitive aspects such as self perception, self concept and anxiety related to mathematics are fundamental to explain the reason of the observed gender gap (Fredericks & Eccles, 2002; Cargnelutti, Tomasetto, & Passolunghi, 2016; OECD, 2016; Pajares, 2005). Finally, recent research has revealed that factors related to classroom practices, learning strategies and curriculum variables have a strong influence on gender differences in mathematics (Leder & Forgasz, 2008; Giberti, Zivelonghi, & Bolondi, 2016; OECD, 2016). Moreover, in previous studies we have shown the influence on gender differences of micro-social factors, strictly related to the *milieu* habits (Brousseau, 1988) and to the interrelation between the student and the teacher. From this perspective we highlighted that misconceptions, as a product of

classroom practices, have a stronger impact on females rather than males (Bolondi, Cascella & Giberti, 2017) and our aim is to investigate more in depth this issue.

In this paper we propose the analysis of a specific item, which is part of a wider research program called “Variazioni 2” and financed by INVALSI, aimed at exploring the relationship between variations in item formulation and in its psychometric functionality. Much research in mathematics education has studied the impact of a variation in item formulation with a particular attention to ‘word problems’. An updated literature review has been proposed by Daroczy and colleagues (2015). Literature considers the influence of linguistic variations as well as other kinds of minor changes on students’ responses and solving strategies (e.g. Nesher, 1982; De Corte, Verschaffel & Van Coillie, 1988; D’Amore, 2000). Duval in 1991 defines all these modifications as “redactional variables”, and Laborde in 1995 uses this term to include also non-verbal changes, e.g. introduction or modification of pictures. Using a specific statistical strategy, in this paper we analyze data collected in the project “Variazioni 2” to understand if and how a specific variation might affect differently male and female solving strategies to solve a mathematics item. In particular, we analyze an item included into a mathematics achievement tests to explore a specific didactical issue concerning misconceptions in multiplying decimal numbers (Fischbein, Deri, Nello, & Marino, 1985; Sbaragli, 2012).

### Research questions.

The term misconception is widely used in research in education and takes different meanings; in this research, following D’Amore & Sbaragli (2005), we define a misconception as a concept momentarily incorrect, standing by for a more critical and developed cognitive arrangement. A typical misconception (D’Amore & Sbaragli, 2005; Hart et al., 1981) is due to the premature formation of a conceptual model of multiplication when students operate exclusively with natural numbers. Students learn multiplication with natural numbers and, observing that the product of two numbers is always greater than its factors, they are led to believe that “multiplication always increases”. This is true for natural numbers (excluding 0 and 1), but this is not always true for decimal numbers. This misconception, thus, leads students to make mistakes when they operate with decimal numbers, and, for instance, D’Amore and Sbaragli (2005) explain that the answer of many students of different grades to the question “What is the result of  $4 \times 0.5$ ?” is 8. In order to explore this phenomenon, we compared two versions of the same item (Table 1).

Booklet F1 and F2	Booklet F3 and F4
<p>D9. Which is the result of <math>4 \times 0.5</math>? Choose one of the following options.</p> <p>A. <input type="checkbox"/> 8</p> <p>B. <input type="checkbox"/> 4</p> <p>C. <input type="checkbox"/> 2</p> <p>D. <input type="checkbox"/> 20</p>	<p>D9. Which is the result of <math>0.5 \times 4</math>? Choose one of the following options.</p> <p>A. <input type="checkbox"/> 8</p> <p>B. <input type="checkbox"/> 4</p> <p>C. <input type="checkbox"/> 2</p> <p>D. <input type="checkbox"/> 20</p>

**Table 1: Different formulations of the item D9**

The two formulations differ only in factor order. This allows us to understand if the idea that “multiplication always increases” is related to both factors of the multiplication or mostly to one of the two factors. In particular, our hypothesis is that the intuitive model (Fischbein, Deri, Nello & Marino, 1985; Mulligan & Mitchelmore, 1997) of multiplication as a repeated sum is easier to apply

in the second version ( $0.5 \times 4$ ) and this strategy led students to overcome easier the misconception. This is of course also related to the language used: in Italian we read the multiplication  $4 \times 0.5$  as “4 repeated 0.5 times” while in English and in many other languages it is “4 times 0.5”.

This only one of several misconception related to the transition between natural numbers and decimals and, in previous studies focused on misconception in comparing decimal numbers (Bolondi, Cascella & Giberti, 2017; Giberti, 2018) we observed that females have more difficulties than males. For this reason, we decided to investigate if this misconception and the variation carried out, affects differently boys and girls. Therefore, our research questions are: 1) Does the misconception here analyzed act on boys and girls differently? In other words, does this misconception cause different item functioning in male relative to female subgroup? 2) What is the impact of the inversion of factors into a multiplication (e.g.,  $4 \times 0.5$  in place of  $0.5 \times 4$ ) on students’ answers? What is its impact on item functionality? Does the inversion of factors have different effects on boys and girls?

### **Participants and measures.**

Starting from a mathematics achievement test developed by INVALSI for students attending grade 8 (lower intermediate school), in the project ‘Variazioni2’, we developed three further mathematics achievement tests, complete in terms of mathematical content and level of difficulty. These four forms (F1, F2, F3 and F4) were administered to a probabilistic sample of 1647 students attending grade 8.

### **Analytic strategy.**

Our four mathematics achievement tests were administered by means of a spiraling process (according to which different forms are administered to different students within each classroom) in order to randomly assign forms, in this way each form was administered to approximately 400 students. When using this design, differences between group-level performance on administered forms are taken as direct indications of the differences in difficulty between forms (Kolen & Brennan, 2004) and it is particularly adequate to make comparable answers given by different subgroups of students. In addition, all achievement tests were equated to make estimations directly comparable. Both item and person parameters estimated via the Rasch model (Rasch, 1960) were scaled in an empirical range equal to  $[-4; +4]$  logits, where 0.00 logit does not mean absence of ability but it is the ability-difficulty level in relation to which students have a probability equal to 0.5 of encountering an item successfully.

In the result section, we provided a summary of psychometric characteristics of the item D9 in F1, F2, F3, and F4. In order to compare, male and female performances, we provided a visual display of the set of observed means for each person factors level (i.e., for boys and girls) across each of the class interval present in the item-trait test-of-fit specifications. Each level is plotted in relation to the Item Characteristic Curve, i.e. the theoretical curve estimated by the Rasch model according to which no factor other than students’ intrinsic ability can explain the probability of a correct answer. At the bottom of the table, we reported the distractor plots drawn for males and female, separately, in order to explore their answer behavior in relation to each answer option.

## Results.

The table below (Table 1) reports on differences in item functionality in F1, F2, F3, and F4. For each of them, in addition to information about fit (i.e., Weighted MNSQ) always close to 1 and thus good, the distribution of correct and wrong answers provided by students is available in order to provide a first glance on the differences between booklets.

**Table 1. Item functionality in F1, F2, F3 and F4**

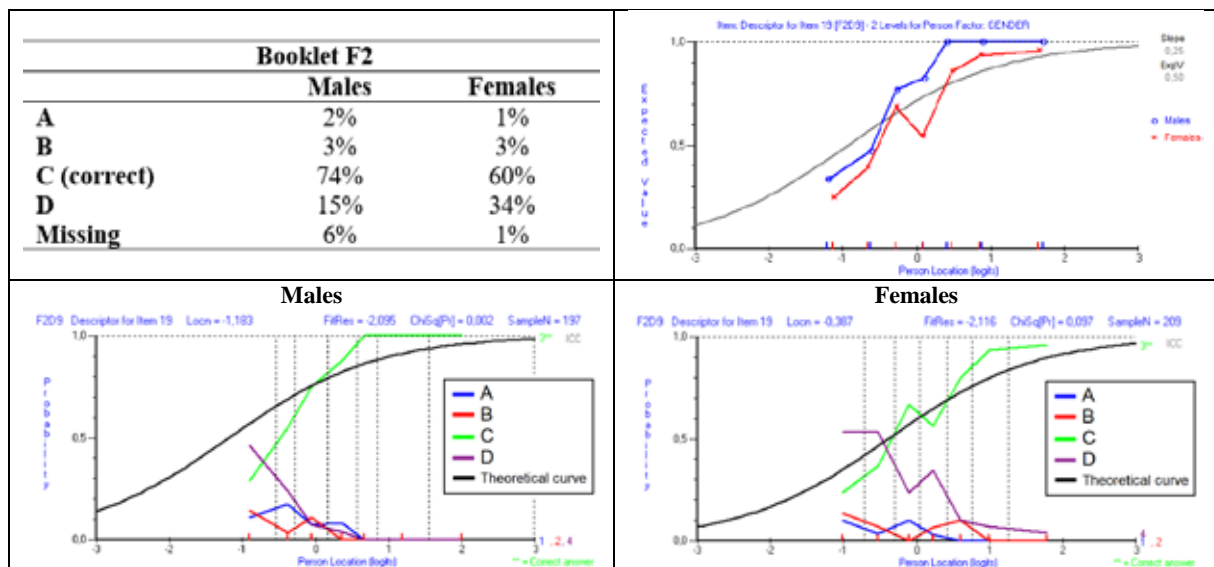

Item formulation shows little variation comparing booklets F1 and F2 and it's the same also comparing booklets F3 and F4. As already explained, in both versions the question intent is the same but the inversion of factors into the multiplication might change the influence of the misconception on decimal numbers and the answering strategy activated by students to solve the item might change. Indeed, we observe a lower percentage of correct answers (Table 1) in the first version, included in booklet F1 and F2, than in the second one, included in F3 and F4.

To analyze gender differences, we provided a visual display of the set of observed means for each person factors level (i.e., for boys and girls) across each of the class interval present in the item-trait test-of-fit specifications. Each level is plotted in relation to the Item Characteristic Curve, i.e. the theoretical curve estimated by the Rasch model according to which no factor other than students' intrinsic ability can explain the probability of a correct answer. Distractor plots drawn for males and female, separately, showed differences in answer behavior between boys and girls in relation to each answer option (Table 2). In particular, option B is more attractive for low-ability male students relative to females with the same ability level. Instead, it is evident that females are more attracted by option D, which is strictly related to the misconception, since they give the result of  $4 \times 5$  instead of  $4 \times 0.5$ . Little differences can be disclosed also in relation to option A, more attractive for low-ability girls and all these evidences are confirmed also by percentage reported in Table 2. Most of these differences are more remarkable in F2 (Table 3), with a clear advantage of males relative to females. Nevertheless, by exploring Distractor Response Curves drawn by gender, response patterns for the set of distractors associated with D9 presented in F1 and D9 presented in F2 are similar. The main difference between them can be disclosed into the distractor plot drawn for males in Table 3: high-ability boys are not attracted by any distractors, while distractor D is attractive also for high-ability females.

**Table 2: Responses by gender and Analysis of Variance by Gender for item D9 administered in booklet F1 (top-left) - DIF-plot (top-right) - Distractor Plot of males (bottom-left) and females (bottom-right)**

**Table 3: Responses by gender and Analysis of Variance by Gender for item D9 administered in booklet F2 (top-left) - DIF-plot (top-right) - Distractor Plot of males (bottom-left) and females (bottom-right)**

Both in booklet F3 and F4 (Table 4 and 5), the item D9 proposes the inversion of factors, i.e.  $0.5 \times 4$  in place of  $4 \times 0.5$ . The analysis of answers to the item D9 in booklet F3 confirms an overall advantage of males. Differently from previous cases, higher differences are observable especially at medium-ability level along the latent trait (around 0.0 logit). Nevertheless, differences observed for low ability students are the most result of this analysis: from -1.5 to -0.5 logit all differences are in favor of females. This evidence is strongly confirmed by analyzing F4 data: the probability of a correct answer is 20% higher in female than in male group, from -1.50 to -0.5 along the latent trait. In both cases, distractor analysis shows interesting dissimilarities. The most interesting differences between boys and girls can be observed in F4. In particular, option B is attractive for males and not attractive for

females, while option D is more attractive for girls especially at the lower level of the latent trait, confirming the evidences emerged in F1 and F2.

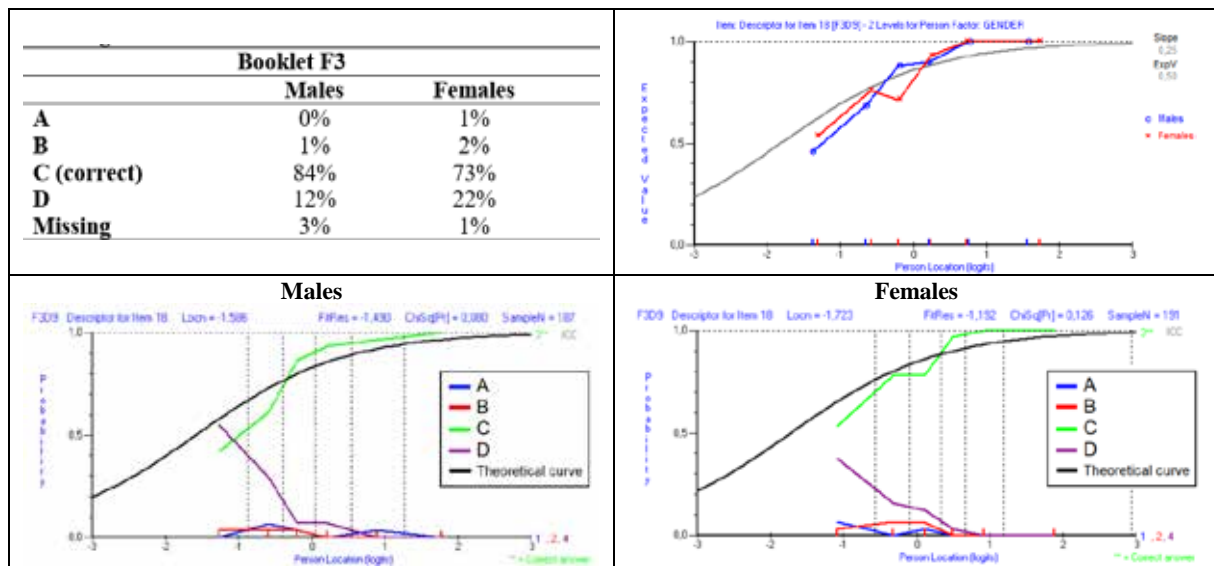

Table 4: Responses by gender and Analysis of Variance by Gender for item D9 administered in booklet F3 (top-left) - DIF-plot (top-right) - Distractor Plot of males (bottom-left) and females (bottom-right)

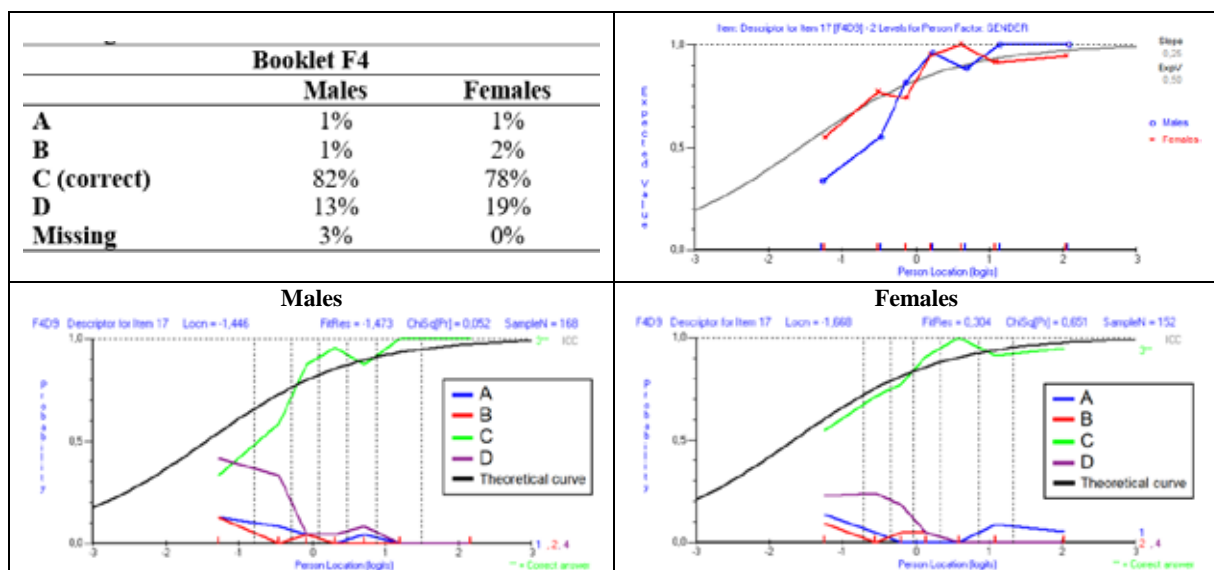

Table 5: Responses by gender and Analysis of Variance by Gender for item D9 administered in booklet F4 (top-left) - DIF-plot (top-right) - Distractor Plot of males (bottom-left) and females (bottom-right)

## Conclusions.

In this paper, we compared two versions of the same item with the purpose of analyzing a specific misconception concerning multiplication with decimal numbers. The results showed interesting evidence that will be investigated in further studies from a qualitative point of view. The analysis showed that our new formulation ( $0.5 \times 4$ ) is simpler (in terms of item difficulty) than the first one ( $4 \times 0.5$ ) and this is particularly due to the improvement of the performances of girls. This result is

coherent to the model of multiplication as a repeated sum proposed by Fischbein, Deri, Nello, & Marino (1985) or by Sbaragli (2012). In particular, our new formulation seemed to affect low-ability girls positively suggesting that they are more prone than boys to the effect of misconception. Moreover, empirical findings showed a sharper difference between boys and girls at the higher ability level, unless boys confirmed their superiority in encountering this task independently on its formulation at the top level of the ability distribution. Furthermore, in both versions, distractor D (i.e., product equal to 20) which is strictly related to the misconception, is always preferred by females. In particular, we observed that the inversion of the two terms of a multiplication has a huge impact on students' answering behavior especially on females: strong gender gap emerges in favor of males in the first version ( $4 \times 0.5$ ) for students scaling at the upper-tail of the latent trait and in favor of females in the second version ( $0.5 \times 4$ ), especially at the lower tail of the ability distribution. In the second form the influence of the misconception appears lower and (probably for this reason) the item is easier since students can calculate the product by using the implicit model of multiplication as repeated addition and this particularly helps low-ability girls.

*Multi-theoretic research designs are increasingly seen as a useful approach to connect and compare multiple theories employed in the in-depth investigation of specific research settings or specific phenomena. Central to multi-theoretic designs is the comparison of the analytical accounts arising from the application of different theoretical lenses to data relating to the same research setting. We argue that the selection of a suitable unit of analysis is critical to the legitimacy of these acts of comparison. This paper discusses the issues arising from consideration of the unit of analysis in multi-theoretic research designs and illustrates these issues with examples drawn from the Social Unit of Learning project. The degree of correspondence between the units of analysis employed in the different analyses has implications for the connections that might be made between the parallel analyses.*

*Keywords: Classroom research, research design, research methodology, social interaction.*

## **Introduction**

Multi-theoretic research designs are increasingly seen as a useful approach to connect and contrast multiple theoretical perspectives on the same research settings or in relation to the same phenomena (Bikner-Ahsbahr & Prediger, 2014; Clarke et al., 2012). Such research designs generally involve the parallel application of multiple theories and associated research methodologies and methods within a single research design for analysing data relating to the same setting or situation in order to investigate the phenomenon and the theories of interest. Although many educational researchers over the years have drawn from multiple perspectives in their work (cf. Cobb, 2007), the meta discussion of the issues, contradictions, and affordances of such research designs is an emerging discourse in the field of educational research, resembling the discourse concerning mixed methods research designs in the early 2000s (Johnson & Onwuegbuzie, 2004). This paper particularly addresses the issues arise from the consideration of the unit of analysis in multi-theoretic research designs.

Multi-theoretic research studies (e.g., Clarke et al., 2012; Even & Schwarz, 2003) create a need for researchers to consider more carefully the epistemological, theoretical and practical implications for juxtaposing multiple theoretical perspectives within a single research study. As argued elsewhere (Chan & Clarke, 2017a), we posit that theories can be complementary in their conceptual totality (having different epistemological and ontological bases) but nonetheless invoke operationalised versions of specific constructs common to both theories, which could be used to interrogate the setting, and form the basis for interpretive accounts which can then be juxtaposed with respect to their implications for practice. Commensurability was suggested as a possible important

consideration in multi-theoretic research, as it obliges researchers to articulate the nature of the comparability between theoretically-grounded interpretive accounts when juxtaposing theories. We argue that the commensurability between separate analyses can be examined in terms of: (a) what constitutes evidence within the realm of an analytical framework, (b) the unit of analysis, and (c) the conclusions that can be drawn from the analyses (Chan & Clarke, 2017a).

### **The unit of analysis**

Central to multi-theoretic designs is the need to compare and connect the analytical accounts arising from the application of different theoretical lenses to data relating to the same research setting. We argue that the selection of a suitable unit of analysis is critical to the legitimacy of these acts of comparison. Säljö (2009) suggested that in the area of learning theories, there is a need to recognise the differences and possible incompatibilities in ontologies and epistemologies between different research traditions (e.g., behavioural, cognitive, and socio-cultural theories) through dialogues regarding what counts as evidence of learning in these different traditions. This paper argues that the discussion of the unit of analysis can serve such an important dialogic function because the unit of analysis reflects “the choice of a conceptualisation of a phenomenon that corresponds to a theoretical perspective or framework” (Säljö, 2009, p. 206). We take the position that the unit of analysis also operationalises the focal construct in terms of specific empirical data.

According to Neuman (2003), unit of analysis refers to “the type of unit a researcher uses when measuring” (p. 156). The unit of analysis employed in a study can differ depending on the field of research (e.g., psychology or sociology), research techniques (e.g., survey or content analysis), and research topics and questions. Although the concept of the unit of analysis seems to have come from quantitative research, the concept appears to be a useful research consideration in other forms of research (e.g., qualitative research) for examining the internal coherence of a study (Neuman, 2003) and the commensurability between studies (Chan & Clarke, 2017a). In order to expand the concept of unit of analysis to go beyond quantitative studies in terms of measurement, we define unit of analysis as the unit of empirical data a researcher uses to make distinction in relation to a focal construct. This definition is further elaborated.

As will be argued in this paper, the choice of the unit of analysis also affects the meaningful comparison between theoretical perspectives and between interpretive accounts (Chan & Clarke, 2017a). The next section provides an overview of a research project which utilised a multi-camera technology to generate a rich source of classroom data for multi-theoretic analyses. Three parallel analyses that were employed using the same data set are used in this paper as illustrative and contrasting examples. The paper addresses the questions, “What was the decision-making process involved, relating to the selection of the units of analysis in the project?” and “What are the possible consequences where the units of analysis employed in parallel analyses are the same or different?”

### **Method**

The Social Unit of Learning Project used the Science of Learning Research Classroom (SLRC) at the University of Melbourne to examine individual, dyadic, small group (four to six students) and whole class problem solving in mathematics and the associated/consequent learning. The project

aimed to distinguish the social aspects of learning and, particularly, those for which “the social” represents a fundamental and useful level of explanation, modelling and instructional intervention.

### **Data generation**

The SLRC laboratory classroom is equipped with 10 built-in video cameras and up to 32 audio channels. Intact Year 7 classes were recruited with their usual teacher in order to exploit existing student-student and teacher-student interactive norms. Two classes of Year 7 students (12 to 13 years old; 50 students in total) provide the focus for this report. Each of the classes participated in a 60-minute session in the laboratory classroom involving three separate problem solving tasks (e.g., Sullivan & Clarke, 1991) that required them to produce written solutions. The students attempted the first task individually (10 minutes), the second task in pairs (15 minutes), and the third task in groups of four to six students (20 minutes). The resulting data collected in the project included: all written material produced by the students; instructional material used by the teacher; video footage of all of the students during the session; video footage of the teacher tracked throughout the session; transcripts of teacher and student speech; and pre- and post-lesson teacher interviews.

### **Parallel data analyses**

As an entry point for analysing the project data, the written solutions, transcripts, and video record were used to understand the social process that took place to produce the written solution. The instructional material and teacher pre- and post-lesson interviews provided insights about the class capabilities and social relationships that the researchers would not otherwise be able to access.

In this project, a theory was recruited for its capacity to address constructs, artefacts or situations distinct from those addressed in other theories being employed – that is, for its capacity to complement those already selected. Several parallel analyses were undertaken, drawing on the established research expertise of classroom research communities in multiple countries. This paper particularly focuses on three of the analyses as illustrative examples of different definitions of units of analysis:

- 1) Student negotiative foci led by Chan and Clarke;
- 2) The sophistication in mathematical exchange led by Tran; and
- 3) Student motivating desires led by Tuohilampi.

Chan and Clarke (2017b) conducted an analysis that identified the negotiative foci of the students' social interactions during collaborative problem solving, taking the social negotiation of meaning as a key constitutive element of learning (e.g., Clarke, 1997). Tran (Tran & Chan, 2017) examined the sophistication of the mathematical exchange between students by applying the frameworks of cognitive demand (Stein & Lane, 1996) and mathematical practices (Common Core State Standards Initiative [CCSSI], 2010). While the cognitive demand framework assumes a hierarchy of skills, the mathematical practices framework does not assume a hierarchy and suggests possible co-occurrence and interrelation between each type of mathematical practice. Tuohilampi (2018) carried out an investigation of the affective enablers and disablers of student participation in collaborative group work, drawing on the work of motivating desires (Goldin, Epstein, Schorr, & Warner, 2011) to explore the extent to which a group of students established a productive affective micro-culture.

These three analyses offer distinct perspectives and approaches for examining the data in the project. Initially, attempts were made to standardise the unit of all the analyses applied in this study in order to make “fair” comparisons between the coding. However, we soon realised that such standardisation would create a mismatch between the theories underpinning some of the analyses and the coding or categorisation that these different theories required to be applied to the data (cf. Säljö, 2009). Several analytical approaches were considered, including: coding using a fixed, common transcript unit as the unit of analysis (e.g., negotiative events or speaker turns); the interpretive annotation of interactions; or the narrative reconstruction of interactive sequences. In each of these analytical approaches, the degree of researcher interpretation and reconstruction of the data is different. However, some of the particular analyses undertaken in this project (e.g., negotiative focus and mathematical sophistication) could be carried out using the same or very similar units of analysis, while some (e.g., student motivating desires) required a different unit of analysis entirely. The degree of correspondence between the different units of analysis has implications for the connections that might be made between the parallel analyses.

The analysis of negotiative foci by Chan and Clarke (2017b) employed the negotiative event as the unit of analysis for analysing the transcripts. In this analysis, a negotiative event is defined as “an utterance sequence constituting a social interaction with a single identifiable purpose” (Clarke, 2001). For example, consider the following excerpt during the discussion of the Task 2 pair activity between Pandit and Anna (the number within the square brackets denotes speaker turn):

- [28] Pandit: ... The average.
- [29] Anna: No. The average age is 25.
- [30] Pandit: I know. So 25 times five is average.
- [31] Anna: No.
- [32] Pandit: What do you mean? Do you know average?
- [33] Anna: You know what average is?
- [34] Pandit: Yes. Do you know what average is?
- [35] Anna: Yes.
- [36] Pandit: (Laughs) Okay. What's an average (laughs)?
- [37] Anna: So one of them is Year 7, right?
- [38] Pandit: Yeah. One of them is Year 7.
- [39] Anna: Yeah.
- [40] Pandit: So there's one dude that's 13 years old. Year 7 is 13 years old.

The excerpt began with Pandit and Anna trying to clarify each other’s understanding of average. When Pandit persisted and requested an answer from Anna (Turn 36), Anna changed the subject (Turn 37) and revisited the task instructions in terms of the Year 7 student that they had to take into account as part of the task. Turns 28 to 36 can be considered a single negotiative event related to clarifying each other’s understanding of average (a goal that is not really achieved), while Turns 37 to 39 constitute a separate negotiative event. In the negotiative foci analysis, the full transcript was partitioned into negotiative events and then subsequently coded according to the negotiative focus of each event (mathematical, sociomathematical, or other social focus).

In the case of Tran's analysis (Tran & Chan, 2017), he initially considered an overall rating of each group of students in terms of the mathematical sophistication of the students' exchange. However, an overall rating of the entire interaction was deemed too coarse grained, as it overlooked the dynamics of the student reasoning as the conversation progressed. Tran's later analytical approach involved interpretive annotation of student interactions looking for demonstration of a particular level of thinking process (e.g., unsystematic or non-productive exploration; memorisation; use of procedures without connections to concepts, meaning, and/or understanding; or use of procedures with connections to concepts, meaning, and/or understanding) (see Stein & Lane, 1996) or a particular set of mathematical practices (e.g., making sense of problems and persevering in solving them; reasoning abstractly and quantitatively; constructing viable arguments and critiquing the reasoning of others; model with mathematics; etc.) (CCSSI, 2010, pp. 6–8). Also applying negotiative events as the unit of analysis (Clarke, 2001), Tran summarised the student interactions in terms of the highest level of cognitive demand attached and types of mathematics practices displayed by the student pair within each negotiative event. Different from Chan and Clarke (2017b), only verbal exchange between students with a mathematical focus was considered in the coding. The definition of "negotiative focus" was also re-defined in his analysis in terms of mathematical reasoning resulting in generally larger "event chunks" than that in the analysis conducted by Chan and Clarke. In addition, employing an entirely different unit of analysis, Tran also created storylines to trace the reasoning of the students individually and as a cognising student pair and a small group unit.

The analysis of motivating desires by Tuohilampi (2018) focused on the key affective events (Goldin, 2017) of student interactions. Her analysis involved reconstructing the interactive sequences between the students during video episodes of half a minute to one minute each. For example, Tuohilampi (2018) described a one-minute episode (Episode 0) involving Anna, Pandit, John, and Arman during the group task (Task 3). During that episode, the motivating desire of John appeared to be Commitment, where he was pondering about the task on his own without a lot of interaction with the other three people in the group. However, when the previous half-minute episode (Episode -1) was taken into consideration, the interpretation of John's motivating desires in the initial episode had to be revised to account for his apparent difficulty with communicating with the other people in the group due to language difficulties (Avoidance). Yet, when another half-minute episode (Episode -2) which took place one minute before the initial episode (Episode 0) was considered, John's language difficulty did not seem to have affected his friendly interaction with Arman. The researcher's interpretation of the students' motivating desires therefore could change as more episodes and more background information about the students were considered.

## Discussion

Using unit of analysis as a connecting construct, we can begin to examine the commensurability (Chan & Clarke, 2017a) between the various analytical approaches reported in this paper. Consistent with Säljö (2009), central to the decision-making process involved relating to the selection of the units of analysis in the project, is consideration of the correspondence between the unit of analysis, the conceptualisation of the phenomenon of interest, and the theoretical perspective employed. The above examples of parallel analyses applied in the Social Unit of Learning Project

illustrate the close connection between the unit of analysis and the conceptualisation of the phenomenon of interest, which in turn corresponds to the theoretical perspective or framework. In the case of the negotiative focus analysis, the social negotiation of meaning was taken as a key constitutive element of learning (e.g., Clarke, 1997). The application of negotiative events as unit of analysis (Clarke, 2001) helps the researchers to focus on the purpose and content of the student exchange.

The multiple analytical approaches used by Tran (Tran & Chan, 2017) highlighted the variety of possibilities for examining the mathematical sophistication of student exchanges. When the goal of the analysis of the mathematical sophistication level of the student exchange was set at the characterisation of the overall individual, student pair, or student group level, this focus on “mathematical sophistication” as a generalised attribute true of a particular social unit (individual, pair, group), demonstrated throughout a particular episode, reflected a theory of competency of learning, where a person’s behaviours are a reflection of the skills or knowledge that the person holds (cf. Gagné, 1962). Despite the re-conception of the unit of analysis as indicative of levels of thinking processes displayed throughout the student exchange, the approach still assumes a hierarchy of behaviours consistent with a competency view of learning. The application of the mathematical practices framework (CCSSI, 2010), on the other hand, appears to assume a process model where students may call upon or generate different skills and knowledge as they interact with each other during a collaborative task.

Tuohilampi’s (2018) analysis suggests that a fixed unit of analysis such as negotiative events employed in the negotiative focus analysis (Chan & Clarke, 2017b) and the analysis of the mathematical sophistication of student exchange (Tran & Chan, 2017) is unsuitable for the analysis of motivating desires. A negotiative event based on the transcript appears to be too restrictive to interpret a person’s affective responses and ascertain the person’s motivating desire. The analysis of motivating desire requires interpreting the intention(s) of the actor, where the intention(s) are fluid and can be defined and re-defined depending on how the situation perceived by the researcher, taking in to account the prior and subsequent behaviours of the people involved, and the consequence(s) of the interactions.

The second question that this paper addresses is: “What are the possible consequences where the units of analysis employed in parallel analyses are the same or different?” The multi-theoretic research design of this study makes possible the comparison and contrasting of multiple analytical approaches. While the use of a standardised unit of analysis may suggest that it is possible to directly compare the results of the parallel analyses in terms of their application to a specific “piece” of data, the validity of individual analyses could be compromised in terms of their correspondence to the theoretical perspective and the phenomenon of interest. In order to preserve the coherence of individual analyses, the standardisation possible between analytical approaches is limited. Nevertheless, the common data source and setting that the separate analyses draw upon provide important points of connection between the analyses.

In the past, our capacity to connect analyses of the learning process employing different theoretical perspectives has been limited to comparison of the reports of research undertaken in relation to

different individuals interacting in different learning environments. The inevitable internal alignment of data with the choice of analytical lens within each separate report has made the comparison and connection of these separate analytical accounts difficult. Multi-theoretic research designs afford the comparison and connection of analytical accounts in relation to the same setting and data source. This represents a significant advance in our capacity to deal with the complexity of a particular social setting, through the combination of perspectives offered by multi-theoretical designs. This also affords the delineation of the zone of applicability of each of the theoretical lenses applied. These advantages remain whether or not the different analytical accounts employ the same unit of analysis.

The use of multiple theories is motivated by two goals: understanding of the setting and delineation of the field of feasible application of the theory. Careful attention to the unit of analysis is required, if these two goals are to be met. It is through analytical accounts grounded in the designated units of analysis that comparisons are made and whether comparison of these accounts can serve as an adequate surrogate for the comparison of the related theories will depend on the coherence with which each unit of analysis is connected to the relevant superordinate construct and the theory from which it was drawn.

## Conclusion

Acts of comparison are fundamental to all forms of research, and are dependent on the careful selection of the units of analysis by which these acts of comparison are undertaken. Our use of multiple theories serves to highlight this critical consideration. It is not surprising that analyses informed by different theories should require different units of analysis. We would like to emphasise, however, that strategic consideration of the units of analysis can facilitate the identification of connection and distinction between multiple theories and therefore enhance our understanding of both the theories and the phenomenon of interest. With the emerging meta-discourse about multi-theoretic research, it is hoped that the explication of the issues concerning units of analysis provided in this paper will contribute to the further theorisation of multi-theoretical research approaches.

# Impact of access requirements on the mathematical knowledge of students admitted to Primary Teaching programs: a micro-comparative study

Núria Gorgorió<sup>1</sup>, Lluís Albarracín<sup>2</sup>, and Anu Laine<sup>3</sup>

<sup>1</sup>Universitat Autònoma de Barcelona, Spain; [nuria.gorgorio@uab.cat](mailto:nuria.gorgorio@uab.cat)

<sup>2</sup>Universitat Autònoma de Barcelona, Spain; [lluis.albarracin@uab.cat](mailto:lluis.albarracin@uab.cat)

<sup>3</sup>Helsingin Yliopisto, Finland; [anu.laine@helsinki.fi](mailto:anu.laine@helsinki.fi)

*We present a comparative micro-study analyzing whether the changes made to the admission requirements to the primary teacher training programs of the Universitat Autònoma de Barcelona and the University of Helsinki in the academic year 2017-18 have had an impact on the background mathematical knowledge of those admitted to the programs. We are interested in finding elements that provide information for university admission policies. Our results show that significant changes only took place in Barcelona and these were a consequence of the variations in the academic profile of the students admitted. We conclude that working with a context-bound instrument, while making comparison difficult, directs the researchers' attention to the need for an in-depth theoretical discussion about the mathematical knowledge of candidates to initial teacher education programs and a methodological discussion on how to evaluate this knowledge.*

## Introduction

Our study is among those that attempt to determine what factors influence the development of mathematical knowledge for teaching during teacher education. According to Blömeke and Delaney (2012), some of these variables are the institutional characteristics of each program, the idiosyncrasies of the national and social context, and the individual characteristics of the students attending the programs. The survey we present here is a small part of an emerging comparative study that aims to contribute to the discussion of university policies regarding access to primary teacher education programs while promoting a theoretical debate about what the desirable mathematical knowledge of students admitted to these programs would be (for more details about the project, see e.g. Albarracín, Gorgorió, Laine, & Llinares, 2018; and Gorgorió et al., 2017). We understand that the admissibility criteria and the requirements for access to educational programs, as institutional particularities, contribute to defining the individual characteristics of their students. We assume that the mathematical knowledge with which students access primary teaching programs – henceforth, background mathematical knowledge – influences the development of the knowledge needed to teach mathematics during their education.

As educators of primary school teachers, we are interested in finding elements that provide information for university admission policies so that requirements can be established to ensure a minimum of mathematical knowledge among admitted students. Comparative studies between

different national realities that evaluate the mathematical knowledge of the candidates in relation to the admission criteria can help to explain the success differences between the different training programs, thus identifying variables that may otherwise remain hidden in national studies and hence remain unquestioned.

Since 2014, at the Universitat Autònoma de Barcelona, Catalonia – henceforth BCN – we have been evaluating the background mathematical knowledge of students admitted to the primary teaching program through a specific test. In the 2016-17 academic year, we decided to also administer the test to the students admitted to the Master of Education degree at the University of Helsinki, Finland – henceforth HEL – to study the results comparatively, taking the entrance requirements into account. We then observed that students at HEL performed significantly better than students at BCN.

In this paper, we present a comparative micro-study analyzing whether the changes introduced in the 2017-18 academic year regarding requirements for admission to the primary teacher training programs in Catalonia and at the University of Helsinki have had an impact on the background mathematical knowledge of those admitted to the programs. The changes are of a very different nature and have to do with the idiosyncrasies of the respective university and school systems. For the students admitted to a teaching degree in Catalonia, and in particular to BCN, September 2017 was the first time they had to pass a specific mathematics test. At HEL the change consisted in increasing the proportion of candidates for whom not only the VAKAVA-test and suitability test but also the mathematics and Finnish grades of the matriculation examination were considered for admission.

We exploited quantitative data collected in the academic years of 2016-17 and 2017-2018, i.e. before and after changes took place in the admission criteria both at BCN and HEL. Here we discuss how the changes introduced have impacted students' performance on the test, comparing the performance across years, both within and between universities. We are especially interested in seeing whether the differences occur as result of the changes in the academic profile of the admitted students prior to their University studies.

### **Admission to a primary teaching degree at BCN and HEL**

The recent introduction of the requirement to pass a specific mathematics test for admission to the primary teaching degrees in Catalonia justifies the presence of BCN in the research study. Since the results of the first PISA Study were published in 2000, there has been widespread international recognition of the success of Finland's educational model. Even though this success is due to many factors, the most important aspect is believed to be the quality and competence of its teachers (Salhberg, 2011). For this reason, it seemed logical to include a Finnish program in this study. In addition, since the policies and admission requirements to the primary teaching program in Helsinki are very different from the Spanish ones, we consider it interesting to compare HEL and BCN.

Since 1979, primary teachers in Finland need to have completed a Master of Education degree (300 ECTS). After compulsory education, youngsters can enter the job market directly or instead attend either university-preparatory Upper Secondary School or Vocational School. At Upper secondary school, students can choose to do either intermediate mathematics or advanced mathematics. At the end of Upper Secondary School, students take the Finnish Matriculation Examination, *Ylioppilastutkinto* in Finnish (henceforth YLIO), which is the only national-level test in Finland. Each

examinee is required to complete at least four exam papers, only one of them (mother tongue) being mandatory. The remaining three are chosen by the student and may include one in mathematics, either intermediate or advanced. Graduates of Vocational School may also gain admission to university. In Finland, students interested in becoming primary teachers, after passing the YLIO, must go through a special two-stage application process. The first stage involves taking an exam (the so-called *VAKAVA testi*) based on a set of education-related readings. Those who perform well on this exam go on to the second stage, a suitability test that assesses their motivation to study and suitability to work as teachers. Universities in Finland agree on the number of new admissions in cooperation with the Ministry of Education. At HEL, fewer than 10% of applicants are accepted annually for the primary teacher education program. In 2016-17, 48 students (40%) were selected based on the suitability test alone and 72 students (60%) were selected based on the suitability test and their grades in the YLIO in 4 subjects – Finnish and 3 optional subjects. In 2017-18, only 24 students (20%) were selected based on the suitability test alone, and 96 students (80%) based on the suitability test and the grades in the YLIO in Finnish and mathematics. Thus, the number of students at HEL who took a mathematics test in the YLIO increased by at least 20 percentage points.

In Spain, primary teachers are required to have completed a Degree in Primary Teaching (240 ECTS). Access to primary teaching degrees can be gained via the Baccalaureate (2 years of non-compulsory education) or through a vocationally-oriented Professional Cycle. Those who study Baccalaureate may choose a track containing mathematics – either mathematics or mathematics for social sciences – but some tracks do not contain any mathematics subjects. The professional cycles from which students gain access to the primary teaching programs do not have mathematics courses. Those that have completed the baccalaureate have to pass the *Pruebas de Acceso a la Universidad* (henceforth PAU) to be admitted to any university program. Four of the exam papers of the PAU are universal for all students across Spain, but this is not the case for mathematics, which is an optional subject. Students who have completed a Professional Cycle may also gain access to university. Therefore, applicants to teacher education programs in Spain will not have taken any mathematics courses in post-compulsory education unless they have taken one of the two tracks of the Baccalaureate that include mathematics. It is important to point out that the number of student places in primary teaching degrees in Spain bears no relationship to the actual number of teaching jobs in the market. At BCN, around two thirds of the applicants were admitted for the academic years 2016-17 and 2017-18<sup>1</sup>. In the academic year 2016-17, there was no specific requirement for admission to Primary Teaching programs in Spain outside the universal procedure described above. However, in Catalonia, starting in the 2017-2018 academic year, a specific complementary entrance examination – which includes a mathematics test – was implemented.

## Data collection

### Instrument

The instrument we used to collect our data was the mathematics test that had been designed and used to pilot the specific complementary entrance examination in Catalonia mentioned above that had the

---

<sup>1</sup> [http://universitats.gencat.cat/ca/altres\\_pagines/informe\\_i\\_estadistiques/informes\\_i\\_estad\\_pre/](http://universitats.gencat.cat/ca/altres_pagines/informe_i_estadistiques/informes_i_estad_pre/)

administrative purpose of regulating access to primary teaching degrees in Catalan universities. The mathematics test was intended to ensure a minimum mathematical content knowledge of admitted candidates (for a detailed description of how the test was created and validated see Albarracín et al., 2018). The test evaluated disciplinary knowledge of a conceptual and procedural nature.

The test had 25 questions, with an open-answer format, related to the prescribed curriculum of Spanish compulsory education – Numbers and Arithmetic, Space and Shape, Relations and Change, Magnitude and Measure, and Statistics and Randomness. The weight given to each content area was related to the actual presence of said contents in the school practice. Thus, there were 7 items on numbers and arithmetic (procedural and conceptual exercises with natural, integer, fraction and decimal numbers), 5 items on magnitude and measure (concepts of length and area, calculation of perimeter and area, and units change, in both decimal and sexagesimal systems), 5 items on relations and change (3 items on proportionality, 1 patterns, and 1 graph interpretation), 4 items on space and shape (2 conceptual on plane geometry, 1 visualization, 1 representation) and 4 items on statistics (1 reading and 1 construction of bar charts, 1 interpretation of a pie chart, all of them procedural, and 1 on conceptual measures of central tendency). Students had 90 minutes to answer the test and no calculators were allowed.

The following are examples of the items in the test:

- 4- *A product is on sale. According to the label, the normal Price is £125. The sale price is £100. What percentage of discount has been applied?*
- 7- *Which prime number can be made by subtracting two multiples of 7?*
- 14- *What is the surface area of a square with a perimeter of 32 cm?*
- 16- *Which of the following figures must have equal diagonals? a) square; b) rhombus; c) rectangle; d) trapezium*
- 18- *How many cm are in 7.8 km?*
- 24- *What number would we add to the list in order for the mean to equal 7? {2, 6, 6, 6, 8, 8, 9}*

From the beginning we were aware that the test, as it had been defined, was going to be culturally context-bound to the idiosyncrasies of the educational system in which it had arisen. Although the curricula in Finland and Spain are not so different, the emphasis placed on each of the subjects and the way they are taught in class is. We have purposely included some of the items of the questionnaire as examples that will serve to illustrate how the questionnaire was bound to the context. For example, it was already expected that item 7 shown above would harm students' results in HEL, since, although they work on divisibility, the term "prime number" is not as familiar to them. Another example would be item 16 since it includes the idea of a rhombus, which is rarely used in Finland – it is not a category in itself in the classification of quadrilaterals that schoolchildren learn, contrary to what happens in Spanish school mathematics lessons, where the rhombus gives rise to a category in itself. A full discussion of how the test was context-bound can be found in Albarracín et al. (2018).

### **Participants and data collection**

In HEL, the test was taken by the 116 students starting their primary teaching education program in 2016-17 and 2017-18, at the very beginning of their courses in August. In BCN, the 254 students that initiated their teaching education in 2016-17, and the 276 that did so in 2017-18, took their test in

February, at the beginning of the second semester. Neither in HEL nor in BCN had students taken any university class on mathematics or mathematics education at the time of the test.

Students had to answer the test on a worksheet, without using a calculator and in a maximum time of 90 minutes. The answers were marked, assigning 1 point when the answer was completely correct (meanings, calculations, units, etc.) and 0 points if it was not. The students' grades in the exam are part of our data, the other group being the information they gave us about their previous academic trajectory, allowing us to gain information on which (if any) mathematics courses they had taken as part of their pre-university education.

## Results

### Reliability of the instrument

First, to test the reliability of the data obtained in the test, we calculated the Cronbach's alpha, both overall and for each campus, as an internal consistency estimate of the reliability of the test scores. The results that we obtained ( $\alpha$  BCN·16·17 = 0.8157;  $\alpha$  HEL·16·17 = 0.8106;  $\alpha$  BCN·17·18 = 0.7963;  $\alpha$  HEL·17·18 = 0.7579;  $\alpha$  Overall = 0.7985), in all cases higher than the reference value of 0.7, were a suitable indicator of the internal consistency of the instrument, meaning that the different questions of the test evaluate the mathematical knowledge with which students arrive at the teacher education programs, in a coherent way and from a disciplinary perspective. In this way, we consider that the instrument sufficiently and consistently approaches our idea of background mathematical knowledge.

### Differences in performance

Table 1 presents the basic statistics that describe the centrality and distribution of the scores in the test by the students in HEL and BCN in 2016-17 and 2017-18 academic years.

Variable	HEL·16·17	HEL·17·18	BCN·16·17	BCN·17·18
N	116	116	254	276
Mean	17.233	17.595	15.996	17.750
SE Mean	0.405	0.368	0.302	0.264
StDev	4.363	3.963	4.812	4.389
Minimum	7.000	6.000	3.000	4.000
Q1	14.000	15.000	12.000	15.000
Median	17.500	18.000	16.000	18.000
Q3	21.000	21.000	20.000	21.000
Maximum	25.000	24.000	25.000	25.000

**Table 1: Centrality and distribution of marks**

A series of mean comparison t-tests allows us to establish the significance of differences (Table 2)

	Estimate for Difference	Confidence Interval for difference (95%)	p-value
HEL·17·18 vs. HEL·16·17	0.362	(-0.716; 1.440)	0.509
BCN·17·18 vs. BCN·16·17	1.754	(2.539; 0.969)	0.000
HEL·16·17 vs. BCN·16·17	1.237	(0.242; 2.232)	0.015
HEL·17·18 vs. BCN·17·18	-0.155	(-1.084; 0.773)	0.743

**Table 2: T- tests comparison of score means across universities**

As can be seen in Table 2 for 2016-17, students at HEL obtained significantly better results than students at BCN. It also shows that at HEL there was no significant change in performance between 2016-17 and 2017-18. However, results at BCN were significantly better in 2017-18, to the extent that such results cannot be statistically distinguished from the results in HEL of the same year.

### **Impact on the academic profile of students admitted to BCN**

We note that there are only significant differences between the results before and after the implementation of a new requirement at BCN, this being the only change affecting entry conditions at BCN. In Albarracín et al. (2018) we had found that the academic profile of students prior to entering university generated different results. Therefore, it is interesting to explore what aspects have changed in the profile of admitted students – we have no information about those who applied for admission but were not admitted.

We labelled BCN students who had only taken the compulsory mathematics BCN·COM and those who had followed the Baccalaureate track containing mathematics BCN·BAC. Table 3 shows the proportion of students and the mean of the scores obtained in the test by the students in each subgroup, as well as the standard deviations. Table 4 shows the results of the T-tests comparing the mean scores of the subgroups.

	Percentage of students in each subgroup	Mean score (max. 25)	Standard deviation
BCN·COM·16·17	42.52%	13.611	4.488
BCN·BAC·16·17	57.48%	17.760	4.263
BCN·COM·17·18	32.61%	15.967	4.348
BCN·BAC·17·18	67.39%	18.613	4.153

**Table 3: Proportion of students that had taken mathematics after compulsory education, and the mean scores of each subgroup, with standard deviations**

	Estimate for difference	Confidence interval for difference (95%)	p-value
BCN·COM·16·17 vs. BCN·BAC·16·17	-4.033	(-5.175; -2.891)	0.000
BCN·COM·17·18 vs. BCN·BAC·17·18	-2,646	(-1.580; -3.712)	0.000
BCN·COM.1718· vs. BCN.COM.1617	2.356	(3.601; 1.110)	0.000
BCN.BAC.1718 vs. BCN.BAC.1617	0.853	(1.766; -0.061)	0.067

**Table 4: Results of the T-tests comparing the mean scores of the subgroups depending on whether they had taken mathematics after compulsory school**

In both the 2016-17 and 2017-18 academic years, students who had studied mathematics during Baccalaureate obtained better test results than those who had not. In addition, the 2017-18 academic year increased the number of students in the first group by 10 percentage points. In the 2017-18 academic year, students who had studied mathematics during Baccalaureate obtained better results than the same group in the previous academic year, but by a few thousandths we cannot say that this difference is significant. However, the difference is significant between 2016-17 and 2017-18 for those who had not studied mathematics during their post-compulsory education.

## Discussion

In our contribution we analyzed the impact of changing the criteria and requirements for admission to the teacher education programs of the Universitat Autònoma de Barcelona and the University of Helsinki. In both cases, the change implies a greater demand in relation to mathematics. However, we see that while in Barcelona the impact is significant, in Helsinki it is not so.

The results from BCN show that the introduction of the mandatory requirement to pass a mathematics test in order to gain access to the teachers' education program has generated a change in the academic profile of admitted students and their mathematical background knowledge has improved significantly compared to the previous academic year. We found that the number of students who continued to study mathematics after completing their compulsory schooling has increased by 10 percentage points. Our knowledge of the Catalan university system allows us to state that the only variable that could have generated this change in the academic profile of the students is the introduction of this new requisite. In addition, those who dropped out of mathematics at the end of compulsory schooling have also proven to have a better background mathematical knowledge than those in the same group the previous year. From informal conversations with the students, we dare to say that they have prepared for the new specific mathematics test that was part of the new entrance requirements.

However, we did not observe any significant changes in Helsinki. We believe that this is essentially due to the fact that the instrument used to collect our data was bound to the Catalan context. Although access to the primary teaching program in Helsinki had increased its mathematical demands, the terminology and formalism of the test that we used are still elements that have little weight on the education of Finnish students. In Hel, the new entrance requirement implies that a greater number of admitted students have studied secondary mathematics. However, the mathematics of intermediate or

advanced courses of upper-secondary in Finland are of little help to answer test questions linked to an approach that is characteristic of another national context.

We find it interesting to compare data from two cultural realities as different as the university systems of Finland and Catalonia. These results provide us with ideas that a study restricted to only one country would not generate, and these ideas can contribute to decision making. In particular, the changes introduced in Helsinki in the 2017-18 academic year are a consequence of the analysis of the results obtained by its students in the 2016-17 academic year. In Catalonia, our study can help to support the changes introduced that are beginning to be questioned by the media. We plan to incorporate data from other European universities into our study in the near future.

We are aware that working with a context-bound data collection instrument generates dilemmas, such as those suggested by Clarke (2013), that appear when an international comparative study is carried out. In spite of this, researchers working together who are outsiders with respect to each other's data, cultural contexts and national realities leads to richer and more nuanced interpretations. In addition, working with a context-bound instrument, while it makes comparison difficult, directs the researchers' attention to the need for an in-depth theoretical discussion about what the desirable mathematical knowledge would be for candidates to initial teacher education programs. An agreement on the theoretical level on what basic knowledge an entrance examination should evaluate would help to agree on the characteristics of the examination on the methodological level, to avoid it being strictly tied to a context.

### Acknowledgment

The research presented has been developed under the auspices of the research grants EDU2013-4683-R and EDU2017-84427-R –Spanish Ministry of Science, Innovation and Universities.

*This cross-cultural study focuses on specific features concerning the introduction to early algebra in three neighbouring countries – Estonia, Finland and Sweden – that, despite having relatively similar school systems, have different student results in international evaluations. The data consists of commonly used mathematics textbooks for Grades 1-3, and the focus of analysis is particularly on the treatment of expressions, equations, inequalities, and the meaning of the equal sign. The results show differences not only between the countries but also between different language groups within the same country, and similarities between the same language groups in different countries. We exemplify the most significant characteristics identified in different contexts in relation to various approaches to early algebra described in research literature, and discuss the implications of the findings for our research field.*

*Keywords: early algebra, comparative analysis, mathematics curriculum, primary education*

### Background

Early introduction to algebra has been in focus in recent research, and several researchers point out that it is beneficial to start working with important ideas within algebra already in primary school (e.g. Blanton, Stephens, Knuth, Murphy Gardiner, Isler & Kim, 2015). For example, an intervention study by Blanton et al. (2015) shows that students can improve their understanding of so-called big ideas of algebra with an appropriate teaching approach and relevant material. International comparisons show that there are great differences between approaches to the teaching and learning of algebra in different countries (e.g. Cai, Lew, Morris, Moyer, Ng & Schmittau, 2005; Leung, Park, Holton & Clarke, 2014). These comparisons have mainly concerned countries with significantly different cultures and school systems. In contrast, the present study investigates the early introduction to algebra in the three neighbouring countries of Estonia, Finland and Sweden, where the school systems are quite similar. For example, all three have nine years of compulsory school with no tracking. Moreover, national steering in the three countries is relatively weak, with no approval process for curriculum materials that are commercially produced. We deem that the similarity of the school systems facilitates the identification of specific features concerning the views on early progression in algebra in these countries. In international evaluations, there are differences between the countries in students' learning outcomes, making it interesting to discuss different approaches to early algebra in relation to this variation. While Estonian and Finnish students' results in international comparisons have been relatively good, algebra has not been the strongest area in Finland (Yang Hansen et al., 2011). In Sweden, students' results in algebra have

been low since the 1960s regardless of the variation in other mathematical topics (Hemmi et al., 2018).

Curriculum materials are produced within certain educational traditions, and may therefore be shaped by national perspectives on the specific school subjects (cf. Andrews, 2007). In all three countries, mathematics textbooks are an important part of classroom work. Therefore, in this paper, we exemplify and discuss typical characteristics of the approaches to early algebra in Estonia, Finland and Sweden as identified in our textbook analysis concerning Grades 1-3 (ages 7-9 years). We have also included textbooks produced by Finnish Swedish<sup>1</sup> authors in the analysis, as there are differences between the two language groups in Finland when it comes to students' learning outcomes, as well as teachers' relation to mathematics textbooks (e.g. Pehkonen, Hemmi, Krzywacki & Laine, 2018). We acknowledge that the textbooks can be used by teachers in various ways when designing and enacting mathematics lessons (e.g. Lepik et al., 2015; R j-Lindberg, Partanen & Hemmi, 2017; Kilhamn, 2014). However, we deem these kinds of studies important as we learn how textbook authors interpret the introduction of early algebra in different cultural-educational contexts. The following research question guides the study: *What are the specific characteristics of early algebra in textbooks series produced in four different contexts?*

## Relevant research and theories

Few comparative studies address the progression of algebra in different countries' curricula. Cai, Lew, Morris, Moyer, Ng and Schmittau (2005) study how algebraic concepts are developed and represented in the curricula of the US (Investigations curriculum), China, Singapore, South Korea and Russia (Davydov curriculum). The study by Cai et al. (2005) shows that the three Asian countries build informal equation solving on the use of inverse operations and the related doing-undoing. In the Russian Davydov curriculum for Grades 1-3, children develop algebraic thinking by exploring and comparing quantities before the study of arithmetic and, in contrast to the US Investigations curriculum, letters are used from the very beginning (Cai et al., 2005). Both the Russian and the US curricula address real-life problems, but in fundamentally different manners. In the former, they are carefully planned and sequenced to help students develop a theoretical understanding of mathematical concepts and an ability to analyse problem situations (Cai et al., 2005). Rather than proceeding inductively from the concrete to the abstract as Investigations does, the Davydov curriculum develops students' ability to see the same abstract relationships across different concrete contexts. Investigations engages students in mathematical problems embedded in authentic contexts and these applied problem-solving activities require US students to explore problems in depth, construct their own strategies and approaches utilizing a variety of tools (e.g., manipulatives, computers, calculators), and communicate their mathematical reasoning through drawing, writing, and talking (Cai et al., 2005).

Based on recent research on early algebra and the language of learning progression, Blanton et al. (2015) have identified five so-called big ideas connected to algebraic thinking. These big ideas

---

<sup>1</sup> About 5% of the Finnish population has Swedish as their mother tongue, and have the right to receive education in Swedish.

consist of: 1) equivalence, expressions, equations and inequalities; 2) generalized arithmetic; 3) functional thinking; 4) proportional reasoning; and 5) variables. In a recent study, we used the big ideas as the basis for an analytical tool in order to analyse the algebraic content in the current Swedish curriculum for mathematics as well as two Swedish textbook series for Grades 1-6 (Bråting, Madej & Hemmi, 2019). In the study reported in this paper, we look more in-depth at Grades 1-3 and the first two big ideas. The first – equivalence, expressions, equations and inequalities – includes relational understanding of the equal sign; representing and reasoning with expressions, equations, and inequalities; as well as relationships between and among generalized quantities. The second big idea – generalized arithmetic – involves reasoning about structures of arithmetic expressions (rather than their computational value) as well as generalizations of arithmetical relationships, which include fundamental properties of numbers and operations (e.g., the commutative property of addition) and inverse properties of operations (Blanton et al., 2015).

## Method

We chose the textbooks to be analysed based on our knowledge of their popularity in each region. In order to examine the variation within different contexts, we chose two textbook series each in Estonia (*Matemaatika* by Koolibri and *Matemaatika* by Avita), Finnish Finland (hereafter FinFin) (*Kymppi* and *Tuhattaituri*), and Sweden (*Eldorado* and *Matte Safari*). Only one series has been produced in the Finnish Swedish context (hereafter FinSwe), *Lyckotal*. In the data analysis, we identified the sections connected to the big ideas of equivalence, expressions, equations, and inequalities as well as generalized arithmetic. The insider(s) in each region conducted the analysis according to our collective interpretation of the categories based on our thorough discussions, and the analyses were then discussed by the whole research team. The analysis was qualitative, identifying the character of the texts and their order/place of appearance throughout the three grades in order to understand the progression of this big idea within various topics. The only quantification that took place in the analysis was connected to the identification of possible dominating topics. For example, if a certain kind of task occupied a great number of pages in a textbook or occurred regularly throughout the grades, it was marked in the analysis protocol. While it is not possible to report the results of the entire study within the scope of this paper, in the following we will describe, exemplify, and discuss the most striking differences and similarities displayed in the textbooks from the four regions.

## The results with illustrative examples

### Estonia

Addition and subtraction are introduced simultaneously in Grade 1, with subtraction introduced as the inverse of addition. In Grade 2, multiplication and division using whole numbers are introduced in a similar manner. Students are to find missing values using the inverse property of the operations (Figure 1). They should learn the names of the components and results of the four arithmetic operations in order to be able to reason about informal equation solving using the inverse property of the operation at a more general level. In addition, the trial and error strategy is introduced for searching the value of an unknown. At this stage, various symbols (box, blank, letter) are widely used in the textbooks to represent a variable or an unknown. Children are expected to learn to use

letters to express the relationships between quantities and determine the correct order of operations in expressions (parentheses, multiplication/division and addition/subtraction) from Grade 2. The notions of equivalence and inequality of two expressions (incl. letter expressions) are introduced and practiced using the formal signs ( $=$ ,  $<$ ,  $>$ ) from the beginning.

**Figure 1. Division as the reverse of multiplication in Estonian Grade 2 textbook, (*Matemaatika* by *Koolibri*)**

Rather than seeing equations as simply objects to manipulate, in Estonian primary textbooks from Grade 2 the equations describe relationships between varying quantities that arise from contextualized situations. Children are required to schematically represent the internal quantitative relationships in word problems and to write expressions of these relationships (Figure 2). This process is sequenced by the authors so that the same abstract relationship appears in different concrete contexts. Textbooks also systematically guide students in composing their own word problems for given expressions.

**Figure 2. Modelling word problems in Estonian Grade 2 textbook (*Matemaatika* by *Koolibri*)**

## Finland

In the FinFin textbooks, equalities and inequalities are presented with formal signs ( $>$ ,  $<$ ,  $=$ ) in parallel from the very beginning of Grade 1 and are used consistently throughout the three grades. First, only numbers are compared, and later during Grade 1, expressions are compared. This approach is different from the FinSwe style, in which the equal sign is introduced in Grade 1 while the signs for inequalities are only briefly introduced and practiced. Similar to the Estonian textbooks, one of the FinFin textbooks (*Tuhattaituri*) introduces the inverse property of addition and subtraction and guides students in using it in informal equation solving during Grade 1. The same is done with multiplication and division in Grade 2. This is not the case in the FinSwe textbooks, however, where equations start to appear at the beginning of Grade 1 in connection with the partition of specific numbers, for example with the number 5 in Figure 3.

The inverse property of addition and subtraction is introduced very briefly in the FinSwe textbooks during the first school year using so-called *number families*, whereby the student is tasked with writing out different expressions with the numbers 10, 3 and 7 in the shape of a triangle with + and – signs included. Hence, the students are expected to see how the members of this “family” are connected to each other via the operations. No explicit connections are made to guide students in using the inverse properties in equation solving. In the FinFin textbooks, the informal equation solving proceeds step-by-step by first focusing only on equations in which the same term of the operations is missing, while in the FinSwe books, diverse and sometimes open equations start appearing quite early in Grade 1. For example, students are asked to create two different expressions that are equal to each other during the first school term by filling out empty spaces (e.g.  $\_ + \_ = \_ + \_$ ), or with expressions in which the operations are missing (e.g.  $4 \_ 3 = 5 \_ 2$ ).

$$\begin{array}{l} 1 + \_ = 5 \\ 2 + \_ = 5 \\ 3 + \_ = 5 \\ \dots \end{array}$$

**Figure 3. Partition of the number 5 in the FinSwe textbook (*Lyckotal*)**

Contrary to the FinFin textbooks, at no point during Grade 1 are students asked to check their solutions by using the inverse operation. Neither the FinFin nor the FinSwe textbooks use letters for variables or unknown quantities during Grades 1-3; instead, they use gaps or pictures such as flowers and hearts. Thus, in the textbooks from the two language contexts students are expected to write the expressions of operations based on pictures or real-world problems from the beginning. The FinSwe textbooks also guide students in finding real-world problems for expressions, which we do not find in the FinFin textbooks.

a)  $16: 4 + 15: 5$   
 $= 4 + 15: 5$   
 $= 4+3$

b)  $\text{apple} + \text{apple} + \text{apple} = 9$   
 $\text{apple} + \text{apple} = \text{banana}$   
 $\text{banana} - \text{orange} - \text{orange} = \text{orange}$

**Figure 4. Handling of expressions (a) and informal equation systems (b) in the FinFin mathematics textbooks**

In the FinFin context, the priority rules are presented in Grade 2 and students learn to systematically calculate the value of expressions with two operations, stepwise marking every new phase below the previous expression. In Grade 3, students are to handle expressions with three operations in a similar matter, as in Figure 4a, where the first line includes two divisions and one addition. For Grade 3 the FinSwe textbooks state that the multiplicative operation is done before the additive, but all calculations are done in a straight line, i.e., not each below the previous as in the Finnish textbook *Kymppi*, shown in Figure 4a. The commutative properties of operations are presented during Grade 1 (addition) and Grade 2 (multiplication) in the FinFin textbooks. The formal names

of the operations are used from the beginning, and in Grade 3 students are to choose the correct expressions for sentences, for instance “Subtract from the quotient of 18 and 2 the product of 2 and 3.” A special feature of the Finnish textbook is its repeated exercises from the very beginning in solving systems of equations in an informal manner (see Figure 4b).

## Sweden

What characterizes the Swedish textbook series, especially *Matte Safari*, is the emphasis on open number sentences (see Figure 5). Inverse expressions occur in the context of number families, but the connection between addition and subtraction is barely visible in practice. As in the FinSwe textbooks, no explicit connections are used to guide students in applying the inverse properties in equation solving. We found only one example in a single textbook (*Eldorado*) in which students were to check their solutions using the inverse property.

$32 + \underline{\quad} = 36$	$51 + \underline{\quad} = 58$	$75 + \underline{\quad} = 80$
$34 + \underline{\quad} = 39$	$43 + \underline{\quad} = 47$	$22 + \underline{\quad} = 30$
$36 + \underline{\quad} = 38$	$84 + \underline{\quad} = 85$	$53 + \underline{\quad} = 60$

**Figure 5. Practicing of open number sequences (*Matte Safari*)**

Both textbook series present the commutative property of addition and state that subtraction is not commutative. Multiplication is introduced in Grade 2, and the commutative property of multiplication is shown in both textbook series. The inverse relation between multiplication and division is only presented in *Eldorado*. Expressions are addressed in both textbook series, but more often in *Eldorado*. In both series, the expressions go “both directions”, i.e. students are expected to write an expression from a real-world problem or a picture, but also to create their own text problem for a given expression. This is similar to the Estonian and FinSwe textbook series. An example of this is the task “Draw and write text problems” in Grade 1, in which students are to create text problems for the expressions  $5+3+2$  and  $12-5$ .

<p><b>Symbolen x</b></p> <p>Symbolen x har ett värde så att likheten stämmer.</p> <p><math>3 + x = 5</math>      <math>x = 2</math></p>	<p><math>40 + x = 48</math>    <math>x = \underline{\quad}</math></p> <p><math>x + 70 = 71</math>    <math>x = \underline{\quad}</math></p>
-----------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------

**Figure 6. Examples of equations in the Swedish Grade 1 textbook (*Eldorado*)**

Priority rules are not considered in either of the two Swedish textbook series; and neither are inequalities, even though one of the textbooks guides students in using the symbols for “greater than” and “less than” to express which of two numbers is larger or smaller. However, this appears only one single time and in the other textbook these symbols are not used at all. The relational meaning of the equal sign is emphasized in both textbook series, especially *Matte Safari*. For example, students are asked to write  $=$  or  $\neq$  between expressions like  $9 - 2$  and  $4 + 4$  or  $7 + 3$  and  $2 + 8$ . There are also fully open number sentences, such as  $\_ + \_ = \_ + \_$ , in line with the FinSwe

textbooks. Neither of the textbook series introduces formal equation solving. Yet, one of the textbooks introduces “the symbol  $x$ ” as a placeholder in Grade 1, using the sentence “The symbol  $x$  has a value which makes the equality true”, and lets students find the value of  $x$  through inspection (Figure 6). However, this is not followed up in Grade 2 or 3.

## Discussion and conclusion

Our analysis reveals both differences and similarities between the four regions. Next, this will be discussed in light of relevant research.

The Estonian textbooks and one of the Finnish textbook series frequently use inverse properties of operations in connection with informal equation solving, which is similar to how informal equation solving is prescribed in the Singaporean and Chinese curriculum documents (Cai et al., 2005). Meanwhile, the Finnish Swedish and the Swedish textbook series use inverse properties of operations in the context of “number families” (Figure 3), but not explicitly in connection with informal equation solving. Instead, they both frequently use open number sentences to introduce students to equation solving. In Sweden, this approach might be connected to the emphasis on the meaning of the equal sign, which is explicitly pointed out in the current Swedish mathematics curriculum for Grades 1-3 (Bråting, Madej & Hemmi, 2019). In all textbook series from the four regions, the handling of expressions appears to varying degrees and students are expected to write expressions based on real-world problems. However, it is only in the Estonian textbooks that students are expected to create letter expressions and equations, which is in conformity with the Russian Davydov curriculum in which letters are used from the very beginning (Cai et al., 2005). The Swedish and the FinSwe series guide the students in finding real-world problems for expressions by means of writing and drawing. This approach is analogous to the US Investigations curriculum, in which students are required to explore problems in depth and construct their own strategies using a variety of tools (Cai et al., 2005).

We know that both Estonian and Finnish students have had outstanding results on PISA (Programme for International Student Assessment), in which concrete real-life problems are solved. Both Estonian and FinFin textbooks focus on the creation of quite complicated expressions in Grades 1-3, which might enhance students’ structural understanding of problems. This is something to delve into more deeply in further studies. Perhaps the most striking result is the difference we found between the Finnish language contexts. Although they follow the same national curriculum, the FinFin textbooks contain elements similar to the Estonian textbooks, while the FinSwe textbooks seem to have been influenced by Swedish traditions or vice versa. In fact, there seems to be a greater difference between the two Swedish textbook series than between one of the Swedish series and the Finnish Swedish textbook series. There is no government auditing of the textbooks in the three countries, and we are seeing an increased exchange of curriculum material between countries (e.g. Hemmi, Krzywacki & Liljekvist, 2018). In addition, some publishing companies have emerged across the countries. This might lead to greater variation between textbook series within single contexts, but also similarities across various contexts, making our understanding of the connections between curriculum materials and student outcome within a certain context more difficult.

## **A preliminary comparison of Chinese and German state mandated curricula for mathematics education (years 1 to 6)**

Eva Jablonka

Freie Universität Berlin, Department of Education and Psychology, Germany;

Eva.jablonka@fu-berlin.de

*The paper presents a preliminary analysis of official state-mandated curriculum documents for compulsory school mathematics education in China and Germany with a focus on years one to six. Both documents were issued in the context of relatively recent reform initiatives. In the context of these reforms some have observed an international harmonization of curriculum goals via the educational discourse disseminated by the OECD. This trend motivates the comparison. The preliminary comparison presented in this paper is part of a larger upcoming project that investigates how curriculum objectives are interpreted by actors at different levels of governance in systems with differing policies for controlling curriculum implementation. As a starting point for investigating the discretionary space granted to schools and teachers in their micro-curricular planning, the comparison presented here identifies the level of detail in the content standards.*

*Keywords: Mathematics curriculum, curriculum research, cross cultural studies, educational goals.*

### **China and Germany – comparing the incomparable?**

In China, after an incipient period in the 1950s where Soviet mathematics education was investigated and “sinocised” through translating and adapting Soviet textbooks (Ye, 2018), subsequent explorations of other systems appear much more diverse and critical. At a national forum convened by the Ministry of Education of the P.R.C. in 1959, investigations of Eastern European curriculum reforms were initiated; in the 1960s comparisons included the German Democratic Republic, the Soviet Union as well as the United States and Japan. In the late 1970s and the 1980s, the People’s Education Press investigated textbooks from Germany (along with some from England, France, Japan and the United States) in order to look at the structuring of mathematical knowledge and arrangement of topics (Xu, 2013). Some dimensions of the recent Chinese curriculum reform were originally initiated by investigations of trends in mathematics education in a range of countries, including Germany, Hong Kong, the United States and Taiwan in the 2000s (Lv & Cao, 2018; Ye, 2018).

In the context of incipient reforms in the 1950s, classroom pedagogy in some regions in northern China was found to draw on a five-step formal sequencing model for instruction (preparing; prompting; making comparisons; summarizing; applying) developed by the German philosopher Friedrich Herbart (who held Emmanuel Kant’s chair in Königsberg) and his followers; the model was imported during the New Culture Movement. According to Ruan and Zheng (2012) this sequencing of instruction is still seen in many classrooms in China at the beginning of the 21st century.

Over the last decade the Chinese mathematics curriculum has been subjected to continuous reforms. Some shift in focus is according to Zhang (2018, p. 480) motivated by the needs created in an era of “knowledge-based economies and information-based societies, the fierce international competition and challenges”, which require a capability for “knowledge innovation and scientific innovation, to

be able to collect, sort and express information using mathematical methods, establish models, solve problems, and create value for society.” The resulting revised compulsory mathematics curriculum standards (issued in 2011; implemented in autumn 2012) stress the importance of mathematical thinking and problem solving, including problems in real-world settings, in addition to the traditional emphasis on developing basic mathematical knowledge and skills (Wang et al., 2018). Further, aspects of what often is associated with allegedly ‘Western’ pedagogies, including ‘student-centered’ activities such as experimenting and conjecturing, argumentation and discussion have found their way into official Chinese recommendations for curriculum implementation (Li & Li, 2018). The changes in China also entailed a de-centralizing of educational administration and textbook production in order to allow for more diversity (Cai & Nie, 2007). In comparison to the previous policy for controlling curriculum implementation via textbooks, this entails a shift towards proposing the use of a range of resources, only harmonized by the national standards, which consequently (compared with the old syllabus) expanded in scope and depth (Xu, 2013; Wang et al., 2018).

In Germany, the unexpectedly low national performance in the OECD’s PISA as well in the IEA’s TIMSS-tests at the turn of the millennium stimulated a major debate on the quality of schooling and resulted in a new focus in educational policy. The Federal Ministry of Education and Research (BMBF) *inter alia* justified the need for developing outcome-oriented national educational standards by comparisons with some more successful education systems in the PISA-ranking. As a matter of fact, the selected comparator countries not only had adopted national curriculum standards, but also engaged in regular external evaluations of student achievement-outcomes. As Ertl (2006) points out, this new attempt of curriculum alignment across the Länder of the Federal Republic of Germany was conceptually different from earlier approaches of the Standing Conference of the Ministers of Education and Cultural Affairs (KMK) to reaching agreement on shared national standards since the late 1990s. The initiative not only aimed at modernizing and homogenizing local curricula, but also at alignment of educational aims and assessment. According to an expertise commissioned by the BMBF, the new national curriculum should describe competencies at a level of detail that not only affords conversion into learning tasks for students but in principle also into test items so that it becomes “possible to check whether the desired competencies have actually been acquired.” And further, “This will determine the extent to which the education system has fulfilled its mandate (educational monitoring), and schools will receive feedback on the results of their work (school evaluation)” (Klieme et al., 2003, p. 10, transl. EJ). At the same time the expertise recommended that standards should determine competency outcomes (instead of listing topics to be covered) and so leave sufficient freedom for schools and teachers for micro-curricular planning.

The resulting national curriculum document bears some similarities with the US National Council of Teachers of Mathematics (NCTM, 2000) standards in its descriptions of general (topic- and context-independent) processes and the structuring of mathematical topics in broader areas. All Länder have agreed to use the national standards as a basis for developing new local curricula as well as in teacher education. In parallel they also founded institutes responsible for the control and the improvement of the quality of schooling. These institutes not only employ assessment for educational monitoring and school evaluation, but also aim at developing teachers’ professional practices by exemplary operationalization of the curriculum standards in the form of assessment tasks (Blum et al., 2006).

The above sketch of diverse reform movements, in the context of which the Chinese and German mathematics curriculum documents have been produced, suggests that the texts under scrutiny represent hybrids of a range of pedagogic discourses from antecedent national curricula and other educational policy texts, international curricula as well as national recontextualisations of policy texts produced by supra-national institutions. The stated curriculum objectives in both systems reflect international mathematics education discourses that frame the outcomes as not only relevant for developing disciplinary knowledge, but stress applications ('mathematical literacy', 'practical mathematics', 'numeracy') (Jablonka, 2015). Consequently, these curricula can be expected to share some objectives and so have sufficient in common to make an investigation of their differences meaningful. Further, while in both systems there are centralized education regulations, there are differences in modes of governance that shape the decisions of actors (schools, teachers, textbook writers etc.). The production of textbooks in the two systems certainly recontextualises official pedagogic discourse in different spheres, with more or less intersections with the economic field.

### **Goals and methodology**

In addition to other curriculum control instruments, such as officially sanctioned textbooks, external assessments, school inspections and other measures of evaluation, an investigation of curriculum documents provides a starting point for investigating how much interpretive action is granted to teachers. Depending on the level of detail in prescriptions of curriculum standards, teachers might perceive greater or lesser freedom to decide upon what content to bring into focus and how to adapt their instructional strategies in line with their school ethos, their professional identities, and personal values. In turn, such curriculum adaptations might either mitigate or (unintentionally) reinforce unequal access to mathematical knowledge: on the one hand, access to the generative principles and styles of mathematical reasoning that underpin disciplinary knowledge, and on the other, to more skill-based forms (e.g., Dowling, 1998; Jablonka & Gellert, 2012). This concern has been raised in the context of curriculum reforms in both systems: in China particularly with respect to increasing social inequality (Cai & Nie, 2011); in Germany with a focus on the challenges for teachers in finding ways to address the needs of heterogeneous groups of students (Siller & Roth, 2016).

Based on the general research interest stated above, this preliminary comparison explores at which level of detail the prescriptions operate and which forms of mathematical knowledge and skills they privilege. It is part of a larger upcoming project that investigates how curriculum objectives are interpreted by actors at different levels of governance in systems with differing policies for controlling curriculum implementation. The larger project will investigate the articulation of curriculum objectives at three levels, which are commonly conceptualized as macro-, meso- and micro-levels, and will include case studies of classroom practice. While conceptualising the relation between these levels as "recontextualisation" of pedagogic discourses (Bernstein, 1996), in the project this is not interpreted as constituting a hierarchical relation.

The focus of the comparison are the state mandated curricula for mathematics education for years 1 to 6. For Germany, the recently issued common mathematics curriculum standards for Berlin and Brandenburg (Senatsverwaltung für [...], 2015; henceforth the "G-BBM") has been chosen as an example. The document has been developed in order to align the local with the statewide standards.

In the two Länder primary school comprises 6 grades (instead of the usual four). The Chinese national curriculum standards for compulsory mathematics education (Ministry of Education P. R. C., 2012; henceforth the “C-NCM”) are grouped into three stages, grades 1-3, grades 4-6, and grades 7-9. Only the first two stages are of interest for the comparison. The G-BBM is for grades 1-10. It is structured in levels A-H within topics. For years 1-6, “as a rule” the levels A-D are to be reached and so these have been chosen for the comparison. One shared feature of the two documents is the coherent structuring of the mathematical topics beyond grade six, which affords useful comparison.

The most obvious challenge of this comparison is language. The Chinese document was subjected to a machine translation into English as well as into German. In some instances, these versions complemented each other and lead to improvements. The draft was further edited with the aid of an online German-Chinese dictionary. In many cases only knowledge of school mathematics helped to edit the translation. In addition, a semi-official English translation of an early trial-version has been consulted along with translations of key concepts in publications authored by insiders. Still, there remained quite some nonsensical portions of text.

Both the C-NCM and the G-BBM contain sections with mathematical topics (entitled “Content Standards” and “Topics and Content”, respectively). These sections contain short statements with some thematic coherence under one or two levels of headings and subheadings with names for school mathematical areas and specific topics. In the texts, these statements are clearly separated by lay-out (paragraph spacing, arrangement in table cells, numbering). For the analysis, each visually separated portion of text has been counted as one statement. While simply counting statements admittedly does not provide deep insights about the authority relations established by the state-author with the teacher-reader, this simple comparison of content standards might reveal differences to be explored further.

A difference that emerged when reading the content statements concerns the “discursive saturation” of the suggested student activity; the notion here is used in the sense of Dowling (2009). While interpreting the translated curriculum statements has been aided by an explanation of “action verbs” used in the curriculum document found in the Appendix of the C-NCM, an in-depth analysis of envisaged student learning activities clearly is not possible with the machine translation. However, Bernstein’s (1996) notion of “classification” can be applied to the structuring of the content in the documents, as his notion does not differentiate between forms of expression and content.

## Outcomes

The C-NCM has four main sections: “Section I: Preamble”; “Section II: Curriculum Objectives”; “Section III: Content Standards”; “Section IV: Recommendations” (including suggested pedagogic strategies, evaluation recommendations, guidance on textbook development, development and usage of resources). If from Section III only the text for grades 1-6 is taken (which is relevant here), the proportions of the sections (pages of the English version) are very roughly as follows: One fifth for sections I and II together; one fifth for section III; three fifths for section IV. Obviously, the section that describes content standards is comparatively short.

The German G-BBM has three main sections: “1. Development of Competencies in Mathematics”, “2. Competencies and Standards”, “3. Topics and contents”. If from Section 3 only the text for levels A-D is taken, the proportions of the sections (pages) are very roughly as follows: Five eighths for

sections 1 and 2 together; three eights for section 3. Obviously, the section that describes “topics and content” is also comparatively short, but fills a larger proportion of the document than in the C-NCM.

Table 1 depicts the number of statements for each stage by topics and subtopics in “Section III: Content Standards” of the C-NCM. The abbreviations are explained under the table. Topics and subtopics are enlisted in rows and columns in the order of appearance in the text. “Practical and integrated applications” (in some publications the English term is “Practice and Synthesis Application”), aims at providing opportunities for cross-disciplinary work as well as for inner-disciplinary connections, and so guide “students to focus on practice and application” and “making the abstract mathematical concepts deeply rooted in children’s real lives” (Wang et al., 2018 p. 67). The standards for statistics and probability obviously are less detailed than for the other topics.

	First Stage (Grades 1-3)				Second Stage (Grades 4-6)					Sum
Numbers and Algebra	NA <sub>1</sub>	NA <sub>2</sub>	NA <sub>3</sub>	NA <sub>4</sub>	NA <sub>1</sub>	NA <sub>2</sub>	NA <sub>5</sub>	NA <sub>6</sub>	NA <sub>4</sub>	
	7	8	5	1	9	10	4	4	1	49
Graphics and Geometry	GG <sub>1</sub>	GG <sub>2</sub>	GG <sub>3</sub>	GG <sub>4</sub>	GG <sub>1</sub>	GG <sub>2</sub>	GG <sub>3</sub>	GG <sub>4</sub>		
	7	6	3	2	9	8	4	4		43
Statistics and Probability	no sub-division				SP <sub>1</sub>	SP <sub>2</sub>				
	3				6	2				11
Practical and Integrated Applications	no sub-division				no sub-division					
	3				4					7
Sum Total										110

**Table 1: Number of statements in “Section II: Content” (First Stage and Second Stage) of the C-NCM.**

Abbreviations used for subtopics in Table 1 are as follow: NA<sub>1</sub> *Knowing Numbers*; NA<sub>2</sub> *Number Operations*; NA<sub>3</sub> *Common Quantities*; NA<sub>4</sub> *Exploring Patterns*; NA<sub>5</sub> *Expressions and Equations*; NA<sub>6</sub> *Direct and Inverse Proportion*; GG<sub>1</sub> *Knowing Figures*; GG<sub>2</sub> *Measurement*; GG<sub>3</sub> *Figures and their Transformation*; GG<sub>4</sub> *Figures and their Positions*; SP<sub>1</sub> *Simple Statistical Data Processing*; SP<sub>2</sub> *Random Phenomena*.

Table 2 (next page) depicts the number of statements for the levels A-D by topics and subtopics in the section “3. Topics and contents” of the G-BBM.

A comparison of the two tables suggests that the German content standards (Berlin-Brandenburg) provide more detailed descriptions than the Chinese. There are three levels in structuring the content in G-BBM, while in the C-NCM there are only two. As to the content, the school mathematical area *Quantities and Measuring* of the G-BBM, a topic that only appears in the German document, is in the C-NCM integrated into *Numbers and Algebra* in the subtopic *Common Quantities* (NA<sub>3</sub>), and into *Graphics and Geometry* in the subtopic *Measurement* (GG<sub>2</sub>). Here the classification of the C-NCM is stronger as it reflects classificatory principles of academic mathematics. The other extra topic in the G-BBM, namely *Equations and Functions*, is in the C-NCM largely contained in the topic *Numbers and Algebra*. The German G-BBM does not include an extra cross-topic field (such as *Practical and Integrated Applications* in the C-NCM), but outlines six mathematical “process

standards” (generic skills or key competencies), which are described in the section “1. Development of Competencies in Mathematics” and “2. Competencies and Standards”.

	Level B (End of grade 2)					Level C (End of grade 4)					Level D (End of grade 6)					Sum

Abbreviations used for subtopics in Table 2 are as follow: **Na** *Conceptions of Number*: **Na<sub>1</sub>** Perceiving and representing numbers; **Na<sub>2</sub>** Ordering numbers; **Na<sub>3</sub>** Describing number relationships; **Nb** *Conceptions of Operations and Calculation Strategies*: **Nb<sub>1</sub>** Developing conceptions of operations; **Nb<sub>2</sub>** Using calculation procedures and strategies; **Qa** *Conceptions of Quantities and Measuring*: **Qa<sub>1</sub>** Utilizing conceptions of quantities and their units; **Qa<sub>2</sub>** Determining expressions for quantities; **Qb** *Calculating with Quantities*: **Qb<sub>1</sub>** Calculating quantities in contexts; **Sa** *Geometrical Objects*: **Sa<sub>1</sub>** Describing geometrical objects; **Sa<sub>2</sub>** Describing relationships between geometrical objects; **Sa<sub>3</sub>** Representing geometrical objects; **Sb** *Geometrical Transformations*: **Sb<sub>1</sub>** Utilizing geometrical transformations and their properties; **Sb<sub>2</sub>** Carrying out geometrical transformations; **Ea** *Terms and Equations*: **Ea<sub>1</sub>** Representing terms and equations; **Ea<sub>2</sub>** Solving equations; **Eb** *Mappings and Functions*: **Eb<sub>1</sub>** Exploring mappings and functions; **Eb<sub>2</sub>** Representing mappings and functions; **Eb<sub>3</sub>** Utilizing properties of functional relationships; **Da** *Data*: **Da<sub>1</sub>** Collecting data; **Da<sub>2</sub>** Representing data; **Da<sub>3</sub>** Evaluating statistical investigations; **Db** *Counting strategies and probabilities*: **Db<sub>1</sub>** Using counting strategies; **Db<sub>2</sub>** Determining probabilities of events.

## Concluding comments

Contrary to what might have been expected, the German content standards (Berlin-Brandenburg) describe learning outcomes at a much higher level of detail than the Chinese. This conflicts with the

official policy discourse which preceded their development. According to Klieme et al. (2003), the new standards should describe broader competency outcomes. The similarities in the main structuring of the topics in both documents suggests some cross-system harmonization of objectives in the 2000s (see Lv & Cao, 2018; Ye, 2018). The Chinese content standards, however, appears to leave more discretionary space to teachers and schools for making micro-curricular decisions. In both contexts, the role of accountability measures vis-à-vis the standardization of the curriculum needs to be investigated. Regarding the naming of the topics and sub-topics, the Chinese appears to be more specialized, but complemented by the topic *Practical and Integrated Applications*. If Bernstein's (1996) concept of "classification" is applied here, this interpretation suggests an intended move towards weakening (internal and external) classification by establishing more relations with other school subjects as well as with everyday practice. This might be one of the reasons for the opposition against the reform from mathematicians reported by Yin (2013).

One conspicuity that emerged in the course of the investigation concerns the use of verbs that refer to students' competencies in terms of "experiencing", "developing a feeling for" or "grasping". Examples of such statements are, "[Students are] able to feel the meaning of large numbers when associated with realistic material, as well as to make estimations." (First Stage, "Numbers and Algebra: Knowing Numbers"), "Experience that amongst all lines connecting two points the segment is the shortest." (Second Stage, "Graphics and Geometry: Knowing Figures"). The German document does not contain similar statements. A consistent investigation of this observation has been hampered by the low-quality machine translation. However, it can be taken as an indication for a greater focus on non-discursive dimensions of mathematical practice. A systematic investigation of differences in curriculum statements with regard to privileged forms of knowledge and skills will have to include an analysis of stated overall objectives as well as pedagogic recommendations or examples of student activities that are given to exemplify the envisaged classroom practice. An important follow up question then is whether the documents aim at providing insights into the principles on the basis of which the curriculum has been developed.

# Reform on a shaky ground? A comparison of algebra tasks from TIMSS and Swedish textbooks

Kristina Palm Kaplan

Uppsala University, Department of Education, Sweden; [Kristina.Palm.Kaplan@edu.uu.se](mailto:Kristina.Palm.Kaplan@edu.uu.se)

*Keywords: Algebra, curriculum reform, large-scale assessment, textbooks.*

*URL: <http://dx.doi.org/10.13140/RG.2.2.30727.65448>*

## Background

In the Swedish curriculum reform of 2011, TIMSS and PISA were explicitly mentioned as a point of departure (Skolverket, 2011). More precisely, algebra was singled out as a topic where students needed to improve their knowledge. Given the large influence of international large-scale assessments, ILSAs, the items of these tests should be further investigated (Säljö & Radišić, 2018).

Comparative studies using data from ILSAs have concentrated on their results, not their tasks (Jablonka, Andrews, Clarke, & Xenofontos, 2018). Moreover, while textbook tasks are common in comparative studies, these often focus on how the learning of a specific topic is presented in textbooks from different countries (Jablonka et al., 2018). They are not considered in relation to curriculum reforms.

The aim of this study is to problematize the role of ILSAs in national curriculum reforms. It builds on results from a previous study of textbook tasks by Palm Kaplan and Prytz (submitted) and is a part of a thesis project which problematizes the role of ILSAs and textbooks in curricular reform, by looking at the algebra in TIMSS 2003–2015 and algebra chapters in Swedish textbooks. This study focuses the case of Swedish school algebra and the 2011 curriculum reform through looking at algebra items from TIMSS 2003, compared to changes in year 8 algebra tasks in three Swedish textbook series. The research question is

- To what extent is the algebra in TIMSS consistent or in conflict with algebra chapters in Swedish textbooks?

## Theory and method

The algebra items in TIMSS 2003 are studied to understand what the student is expected to engage with, when solving the items. To get a detailed picture of the items, discourse analysis is combined with an analysis of the algebra offered. These two aspects are discussed in terms of *school algebra discourses* and *algebraic activities* respectively. The school algebra discourses are constructions in linguistic resources (Luke, 1995), steering what choices are possible to express different ideas while the algebraic activities mainly builds on Blanton et al.'s (Blanton et al., 2015) 'big ideas' in algebra. One of these is *functional thinking*, which is the activity to investigate, represent and generalize relationships between co-varying entities (Blanton et al., 2015), e. g. number patterns. The analytic frameworks are further developed on the poster and in Palm Kaplan and Prytz (submitted).

The analysis is conducted in several steps. The two aspects mentioned above are analyzed in the items to obtain the distribution of the algebraic activities in the school algebra discourses. The distribution is then compared to the results of the Palm Kaplan and Prytz (submitted) textbook analysis of 1557

algebra tasks from algebra chapters in six Swedish textbooks. These books come from three textbook series which were on the market before and after the 2011 curriculum reform. TIMSS 2003 entail 45 valid algebra items out of 47. Two trend items are left out since in TIMSS 2007, they are coded by TIMSS as data and chance instead of algebra. Items including more than one activity or more than one discourse are also left aside in this study, for reasons concerning statistical analysis in the thesis. All items are used with permission from the Swedish National Agency of Education. They are chosen as a starting point for further analysis, which will also include the algebra items from TIMSS 2007, 2011 and 2015 in order to understand the development of TIMSS' algebra.

## Results

The distributions of the algebraic activities in the school algebra discourses are reasonably corresponding when TIMSS-items are compared to Swedish algebra chapters. However, there are differences between the proportions in the distributions: Swedish algebra chapters concentrate on mainly two algebraic activities while TIMSS 2003 entail other algebraic activities to a larger extent. For example, functional thinking is more stressed in TIMSS. The proportions of the school algebra discourses also differ in the TIMSS-items from the Swedish algebra chapters, and a whole new discourse, the *Relational discourse*, was identified in the TIMSS-items. This discourse constructs algebra as relationships between variables in graphs, tables and symbols; whereas the other discourses, identified in the algebra chapters, do not use graphs as a resource and only occasionally use tables. In Swedish textbooks though, chapters on functions and relations are often saved for year 9, which is the year after the TIMSS-test is taken. Though it is difficult to assess since there are few algebra items in one TIMSS-test compared to in textbooks, these results make one of the points of departure for the Swedish curriculum reform in 2011 questionable.

# Time series analysis: Moving averages as an approach to analysing textbooks

Jöran Petersson<sup>2</sup>, Judy Sayers<sup>1</sup> and Paul Andrews<sup>2</sup>

<sup>1</sup>Leeds University, England; <sup>2</sup>Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden; [joran.petersson@mnd.su.se](mailto:joran.petersson@mnd.su.se)

*In this study we introduce time series analysis, specifically moving averages, as a novel strategy for analysing mathematics textbooks. Such analyses show how different topics or mathematical processes are emphasised over different time periods, whether at the level of the lesson, the week, the month or year. In this paper, by way of example, we show how one of the eight categories of foundational number sense (Andrews & Sayers, 2015), namely simple addition and subtraction, is distributed and sequenced across three English, year one, textbooks. The analyses are compared empirically with four other methods found in the literature to show how time series analysis using moving averages helps address the shortcomings of these different approaches.*

*Keywords: comparative textbook analysis, foundational number sense, moving average, time series.*

## Introduction

For many teachers of mathematics, irrespective of where they work, the textbook they use is not only the major resource for lesson planning and the provision of tasks for students but also the means by which the curriculum within which they work is realised (Stein & Kim, 2009; Tarr, Chaves, Reys & Reys, 2006; Stacey & Vincent, 2009). However, textbook analysis is in some way probabilistic in the sense that teachers make decisions as to how they use any book, leaving the analytical question “what would students learn if their mathematics classes were to cover all the textbook sections in the order given? What would students learn if they had to solve all the exercises in the textbook?” (Mesa, 2004, pp. 255–256). That is, researchers are typically interested in understanding the “likely impact of the text on the users (teachers and students)” (Stacey & Vincent, 2009, p.276). Moreover, in those cultures in which textbooks are unregulated, often leading to a plethora of choice for teachers, students may receive very different opportunities to learn (Charalambous, Delaney, Hsu & Mesa, 2010; Huntley & Terrell, 2014; Tarr et al., 2006).

Much of the world’s textbook-related research has employed some form of qualitative description, typically aligned with an analytical framework related to the topic under scrutiny, supplemented by frequency analyses. That is, researchers often count and compare the number of occurrences of particular forms of task in different textbooks. Such studies usually focus on either mathematical content knowledge or mathematical processes, although there are exceptions such as Borba and Selva’s (2013) study of calculator use in Brazilian primary school textbooks. Research focused on mathematical content knowledge has included, for example, studies of primary school textbooks’ treatment of fractions in Kuwait, Japan, and the USA (Alajmi, 2012), Cyprus, Ireland, and Taiwan (Charalambous et al., 2010), division of fractions in grades six and seven in Chinese, Japanese and US textbooks (Li, Chen & An, 2009), multiplication and division of fractions in grades five and six in the textbooks of the USA and Korea (Son & Senk, 2010), inverse relations in US and Chinese primary textbooks (Ding, 2016), functions in the middle school textbooks of 15 countries (Mesa,

2004); geometry in English and Japanese grade eight textbooks (Jones & Fujita, 2013), number sense in year one textbooks in England and Sweden (Löwenhielm, Marshall, Sayers & Andrews, 2017) the distributive property (Ding & Li, 2010) and so on.

Textbook-related studies on mathematical processes has included, for example, examinations of mathematical problem solving (Brehmer, Ryve & Van Stenbrugge, 2016; Fan & Zhu, 2007), mathematical problem posing (Cai & Jiang, 2017), general perspectives on reasoning and proof in Australia (Stacey & Vincent, 2009) and the USA (Stylianides, 2009), geometry-related proof for students in the grades 6-9 in the USA (Otten, Gilbertson, Males, & Clark, 2014) and France and Japan (Miyakawa, 2017), calculus-related reasoning and proof for upper secondary students in Finland and Sweden (Bergwall & Hemmi, 2017).

Other studies have attempted to identify and demonstrate the different emphases within a textbook by going beyond simple quantification. For example, Tarr et al., (2006), in their analysis of American teachers' use of different types of textbooks, introduced what they called the emphasis index, which was defined as the number of lessons taught by a teacher on a topic divided by the number of lessons in the textbook on the same topic. Interestingly, a similar procedure could be applied uniquely to a textbook, where the emphasis index would be the number of lessons on a particular topic in the book divided by the total number of lessons.

However, while frequency analyses have the potential to offer insight into the topics privileged by a textbook's authors they typically offer little with respect to how mathematical ideas are sequenced. Indeed, even though some scholars have conceded that they "examined only proportions of various types of opportunities and did not attend to the sequencing of activities, which may be important with regard to students' learning" (Otten et al., 2014, p.75), few have examined the distribution of codes within a text. Of those studies that have attempted explicitly to examine the distribution of codes, four methods stand out. Firstly, method 1, researchers have identified, in the sequence of all tasks, the position of the first task of interest (Fujita, 2001). Secondly, method 2, researchers have analysed the proportion of a textbook covered before an occurrence of interest (Alajmi, 2012; Li et al., 2009). Thirdly, method 3, studies, particularly those analysing series of textbooks that cross several grade boundaries, have displayed relative percentages across grades (Borba & Selva, 2013; Ding, 2016). Moreover, Ding displayed results in a line diagram, where the distribution of a code per grade level in one book series could be compared with the distribution of the same code per grade level in another book series. This takes us to our final method and the inspiration for our contribution. Fourthly, method 4, studies have exploited timeline analyses, whereby coded observations were presented as dots on a horizontal axis representing the sequence of all tasks through the textbooks. With such an approach, "large swaths of these textbooks were not coded", allowing the reader to see, at a glance, how topics under scrutiny are both located and emphasised (Huntley & Terrell, 2014, p. 758). One advantage of such diagrams is that they give a picture that is fine-grained down to occurrence of individual codes. However, this is also its draw-back. For larger data sets, the graphic in the time-line diagram might get too jammed making it difficult to discern any useful information in the diagram. In this paper we present a comparison of several of these methods before offering a novel methodological perspective on the analysis of textbooks that goes beyond what others have achieved.

In so doing, we aim to make a meaningful contribution to the methods of comparative textbook analysis.

## **The context of this study**

This paper is a preliminary account of textbook analyses conducted as part of the Foundational Number Sense (FoNS) project, which is an ongoing Swedish Research Council-funded study of how FoNS, a set of eight core number-related competences, is acquired by year one children in England and Sweden. These core competences, which research has shown to be essential for later mathematical success, derived from a constant comparison analysis of literature from mathematics education, psychology, special educational needs and generic education (Andrews & Sayers, 2015). While it is important to understand how textbooks structure opportunities for learning, England and Sweden are of particular interest as both systems, due to perceptions of systemic failure on international tests of achievement like TIMSS and PISA, have begun importing and adapting textbooks used in high-achieving countries. In Sweden, textbooks from Finland and Singapore have been imported, while in England, textbooks from Singapore and Shanghai.

In the study presented here, which is principally a methodological contribution, we examine aspects of three textbooks used with English grade 1 classes, Abacus, Inspire Maths (hereafter, Inspire), and Maths - No Problem (hereafter, MNP). These were chosen because Abacus is a long-standing series written by a well-known primary mathematics education researcher. The other two, drawing on societal perceptions that English mathematics teaching would be improved by the adoption of Singaporean practices, were English-authored adaptations of Singapore textbook series.

## **Comparing different display methods on the same data**

Many educational research analyses yield codes of zeros and ones for the absence or presence of specific phenomena, particularly analyses of the tasks found in textbooks. Thus, depending on whether analysed properties are present in each task, one outcome of this process might be a sequence {0, 0, 1, 0, 1, 1,...} of ones and zeros. The manner in which the results from such analyses are displayed necessarily depends on the research question and could be the presentation of frequencies or the distribution of such codes throughout the data. When comparing textbooks, differences in the frequencies of particular codes can be compared by means of, say,  $\chi^2$  tests. However, when the research goal is to focus on the sequential distribution of codes, the focus of this paper, other methods are needed. In this paper, as a response to this, we offer time series analysis as a novel method for comparing the sequential distribution of particular task properties in textbooks. In so doing, we compare this novel approach with others found in the literature.

In the following, as indicated above, we draw on FoNS-related analyses of three English year one textbook series, in which every task that explicitly expected a student response was coded for its FoNS-related opportunities. Thus, every task could be represented as set of eight ones and zeros ranging from (0, 0, 0, 0, 0, 0, 0, 0), in which no FoNS-related codes were identified, to (1, 1, 1, 1, 1, 1, 1, 1), in which all FoNS codes were identified (Löwenhielm et al., 2017). However, with the objective of comparing methodologies, space prevents an analysis of all eight FoNS categories, so we restrict this presentation to just one, in order to exemplify the advantages and disadvantages of different analytical approaches. Thus, the following focuses solely on FoNS category seven, simple

addition and subtraction within the number range 0 – 20 due, in part, to the significance of such competence in later mathematical learning.

The figures of table 1 show the results of the two methods employed by Fujita (2001) and Alajmi (2012) respectively. The first, based on the position of the first occurrence of the code in question (Fujita, 2001), shows substantial differences in the number of tasks completed before simple arithmetical operations are introduced. However, due to differences in the total number of tasks in each series, it is not necessarily straightforward, without additional calculation, to discern whether the positions of the first occurrence are comparable across the three books. In this respect, the second method, based on the percentage of all tasks presented before the first occurrence (Alajmi, 2012), gives a better indication of how deep into the book the first occurrence of each code occurs and, of course, their relative positions. Thus, it can be seen that the introduction of simple arithmetic in the two textbooks based on the Singaporean tradition, Inspire and MNP, occurs not only substantially later than in the English textbook, Abacus, but also in different positions relative to each other.

Book	FoNS category	Position of first occurrence	Percentage of tasks before first occurrence
Abacus	7	22nd of 1522	1%
Inspire	7	168th of 907	18%
MNP	7	175th of 1955	9%

**Table 1. Method 1 (1st occurrence) and method 2 (% tasks before first occurrence)**

The third method, represented in Table 2, shows the relative percentages across the various workbooks in each series (Borba & Selva, 2013). Here, each series is partitioned into a different number of booklets; Abacus is in three booklets, Inspire in four and MNP in two. What is clear, interestingly, is the variation in the distribution of tasks focused on code 7, simple addition or subtraction, across the three sets of workbooks; Abacus incorporates substantial proportions of such material across all three booklets, while both Inspire and MNP incorporate such tasks only in the first half of their respective series. Of course, presenting the same data as line diagrams in the manner of Ding (2016) may have offered a clearer picture, but little by way of additional insight into the actual sequencing of the tasks.

The fourth method, Figure 1, shows a timeline with the position of each task coded for simple addition or subtraction, code 7, shown as a dot (Huntley & Terrell, 2014). As with method 3, this highlights well differences between Abacus and the two Singapore-based books, Inspire and MNP. The former shows simple arithmetic tasks distributed throughout the workbooks, while the latter confirms that such tasks only occur within the first half of the series. They also show a not dissimilar pattern within the two Singapore-based books, with periods of extended opportunity, followed by a gap with occasional revisitations before a second extended opportunity. That being said, such graphs offer

insight only into the sequencing of activities within a textbook and not necessarily an indication how children's day-to-day learning may be structured.

Abacus (3 booklets)	Inspire (4 booklets)	MNP (2 booklets)
56%	55%	40%
24%	35%	0%
35%	0%	
	0%	

**Table 2. Method 3 (% occurrences per booklet) for code 7**

**Figure 1. Method 4 (timeline dot plot) for code 7**

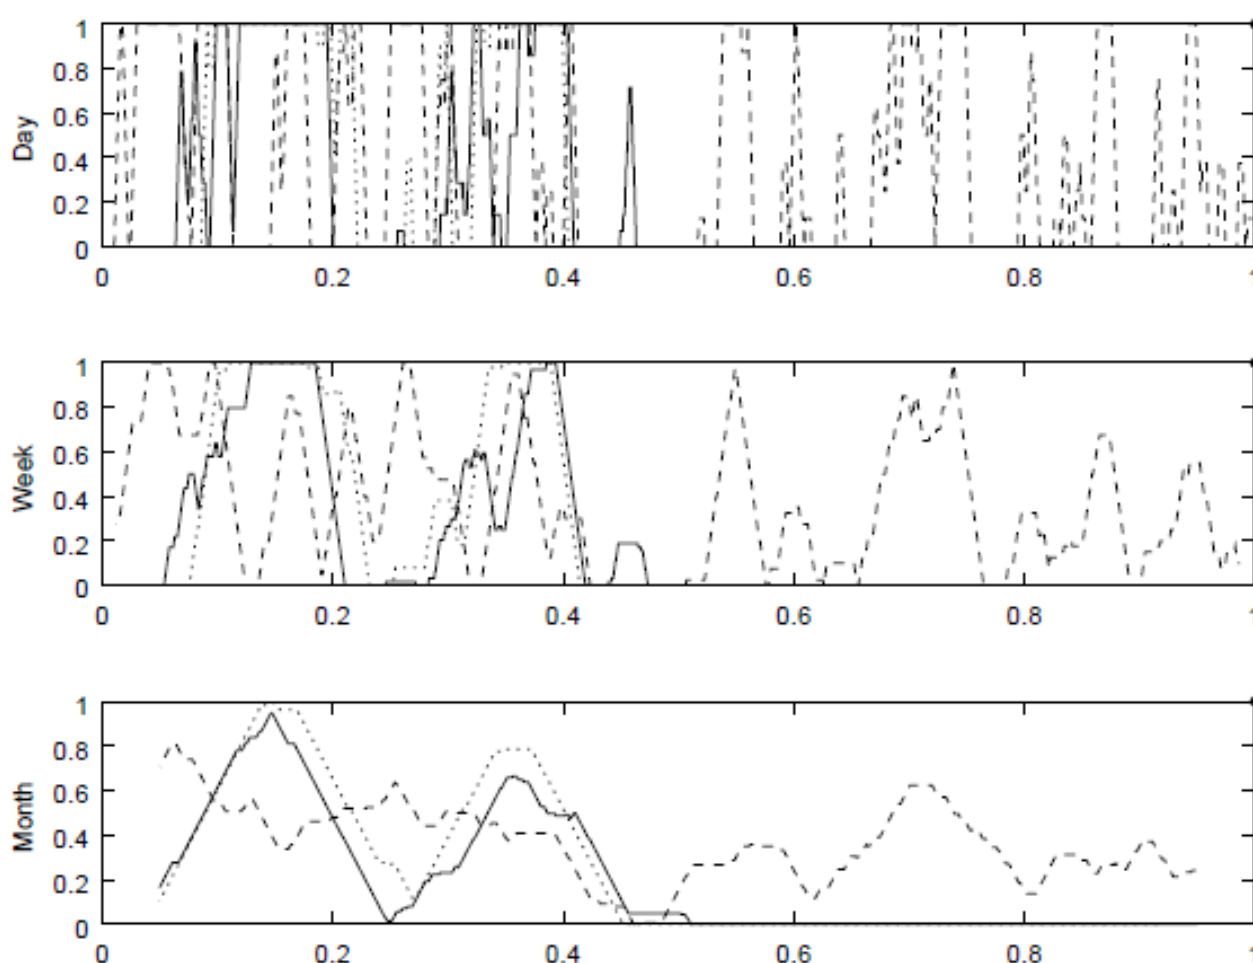

### Moving averages

The fifth method, which is our contribution to the debate, involves moving averages as an approach to time series analysis in which data are logged at equally spaced points in time. Typically, these are undertaken to “understand the underlying dynamics, forecast future events, and control future events via intervention” of stochastic processes (Fan & Yao, 2003, p. 9). Now, while a school mathematics textbook is not stochastic, the use of time series, whereby data are successive tasks, should offer a clear indication of a textbook's sequential emphases over time. However, the graphs yielded by time series analyses are typically extremely noisy, as with daily records of air temperature (Wakaura & Ogata, 2007), a problem that can be overcome by means of moving averages. Here, rather than report single data points, moving averages are based on a sequence of overlapping sets of data or moving windows. This process smoothes out short-term fluctuations in time series so that longer-term patterns become more visible and the influence of outliers is eliminated. Mathematically, a moving average means substituting a single data point  $(t_k, y_k)$  with  $(t_k, \hat{y}_k)$ , where  $\hat{y}_k$  is the arithmetic mean of its neighbouring data points  $y_j$  as in equation 1.

$$\text{(Equation 1)} \quad \hat{y}_k = \sum_{j=k-n}^{k+n} \frac{1}{2n+1} y_j$$

Of interest here, is the size of the divisor,  $2n + 1$ , which represents the total number of data points included in the calculation and is dependent on the time period chosen for the calculation. That is,  $2n + 1$  refers to the original point,  $y_k$ , and its  $2n$  neighbouring data points,  $n$  before and  $n$  after. In the context of a mathematics textbook, the width  $2n + 1$  of this window could be the number of tasks

that an average student is expected to cover each day, or each week or each month and this choice depends on the research question. Thus, one choice of the width of the moving average window could be  $\frac{\text{all items in a book series for one year}}{40 \text{ school weeks}}$ , roughly corresponding to a single week's workload across the year. This means that wherever the moving average diagram shows 'above zero', then the pupil would have met that coded property during that week. Figure 2 shows the results, for code 7, simple addition or subtraction, for different time periods. The vertical axis refers to the average code score, taking values from 0 to 1, for any given time interval, and the horizontal axis the year for which the textbook is intended for use. The solid line refers to MNP, the dotted line to Inspire and the dashed line to Abacus.

**Figure 2. Method 5 (moving average) for code 7**

As can be seen, analysing the daily opportunities for code 7 produces a noisy diagram that is difficult to interpret, particularly with the three textbooks are presented together. However, as seen in the weekly graphs, a longer time period begins to smooth out much of this short-term variation and expose patterns of emphasis. Therefore, in such analyses it is important to select a window that is sensitive to the context of the data source in to obtain a graph that shows neither too little nor too much of the data's details. In the context of this study, the monthly graph is probably the most illuminating. The two Singapore books are virtually indistinguishable but Abacus, shows continued exposure, albeit at different levels of intensity, to tasks focused on simple addition and subtraction,

opportunities, we know from several of the analyses above, missing in the second half of the two Singapore-inspired series.

In conclusion, we believe that graphs presenting moving averages offer a novel but methodologically important tool in the analysis of textbooks. In fact, it can be argued that it represents a generalisation of the four methods compared above, albeit dependent on the choice of time interval. For example, where the moving average curve in figure 2 rises above zero, it shows where the first occurrence of a code occurs, which is the information provided by methods 1 and 2 in table 1. Moreover, it shows where in a series of books a code occurs, as yielded by method 3 in table 2, corresponding to a non-overlapping (disjoint) average, while moving averages do overlap. Finally, moving averages offer a direct generalisation of strategy 4, since a moving average with a window of length one would reproduce the diagram in Figure 1.

*This paper relates to the mathematics curriculum systems of the United States, Finland, Sweden, and Flanders (Belgium). These four regions are in the midst of curriculum reform, which provides interesting grounds for cross-cultural comparison. Our analysis builds on a framework that focuses on curriculum policy, design and enactment in each of these regions and draws on interview data with teachers in all four regions, sample cases of curriculum use, context descriptions, and available descriptions of mathematics education in these four regions. This leads to a more nuanced understanding of the particular curriculum systems through which reform manifests, and sheds light on a challenging balance concerning a curriculum reform that is both coherent across a region and supported by teachers.*

*Keywords: Cross-cultural study, Curriculum reform, Mathematics education*

## Mathematics curriculum reform: a delicate process

Curriculum reform is a delicate process because multiple factors influence implementation, and, ultimately, student performance. If a curriculum is to promote region-wide reform, it should be coherent across that region. Further, there is evidence that the teacher has a crucial role, in that teachers should embrace the underlying vision (e.g., Tarr et al., 2008). Also crucial for educational change is to understand the educational system to which the reform applies (Andrews, 2007; Miyakawa & Winsløw, 2017; Stigler & Hiebert, 1999). This paper aims to add to a better understanding of the mathematics curriculum systems in the U.S., Finland, Sweden, and Flanders (Belgium). All four regions have recently undergone mathematics reform, or are in the midst of reform, which makes them interesting sites for comparison of curriculum systems. The paper's central goal is to describe the curriculum systems of these four regions, and to consider consequences for teacher involvement in, and region-wide coherence of the region.

## Curriculum policy, design, and enactment framework

Because we understand teachers' use of resources to be situated in a broader school system, we draw on the curriculum enactment process as conceptualized in Remillard and Heck (2014) (See Figure 1). Remillard and Heck differentiate between an official and operational curriculum. The official curriculum, authorized by governing agencies includes curricular aims and objectives; assessments; and the designated curriculum – a set of instructional plans specified by a governing agency. The operational curriculum captures the enactment process. It acknowledges the central role that teachers have in interpreting and mobilizing curriculum resources and differentiates between a teacher-intended and enacted curriculum and student outcomes. The location of instructional resources outside of the official and operational curriculum allows to fit both (centralized) systems in which the instructional resources are part of the official curriculum, and other systems in which they are not.

The framework assumes a definition of curriculum, which we also subscribe to: “a plan for the experiences that learners will encounter, as well as the actual experiences they do encounter, that are designed to help them reach specified mathematics objectives” (Remillard & Heck, 2014, p. 707). We use the term instructional resources to refer to the resources used to support curriculum enactment. These resources include curriculum resources that sequence a particular content such as student textbooks and teacher's guides, but also other resources such as digital (online) applications.

**Figure 1. Visual model of the curriculum policy, design, and enactment system (Source: Remillard & Heck, 2014, p. 709)**

## Context and method of study

This study is part of a larger cross-cultural study on elementary school teachers' use of printed and digital instructional resources in the U.S., Finland, Sweden, and Flanders (the northern part of Belgium, which has its own educational system). Although largely an opportunity sample, the selection of these four regions addresses both constants and contexts (Osborn, 2004) comprising a sound rationale for comparison. Talking to the constants, all four regions value local educational authority, emphasize similar aspects as to the mathematical curriculum, and teachers rely on (printed) curriculum resources when teaching mathematics. Our previous analyses of printed curriculum

resources also shed light on differences in provided teacher support, surfacing context-specific assumptions of teaching and learning mathematics (e.g., Remillard, Van Steenbrugge, & Bergqvist, 2016).

When designing and analyzing interviews on resource use in the four regions, we were faced with challenges of equivalence, validity, and comparability (Clarke, 2013; Osborn, 2004), and with challenges related to the undertake of such a study in a cross-cultural team of researchers. To develop the team's prerequisite intersubjectivity (Andrews, 2007) needed to fully understand the completed interviews as situated in their specific context, we developed case descriptions illustrating curriculum use for one teacher per context, and context descriptions. This paper draws primarily on these four case and context descriptions, but also on interview data specifically relating to the selection of instructional resources and additional readings on mathematics curricula in these four regions (i.e., Hemmi, Krzywacki, & Partanen, 2017; Remillard & Reinke, 2017; Van Steenbrugge & Ryve, 2018; Verschaffel, 2004).

Ten teachers in Finland, the U.S., Flanders, and Sweden were interviewed in fall 2017 and again in spring 2018 on their use of resources when planning and teaching mathematics (Note: In Sweden and the U.S., one teacher was unavailable for the second interview; in Finland, nine instead of ten teachers have been interviewed so far). The first interview was more general and addressed teacher and school backgrounds, what resources teachers used, teachers' views on the curriculum resources being used, and teachers' general beliefs on teaching and learning mathematics. The second interview focused in more detail on teachers' actual use of both print and digital resources, centered around a walk-through of planning, decisions, and enactment of a lesson that the teacher taught recently. Input for Interview 1 initially came from team members' previous related research on curriculum use and was modified during subsequent team meetings. Interview 2 was also developed collaboratively, based on findings and experiences from Interview 1 and our knowledge of each of the contexts.

Each case description was prepared by a team member who is a cultural insider, written in English for shared use. We first applied low-inference codes to the interviews to index excerpts of the interviews. These codes identified, for instance, teachers' descriptions of resources, how they were used, reasons for use, background information on the teacher and school, and teacher beliefs on curriculum use and teaching and learning mathematics. The process of coding was tried out individually, discussed in, and refined by the team. Having coded two interviews for one teacher per region, we gathered similarly-coded statements and applied the following structure to the cases: a) teacher education and teaching background, b) information about school and class, c) selection process of the resources, d) use of resources and purposes for use, e) teacher beliefs and conceptions, f) changes in resource use.

The process of writing and reading cases made us aware that significant insider knowledge was necessary to make sense of them, which is why we also developed context descriptions. Context descriptions are organized according to the following structure: a) school system-structure, b) pathways into teaching elementary mathematics, c) school environment, d) financial resources for organizing education, e) decision-making mechanisms in schools in relation to mathematics education (including the selection of instructional resources), f) student assessment, and g) monitoring and quality assurance of education.

An important step in the process of developing the cases and context descriptions was full-team review and discussion of them. In fact, we arrived at a common structure and approach through incremental development, review, and discussion.

Building on the curriculum policy, design, and enactment framework (Remillard & Heck, 2014), we came to the following analytical structure to compare the four educational systems, based on case and context descriptions, interview data, and the abovementioned additional readings:

- Educational jurisdiction and school funding;
- Most recent central mathematics curriculum, including name and launching date, initiators, structure, novel aspects, requirement of adoption;
- Role of assessments;
- Curriculum specification in addition to central curricular aims and objectives;
- Instructional resources and influential factors, including resource market, designers of curriculum resources, embedment of a digital platform, selection of resources, acceptance criteria.

## Curriculum systems in the U.S., Finland, Sweden, and Flanders

Table 1 includes our descriptions of the curriculum systems of the U.S., Finland, Sweden, and Flanders. Looking across the table helps to attain a more nuanced understanding of these curriculum systems, which, from the outset share similarities such as local authority, use of a primary (usually printed) curriculum resource available from a commercial publishing market, and the raise of digital resources. Surfaced similarities and differences relate to a) regulations and incentives to steer local authority, b) role of curriculum resources in curriculum reform, and c) curriculum interpretation. We discuss these aspects below and relate them in a final section to two crucial aspects of curriculum reform: coherence and embracement of the reform by teachers.

	U.S.	Finland	Sweden	Flanders
<b>Educational jurisdiction and school funding</b>				
<b>Jurisdiction</b>	School districts with oversight from states	Finnish government	Swedish government	Flemish government
<b>School funding</b>	State and local taxes	National and local funding	Government to municipalities to schools	Government; also targeted funding
<b>Most recent central mathematics curriculum</b>				
<b>Name &amp; launching date</b>	Common Core State Standards (CCSS), 2010	National Core Curriculum (NCC), 2016	Läroplan (LGR 11), 2011 – revised 2018	Attainment targets; 1998/under development
<b>Initiative</b>	State governors & educational leaders, private foundations	Finnish National Board of Education commissioned expert group	Swedish government commissioned the National	Flemish government commissioned an entity

		(about every 10 years)	Agency of Education	
<b>Structure</b>	Grade-by-grade content and practice standards	Content, competences, learning environment descriptions, assessment criteria; grades 1-2, 3-6, 7-9	Core content, mathematical abilities, knowledge requirements; grades 1-3, 4-6, 7-9	Required knowledge, skills, attitudes by end of grade 6
<b>Novel aspects</b>	Emphasis on visual models and conceptual understanding	Cross-curricular competences (e.g., digital competence)	Mathematical competences, digital competence	Structured around 16 key competences (e.g., digital competence)
<b>Adoption</b>	Not required; Federal government incentivizes states toward CCSS & assessment adoption	Required, but not checked	A nationwide professional development program was launched (2012-2016) to support adoption; checked by school inspectorate	Required, checked by school inspectorates
<b>Assessments</b>				
<b>Grades &amp; aim</b>	Grades 3-8: annual standardized tests, often consequential for student promotion, teacher employment, school funding	Schools are not monitored by national assessments; Teachers are responsible for assessment	Grades 3, 6, 9: Mandatory national tests support equality & check performance on school and population level	Tests assess mastery of attainment targets on student population level (since 2002 and on a 7-year interval)
<b>Continued curriculum specification</b>				
<b>Level &amp; content</b>	Districts and schools often specify instructional resources to be	National board of education hosts a website that lists available	/	Three umbrella organizations issue learning plans, which break down

	used, and issue pacing guidelines	instructional resources;  School teams and/or local authorities concretize NCC into a central school-level curriculum		attainment targets per grades, add goals and didactical suggestions
<b>Instructional resources and factors that influence resources and use</b>				
<b>Instructional resource market</b>	Commercial enterprise, limited number of publishers	Commercial enterprise, limited number of publishers	Commercial enterprise, limited number of publishers	Commercial enterprise, limited number of publishers
<b>Designers (printed) curriculum resources</b>	Mathematicians, prior teachers, researchers	Teacher educators, researchers, teachers	Teacher educators, teachers (during their free time)	Teacher educators, teachers, members of inspectorates, representatives umbrella organizations
<b>New curriculum resources accompanied by digital platform?</b>	Yes	Yes	Yes	Yes
<b>Selection instructional resources</b>	Main curriculum resources & larger digital platforms: districts & schools;  Digital resources: teachers	Main curriculum resource & digital resources: teachers	Main curriculum resource: schools;  Digital resources: teachers	Main curriculum resource: schools; Digital resources: teachers, schools, school groups, umbrella organizations
<b>Acceptance criteria</b>	By some states/districts	No	No	No

Table 1. The curriculum systems of the U.S., Finland, Sweden, and Flanders

Regulations and incentives to steer local authority are present to different extents. The curriculum systems of the U.S. and Flanders have the most explicit mechanisms to steer local authority. In the U.S., states possess authority in relation to educational policy and, sometimes, delegate policy to school districts, but the Government by means of applying specific funding mechanisms influences policy and curriculum use at state, district, and school level. In Flanders, schools are in principle free to determine how to work toward the attainment targets, but the Government, through regulations such as school inspectorates and the requirement to adopt a learning plan, and through targeted funding, sets the framework of the curriculum system and influences curriculum policy and use at the local school level. In Sweden, the Government also sets the framework of the curriculum system, but influences curriculum use at a more implicit level, through rolling out a nation-wide professional development program following the curriculum reform. From our study, it appears that central regulation is the least well manifested in Finland. The Finnish National Board of Education commissions on regular interval-base an expert group to develop a new curriculum. Schools and teachers are provided with guiding documents and regulations, but are not checked upon application of the guidelines and regulations.

Across the four regions, curriculum resources served as interpreters of the official curriculum, hereby serving as mediators between the intended curriculum and the classroom (Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002). Additionally, and talking to the systems of Finland and Flanders, curriculum resources can also potentially influence curriculum making. In Finland, teachers at times rely on the learning sequence in commercial curriculum resources to design their crucial school-level curriculum. Currently in Flanders, new curriculum resources, often complemented with digital applications, are published before the actual launch of the new attainment targets, hereby possibly influencing the novel aspects of the mathematics reform related to digital competence.

Following the curriculum policy, design, and enactment framework (Remillard & Heck, 2014), we allocate teachers to have a central role in interpreting and mobilizing the curriculum. Indeed, we find related evidence in our interview data. Our comparative analysis also reveals differing levels where significant curriculum interpretation happens to reside. In Sweden, the bulk of interpretation happens at the individual teacher level. In Finland, significant interpretation is applied to compose a school-level curriculum, whereas in Flanders, major interpretation of the attainment targets is located above the school-level, by the umbrella organizations issuing learning plans. In the U.S., significant curriculum interpretation resides in the assessments.

### **Curriculum reform: a delicate balance between region-wide coherence and teacher approval**

Our study of the mathematics curriculum systems of the U.S., Finland, Sweden, and Flanders, suggests that a curriculum reform that is both region-wide and supported by teachers, is a challenging balance. Both Flanders and the U.S., through their layered curriculum infrastructure, succeed most toward a region-wide curriculum coherence, but this goes at the cost of teacher involvement in the reform process. In Finland, teachers are most involved in reform through the design of a school-level curriculum, but this goes at the cost of a nation-wide curriculum-coherence. Sweden stands out in that teachers were asking for reform and that the Government answered the call by means of rolling out a nationwide professional development program. It still has to be seen to what extent that results in curriculum coherence. In all four regions, commercially published curriculum resources are a central aspect in a region-wide curriculum reform. Given this significant position, it is remarkable that only in the U.S., sometimes quality criteria are issued that curriculum resources have to pass.

# The use of *problem* in upper-primary and lower-secondary textbooks of the Republic of Cyprus

Constantinos Xenofontos

University of Stirling, United Kingdom, [constantinos.xenofontos@stir.ac.uk](mailto:constantinos.xenofontos@stir.ac.uk)

*Research suggests that transitions from primary to secondary education typically have negative influences on pupils' mathematical performance, motivation, and self-efficacy. In acknowledgement of these issues, I examine how the term 'problem' is used in the upper-primary and lower-secondary national maths textbooks in the Republic of Cyprus, in an attempt to explore the coherence between the instructional materials pupils are exposed to in the two school levels. More specifically, all tasks explicitly labelled as 'problems' in the two textbook series were identified. For analysing the tasks, an adapted version of Borasi's (1986) framework about the structural characteristics of problems was utilised. Findings conclude that coherence between the two textbook series is limited, as in the primary series the term 'problem' is extensively used in a particular way, while in the secondary series, a significant decline of the number of tasks labelled as problems is observed.*

**Keywords:** Transitions, mathematical problem, textbooks, primary, secondary

## Transitioning from primary to secondary school

Many pupils preparing to transition from primary to secondary school appear to have predetermined ideas about the challenges and difficulties of mathematics at the next school level (Attard, 2010). As a consequence, there is a general decline of pupils' engagement with mathematics as they move from primary to secondary education (Martin, Way, Bobis, & Anderson, 2015), a decline of their self-efficacy beliefs, motivation, and performance (Bouffard, Boileau, & Vezeau, 2001), and the reinforcement of stereotypes regarding gender and mathematics performance (Denner, Laursen, Dickson, & Hartl, 2018). While research evidence suggests that the observed differences could partly be attributed to teachers' self-efficacy beliefs (Midgley, Feldlaufer, & Eccles, 1989), as well as to teachers' and parents' emphases on goal (Friedel, Cortina, Turner, Midgley, 2010) across the two school levels, little is known about the impact of the use of instructional materials by primary and secondary mathematics teachers (Howard, Perry, & Tracey, 1997), and more specifically, how similarly or differently textbooks are used at these two school levels (Fan, Zhu, & Miao, 2013).

Here, I focus on the national textbooks of a highly centralised educational system, that of the Republic of Cyprus. The mathematics curriculum of Cyprus (as with all school subjects) is prescribed centrally by the Ministry of Education and Culture - MoEC (Mullis, Martin, Goh, & Cotter, 2016). In order to bridge the gap between the previous primary and secondary mathematics curriculum, the curriculum in effect, introduced in 2010, is built around the same five general topics, from pre-primary education up to the last year of upper-secondary education (MoEC, 2010). These five topics are numbers, algebra, geometry, measurement, and statistics-probability. Furthermore, this unified mathematics curriculum claims to be built on four principles, with principle 2 stating that the curriculum places emphasis on problem solving (MoEC, 2010). Yet, no further clarifications are provided as to what a problem is, what problem solving means, and what kind of related skills are desirable.

Both in primary and secondary education, the vast majority of mathematics teachers' instruction methodology depends on the respective national textbooks, prepared by the MoEC (Xenofontos, 2014; Xenofontos & Papadopoulos, 2015). Although I do not, in this study, examine textbook use by teachers, I do explore how the concept of *problem* is presented in the upper-primary (grade 6) and lower-secondary (grade 7) textbooks, which were introduced after the initiation of the reform in 2010. Such an approach sees textbooks as a *potentially implemented curriculum* (Schmidt, McKnight, & Raizen, 1997), or, as Mesa (2004, p. 255–256) puts it, “a hypothetical enterprise: What would students learn if their mathematics classes were to cover all the textbook sections in the order given? What would students learn if they had to solve all the exercises in the textbook?”

### **Why *problem*?**

In the mathematics education literature, the term *problem* is one of the most widely used; yet, there does not seem to be an agreement as to what it means. In general, my views coincide with Schoenfeld's (1985, p. 74) statement that “being a ‘problem’ is not a property inherent in a mathematical task. It is a particular relationship between the individual and the task that makes it a problem for that person”. For the purposes of this study, however, I do not want to use any particular definition of the term, as my goal is to examine how *problem* is conceptualised and formed in the national textbooks of Cyprus. Such a deliberate choice may serve as a proxy to how problems and problem solving are conceptualised at the level of policy-making, that is, the intended curriculum (Mullis et al., 2016; Schmidt et al., 1997). Also, I acknowledge that a number of comparative studies have concluded that *problem* and *problem-solving* are perceived differently across educational systems (Cai, 1995; Xenofontos & Andrews, 2014).

In attempts to analyse the types of problems found in mathematics textbooks, various colleagues have used well-defined frameworks. For instance, in their work with two widely used textbook series in Singapore, Fan and Zhu (2000) distinguish between routine and non-routine problems, with various other categories falling under the latter (namely problem-posing problem, puzzle problem, project, journal task). In subsequent work, Fan and Zhu (2007) identified various similarities and differences in the promotion of problem-solving strategies in Chinese, Singaporean, and US textbooks, again, using a very structured, predetermined framework related to how the researchers understood the concepts of problem and problem-solving. In the same spirit, Xin (2007) examined the distribution of seven types of word problems (namely: multiplicative comparison-compared, multiplicative comparison-referent, multiplicative comparison-scalar, rate times a quantity, fair share or measurement division, and proportion problem type) in Chinese and US middle school textbooks, noting a more balanced distribution in the former than the latter. In turn, Son & Kim (2015) investigated how teachers select problems from textbooks and present them in class; however, the researchers “use problems and tasks interchangeably” (p. 493), meaning that they did not utilise a specific definition of what a *problem* might be.

### **Methodology**

This study is based on the following research question:

*How similar/different are the characteristics of the tasks explicitly labelled as problems in the upper-primary and the lower-secondary national textbooks of Cyprus?*

This question is of particular significance, mainly because in its rhetoric the MoEC declares that the new unified curriculum aspires to promote a smooth transition from one school level to another (MoEC, 2010).

Instead of utilising a predetermined definition of the term *problem*, I chose to focus only on those tasks explicitly labelled as problems in the two textbook series. By *explicitly*, I refer to a presentation of the term ‘problem’ in the instructions provided, i.e. “solve the following problems”. Nonetheless, to enable comparisons to be made, I used an adapted framework based on Borasi’s (1986) ideas about the structural characteristics of problems. In her work, Borasi acknowledges the difficulties in deciding whether a specific task *is* a problem or not, the same way Schoenfeld (1985) recognises the role of the individual solver in the labeling of a task as a problem. Borasi, therefore, proposes four structural characteristics of tasks, which are independent of the solver. The first is the *formulation*, and refers to how instructions about what needs to be done are presented. These can take three forms: a question, a statement, or no presentation of instructions at all (open for the solver to decide). The second is the *context* in which the task is presented, and can take two forms: purely mathematical or applied (Blum & Niss, 1991). The third is the *set of the acceptable solutions*. There may be no acceptable solution to a problem, one and only solution, or more than one. Finally, the fourth characteristic has to do with the *methods of approach*. In respect to this, Polya (1981) classified problems in four categories: *one rule under your nose* (when the problem can be solved by simply applying an algorithm just presented), *application with some choice* (when the suitable algorithm must be selected among others previously studied), *choice of a combination* (when in order to reach the solution some of the algorithms previously learnt must be suitably combined), and *approaching research level* (when the elaboration of a new algorithm is required or when the task cannot be solved algorithmically). The term ‘approaching research level’ is used by Polya himself to refer to tasks that are genuinely problematic, and perhaps is closer to Schoenfeld’s (1985) views about what a problem is.

As explained earlier, this paper focuses on the tasks explicitly labelled as problems in the upper-primary (grade 6) and lower-secondary (grade 7) national mathematics textbooks of Cyprus. Each task was described in terms of the four structural characteristics (formulation, context, set of acceptable solutions, methods of approach). For grade 6, the textbooks are organised in six parts, while for grade 7 they are organised in two parts.

## Findings

In grade 6 textbooks, 228 tasks were identified as being explicitly labeled as *problems*, while in grade 7 textbooks, only two tasks were identified. Although the total number of tasks (labelled as problems or not) in the two series was not counted, a quick scan through the textbooks shows that in each grade (6 and 7) there are more than 1000 tasks.

Below, figure 1 presents an example from grade 6, and how it was coded with the use of Borasi’s (1986) four structural characteristics. Figure 2 demonstrates another example from the textbooks of grade 6, which, contrary to the algorithmic task of figure 1, was identified as approaching research level, as there is no standard algorithm that could be applied for its resolution. In figure 3, one of the two tasks identified in grade 7 textbooks is presented. In fact, both tasks were coded under

“approaching research level”, due to their high complexity and lack of any particular algorithm to be applied.

Table 1 illustrates the distribution of these tasks for each form of a structural characteristic.

The Grade 6 pupils are  $\frac{1}{6}$  of the total pupil population in a school. There are 258 pupils in total. Find how many pupils are in Grade 6.

(α) Οι μαθητές της ΣΤ' τάξης αποτελούν το  $\frac{1}{6}$  των μαθητών ενός σχολείου. Όλοι οι μαθητές του σχολείου είναι 258. Να υπολογίσετε τον αριθμό των μαθητών της ΣΤ' τάξης.

**Figure 2: An example of a task (grade 6, part B, page 106)**

In both grades' textbooks, certain tasks were identified, in which the term problem appeared in the instructions. However, these were classified as problem-posing tasks, as they invited pupils to write a problem that would meet particular criteria (i.e. 'translate' a symbolic expression/representation into a real world situation). In the textbooks of grade 6, eleven such tasks were identified, while in the textbooks of grade 7, there were four tasks of this type. Below, figures 4 and 5 demonstrate an example from the primary and secondary textbooks, respectively.

One of the problems in number theory says:

11. Ένα από τα προβλήματα της θεωρίας αριθμών λέει:  
Μετά από πολλά χρόνια συναντούνται δύο συμμαθητές, ο Πυθαγόρας και η Υπατία, που είχαν ιδιαίτερη αγάπη στα μαθηματικά και διεξάγεται ο πιο κάτω διάλογος:

Π: Παντρεύτηκες. Έχεις παιδιά. Πόσα; Πόσες ηλικίες;  
Υ: Ναι, τρία και το γινόμενο των ηλικιών τους είναι 36.  
Π: (όσοτερά σου ακίνητα) Δεν μπορώ να βρω τις ηλικίες τους, τα στοιχεία που μου έδωσες δεν είναι αρκετά.  
Υ: Σωστά, και αν σου πω ότι το άθροισμα των ηλικιών των παιδιών μου είναι το ίδιο με τον αριθμό του σπιτιού σου.  
Π: Ούτε και τώρα μπορώ να βρω τις τρεις ηλικίες. Θέλω και άλλη βοήθεια...  
Υ: Σωστά! Και αν σου πω πως το μεγαλύτερο παιδί έχει ξανθή μαλλιά...  
Π: Τώρα ναι! Μπορώ να σου πω τις ηλικίες των παιδιών σου, χωρίς καμιά αμφιβολία!

Ποιες είναι οι ηλικίες των παιδιών και τι σκέψες έκανε ο Πυθαγόρας για να φτάσει στην απάντηση;

After many years, two old friends, Pythagoras and Hypatia, met. They both loved mathematics. Below, is presented the discussion between them:

P: Are you married? Do you have kids? How many? How old are they?

H: Yes, I have three, and the product of their ages is 36.

P: (after some thought) I can't find their ages, the information you gave me isn't sufficient.

H: You're right, but what if I tell you that the sum of their ages is the same as the number of your house?

P: I still can't find the age of each. I need another clue...

H: You're right! What if I tell you that the eldest has blond hair?

P: Oh, yes! I can tell you the ages of your kids, without a doubt!

formulation: question

context: applied

acceptable solutions: one

methods of approach: approaching research level

What are the children's ages and what thoughts did Pythagoras have to reach the answer?

Figure 3: An example of a task (grade 7, part A, page 94)

19. Ποιο πρόβλημα μπορεί να διάβασε η Αννίτα, αν ξεκίνησε να το λύει ως εξής:

Which problem might Annita have read, if she began solving it as follows:

Aris:  $a$   
 Christina:  $2a + 5$   
 EQUATION:  $a + 2a + 5 = 46$

Figure 5: A problem-posing task (grade 7, part A, page 80)

## Discussion

When approached from different perspectives, the findings of this study offer insight into at least two matters. Firstly, regarding transition from primary to secondary education, this paper suggests that pupils in grade 6 (upper primary) are significantly exposed to the term *problem* when interacting with their mathematics textbooks, compared to grade 7 (lower secondary). There appears to be a change of discourse, as we move from grade 6 to grade 7. This does not necessarily mean that children in grade 7 are exposed to less tasks that, according to Polya (1981), *approach research level*. Nonetheless, an abrupt disappearance of the term *problem* as children move from primary to secondary education is apparent. Although the latest educational reform intends to bridge the gap between the mathematics curricula at various transition points (MoEC, 2010), this does not seem to be happening in an effective manner. In fact, questions are raised about the extent to which the intended “cohesive and coherent curriculum from pre-primary to upper secondary education” (MoEC, 2010, p. 15) is, in reality, cohesive and coherent. Secondly, when these findings are taken as a whole, and especially when the problem-posing tasks in the two series are added to the equation, the study echoes my previous work examining pre-service teachers’ problem-solving related beliefs (Xenofontos, 2014; Xenofontos & Andrews, 2014). In the Republic of Cyprus, there seems to be a very particular, perhaps culturally specific, understanding of what a mathematical problem *is*:

A ‘problem’, for the educational system of Cyprus, seems to be a real-world task, in which the instructions regarding what needs to be done are mainly presented in the form of question, or, sometimes, with a statement. There is always one (and only) acceptable solution to this task, which can either be solved by applying a straight-forward method/algorithm or a combination of methods/algorithms, which in any case, are already known.

Such a cultural perception of mathematical problems is, I think, extremely problematic, especially when the new curricula claim, in their rhetoric, to be placing emphasis on problem solving (MoEC, 2010). Nevertheless, I do acknowledge that this study, as all studies, carries a set of limitations that has the potential to introduce new research avenues. As explained, in this paper I only examine those tasks explicitly labelled as problems. There appear to be other tasks in the textbooks that are not labelled as problems, the methods of approach of which, in Polya's (1981) terminology, approach research level. Furthermore, even though teachers in Cyprus seem to rely heavily on textbooks (Xenofontos, 2014; Xenofontos & Papadopoulos, 2015), what we don't know is *how* they use textbooks and other instructional materials in the classroom. Finally, future research could examine and compare primary and secondary in-service teachers' beliefs and practices in relation to problem-solving, so that we can have a complete picture of how to make the transition, as smoothly as possible, from one school level to another.

*Teacher questioning has been extensively studied in countries such as the UK since 1980s, however, such study within the specific context of mathematics classrooms has not received much attention. Moreover, there does not exist a direct comparative study between the UK and China with a focus on teachers' questioning in secondary mathematics classrooms. Therefore, this article aims to fill the gap in the literature. This paper looks for similarities and differences in the sequences and patterns of teachers' questioning practices in secondary mathematics classrooms in the UK and China. By making a comparison between the two countries, it is possible to examine the perceived cultural differences and similarities underpinning the use of teachers' questioning.*

**Keywords:** *Teacher questioning; Secondary mathematics classrooms; the UK; China*

## **Introduction**

The UK government launched a project called 'The Mathematics Teacher Exchange' in 2014, which involved secondary mathematics teacher exchange between schools in England and Shanghai (Boylan et al., 2017). Its intention is to improve students' achievement through copying the Chinese education model. This programme is believed to be successful (ibid) and has been extended to 2020. However, despite the fact that Chinese students have repeatedly outperformed their UK counterparts in school mathematics in various international comparative assessments, there is little comparative research into teacher questioning between the UK and China. Alexander (2009) further suggests a deliberate ignorance of comparative studies of pedagogy in the UK. To address this gap, this exploratory study aims to direct comparative studies of pedagogy in the UK and China, with a focus on teachers' questioning in secondary mathematics classrooms in the hope of providing some explanations from a social-cultural perspective.

There has been a long history of research investigating teacher questioning in the UK context. Extensive research into teacher questioning has witnessed a radical shift in focus from exploring the relationships between teacher questioning and student achievement based on the process-product paradigm in studies conducted before the 1980s (e.g. Mehan, 1979), towards examining questioning from social constructivist perspectives (Chin, 2007). This has followed the educational reform from a traditional transmissive teacher-centred teaching to an inquiry-based teaching that emphasises the social and linguistic nature of knowledge construction in UK classrooms. However, very few studies of teacher questioning have been carried out in

places like China (Ma & Zhao, 2015), where cultural values are different from the UK (Leung, 2001) and where teachers may be constrained by having to deal with larger classes (Chin, 2007) or high-stake examinations (Wong et al., 2012). Traditionally, Confucianism was first and foremost a distinctly Chinese teaching, but it then spread into many East Asian countries such as Japan, Korea, and as well as territories with predominantly Chinese populations such as Hong Kong and Singapore. Confucianism defines much of these East Asian countries' identity, especially in relation to philosophical thoughts and practice (ibid). Wu (1993) studies teachers' questioning patterns in Hong Kong and discovers that students generally have a habit of waiting to be called up before answering teachers' questions. Such student passiveness and reluctance may be explained from a cultural perspective. Chin (2007) carries out several investigations of teacher questioning in science classrooms in Singapore and goes on to suggest that, given the predominant Confucian views of teaching and learning, teachers typically are perceived as expert role models for students, which makes them relatively active in lessons compared to students. Such activeness of a teacher in a lesson can manifest in the form of teacher monologue. Lending support to such findings, Ma & Zhao (2015) have observed 13 primary mathematics lessons in China, and found question-answer exchanges to be the most dominant dialogic form between teachers and students, in which almost all mathematical questions are raised by the teachers.

Teacher questioning is a frequent component of classroom talk. The use of questioning in the West can be traced back to Plato and Socrates, and contemporaneously teachers use questions to stimulate students' thinking (Chin, 2007). Research examining teacher questioning has shown the importance of the kinds of questions teachers ask. Open-ended questions that are not limited within a set of answers can encourage more meaningful responses from students and further stimulate students' logical thinking; whereas closed questions which often refer to those with predetermined answers, tend to limit students' responses into a few simple words and produce merely recall of facts and concepts (Chin, 2007). Thinking about the questions teachers ask is vital, but equally important is thinking about the questioning patterns or sequences that they employ. It is therefore necessary to understand more deeply what happens in classroom exchanges after an initial question is posed, or in other words, what questioning patterns or sequences can occur. Franke et al. (2009) examine teachers' questioning sequences following students' explanations and find that students tend to produce fully complete and correct explanations of their mathematics when asked by teachers' sequential probing questions. Therefore, the focus of this paper is to explore teachers' questioning sequences and patterns employed by two groups of teachers in the UK and China in order to investigate the following research questions:

What are the similarities and differences in UK and Chinese teachers' questioning sequences and patterns in practice?

## Methods

A combination of both classroom observation and individual interview were employed, with a group of 11 mathematics teachers of Key Stage 3 pupils (aged 11-14 years) in the UK and a group of 12 mathematics teachers of Year 7 and Year 8 students (aged 11-14 years) in China. Four lower-secondary schools (two from Beijing and Hangzhou, two from Coventry and

Birmingham) were selected, all of which were national-run, state schools. The teachers were teaching various different topics from multiplying decimals to equations with algebraic fractions, and with a wide range of years of teaching experience from newly qualified to very experienced (e.g. some teachers had been teaching for nearly 40 years). The class size ranged from 8-55 students (50 students on average in China, 30 in the UK). Classroom observation was undertaken to answer the research question, focusing on identifying questioning strategies that the teachers might adopt in practice. These were carried out in naturalistic settings in the hope that they could provide rich descriptions of classroom settings to examine naturally occurring teacher questions and to understand the underlying silent social norms and cultural values behind the teachers' behaviours. The individual follow-up interviews were semi-structured and conducted as a supplement to observation to further understand and justify certain patterns of teachers' questions from their own perspectives, which may differ from the researchers' interpretations. Through this, it was hoped that some interesting themes would be uncovered which may not otherwise have been accessible to the researcher. All data were audio-recorded and transcribed and analysed in original languages. Thematic analysis was adopted in this study as it is the most widely used method for identifying themes and patterns of meaning with a clear set of procedures in qualitative research (Braun & Clarke, 2006).

To consider a teacher's question, the research focused on a teacher's utterance that had the grammatical and intonation form of a question, whether it was for the purpose of eliciting information about students' knowledge or thinking or was social act for keeping students' attention. Questions in whole class settings were selected from each observation to analyse. The research attempted to use a discourse analysis approach to analyse the teachers' questioning. The main unit of analysis here was of content units (Hsu, 2001). "A content unit is a piece of discourse that consists of a main question and all the verbal moves made by classroom participants that are directly related to that question in content" (ibid, p. 62). A content unit may not only include a question-answer exchange but might go beyond into the sequences of connected talk associated with a main question. The following extract offers a good example of a content unit:

Excerpt 1 (example from a Chinese lesson)

- Teacher: It is what of the previous call? What exactly?
- Student: The cost of a call.
- Teacher: What? Is it the cost of a previous call?
- Students: Length of a call.
- Teacher: It is it call cost or length of a call?
- Students: Length of a call.
- Teacher: S3, is it the call cost or length of a call?
- Student: Length of a call.

In the process of analysing interview data, both an inductive and deductive approach were used, which included some of the themes taken from the classroom observation. During the analysis,

new issues emerged from the data, therefore, the researcher worked to refine the codes and sub-codes back and forth in a process of inductive and deductive coding.

## Results

### *Individualised vs. collective questioning*

One distinct difference lay in the number of students involved in teachers' questioning, which illustrated two opposite questioning patterns. The questioning patterns used by Chinese teachers often took the form of collective questioning, whereas British teachers' questioning patterns were more likely to involve individualised questioning. Specifically, the Chinese teachers frequently posed their questions to the entire class and often involved verbal interaction more than one student. The excerpts above (Excerpt 1) and below (Excerpt 2) are respectively typical examples of questioning to the entire class and questioning to individuals that also involves the rest of the class. The following distinct pattern was only found in the Chinese classrooms. Every single teacher observed adopted this questioning strategy, and used it multiple times in their lessons. A teacher asked students to solve a practical mathematical issue in choosing from three sampling strategies in the textbook.

#### Excerpt 2

In order to know the eye health of all students from secondary schools across the nation, someone presented the following three sampling methods:

1. To get eye tests for all secondary school students
2. To get eye tests for students from one secondary school
3. On the country level, firstly, divide the country into five areas: east, west, south, north, and middle. Secondly, pick three secondary schools from each area. Thirdly, carry out eye tests for all students from the 15 secondary schools picked.  
*Which sampling method do you think is the most appropriate?*

Teacher: So, someone presented these three sampling methods in order to understand the vision situation of all secondary school students across the country. Li, which one do you think is best?

Li: The third one.

...

Teacher: ... what kinds of issues would rise if we get eye tests for the entire country?

Students: Waste of time.

Teacher: Waste of time. Some students are right. What do we waste?

Students: Waste of energy, waste of people and waste of money...

T&S: Waste of money.

In this excerpt, the teacher asked questions to an individual student Li, but his questions were not individual-centred, because when the teacher continued questioning Li, he set his eyes on the rest of the class, welcoming others to join in this process. Along with the question-answer

exchanges, his follow-up questions with Li were shared and answered among all students in the class, and eventually the teacher and students answer the questions all together.

In contrast, UK teachers asked their questions mostly at an individual level, sticking to one individual student, and keeping eye contact with that individual student until they finished answering the questions or came to the correct understanding. In the process, no other students were allowed to interrupt the interaction between that individual student and the teacher, even when the individual student's solution was incorrect. A classic example can be seen below in Excerpt 3. In one lesson on grouping different cubes and a list of numbers to make a square, rectangle and stick, a teacher had given each group a set of different tasks to complete. As they were looking at square 4 on the board, the following conversation ensued.

#### Excerpt 3

- Teacher: Hannah, how's that 4 made up on the board? How many rows?
- Students: (Inaudible)
- Hannah: (Inaudible)
- Teacher: No, it's Hannah I'm talking to. The 4, Hannah, how many rows has it got?
- Hannah: 2.
- ...
- Teacher: 5, well done.

Moreover, the UK teachers often began by asking questions based on the tasks for all the students, but soon followed this with individual students. Depending on how well they answered the questions, their follow-up questions were frequently modified according to the student's response. In one lesson on Trigonometry's problems, a teacher asked Jane to give solutions to question 2, as shown below.

#### Excerpt 4

Question 2:  $\angle C = 71^\circ$ ,  $BC = 8$  cm, get  $y$ .

- Teacher: ...means the hypotenuse on this side. (*Pointing to line BC*) What is 8? (*Using SOHCAHTOA approach*)
- Jane: Opposite.
- Teacher: Why Opposite?
- Jane: Because it's the shortest one.
- Teacher: No... Is the 8 opposite the given angle?
- Jane: No it's the other one.
- Teacher: Okay so what's the 8?
- Jane: Adjacent.
- ...

- Teacher: Which one has got the adjacent and the hypotenuse in? Is it sin, cos or tan?
- Jane: The middle one.
- Teacher: The middle one which is what?
- Jane: I don't know.
- Teacher: The middle one which is what? Sin, cos or tan?
- Jane: Cos.
- Teacher: Cos, lovely.

In the excerpt above, the teacher insisted on questioning Jane alone until she came to the final correct answer. Every time when she replied with 'I do not know', the teacher asked more followed up questions that probed or guided her understanding.

The findings from interviews reveal that class size has always been a challenge for Chinese teachers. In order to accomplish lesson objectives in such a short, limited time, it was very hard to ask individualised questions. The UK teachers, in contrast, tried to question every student during the lesson. The lower the ability of the group, the smaller the group size would be: a higher ability group tended to be bigger in class size, but no bigger than 30 students. Classroom management was also seen as a concern by the Chinese teachers. They were not as interested in their students' answers but instead on keeping the lesson going and keeping students all focused. Furthermore, it is believed that most mathematics questions were shared by all students. Instead of questioning one student alone, it would be best to ask the entire class, so that everyone could benefit. Their lesson objectives took priority, the lesson pace was fixed and set to get 2/3 of their students to understand their lessons. In contrast, the UK teachers believed that individualised questioning worked best for their individual students' needs. Each student has their own capacity in learning mathematics, and they should work at the pace of their individual students. When a child fell behind, they would increase questioning specifically to that child.

## Discussion

The Chinese questioning pattern has been described by Alexander (2017, p. 28) as "teachers and children address learning tasks together, whether as a group or as a class, rather than in isolation". In the Chinese classrooms observed, teachers and students were facing each other during the whole lesson, and maintained eye contact as much as possible between one adult and a class. These teachers indicated an orientation towards learning together, also called collective orientation (Leung, 2001), and the questioning pattern in their classrooms became a rather collective form of questioning. This collective questioning has been found in other studies investigating Chinese classrooms (Ma & Zhao, 2015). Most of the teachers' questions were answered by all students in unison, echoing the notion of social harmony and the 'obligation of the individual to fit into the social structure' (Leung, 2001, p. 44). In contrast, the UK teachers' questioning pattern demonstrates an orientation towards individualised learning described as individual orientation (ibid), illustrating a relatively individualised questioning pattern. The UK teachers observed firstly started questioning with a task-driven

purpose, but soon followed this conversation with individual students and assessed how well they answered the questions. Their follow-up questions were frequently modified to accommodate the individual student's response, in a much more student-centred approach, which fits the description of Western culture seeing the individual as being of prime importance (Leung, 2001). The difference in the two groups of teachers' questioning patterns is in line with Alexander's (2017) conclusions of collectivism- individualism in Western and Eastern countries. The collectivism-individualism concept refers to "the extent to which the individuals of a society are perceived as autonomous" (Kaiser & Blömeke, 2014, p. 406). The underlying assumptions are about the relations between individuals and the community. Collectivism emphasises "human interdependence, caring for others, and sharing and collaborating, but only in as it serves the larger needs of society, or the state, as a whole" (Alexander, 2003, p. 25). Individualism as its counterpoint, puts "the self above others and personal rights before collective responsibilities". This may create different joint identities for students and teachers in China and the UK, which may then explain their classroom questioning behaviours and their explanations for choosing certain questioning patterns. Most of the time, the Chinese teachers questioned students as a group, rarely as isolated individuals, as they emphasised learning common mathematical knowledge together and sharing uniform learning outcomes, following a single curriculum for all. On the contrary, the UK teachers' student-centred questioning strategy viewed "knowledge as being personal and unique", embracing "individual intellectual differentiation and divergent learning outcomes" (Alexander, 2009, p. 936).

Another issue pertinent difference is class size. Consistent findings concerning class size effects on classroom processes show that small class size is strongly related to the individualisation of teaching, whilst large class size is associated with classroom management and classroom control (Blatchford et al., 2011). Specifically, class size seems to alter the proportion of time spent questioning the whole class, or with individuals. With a large class size of over 50 students, the collective questioning pattern may be adopted in the interest of maximising participation by as many students as possible, encouraging them all as a whole to contribute to the answers. In the smaller class sizes of the UK classrooms, the teachers may be able to offer more personalised questioning to their students who are more often the focus of the teachers' attention (Blatchford et al., 2011). It further reveals that the UK teachers and individual students were often engaged in a sequence of several question-answer exchanges. This may suggest that small class size can sustain teacher-student interactions, whereas large class size tends to cut teacher-student interaction short. The Chinese teachers favoured content-based questioning, the remaining third of their students often comprising the least able students may be potentially left out. In contrast, in the UK, students' abilities are strongly linked to the size of a class. This has given teachers the possibility to challenge and extend all students at their own levels of understanding in mathematics.

To conclude, this study suggests that teacher questioning is a cultural-based pedagogy. Thus, it is hoped that policy makers such as the Department for Education in the UK or the Ministry of Education in China can be openly looking at and learning from other education systems, and incorporating parts in a culturally appropriate way.

### Introduction

History of mathematics in mathematics education, and history of mathematics education continue to receive much attention. However, empirical research and coherent theoretical/conceptual frameworks within this area have emerged relatively recently. The purpose of this CERME TWG is to provide a forum to approach mathematics education in connection with history and epistemology.

TWG12 welcomes both empirical and theoretical research papers, and poster proposals related to one or more of the following issues:

1. Design and/or assessment of teaching/learning materials using the history of mathematics, preferably with conclusions based on empirical data; all levels can be considered, from early-age mathematics to tertiary education and teacher training.
2. Surveys on the existing uses of history or epistemology in curricula, textbooks, and/or classrooms in primary, secondary or tertiary levels, and in teacher training;
3. History of mathematics education;
4. Relationships between, on the one hand frameworks for and empirical studies on history in mathematics education and, on the other hand, theories, frameworks and studies in other parts of mathematics education research.

Even though the inception of this TWG is fairly recent – it started in CERME6 (2009) – it has deeper institutional roots within the maths education research community. Indeed, the *HPM* study-group (*History and Pedagogy of Mathematics*) was created at the 1972 ICME conference; it has been organizing satellite conferences to the ICME meetings since 1984, and has several active regional branches (HPM-Americas, European Summer Universities). In CERME11, 13 papers and 3 posters were presented in TWG12, with participants coming from a large range of European countries and beyond (Brazil, Tunisia). The topics covered by TWG12 were also reflected in Kathy Clark's plenary address on *History and pedagogy of mathematics in mathematics education: History of the field, the potential of current examples, and directions for the future*.

Before going into any details, it should be stressed that this TWG has four general but distinctive features which give these meetings their specific flavour. Firstly, its topic lies at the intersection of different fields of research – maths education research and history of mathematics – which requires versatility and methodological vigilance (Fried, 2001; Chorlay & Hosson, 2016). Secondly, the

strength of the historical and the HPM community varies greatly among countries, and these meetings play a crucial role for researchers working in relative isolation, and with difficult access to resources in the field. Thirdly, the scope of TWG covers both history in mathematics education and history of mathematics education, which are two significantly different research topics (TSG 24 and 25 in ICME13); connecting the two lines of investigations is a constant challenge. Fourthly, since the topic of TWG12 is neither specific to one level of the educational system (from primary education to teacher-training) nor to any single mathematical topic (be it fraction concepts, algebra, proof, etc.), the work in TWG12 intersects that of most other TWGs. It should be noted that, for this edition, there was little intersection with what was covered in TWG8 (Affects and the teaching and learning of mathematics), TWG10 (Diversity and maths education), in spite of the fact that it is not uncommon for outsiders of the HPM research community – among which most policy-makers and curriculum-designers – to ascribe such goals to the historical perspective in teaching.

These four features made this meeting not only useful but also challenging and exciting. As the final discussion made clear, the general feeling among the participants was that one of the main outcomes of this meeting is that we actually *learned* a lot from the one another, both from their papers and from the lively discussions.

### **Some significant features of the 2019 conference**

A large share of the papers bore on teacher training, either for prospective or in-service maths teachers. Two case studies, one presented by Barreras and Oller-Marcén, and one by Bernardes and Bruna-Correa, showed how confronting teachers with mathematical documents from the past can be a tool both for research into teachers' content knowledge, and for the professional development of teachers. From another perspective, van den Bogaart and Schorcht focused on teachers' beliefs, either when studying some history of maths as part as their per-service training, or when assessing the didactical potential of classroom activities with some historical content.

By contrast, few papers were dedicated to what has long been a central line of research in the HPM community, namely the use of historical documents in the classroom. However, these few papers point to fresh research directions. For instance, the poster of Olsen and Thomsen aimed to connect the studies on history of maths in the classroom with those on the use of ICT. Chorlay's paper bore on primary school mathematics and argumentation, thus illustrating the new approach in the French IREM community, with its greater emphasis on the actual teaching effects of experimental sessions and its rather new involvement with pre-secondary mathematics. This new approach led to the publication of a textbook (Moyon & Tournès, 2018), which was awarded the 2019 prize for best science teaching resource by the Paris Academy of science.

On a par with teacher-training, a significant share of the papers bore on the history of mathematical education; a fact which bears witness to the vitality of this research field at the international level. We are pleased that TWG12 of CERME provides opportunities for researchers working in different fields – mathematics education research, history of mathematics, and history of mathematics education – to interact fruitfully. The papers on topics from history of maths education presented in this CERME conference gave food for thought for mathematics education researchers working on textbooks (Hatami and Pejlaré), resources for teaching and the professional development of teachers

(Krüger), testing and assessing (Smestad & Fossum). Several papers (Zwaneveld & De Bock, Weiss & Känders) bore on fairly recent historical developments, thus shedding a new (and occasionally critical) light on current trends. History of education was complemented with inputs from sociology in Hamann's work, in order to sketch a general model for education reform.

# Generalizing a 16<sup>th</sup> century arithmetic problem with prospective Secondary education teachers

Álvaro Barreras<sup>1</sup> and Antonio M. Oller-Marcén<sup>2</sup>

<sup>1</sup>Universidad Internacional de La Rioja, Logroño, Spain; alvaro.barreras@unir.net

<sup>2</sup>Centro Universitario de la Defensa de Zaragoza, Spain; oller@unizar.es

*The use of history of mathematics and, in particular, of historical problems is a very useful tool for teacher training. In this work we present some partial results obtained after the design and implementation of an activity based upon an arithmetic problem from the “Conpusicion de la arte de la arismetica y juntamente de geometria” by the Spanish 16<sup>th</sup> century Dominican friar Juan de Ortega. This activity was conducted with 48 prospective Secondary education teachers enrolled on an on-line Masters’ degree. We focus on the part of the activity related to generalization and, more particularly, on the relation between generalization and use of algebraic language. Our results show that there exists a positive significant relation between generalization and the use of algebraic language. However, we also found out that many students were able to provide correct and satisfactory generalizations using just natural language.*

*Keywords: History of mathematics, word problems, teacher training, generalization, algebraic language.*

## Introduction and objectives.

The use of history of mathematics in mathematics education can be approached in many different ways and with many different motivations and objectives (Jankvist, 2009). Regarding the classroom implementation, one interesting possibility is the use of historical problems and, in particular of problems “having clever, alternative, or exemplary solutions” (Tzanakis et al., 2000, p. 224).

In the context of teacher training, Mosvold, Jakobsen and Jankvist (2014) show how all the different domains of teachers’ Mathematical Knowledge for Teaching (MKT) might profit from the use of history of mathematics. In particular, the analysis of historical problems and their solutions can be a very interesting task for prospective teachers (Meavilla-Seguí & Oller-Marcén, 2015).

Generalization belongs to the two main domains of the MKT model described by Ball, Thames and Phelps (2008): Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK). From the point of view of SMK it is clear that generalizing is one of the main components of mathematical activity (Harel & Tall, 1991). Regarding PCK, Ellis (2007, p. 221–222) points out that “one of the primary aims of educational practice is to help students to develop robust, generalizable knowledge that will support their abilities to create generalizations in the classroom”. Generalizing and specializing are two key aspects of one possible approach to algebra (Lee, 1996) and the use of symbolic algebraic language is strongly related to the generalization of arithmetic properties or to the modelization of different situations (Usiskin, 1988).

Even in the absence of symbolic algebraic language, the search for some kind of balance between generalization and specialization can be clearly seen in many ancient mathematical texts. These texts included very long collections of problems possibly hoping that the reader would be able to

infer the general rules used to solve the seemingly different problems. In the *Zhou bi suan jing*, a Chinese text from the 3<sup>rd</sup> century, this idea was even explicitly stated in a dialogue between a master and a student:

Illuminating knowledge of categories [is shown] when words are simple but their application is wide-ranging. When you ask about one category and are thus able to comprehend a myriad matters, I call that understanding [my] Way. (Cullen, 1996, p. 15)

This underlying philosophy can still be found in Fibonacci's *Liber Abaci* (Sigler, 2002), for example, about one thousand years later. In fact, many mathematical texts written during the 16<sup>th</sup> and 17<sup>th</sup> centuries contained series of problems whose solutions were just the description of the operations that had to be performed with the given data.

In this work, we analyze part of an activity designed for and implemented with prospective Secondary school teachers which is based on an arithmetic problem excerpted from a 16<sup>th</sup> century Spanish arithmetic textbook. Our main objective is to explore if and how the participants are able to provide generalizations of the statement and the solution of the problem. More particularly, we focus on the interplay between generalization and the use of algebraic language. In other words, we focus on two ways to generalize, according to which semiotic register is used: algebraic language or natural language.

### **The source.**

The only known biographical facts about friar Juan de Ortega is that he was born in Palencia, that he was a Dominican and that he taught mathematics in Spain and Italy both publicly and privately (Madrid, 2016).

As far as we know, he only wrote one book, the *Conpusicion de la arte de la arismetica y juntamente de geometria* (Ortega, 1512). Ortega's book was rather popular and it was reedited several times in different countries during the 16<sup>th</sup> century (Rey Pastor, 1926). In fact, it was reprinted (sometimes with slightly different titles) and translated at least in Roma and Lyon (in 1515), Messina (in 1522), Sevilla (in 1534, 1537, 1542 and 1552) and Granada (in 1563). Some authors (Carabias, 2012) point out that the 1515 translation published in Lyon was the first text on commercial arithmetic written in French. Marquant (2016) presents an interesting discussion on the authorship of some of these translations.

Regarding its content, the book consists of 204 folios organized according to 36 chapters and it covers the usual topics in a Renaissance commercial arithmetic text: elementary operations with natural and fractional numbers, progressions, square and cubic roots, rule of three and its applications and some elements of geometry. The editions of 1534, 1537 and 1542 included a method to approximate square roots that improved the known methods at his time, on this issue we refer the reader to the classical works by Rey Pastor (1926, pp. 72–81) and Barinaga (1932). Finally, the 1552 edition included a collection of 13 problems solved using algebraic techniques that was inserted by Gonzalo Busto, the editor of this probably posthumous edition. This is an interesting feature of the text, since the first book with a systematic introduction to algebraic

language written in Spanish, the *Libro Primero de Arithmetica Algebratica* (Aurel, 1552) was published that very same year (Puig & Fernández, 2013).

In addition to many classical problems (Métin, 2018), in chapters 14 through 17, Ortega provides a collection of 34 examples of what he calls “extraordinary rules” and that he defines (Ortega, 1512, fol. 60r) as “rules outside the usual way of adding, subtracting, multiplying and dividing and that involve hidden ways to apprise those who know little”. They are, in fact, a collection of arithmetic problems and their solutions presented in a merely descriptive fashion. For example, the eleventh example from chapter 14 goes as follows (our translation):

If you wanted to know, or if it was asked to you, which are those three numbers such that two fifths of the first one is the same as three sevenths of the second one and the same as four ninths of the third one, you will do the following. Put the numbers as you see here:  $\frac{2}{5} \frac{3}{7} \frac{4}{9}$ . Then, multiply the 5 below the 2 by the 3 above the seven to get a 15. Multiply this 15 again by the 4 above the 9 and you will get 60, which is the first number. After that, multiply the 7 below the 3 by the 4 above the 9 to get a 28, which you shall multiply by the 2 above the 5 in order to get a 56, which is the second number. After that, multiply again the 9 below the 4 by the 2 above the 5 and you will get an 18 which you shall multiply again by the 3 above the 7 to get 54. This is the third number. If you want to check that it is true, look for the two fifths of 60 and you will see that it is 24. In the same way you will see that three sevenths of 56 is 24 and that four ninths of 54 is 24, as you see in the example. (Ortega, 1512, fols. 63r–63v)

### Activity and participants.

The experiment was carried out in the context of the subject “Didactics of arithmetic and algebra” during the academic year 2017-2018 with 48 students of the online Master’s degree in Didactic of Mathematics in Secondary education from the International University of La Rioja. The age of the participants ranged from 25 to 56 (with a mean of 37.7 and a standard deviation of 7.9) and most of them (91.7%) had at least six months of prior experience teaching mathematics at secondary level. Even though background of the students was diverse, most of them had prior teaching experience or a degree on a STEM or education discipline and hence a good knowledge of mathematics could be assumed. Table 1 provides further information about the participants.

Gender		Nationality				Degree		
Male	Female	Spain	Colombia	Ecuador	Mexico	STEM	Education	Other
52%	48%	17%	44%	37%	2%	61%	35%	4%

**Table 1: Some data about the sample**

The designed activity was based upon the problem transcribed above. It consisted of three exercises, each of them addressing to a different issue. Being an online Master’s degree, the students had to complete this activity at their homes and they were given a two-week deadline in order to obtain as many answers as possible.

- In exercise 1, a short version of the original problem was presented using modern natural language and the students were asked to solve it using whichever method they wanted.

- In exercise 2, a short version of the original solution was presented using modern natural language and the students were asked to:
  - § Give their opinion about this solution.
  - § Compare this solution with their own solution from exercise 1.
  - § Explain which of the two solutions is “better” and in which sense.
- In exercise 3, the students were asked to provide a general version of the statement of the problem from exercise 1 and a general solution based on the solution from exercise 2.

As we see, exercises 1 and 3 mostly deal with purely mathematical aspects so they are more related to SMK. Exercise 2, on the other hand, is more focused on PCK because it involves the analysis of different solutions to the same problem, their comparison and the reflection about the advantages and disadvantages of each of them. In this work, we will present the results of the analysis of exercise 3. In particular, we will focus on two variables: generalization and language. For the first one we will focus on its correctness (correct or incorrect) and on its completeness (partial or full) while for the second one we will consider the attributes natural and algebraic.

## Results.

Although in this work we focus only on exercise 3, it is interesting to point out that almost all the students (46 out of 48) were able to solve the problem in exercise 1 at some extent. However, not all the answers were equally complete. For example, very few students mention that the problem has an infinite number of solutions. In any case, we conclude that the students were able to understand the problem

Exercise 3 was answered by 47 out of the 48 participants. Only 28 of them (about 60%) were able to provide some kind of correct generalization for the statement and the solution of the problem. In Table 2 we see that those participants that used algebraic language were more capable to provide a correct generalization of the situation. In fact, performing a  $\chi^2$  test of independence, we obtain a statistically significant relationship between both variables (significance level of about 95%).

	Algebraic language	Natural language
Correct generalization	18	10
Incorrect generalization	7	12

**Table 2: Correctness versus use of algebraic language**

Most of the wrong answers that tried to generalize the problem using only natural language simply provided incomplete statements. One student’s answer, for example, was: “Do the following exercise, multiplying one denominator by the remaining numerators”, which is a just simple explanation of the method rather than a generalization.

General rule

$$\frac{a}{b} = \frac{c}{d} = \frac{e}{f}$$

- $b \cdot c \cdot e$
- $d \cdot e \cdot a$
- $f \cdot a \cdot c$

**Figure 1: Incorrect generalization**

The incorrect generalizations that used algebraic language mostly looked like the example in Figure 1. The statement of the problem (top of the figure) is expressed incorrectly and, at the bottom, we just find the required operations expressed symbolically.

It is noteworthy that some students seem to identify the process of generalization just with the use of symbols. Figure 2 is an interesting example of this phenomenon. There is no generalization in the student's answer, just the use of the letters X, Y and Z to denote the unknown numbers.

Being three quantities X; Y; Z proportional to each other, such that:  
 $\frac{2}{5} X = \frac{3}{7} Y = \frac{4}{9} Z$   
 It is possible to find those quantities multiplying the denominator of each fraction by the numerators of the other two fractions

**Figure 2: Use of symbols that does not imply generalization**

We recall that 28 students provided a correct generalization of the original problem and its solution. However, not all of them provided a full generalization of the situation. In Table 3 we analyze the relation between the use of algebraic language and the degree of generalization of the answer.

	Algebraic language	Natural language
Full generalization	4	7
Partial generalization	14	3

**Table 3: Degree of generalization versus use of algebraic language**

We obtain again a statistically significant relationship between both variables (significance level of about 95%) showing that the students that were able to correctly generalize the original situation using natural language provided full generalizations more often than their partners. The following transcription is a good example of full generalization that essentially uses only natural language:

If in a set of  $n$  numbers that are proportional to each other in a rational way, we multiply the denominator of one of them by the  $(n - 1)$  remaining numerators, we obtain that number. If we successively proceed in this way, we will obtain the  $n$  numbers of the solution. Since it is a compatible and indeterminate system with  $(n - 1)$  equations and  $n$  unknowns, the system has infinitely many solutions...

<b>a.- General statement.</b>		
Given the following $n$ fractions	$\frac{a_i}{b_i}$	$i \in \{1, 2, \dots, n\}$
find $n$ natural numbers	$x_i$	$i \in \{1, 2, \dots, n\}$
such that	$\frac{a_i}{b_i} x_i = \frac{a_{i+1}}{b_{i+1}} x_{i+1}$	$\forall i \in \{1, 2, \dots, n-1\}$
<b>b.- General solution.</b>		
	$x_i = b_i \cdot \prod_{j \neq i} a_j$	$\forall i \in \{1, 2, \dots, n\}$

**Figure 3: Full generalization using only algebraic language**

Regarding the 4 answers that fully generalized the problem using algebraic language, three of them combined algebraic and natural language and only one (Figure 3) could be described as “completely algebraic”. Only one of these 4 answers stated that the problem has infinitely many solutions.

Now, 17 students provided correct generalizations that were only partial generalizations. In particular, they only considered a situation with three unknown numbers as in Figure 4.

To find three numbers such that  $a/b$  of the first one is the same as  $c/d$  of the second and as  $e/f$  of the third

$$\frac{a}{b}x = \frac{c}{d}y = \frac{e}{f}z$$

**Figure 4: Partial generalization using algebraic language**

Even if most of these 17 answers were very similar to that in Figure 4 (only varying in the degree of use of algebraic language), two of them were particularly incomplete generalizations. For example, in Figure 5, a student considers arbitrary fractions in the statement of the problem but imposes a very particular relation between numerators and denominators inspired by the particular numbers of the original problem.

To find three natural numbers  $a$ ,  $b$  and  $c$  such that the  $x/(x+3)$  of the first one,  $a$ , is the same as the  $(x+1)/(x+5)$  of the second,  $b$ , and as the  $(x+2)/(x+7)$  of the third,  $c$

**Figure 5: A very restricted generalization**

The other restricted generalization imposed the additional conditions that the numerators ( $n_i$ ) of the three fractions are consecutive numbers and the denominators are of the form  $2n_i + 1$ .

## Discussion and final remarks.

From the purely mathematical point of view, it was somewhat surprising that about 40% of the students were not able to provide a correct generalization of the given situation. This might be caused in some cases just by some lack of SMK (Figures 1 or 2) while in other cases it might be related to a misconception about generalization that identifies it with the mere use of symbols in any way (see Figure 2). Regarding the completeness of the generalizations we see that, in terms of Ellis (2007, p. 235), many students generalize just by *removing particulars* (what we called partial generalization, like in Figure 4) rather than by *expanding the range of applicability* (what we called full generalization, like in Figure 3). It is also noteworthy that some students show a different behavior between the statement and the solution. For example, in Figure 2, the student does not generalize the statement at all (he only introduces letters for the unknown quantities) but in the solution he refers to “each fraction” instead of to particular values. This fact probably deserves more attention.

Throughout the students’ responses there is a varying degree in the use of algebraic language. From those using only natural language to those using only algebraic language. Nevertheless, most of the students lie in between showing in their answers a mixture of algebraic and natural language. The results of our work suggest that the use of algebraic language facilitates the process of generalization of the considered problem, illustrating, as Usiskin (1988) points out, that one of the main uses of variables is as “pattern generalizers”. However, and somewhat paradoxically, this use

of algebraic language seems to constitute some kind of obstacle in order to fully generalize the considered situation. There can be several explanations for this phenomenon. One reason can be the context of the exercise, since the answer that was provided to the students only used natural language. Another reason can be related to SMK, because some students might be uncomfortable using algebraic language. Finally, the beliefs, conceptions and expectations of the students about the notion of generalization (Strachota, 2015) might play an important role in their performance.

Zazkis and Liljedahl (2002, p. 400) reached similar conclusions finding out that “there is a gap between students’ ability to express generality verbally and their ability to employ algebraic notation comfortably”. Nevertheless, it must be noted that they worked with preservice elementary school teachers in a context of pattern generalization, while we have worked in a purely arithmetic setting with Secondary education teachers. Either way, there exist contradictory results in the literature. For example, in (Richardson, Berenson & Staley, 2009) most of the elementary prospective elementary teachers participating in the study expressed their explicit generalizations using algebraic notation.

The designed activity, an example of using history as a tool (Jankvist, 2009), involved other exercises. We have already mentioned that most of the students solved the problem correctly. However, after a preliminary and incomplete analysis, we have observed different solving methods some of which involve the use of other semiotic registers besides algebraic or natural language. For example, a few students solved the problem using diagrams. It would be interesting to analyze the influence of different aspects of the students’ solution to the problem over their ulterior process of generalization.

# On the didactical function of some items from the history of calculus

Stephan Berendonk<sup>1</sup>

<sup>1</sup>Universität Duisburg-Essen, Germany; [stephan.berendonk@uni-due.de](mailto:stephan.berendonk@uni-due.de)

*The article draws attention to some individual results from the history of calculus and explains their appearance in a course on the didactics of analysis for future high school mathematics teachers. Specifically it is shown how these results may serve as a vehicle to address and reflect on three major didactical challenges: determining the meaning of a result, concept or topic to be taught, teaching mathematics as a coherent subject and understanding the source of misconceptions.*

**Keywords:** *Didactics of analysis, meaning, coherence, misconceptions.*

Why do we have to learn this *historical* stuff, although this is a course on *didactics*? This is a question frequently posed by future high school mathematics teachers taking my third semester course on the didactics of analysis at the university of Duisburg-Essen. In this course we consider and compare several different approaches to differentiation and integration, uncover some of the relationships of analysis with other mathematical subdomains and try to settle the role and meaning of analysis within the high school curriculum. Although the students have mastered a typical first semester university course on real analysis before taking my course on the didactics, I feel obliged to incorporate several mathematical digressions into this course. These digressions especially include some episodes from the history of calculus that weren't discussed in the course on real analysis. I teach these episodes, however, not as an end in itself or as an introduction to the history of mathematics, but as a means in order to be able to seriously address the didactical issues at stake. In the following article I will mention some of those episodes and I will try to point out their relevance and value from a didactical point of view.

## Three didactical challenges – meaning, coherence and misconceptions

Let us consider a typical first semester university course on real analysis. With such a course we may associate the following keywords: axioms for the real numbers, convergence of sequences and series, Heine-Borel, Bolzano-Weierstrass, differentiability, monotony, continuity, integrability, intermediate value theorem, mean value theorem, fundamental theorem of calculus and epsilon-delta proofs. This course has a lot to offer to its students. It introduces them to the mathematical quest for rigor, generality and structural results. It shows that the knowledge about differentiation and integration learned at school can be embedded into a beautiful large-scale deductive system, and thereby exemplifies the architectural nature of mathematics.

One might believe that this course would form a sufficient background regarding the mathematical content knowledge with respect to analysis for a future high school mathematics teacher. However, teaching analysis at school may serve quite different aims than the university course we considered. For instance one might want to teach analysis as a tool to formulate and understand some Newtonian physics or more generally speaking, one might want to teach analysis as an example showing the applicability of mathematics and its role for the other sciences. In any case, in contrast to the university course, analysis nowadays usually isn't taught architecturally at school and

according to Freudenthal (1973) and his legacy it wouldn't be a good idea to do so either. One should be acquainted with a subject, with local orderings of its results and concepts before one should work on or be confronted with a global ordering of that subject. From this situation, namely teaching analysis in a different way, a didactical challenge arises: Find the role and meaning of the concepts and results to be taught with respect to the overall approach chosen, e.g. genetic, applicational or problem-oriented. In the axiomatic approach the concepts and results receive their meaning from their place within the system. The mean value theorem for instance occupies a central position within the system. It can be seen as the linchpin of the theory. Continuity is treated as a central concept. In a different approach, however, the roles and meanings of the concepts and results might be completely different.

A central concept developed and used by the German-speaking educational sciences in order to direct the discussion of school curricula is called 'Allgemeinbildung'. The concept elaborates on the functions of school and thereby it serves as a framework and a benchmark for the development and analysis of curricula. Each school subject is then requested to determine its individual contribution to the Allgemeinbildung. In Heymann's (1997, p.2) version of the concept, which is especially prominent in mathematics education, one major task of school is to teach the subjects in such a way as to endow cultural coherence, meaning not only the relationship between past, presence and future, which Heymann would rather have called 'cultural continuity', but also the interrelations of different subcultures. Analysis seems the perfect choice when trying to reveal the interrelations of mathematics and physics. However, even in mathematics itself there are subcultures or rather subdomains, whose relationship one should uncover. The didactical challenge, therefore, consists in discussing the unity of mathematics and asks the following questions: How is analysis related to geometry, how is it related to algebra? The first semester course on real analysis imagined hardly addresses this issue, since it rather focuses on presenting analysis as a self-contained subject.

Teacher students are usually keen to learn about pupils' misconceptions and the best recipes on how to treat them. It is important for them to notice, however, that the instruction itself may cause some of those misconceptions and that a different instruction, using for instance a different approach, may again cause quite different misconceptions. Thus, some misconceptions may be 'typical' in general, whereas some of them may only be 'typical' relative to a given instruction. It is an important didactical challenge to determine the misconceptions belonging to a certain instruction. Since every mathematics teacher student shares the experience of roughly the same first semester course on real analysis, it appears to be a good exercise to think about misconceptions that this course might favor.

In the preceding passages I have formulated three didactical challenges ('meaning', 'coherence' and 'misconceptions') and I have tried to indicate their importance for mathematics teacher students. These challenges form an integral part of my course on the didactics of analysis. My students, when confronted with these issues in the beginning of the course, have a hard time dealing with them. This is understandable, considering that their analytical background consists solely of a first semester course on real analysis. However, teaching a few episodes from the history of calculus, already helps them to handle the challenges in a much more appropriate and satisfying way. I will now, for each challenge separately, mention the results from the history of calculus that I teach and I will explain how they may contribute to the discussion on the respective challenge.

## Meaning – the integral integrates, the calculus calculates

What is the meaning of the integral? What is the meaning of the calculus in general? What is the meaning of the fundamental theorem of calculus? A mathematics teacher needs to be able to answer these questions in a satisfying way, since ‘how’ he teaches a certain subject or course should of course highly depend on ‘why’ he regards the content as being worth to be taught in the first place. In my view, the best way to approach these questions is to look at the prehistory of the calculus. Let us consider Roberval’s determination of the area (see Whitman, 1943) under the cycloid (Figure 1) and his comparison of the length (see Pedersen, 1971) of an Archimedean spiral with that of a certain parabola (Figure 2).

Figure 1: Roberval – The area of the cycloid

Figure 2: Roberval – The length of the Archimedean spiral

To solve the ‘area’ problem Roberval uses Cavalieri’s principle. To solve the ‘length’ problem he employs his kinematic approach to tangents (see Pedersen, 1969). Thus, the two solutions are based on two completely different methods. This is interesting, since in the world of calculus both, the length problem and the area problem, have become one and the same, in the sense that both ask you to compute some integral. Apparently the integral does what it promises. It integrates the two basic problems associated with a curve. Determine its length and its area. Of course the concept of the integral incorporates ‘volumes’, ‘centers of gravity’ and many other things as well. Wouldn’t this be one possible meaning of the integral that we might wish to convey to learners of mathematics? After all Poincaré once said (see Verhulst, 2012):

Mathematics is the art of giving the same name to different things. (Poincaré, 1914, p.23)

Let us now think about the meaning of calculus and its fundamental theorem. To this end, let us in addition to Roberval's two results consider Archimedes' quadrature of the parabola (see Dörrie, 1965, p.239) and Huygens' determination of the area (see Maanen van, 2003) between the cissoid of Diocles and its asymptote (Figure 3). After looking at these four problems and their solutions one might get the impression that before calculus every curve was treated individually, that at that time people were extremely well acquainted with the geometrical properties of these curves and that one had to come up with a new ingenious idea for every other curve. Today, on the other hand, it needs no ingenuity to solve these questions. With the calculus at hand, these problems have become more or less straightforward routine exercises. The routine goes like this: Formulate the problem in terms of an integral and apply the fundamental theorem, that is, look for an antiderivative and plug in the limits of integration. Finding an antiderivative might be a problem, but that is where the calculus with its powerful tools, integration by parts or by substitution, sets in. We could therefore view the calculus as a facilitation of a major part of mathematics. With calculus everyone has the chance to learn how to handle areas under curves. It seems to be exactly this meaning that Leibniz himself saw in his calculus:

For what I love most in this calculus is that it gives us the same advantage over the ancients in the geometry of Archimedes as Viete and Descartes gave us in the geometry of Euclid and Apollonius; by relieving us of working with the imagination. (as cited in Blåsjö, 2016, p.17)

**Figure 3: Huygens – The area of Diocles' cissoid**

## Coherence – calculus seen as the algebra for transcendental curves

Which of the following terms does not fit with the others?

‘Similarity of triangles’, ‘Thales’ theorem’, ‘Pythagoras’ theorem’, ‘differential equation’.

Of course the last term does not fit, since the first three terms belong to geometry, whereas the last term belongs to calculus. Huygens’ determination of the area of the cissoid, however, may cast some doubts about this decision. To the modern eye his problem might appear as a ‘calculus problem’. His method, on the other hand, is purely geometrical. Thales, Pythagoras and similarity (compare Figure 3), these are exactly the tools that Huygens employs. Calculus and geometry, this is the morale of Huygens’ result, are not as divorced from each other as the typical courses on these subjects might let one think. By looking for instance at Johann Bernoulli’s lectures on the calculus (Bernoulli, 1924) one realizes that differentials and their equations were just an additional tool incorporated into the old game of geometry. Thales, Pythagoras, similarity and a differential equation, in Bernoulli’s determination of the tangents to a cycloid (Figure 4) we have all this at one place.

Figure 4: Bernoulli – The tangent of the cycloid

We now turn to the relationship between calculus and algebra. A major challenge in teaching these two subjects coherently is to show where the algebra ends and where the calculus begins, that is, to

reveal their line of demarcation. At least according to Leibniz the line runs precisely between the algebraic curves and the transcendental curves:

As far as the differential calculus is concerned, I admit that there is much in common between it and the things which were explored by both you [Wallis] and Fermat and others, indeed already by Archimedes himself. Yet now the matter is perhaps carried much further, so that now those things can be accomplished which in the past seemed closed even to the greatest geometers as Huygens himself recognized. The matter is almost the same in the analytical calculus applied to conical curves or higher: Who does not consider Apollonius and other ancients to have had theorems which present material for the equations by which Descartes later preferred to designate curves. In the meantime the matter has been reduced to calculation by the method of Descartes, so that now conveniently and without trouble that can be done which formerly required much effort of contemplation and imagination. In the same way, by our differential calculus, transcendentals too, which Descartes himself excluded in the past, are subjected to analytical operations. (as cited in Blåsjö, 2016, pp.16-17)

In this picture the relationship between geometry, algebra and calculus is beautifully simple. At first we have the Euclidean geometry with compass and ruler only. Then Descartes allows some other kinds of construction tools, which on the side of the equations correspond exactly with the algebraic curves. This world can be studied by means of algebra. Leibniz, finally, goes even further and includes modes of constructions that allow also transcendental curves to enter geometry. Algebra falls short of these curves and calculus is needed. A good way to experience this situation is by starting with Descartes' double-root method for finding normals and tangents and by trying to get as far as possible with this method. This is performed in detail in (Range, 2011). One first of all shows that there is a unique line through each point of the graph which intersects the graph at that point with multiplicity at least 2. Then one generalizes this fact to rational functions and finally to algebraic functions. When it comes to transcendental functions, of course, one gets stuck. It is at that point, that one has to generalize one's definition of tangent. It is at that point, where the 'limits' come into play.

### **Misconceptions – tangents require limits, areas require rectangles**

Instead of Descartes' double-root method we might also consider the notion of tangent that Euclid employed in his third book when dealing with the circle:

A straight line is said to *touch* a circle which, meeting the circle and being produced, does not cut the circle. (Euclid, 1956, p.1)

How far can we get with this notion? If we take the notion literally, it already fails when confronted with a parabola, since through each point of a parabola there are two different lines that have only one point in common with the parabola, one of them being a line parallel to the axis of symmetry of the parabola. We can, however, rule out these parallels by requiring the tangents to stay on one side of the parabola. This leads to the following modification of Euclid's definition: A line, which has a common point with a curve, is called *tangent* to that curve, if the curve lies on one side of the line and if it is the only line through the common point with that property. Huygens, for instance,

worked with this notion, as one can see in his work on the cycloid (see Aarts, 2015, pp.3-4). For convex curves this notion works fine, but already in the case of such a simple non-convex curve as the cubical parabola ( $f(x) = x^3$ ) not one single point would have a tangent according to this notion. However, for all but one point on the cubical parabola, the problem is easily resolved by only requiring the curve to stay locally on one side of the line. The point not covered by this extended notion is the inflection point. It seems that we have to give up on Euclid's notion of tangents ultimately when it comes to inflection points. Arnold Kirsch, however, has shown in (Kirsch, 1960a) how to overcome this obstacle. After defining *smoothness* of convex functions by means of the modified version of Euclid's notion of tangent, he goes on to define smoothness of functions in general essentially as follows: A function is *smooth* in some point, if the function lies locally between two smooth convex functions that both go through that point and that share a common tangent at that point. In (Kirsch, 1960b), Arnold Kirsch shows that this notion of *smoothness* is equivalent to our usual notion of differentiability. This is certainly an interesting result, since it clashes with the widespread belief that one needs the concept of *limit* in order to define differentiability and tangents in general.

Another major misconception I come across among teacher students more often than one might imagine is the belief that one can determine areas associated with curves only by means of the Riemann integral or rather by exhausting the relevant area with rectangles. This conception seems to consolidate itself in the course of the received instruction, since children, which have not yet been 'enlightened' by a course on calculus, apparently still use all kinds of figures, triangles, trapezoids, squares or whatever suits, in order to cover the area in question. Against this background it seems important to elaborately discuss examples such as Archimedes' quadrature of the parabola (see Dörrie, 1965, p.239), which uses triangles, or Huygens' determination of the area of the cissoid (see Maanen van, 2003), which uses trapezoids and triangles instead of the notorious rectangles.

## Summary and discussion

In this article I have shared my approach on how to address three major challenges ('meaning', 'coherence' and 'misconceptions') in a course on the didactics of calculus for future high school mathematics teachers. In order to discuss the meaning of the calculus I provided the students with results from Roberval and Huygens, which show firstly, what can be done even without calculus and secondly, how much insight is needed for this. In this way the students may see and appreciate the calculus, just as Leibniz apparently does, as a 'mechanization' of geometry. It should be critically noted that the historical episodes chosen play within geometry and due to this we have left the meaning of calculus for other branches of mathematics and especially its role in Newtonian physics completely untouched. In order to show the coherence between calculus and geometry I offered some examples from Bernoulli's lectures on the differential calculus. To this end it is also worthwhile to consider two different rather recent geometrical approaches (Apostol & Mnatsakanian, 2002 and Kaenders & Kirfel, 2017) to the integration of the basic functions, treated in high school. Both of them, the sweeping-tangent approach by Apostol and Mnatsakanian and the approach using geometrical transformations by Kaenders and Kirfel link calculus and geometry each in their own way. To show the coherence between calculus and algebra I focused on the

difference between algebraic and transcendental curves, especially by maxing out Descartes' double-root method. Finally, regarding the misconceptions, I tried to point out that some of them might be 'instruction-generated'. For example, I showed that generalizing Euclid's notion of tangent can lead to a 'limit-free' general notion of tangent, a fact that seems to clash with the calculus related beliefs of many students. By way of the three didactical challenges I tried to show that and to indicate how courses on the didactics of mathematics may benefit from a selective and targeted recourse to the history of mathematics.

## Justifying a calculation technique in years 3 and 6

Renaud Chorlay

Laboratoire de didactique André Revuz (EA 4434), UA, UCP, UPD, UPEC, URN; France

[renaud.chorlay@espe-paris.fr](mailto:renaud.chorlay@espe-paris.fr)

*In this progress report, we present the outline and the first results of a research project which aims to study the argumentative capacity of year 3 (age 8) to year 6 (age 11) students, in a numerical context involving natural and decimal numbers. This project centers on a technique for dividing natural numbers by two, a technique which appears in Al-Khwarizmi's Kitāb al-ḥisāb al-Hind.*

*Keywords: Al-Khwarizmi, primary school, operations, place value, proof.*

Preliminary remark: This paper is a progress report on an ongoing project. In Chorlay (forthcoming), which was written before the first classroom experiments were carried out, we presented in some detail the historical background, the general motivation, and elements on the *a priori* analysis; these will only be sketched here. Our main goal is to present some of the empirical data gathered, and discuss the theoretical tools which can help us analyze them.

### **Rationale.**

#### **Historical background.**

Although Al-Khwarizmi is usually remembered for his treatise on algebra and quadratic equations, he also wrote several other books for which the oldest manuscripts available now are Latin translations. In particular, in his *Book on Indian Reckoning* (*Kitāb al-ḥisāb al-Hind*), he introduced into the Arabic-speaking scientific community a technique to write whole numbers (the decimal place value system), and written calculating techniques relying on this conveniently uniform coding system; techniques for addition, subtraction (with the borrowing method), *mediation* and duplication (i.e. division and multiplication by 2), multiplication, division, and square root extraction (with mediation as one of its steps). Although he found these in the Indian mathematical and astronomical traditions, it should be noted that they were also in use in Chinese mathematics.

Both the book on algebra and that on Indian reckoning were first translated into Latin in the 12<sup>th</sup> and 13<sup>th</sup> centuries, more often than not by scientists working in Andalusia with a prime interest in astronomy. For a recent study on these treatises, we refer the reader to Allard's edition and French translation of the three oldest extant Latin translations/adaptations of the lost Arabic text (Al-Khwarizmi, 1992).

#### **General didactical motivation.**

For reasons which we will spell out below, we thought the algorithm for *mediation* (i.e. division by 2) could be used in mathematics education research, in order to study phenomena which have no direct connections to the use of history of mathematics in the classroom. In a general report on the future of mathematics education published in 2003, a French study-group headed by Pr. Kahane stressed that:

(...) Most of the reckoning algorithms whose teaching and learning took so much school-time are now available in the most basic calculator. By contrast, new questions emerge, in particular about the digital representation of the mathematical objects on which they bear (such as numbers), and about the efficiency of algorithms (beyond their correctness) ... question which were not issues in teaching until now. The calculating power of the new tools (...) calls for renewed investigations into the connections between calculation and reasoning, and fosters exploration, simulation and experimentation. (quoted in (Charnay, 2007, p. 204). Our free trans.)

On this basis, Roland Charnay suggested that the main interest of studying written calculating techniques was that they provide

opportunities to work on the properties of numbers and operations by focusing the greater part of the effort on understanding and justifying these algorithms (...). This requires that we do not content ourselves with a *technicist* teaching (bearing on the *how*), but endeavour to justify the various steps and their connections (the *why*) ... and actually *do* mathematics! (Charnay, 2007, p. 206. Our free trans.).

Of course, these statements call for qualification: on the one hand, it would not be fair to say that the justification of numerical algorithms played no part in teaching, even in elementary school (for instance, see Clivaz (2016) and Constantin (2017) for recent investigations into teacher practices and mathematical-knowledge-for-teaching with regard to the justification of reckoning techniques). On the other hand, it is likely that some familiarity with calculation routines is a prerequisite to entrust students with *meta*-tasks – “*meta*” in so far as do not bear on specific numbers or numerical problems, but on mathematical procedures; procedures which are to be described, reformulated, compared with others, assessed, or justified (Chorlay, 2016). In this context, the procedures change status: from epistemic tools (i.e. answer-generating tools, which can, in themselves, be black-boxes) to epistemic objects (i.e. question-generating objects). It should be pointed out that, as stressed in Chorlay (2016), this change of status allows for the insertion of justification tasks in the larger set of meta-tasks. One of the underlying macro-hypothesis is that enculturation of the students into the class of meta-task could be a viable pathway to the teaching of the specific and highly demanding meta-task “prove”.

### **Al-Khwarizmi's technique.**

The three oldest Latin texts expound variants of the same technique. The *Dixit Algorismi* reads<sup>1</sup>:

To divide any number by two, begin with the first place and divide it by two. If its number is odd, divide the pairs [or: the even one] in two halves, and there will remain one to be divided by two – that is, to be divided in two halves – and you shall set one half, which is a fraction of thirty

---

<sup>1</sup> *Cum volueris mediare aliquem numerum, accipe a prima differentia et media eam. In qua si fuerit numerus impar, media pares, et remanebit unum quod mediabis, idest divides in duas medietates, constituesque medietatem unam triginta partem ex sexaginta (...). Deinde mediabis sequentem differentiam, si fuerit numerus eius par. Et si fueris impar, accipe medietatem paris et pone eam in loco eius, et constitue medietatem unius residui quinque, et pone eos in differentia que est ante ipsam. (...) et similiter operare in universis differentiis.* (Al-Khwarizmi, 1992)

out of sixty (...). Then, you shall divide by two the next place, if its number is even. If it's odd, take half of the even one and put it in its place; set 5 as half of the remaining unit and put it in the place before. (...) Operate the same way for all places. (Al-Kwarizmi, 1992. Our trans. based on Allard's translation into French).

No justification for this specific technique is given, but the three manuscripts provide justifications for most of the others and probably consider this one to be self-explanatory. Even though the meaning of “first place” is ambiguous in this excerpt, it is not in the treatises: it denotes the units; so, if we write the number in today's standard form, the algorithm works from right to left, from units to tens, then to hundreds etc. When applying the technique to 92, one can display the successive states of the slate as the shown in the boxes below:

92 [2 ® 1] 91 [9 = 8+1; 8® 4] 41 [carry 5 to the right, 1 ® 6] 46

In square brackets, we described the operations to be carried out either on the slate (® for “erase and replace”) or mentally (decompose<sup>2</sup>, carry).

From a purely mathematical viewpoint, the validity of this algorithm rests of the fact that halving a sum is the same as summing the halves (which can be seen as a special case of the distributivity of ' over +, if we agree to count “one half” as a number), on the multiplicative linearity of the “halving” and, eventually, on the canonical decomposition of whole numbers in a place value system. The fact that we are working in base ten is reflected in the “carry 5 to the right” rule: a “1” digit in the second place stands for “ten”, so its half is 5 units; a “1” digit in the third place represents one hundred, which is 10 tens, so its half is 5 tens etc. If numbers were written in base 4, the technique would be the same except for a “carry 2 to the right” step. Resting on the same mathematical bases, this algorithm is structurally similar to the other “Indian” algorithms: you don't need to consider the number as a whole; rather, you iteratively apply the same procedure to every digit, which means that you can process any whole number as long as you can process 1-digit numbers. A more detailed analysis can be found in Chorlay (forthcoming).

## First report on the experiments.

### Outline of the experiments and theoretical background.

The fact that this technique is not known to French students, but rests only on the basic principles of the decimal place-value system (namely: place value, and the “exchange rate” of 10 between two adjacent places<sup>3</sup>) led us to assume that it was fit to be used to investigate whether or not *meta*-tasks – including “justify” – could be entrusted to young students. In school year 2017-2018, we designed teaching experiments based on this material and tried it out in a year 6 class (1<sup>st</sup> year of middle-

---

<sup>2</sup> Or “subtract one”, or “consider the predecessor”, or “take the greatest even number less than (or contained in) 9”.

<sup>3</sup> The validity of the algorithm also rests on the distributive property, a property which is not taught explicitly before year 7 in France. However, the distributive property is used *in act* at very early stages in the study of multiplication, either in mental calculation, or in the standard written techniques. We assumed that the distributive property of “halving” would “go without saying” for students, that is, would neither be mentioned nor questioned explicitly.

school in France, students aged 11) and in a year 3 class (students aged 8). A key difference lies in the fact that year 6 students know decimal numbers, whereas year 3 students do not. Indeed, in the experiments, year 3 students typically said that halving 3 is impossible – or cannot be carried out completely accurately – whereas all year 6 students said that half 3 is 1.5.

For the researchers to gather data, students were asked to produce written traces of their individual reflection. These worksheets were collected, and the collective phases were video-recorded. The experiment took place in ordinary classes of about 25 students each. The class was taught by the regular teacher (or maths-teacher in year 6); the teachers had been associated to the design of the sessions from the outset. The researcher was present but played no active part in the sessions.

We have no room here to present the specifics of the teaching sessions, which differed for year 3 and year 6 students. To put it in a nutshell, the starting point was a silent performance – on the blackboard, by the teacher – of a few instances of mediations along Al-Khwarizmi's technique, with even whole numbers, some with even digits only, some with odd digits as well. Over the course of the sessions, the various tasks entrusted to students were:

1. Make hypotheses as to the function performed by the algorithm (that is: division by 2).
2. Emulate the technique with new even numbers (with or without odd digits).
3. Write (for year 6 students) or describe orally (for year 3 students) the method shown.
4. Justify its correctness.

Before we focus on points 3 and 4 (which, as we will see, were not treated independently by most students), let us mention a few empirical results regarding points 1 and 2. Regarding point 1, even year 3 students guess very quickly that it is a halving technique. When asked how they could test this conjecture, they suggested the following three correct techniques: add the output with itself and compare with the input; multiply the output by 2 and compare with the input; subtract the output from the input and compare with the output; they had not yet studied Euclidean division. By contrast, few students managed to identify the procedure for the treatment of odd digits (that is: subtract one, halve the result<sup>4</sup>, and add a carry of five to the digit of the output immediately to the right). Thus, tasks 2 turned out to be significantly more difficult than task 1.

As far as points 3 and 4 are concerned, we wanted to investigate:

- A. What – if any – knowledge about the decimal place value system was used by students to describe, then make sense of or justify the algorithm.
- B. What forms of justification – if any – did students supply.

In our investigation into A, we relied on the work of Frédéric Tempier (2016) who, after Christine Chambris, regards “tens”, “hundreds” etc. as a system of (non-independent) units. In his analysis of the work of students at the end of primary school he identified four interpretations of numbers written in standard form: 1. Juxtaposition of identical units (584 seen as 5 units, 8 units and 5 units); 2. Place-value juxtaposition (the student is able to read in terms of “hundreds”, “tens”, and “units” but with no functional connection between these terms); 3. Simple units (584 seen as 500 units plus

---

<sup>4</sup> Or: halve the greatest even number contained in (less than) the odd number; halve the number before/the predecessor.

80 units plus 5 units); 4. System of units (“units”, “tens”, “hundreds” are seen as units, and relationships such as  $1 \text{ hundred} = 10 \text{ tens} = 100 \text{ units}$  are available). Of course, when dealing with numbers (either in rewriting tasks, as studied by Tempier, or to justify mediation), interpretations 1 and 2 are not functional, whereas interpretations 3 and 4 are. A key aspect is that many students tend to regard written calculation as a black-box operating *only* on number *signs*, and indeed, the strength of place value systems lies in the fact that the algorithms can be described (and applied) as series of graphic operations bearing on written signs; of course, applying these techniques rests on properties of one-digit numbers, properties which are usually to be learnt by heart for an efficient and routine use of the technique. In the following, we will not consider the use of memorized numerical facts bearing on one-digit numbers to be indicative of an engagement in justification.

As far as argumentation is concerned, our starting point is the seminal work of Nicolas Balacheff (1987). He distinguished between two forms of “proof”: pragmatic proof (by actually performing and checking) *vs* intellectual proof (through a discourse bearing on object, thus dependent on means of representation of the objects). He also considered a hierarchy of forms of argumentation: naïve empiricism (check on a few cases), *experimentum crucis* (the generality issue is considered, and addressed by checking a specially difficult or large case), generic proof (where the actions are performed on a specific object which is used as a representative for a class of objects, and one claims that arguments – or moves – hold – or can be performed – for all other cases “just as well”; see (Yopp & Ely, 2016) for a recent survey), the thought experiment (the action is described without being performed on a specific case, and the general properties are indicated in some other way than by the result of their use), and formal proof. This framework has since proved inspirational for many at an international level, also in works bearing on primary school mathematics (Stylianides, 2007). In recent years, Balacheff also suggested that we should distinguish between *explanation* (which strives for coherence) and *demonstration* (striving for a type of proof).

### A sample of results.

We will focus on the results for year 6, with occasional asides about year 3. After silently carrying out several mediations on the blackboard, the teacher staged a first collective discussion on the nature of the results. Once a consensus had been reached on the fact that it worked out halves (or divided by two) the teacher asked students to work on individual worksheets for 5 minutes. The two questions were: 1. “A schoolmate of yours has not seen the teacher carry out this operation and would like to divide by two as he did. Write down the method for him.” 2. “Justify each step of the method”.

One student – we will call him K – gave a remarkable answer; an answer which is actually quite close to that of the medieval treatises:

1. First write down the number that you want to divide by 2. Consider the number of units<sup>5</sup>, if it’s even write down its half, if it’s odd take away 1, write down its half. You add “.5”. Move on

---

<sup>5</sup> Strictly speaking this is incorrect, at least for numbers greater than 9. The correct version would read: the unit digit.

to the number of the tens, if it's even write down its half under it<sup>6</sup>, if it's odd we take away 1 from the number; write down its half under it, and add five to the number that came before. Do the same for the hundreds, the thousands, the millions.

2. It works because even numbers are divisible by 2, and odd numbers are even numbers +1, so we work out the half + 0.5.  $1:2 = 0.5$

Beyond its thoroughness and clarity, this answer differs from all the others in the sample in three significant ways. First, K is the only one who gave separate and clearly distinct answers to questions 1 and 2, thus distinguishing between the algorithmic-imperative and the justificatory genres of text. As we will see below, all the other students gave a single answer, and inserted elements of “justification” as they described the technique. Second, he is the only student who anticipated the adaptation of the technique to odd numbers. Third, we claim that the numerical facts he relied on put him in Tempier’s category 4. In the written worksheet, he resorted to decimals to make sense of the role of “5”, but in the second session, while commenting on a mediation of 256 on the occasion of which another student claimed that “half of 5 is 2.5” but was unable to explain why a “5” should be added to the 3, he explained that “duh! In fact it’s simple, because, for real, it’s not 2.5 but 2.5 *tens*, so ... .5 is for units”. The recordings show that, when the teacher asked the class if they agreed that “2.5 tens” was equal to 25 (which had been suggested by another student to clarify K’s remark), he stirred puzzlement in many, even disbelief in some students.

By contrast, the written work of other students shows no distinction between the expression of the algorithm and attempts at accounting for / explaining / justifying the steps; on the basis of the written traces, we hypothesize that the approach of most students was: 1/ endeavour to devise a technique to divide by two (without using Euclidean division), 2/ check whether or not it gives the correct results, and 3/ compare it with the teacher’s technique. In year 6, for lack of a preliminary phase enabling us to assess whether or not students were able to emulate the technique for new even inputs, we cannot say whether they regarded looking for their own technique as the only possibility, or as something which they took to address the “justify” question. The low level of identification of the technique in year 3 (where it was tested independently of its written description), and the absence of a divide between the “describe” and the “justify” answers suggest that the first alternative holds for a large majority of students. In year 6, besides K, only two students clearly stated the “add five to the right” step in their description, without any justification though.

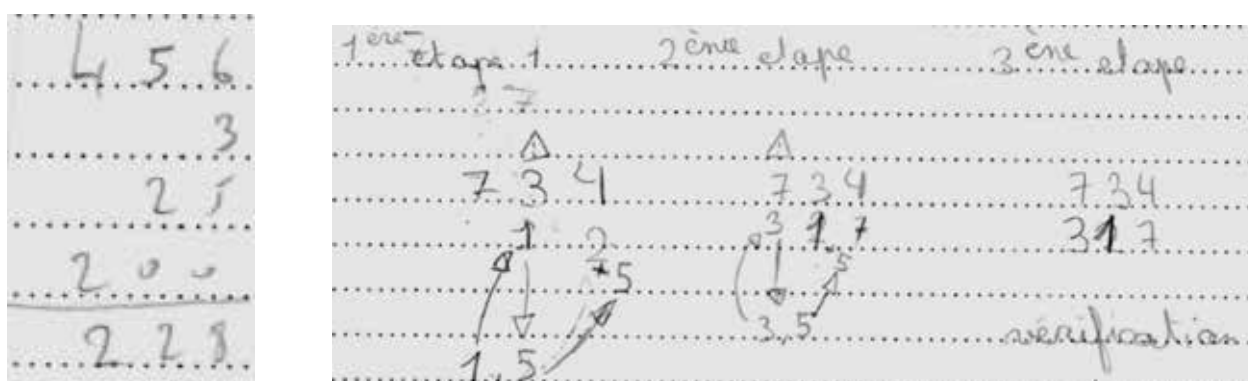

Some students tried to devise a written technique for mediation by adapting steps or moves they were familiar with in other calculating techniques. In year 6, 3 out of 24 students tried to use the “bridge-trick” from their technique for Euclidean division; for instance, in order to divide say 345 by 4, you start from the left and try to divide 3 by 4; since you can’t, you try to divide 34 by 4 etc. Unfortunately, in mediation, this trick works in cases such as 834 (one half of 4 is 2, one half of 3 – stop, one half of 34 is 17 [probably from mental calculation], one half of 8 is 4, so half of 834 is 417), but not so well with several consecutive odd digits. This can be seen in some students’ worksheets, for example when dealing with 334. In year 3, student G suggested a mediation

---

<sup>6</sup> On the blackboard, the output of the algorithm was written under the input.

technique which used the “borrowing” trick from the subtraction technique he knew: to divide 9014 by two, starting from the left, write 4 (half of 8), and in 9014 write 10 instead of 0 (“because we took away 1 from 9”), so the half is 5 etc. This is a correct and efficient techniques, but not Al-Khwarizmi’s. We did not investigate whether G was able to justify this “trick” on the basis of numerical properties, or just performed a graphic operation which he considered legitimate because 1. It was already in use in class (in another context, however), 2. It worked.

Let us finally compare two other suggestions. To do this, we will use the notion of *unfolding* of a numerical algorithm. We will call an unfolding of algorithm X, the description of another algorithm X’ along with: 1. A (possibly crude) description of how its steps are related to that of X, and 2. Indications that its connection to X’ *accounts* for X; as we will see below (analysis of C’s unfolding), we consider that accounts *can* but *need not* be justificatory. This notion emerged from our analysis of Liu Hui’s first justification of the correctness of the technique for fraction multiplication in the *Nine Chapters* (Chorlay, 2017): he described a longer algorithm than the one actually performed, but which necessarily gives the same results (the extra-steps it involves neutralize one another) and whose correctness rests on explicit general properties of multiplication.

**Figure 1: Worksheets of students L (left) and C (right)**

L’s method (fig. 1 left) rests on a type 3 decomposition (in Tempier’s framework), as his oral explanations in session 2 showed: “3 is the half of 6, 25 is the half of 50, and 200 is the half of 400”. So he devised a correct technique for mediation and was able to justify it by mentioning valid and relevant properties of the numbers involved, which we take to be indicative of a proof by generic example. We have no way to say if he only looked for a mediation technique (which he managed to justify), or actually considered this to be an unfolding of the teacher’s technique.

The technique used by C (fig.1 right) is correct in so far as it leads to correct halves, and is clearly an unfolding of Al-Khwarizmi’s technique, embedding it in a larger algorithm involving calculations (with decimal numbers) and a “carry five to the right” step. She described her diagram as something which shows what she “did in her head” when applying Al-Khwarizmi’s technique. However, we do not take C’s correct unfolding to be of a justificatory nature, since, when asked why the .5 in 1.5 and 3.5 could be used as a “+5 to the right”, she mentioned no numerical properties. She justified her moves by saying that writing 1.5 under 3 was “impossible” (meaning: this is not a proper standard form), so she just wrote 1; and the fact that the output had extra “5”s (although in the “.5” form) could account for the move she had identified in the technique: “carry

five to the right”. So she unfolded the technique as a graphic algorithm dealing with number signs, and her unfolding achieves *coherence* (between what she knows about halves of one-digit numbers, and the steps of Al-Khwarizmi’s technique), without providing proof.

### Perspectives.

Let us mention three alterations considered for a new round of classroom experiments in 2018-2019:

- Since a large share of students (even in year 6), fail to identify the “carry 5 to the right”-step, it should be made explicit before any attempts to entrust students with description or justification tasks.
- Asking for written traces helps the researcher gather data, but has several drawbacks: 1. Many students are not willing or able to engage in this writing tasks, which results from a combination of cognitive (in particular when comparing students of different ages) and social factors (Bautier & Goigoux, 2004). 2. As the cases of L and C show, the extent to which written traces testify to an actual engagement in justification is difficult to assess without a follow-up interview.
- We would like to study how students assess the various “arguments”.

# New Math at primary schools in West Germany – a theoretical framework for the description of educational reforms

Tanja Hamann

Universität Hildesheim, Germany; [hamann@imai.uni-hildesheim.de](mailto:hamann@imai.uni-hildesheim.de)

*To describe the implementation of New Math in West German primary schools (known as “Mengenlehre”/“set theory” up to today) in the 1970s, a framework model is developed. The model shows an educational reform as a two-dimensional process, characterized by a chronological as well as an institutional dimension wherein for the latter the educational system is divided into four layers. The model is introduced and specified when used for the description of New Math. Suitability of the framework for this suggests that it might be well transferable to the historical description of further educational reforms.*

*Elementary school mathematics, elementary school curriculum, history of mathematics education, New Math.*

## Initial questions and aim

In West Germany the New Math movement had a massive impact on mathematics education at primary schools from 1972 on, especially regarding the curricular contents and classroom methods of elementary instruction. The most remarkable innovation was the introduction of concepts from naïve set theory to young children and the use of materials such as colored blocks (the most famous being the *Logic Blocks* credited to Z. P. Dienes) in the classroom. However, there is still a broad consensus within a considerable part of German society that the reform failed miserably. A subsequent valuation whether the reform, its concepts and implementations were “any good” cannot be accomplished nowadays as there exists hardly any empirical data from back then. A statement whether “*Mengenlehre*” must be considered a failed experiment from the historical point of view, though, would require a thorough definition of the concept of “failure”, which – as far as the author of this paper is aware – does not exist in this context. An estimation of the historical significance of New Math within the development of primary mathematical education in Germany is yet to be given.

Hitherto, existing analyses of the reform in the Federal Republic are widely limited to works by contemporary witnesses, naturally lacking historical distance (Damerow, 1977; Zumpe, 1984; Keitel, 1980, 1996), and short summaries as part of general overviews of the historical development of primary education (e. g. Padberg, 2011). The need for a broader account that allows a historical grading of the “*Mengenlehre*” reform and a well-founded verdict on its historical impact and role within German mathematics education is obvious. Any judgement from a historical point of view requires a comparative integration of the event into a broader context, and this again requires a description of the historical event first. The challenges one meets when taking up the description of the introduction and implementation of New Math in West German primary schools must be considered typical, as they are inherent in any reform within a public educational system. The aim of this paper is to introduce a theoretical model, which provides a framework that has proven

suitable for describing the case of “*Mengenlehre*” reform. It will then be shown how the model has been used for this purpose.

## A framework model for the description of educational reforms

A reform is never an isolated event, but a process bound in a multitude of influences (general cultural and societal conditions as well as current developments) and outcomes, and for describing it numerous aspects and directions – or dimensions, as will be the term used in this paper – must be taken into consideration and be structured in a sensible way. The obvious dimension is the chronological one as a reform does not happen in an instant but in a certain timeframe. Not only is there an initial situation as well as an aftermath, but the reform period itself takes time and in the course of events ideas, conditions and actions might be subjects to change. But especially in the case of governmental reforms there is another, non-chronological dimension, which might be called the institutional one. Numerous protagonists act on diverse institutional levels and layers and thereby take an active part in the course of reform. These institutional layers do not function independently, but they influence each other in a certain way. So altogether, the description of a public educational reform must consider multi-dimensionality of reforms. In order to allow describing the institutional dimension a model is needed, which identifies separate layers and their respective protagonists.

H. Fend (2008, pp. 30-33) has developed a model for the educational system consisting of four (more or less) separate layers that influence each other from top to bottom. In his model Fend assumes that the protagonists on each of the levels interpret the ideas, that are covered in products from the respective level above, from their very own point of view, in their own specific contexts, and that this re-interpretation always necessarily leads to substantial changes, shortenings and adjustments. He denotes these changes and adaptations as “recontextualizations” (p. 13). The four layers in Fend’s model are the following:

1. the layer of **culture**: within each cultural sphere certain ideals of education exist and from these educational objectives are generated
2. the layer of **curriculum**: educational aims serve as starting point, from which subjects and contents are deduced that seem suitable to meet the aims; products on this layer are curricula as well as textbooks etc.
3. the layer of **practical schooling**: this is the layer where teachers plan and perform their lessons regarding the specific nature of their students
4. the layer of **reception**: pupils (and their parents) comprehend and assimilate contents in their specific, subjective way and make sense of it

Fend has generated his model in the context of his studies in educational sociology, it is therefore not fully applicable to the history of mathematics education. It serves as a suitable starting point but needs to be adjusted to the subject of educational reform.

As the model considers the educational system as one, the subjects play a minor role. Educational research institutions appear as part of the layer of curriculum where their function is limited to a descriptive one, whereas their normative function in designing educational concepts is not

mentioned. Looking upon the educational system from a subject didactical point of view the scientific discipline as well as didactical research and design need an evident place within the model, and regarding New Math this applies even more, as on the one hand the reform has been grounded on subject science to a high degree and on the other hand mathematics educationalists were widely responsible for designing practical concepts, courses and textbooks. Hence, it is obvious that (despite some overlappings) there is a considerable difference between the protagonists responsible for writing curricula (mainly personnel in politics and administration) and those writing textbooks. Due to their importance for classroom practice mathematics didactics is given a layer of their own.

Science in general is part of culture putting it on the layer of culture. However, it belongs to a global kind of culture, that is not limited by a community's borders. Undoubtedly, national culture and traditions in general are highly relevant for any educational reform within a nation's borders but they comprise such a vast number of aspects that they cannot be described in detail within the frame of a work like this and are therefore neglected. Mathematics as a theoretical discipline is different from didactical science regarding the latter's practical implementations and the former's function in providing a basis for the latter's work. That is why the two scientific branches must belong to different layers. Of course, the scientific subject is not the only discipline educationalists refer to when designing their concepts, educational sciences like pedagogy and the psychology of learning play an important role, as well.

As mentioned before, when it comes to New Math contemporary empirical data is scarce and gathering an amount of data to be able to describe the layer of reception in a satisfying way (e. g. by interviewing former pupils) is certainly a desideratum in due research, but as it cannot be part of this work either the layer is integrated in the layer of school practice in this case.

From all these specifications in consideration of an educational reform derive the following adapted layers of the educational system:

1. the layer of **theoretical scientific discipline**: institutions and protagonists on this layer are scientists from subject and educational science; their products are subject-specific foundations, scientific theories for example on the development of knowledge etc.
2. the layer of **curriculum**: institutions and protagonists are personnel from politics (e. g. from the ministry of education) and administration, sometimes educationalists as far as they contribute to decisions concerning curricula; their products are curricula, syllabi, decrees etc.
3. the layer of **classroom concept**: institutions and protagonists are subject didactics, textbook authors (these can be teachers, as well), editors and publishers of schoolbooks etc.; their products are textbooks, workbooks, teacher's handbooks, manipulatives, suggestions for instruction etc.
4. the layer of **practical schooling**: institutions and protagonists are schools, teachers in classroom, pupils, parents; their products are lessons, learning progress, knowledge as well as tests, written tasks, exercise books, portfolios, reports and so on

As for personal overlaps between the layers (i. e. someone acts on more than one level) it is assumed that the actor's function is a different one on each layer and that they must recontextualize their own ideas in another context, as well.

On each of these layers the chronological dimension additionally comes to effect. If we stick to the top-down model developed by Fend, the adapted model can be visualized as follows, the arrows meaning “recontextualized by”.

**Figure 1: Adjusted layer model**

This framework model now allows concretization dependent on the specific reform that is about to be described, the sources that have been selected and the focus chosen. Guiding questions that are implicitly suggested by the model are:

1. What central aims and/or ideas (on content, didactical principles, methods, curriculum concept...) can be deduced from the products of each layer?
2. How can one characterize the process(es) of recontextualization between the different layers?
3. How did ideas and concepts develop and change over time?

## **New Math in West German primary schools – sources, focus and findings**

### **Choice of sources and focus**

We are already dealing with a model naturally underlying diverse reductions. Nevertheless, further reductions become mandatory when one chooses exemplary sources for each layer and decides on a focus.

It has been mentioned before that sources for pupils' (and parents') reception of “*Mengenlehre*” courses are scarce, the same is true for the whole layer of practical schooling, therefore this part of the educational system will not be the focus. From a subject didactical point of view the layers on

which scientific personnel is most active – that are the layer of theoretical scientific discipline and, at least in the case of New Math, the layer of classroom concepts – seem the most relevant, that is why the emphasis will be laid on these. By this, the layer of curriculum gets assigned the role of an intermediary, which is relevant, if one wishes to describe the recontextualization that has been taking place between the other two layers, so that it must be looked at, as well.

In this case however, analysis of curricular documents leads to a specific difficulty, based on the German federal system, which involves that issue of curricular documents belongs to the federal states' field of responsibility. Hence, the number of syllabi that has been generated during the time of reform cannot be surveyed at once, and there is no work yet giving the due overview of primary school curricula in the way Damerow (1977) has provided of secondary school curricula. There are few nationwide documents, though, which must be taken into consideration. Explicitly concerning mathematics as a school subject, there are two directives on behalf of the *Kultusministerkonferenz* (the common conference of the federal states' ministers of education, referred to in figure 2 as KMK), the first one from 1968, which at the same time is seen as the starting point of reform in Germany, and the second one from 1976. In order to get an impression of at least one example of federal state curricula (*Rahmenrichtlinien*, referred to in figure 2 as RRL), those of Lower Saxony were chosen. The latest of these syllabi shows a massive decrease of the concept of “*Mengenlehre*” and therefore, its year of release, 1984, marks the terminal of the time axis.

Of course, the sources for classroom concepts are numerous, as well. Due to the facts that during the New Math reform primary school textbooks were written by mathematics educationalists and that they were widely accompanied by teachers' handbooks giving explicit insight into aims, concepts, didactical foundations and methods intended, samples from textbook series provide adequate sources for the layer of classroom concept. Here, the sample that has been chosen for thorough analysis of conceptual elements comprises 1<sup>st</sup> grade materials from three textbook series.

The textbook series are *alef* by H. Bauersfeld et. al. (1970), *Wir lernen Mathematik* (“We learn mathematics”, referred to in figure 2 as N & S) by W. Neunzig and P. Sorger (1968) and *Mathematik in der Grundschule* (“Mathematics in primary school”, referred to in figure 2 as F & B) by A. Fricke and H. Besuden (1972). *Alef* is a textbook series that derived from the only large-scale empirical project in the history of New Math in Germany, namely the *Frankfurter Projekt*, in the course of which children were educated with specially designed all new materials throughout their elementary school years. *Wir lernen Mathematik* was the earliest textbook containing “*Mengenlehre*” to be released in West Germany, even earlier than the first *Kultusministerkonferenz* directive, and thus it holds a special role in the process of the reform. *Mathematik in der Grundschule* has been chosen because it initially appeared in pre-reform times and has then been adapted to the reform standards. Of all three textbook series several editions exist, which are compared and thus contribute to the question how concepts developed and changed along the time axis.

As for the layer of theoretical scientific discipline, pedagogy has usually not been a point of reference for “*Mengenlehre*” concepts, so there is no need to consider the subject of pedagogy any further. Scientific mathematics, especially the Bourbaki work, is said to have had a big impact on

the global New Math movement but going into the scientific subject any further would lead astray. A major impulse to the start of reform activities within Europe is attributed to the seminar, which was organized by the OEEC (precursor of the OECD) and took place in Royaumont, France, in 1959. The seminar was attended by high school teachers and university mathematicians, who put a strong focus on how modern scientific mathematics could find its way into school, turning them into protagonists from the layer of theoretical scientific discipline. So, the report from the Royaumont seminar (OEEC, 1961) serves as source for the influence of scientific mathematics and according to the impact of the event, the date of the seminar serves as starting point of the time axis.

Another discipline the authors of textbooks have constantly referred to is the psychology of learning. Especially the landmark findings and theories by J. Piaget (e. g. Piaget & Szeminska, 1965) were most prominent. J. S. Bruner on the other hand has had a big influence even on modern day German curricula and his theories, which emerged in pre-“*Mengenlehre*” time, as well, were well-known. One of the biggest influences on primary school math certainly was Z. P. Dienes. Dienes is not easily allocated to one of the layers as he provided a vast amount of concrete classroom examples. As he never created a complete course, though, but rather provided theoretical foundations for German courses which partly arose from his own psychological research, Dienes is assigned to the scientific layer, as well.

From the above the general model can now be specified as it is filled with names of the documents that serve as sources for the description of New Math in West German primary schools. The arrow indicates the focus on the process of recontextualization from basic ideas and concepts as they can be derived from the layer of theoretical science to their concretization in textbooks on the layer of classroom concepts.

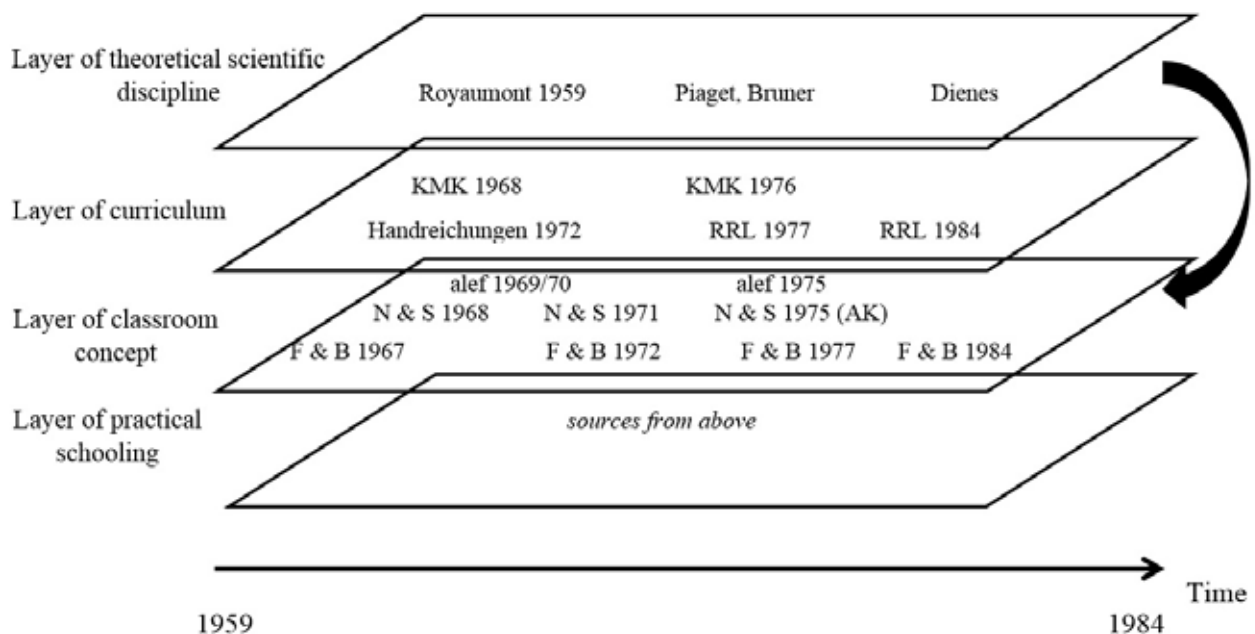

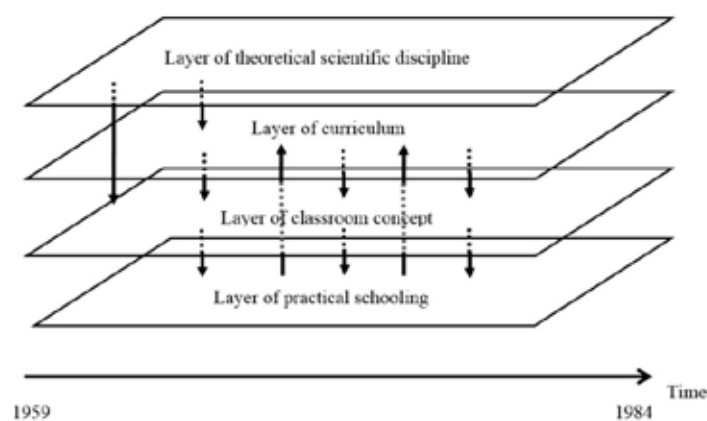

Figure 2: Layer model filled with sources used for the description of “*Mengenlehre*” in West Germany

## Findings<sup>1</sup>

Regarding the focal question for recontextualization of the scientific roots of reform it becomes obvious that the extent to which original ideas have been implemented differs. Altogether they have not been fully transferred to textbooks, but the authors of each course have selected a certain part and by this, shortened the original concept towards their own respective purpose. Bauersfeld comes closest to the ideas from the scientific layer but in this case, he was forced by decisions coming out of the curriculum layer to apply changes to his concept. The shortcomings that are caused by the incomplete transfer of the original concept altogether lead to diverse inconsistencies in the implementation of “*Mengenlehre*”. Independently of what happened on the layer of practical schooling, this finding even allows us to state that New Math at West German primary schools has indeed been a failure, and as educational reforms never go without recontextualization processes there is a high probability for extensive innovations in the classroom to fail according to this definition of failure.

Another finding concerns the influence of the layer of practical schooling. The sources suggest that teachers’ customs, beliefs and attitudes, along with an education that did not meet the demands presented by New Math, proved as an obstacle in classroom. Many parents are said to have had reservations towards reform, anyway, and these most probably increased as soon as things were not implemented according to plan. Presumably, one political reaction to this was a change in curricula, which in turn led to a change in textbooks and therefore, regarding recontextualization processes along the time axis, one finds that the process of reform cannot be described using a top-down-model. Instead, within the framework model, mutual influences rather must be pictured the following way:

**Figure 3: Layer model showing the process of reform**

In this case, even though the original model did not prove fully suitable for a description of New Math in West German primary schools, it still served as a useful device for illustrating the process of reform.

<sup>1</sup> This paper presents an extract from a bigger research project. Due to the focus that has been set here findings can only be displayed in a strongly abridged way. For details and a complete account of the sources see Hamann, 2018.

## Conclusion

It was the aim of this paper to introduce a framework model for description of complex educational reforms from a historical point of view. As for the example of New Math in West German primary schools, the model proved suitable for providing a restricting frame, a helpful device for structuring the work and a starting point that could be adjusted according to the process of the reform. It therefore allowed relevant findings which may function as a ground on further research on the topic. All of this suggests that the model of recontextualization might be suitable for historical studies on other educational reforms, as well.

# Relevance of mathematics journals for Dutch teachers in the 18<sup>th</sup> and 19<sup>th</sup> century

Jenneke Krüger

Utrecht University, Freudenthal Institute, Utrecht, Netherlands; [j.h.j.kruger@uu.nl](mailto:j.h.j.kruger@uu.nl)

*Mathematics teaching took place long before the formation of teacher education institutes and university courses for mathematics teachers. Very little is known about the ways teachers acquired the necessary knowledge and skills before the mid-19<sup>th</sup> century. In the Netherlands, from the late 16<sup>th</sup> century on, a tendency is noticeable to have all children taught reading, writing and increasingly often some arithmetic. Moreover, as was the case in England, there was an expanding group of mathematical practitioners who needed some knowledge of the relevant mathematics. Consequently there were many small schools with lowly paid primary teachers, and there were many private mathematics teachers and small private schools where some mathematics was taught. In the 18<sup>th</sup> and 19<sup>th</sup> century many journals were published in the Netherlands, including mathematics journals for teachers. In this paper the relevance of such journals for teachers' improvement of their mathematical skills and position in society is discussed.*

*History of mathematics education, mathematics journals for teachers, primary schools, teacher examinations.*

## Introduction

In the process of teaching and learning mathematics, the mathematics teacher is an important actor; consequently his/her skills, Mathematical Content Knowledge (MCK) and Pedagogical Content Knowledge (PCK) are the subject of a body of research. Analysis of three historical Dutch cases of mathematics education shows, that already in 1600 the relevant mathematical knowledge and pedagogical qualities of the mathematics teacher were considered very important for the successful implementation of mathematics curricula (Krüger & van Maanen, 2013; Krüger, 2014, pp. 463-474). The question arises how mathematics teachers in the past acquired the necessary knowledge and skills to be successful. Recent research on this topic is often concerned with the present educational structures, restricting itself to the late 19<sup>th</sup> and the 20<sup>th</sup> century, e.g. (Candeias, 2017; Menghini, 2017). However, in Europe as elsewhere, mathematics was taught for centuries before the creation of the present stable educational structures, with its formal teacher education institutes. The Netherlands form a rich case for several reasons:

- Starting in the late 16<sup>th</sup> century, a drive to teach all children reading, writing and gradually also some arithmetic, in combination with a complete absence of central regulation of education, until 1806. There were no teacher training institutes until the 19<sup>th</sup> century, very few until the 20<sup>th</sup> century.
- A relatively high demand for mathematics teaching, due to the growing number of mathematical practitioners (navigators, geometers, wine gaugers, engineers, etc.), who one way or another, had to learn the relevant type of mathematics.
- An abundance of publishers of journals, from the late 17<sup>th</sup> century onwards. Many printers and editors were active in the Netherlands, not only in the larger cities, but also in the smaller towns.

Thus journals, relatively low priced and flexible, could play a role in the dispersal of knowledge for teachers. The first mathematics journal for teachers was published in 1754, probably the first journal for this specific group in Europe (Gispert, 2018). On the topic of mathematics journals for teachers, recent publications mainly concern the second half of the 19<sup>th</sup> century or later, when teacher education institutes were established, e.g. (Furinghetti, 2009; Oller-Marcén, 2017). Preveraud (2015) published a paper on mathematical journals, published during the first half of the 19<sup>th</sup> century in the USA and instrumental in the transmission of French mathematical education to American higher and secondary education. The present paper concerns mathematics journals for teachers in primary and advanced primary education, in the 18<sup>th</sup> and early 19<sup>th</sup> century. Secondary education was not formally part of the educational system until 1863 (Boekholt & De Booy, 1987; Krüger, 2014).

The number of mathematical journals aimed at teachers increased during the first half of the 19<sup>th</sup> century. With regards to the question “How did Dutch teachers of mathematics acquire their knowledge before there was formal teacher education?” the focal question of this paper narrows to *“Which role did mathematics journals have in the acquisition of knowledge by Dutch teachers in the 18<sup>th</sup> and early 19<sup>th</sup> century?”*

The main method of research is analysis of a limited number of journals from the period (1754-1835), with regards to the occupation of the subscribers, the topics treated and the style of treatment. These journals are included in the database of Cirmath<sup>1</sup>.

### **Mathematics: a boost for the teacher’s career, 1750-1800**

In the 18<sup>th</sup> century nearly every village and each town in the Netherlands had at least one primary school, a so-called ‘Dutch’ school, supervised by the local council and the local reformed church, in which children could learn the catechism, reading, writing, and usually arithmetic. There were also many private schools with often more advanced primary education, with a few more mathematical subjects, so-called ‘French’ schools, and there were private schools for specialized mathematical instruction. Subjects taught in these small mathematics schools depended on the specialization of the instructor: algebra, geometry, geography, surveying, navigation, bookkeeping, fortification, astronomy, architecture, etc..

Being knowledgeable in mathematics had several advantages for teachers in primary schools: improved results in the comparative exams for the better paid teaching posts, the possibility to give private lessons to students or to start a French school or even a specialized mathematics school and thus to improve one’s income in several ways (Krüger, 2018, 2). One could also combine working as a mathematical practitioner with teaching. Most aspiring teachers lacked the financial means and the required knowledge of Latin to study at a university. So their main means to learn mathematics were private lessons and self-instruction.

A teacher at a Dutch school usually had a very low salary, supplemented by the fees parents paid for each subject or part of subject taught to their child, by chores for the church and other jobs, e.g. gravedigger. As parents were encouraged, but not obliged, to send their children to school, the

---

<sup>1</sup> *Circulation des mathématiques dans et par les journaux:* <https://cirmath.hypotheses.org/>

income varied through the year, with in rural areas a severely diminished income in the summer months. In the more expensive French schools the pupils were also taught French and other subjects, such as advanced arithmetic, bookkeeping, geometry, algebra, geography and drawing and the fees were paid for longer periods. A consequence of the lack of a national curriculum and of national teacher qualifications was a large variation with regards to the level and quality of instruction between the various Dutch schools and also between French schools.

### **The teachers and their journal**

Working as an assistant-teacher was the usual way to start a teaching career. When there was a vacancy in a Dutch school, local councils usually required a comparative examination, in writing, reading from the Bible, singing hymns and increasingly often in mathematics. Mostly arithmetic, but by the mid-eighteenth century in the western part of the country there were also exams covering several mathematical subjects (Krüger, 2018). Those exams were often set by a teacher, either the departing teacher or from a school in the vicinity. Examples of such examinations, with different levels of mathematics (*Mathematische Liefhebberye*, 1754, 1755):

- On 24 November 1754 in Lopiker-Kapel, a small village in the province of Utrecht (in the middle of the country), the exam consisted only of reading from the Bible and singing a hymn. It was not a well paid position, only assistant-teachers applied.
- On 8 December 1754 in Oost-Zaan, a small town in Holland, near Amsterdam, 4 teachers took part in the examination, which included ten arithmetic problems.
- In 1751 in Purmerend, a slightly more important town in the same area as Oost-Zaan, a new town's schoolmaster and cantor was appointed after a strenuous exam, consisting of fourteen questions on arithmetic, twelve questions from geometry (plane and solid), ten problems on navigation and six problems on spherical trigonometry.

From 1754-1769 Pieter Jordaan, librarian in Purmerend, published the first Dutch mathematics journal for teachers, a monthly with news of primary schools (vacancies, examinations, etc.) and a section on mathematics, *Mathematische Liefhebberye* [Mathematical Pastimes]. Each month mathematical problems, from the editor and the readers, were published, as were solutions to problems published in previous months, also from the readers, sometimes discussed by the editor. The mathematics editor until 1765 was Jacob Oostwoud, teacher in Oost-Zaandam, surveyor, mapmaker and author; he was succeeded by Louis Schut, also a teacher. A specific goal of the editors was support for teachers who were inexperienced in mathematics, by more experienced teachers and practitioners. In total 3000 problems were published, apart from the questions of the local examinations for teaching posts, also published frequently. There was some theory, on topics such as arithmetic theorems, series and probability. More than 100 subscribers, amongst whom a few women, were active in sending questions and even more sent solutions. The problems mainly came from existing publications, recent ones, but often from the 17<sup>th</sup> century as well. German authors were a favourite source; later on English journals were mentioned as origin of some problems. Over the years a wide range of topics was addressed, arithmetic and algebra, but also geometry (calculations and constructions), both plane and solid geometry, simple problems in probability, navigation problems (spherical trigonometry) and maximum-minimum problems, solved by means of a new technique, differentiation. Obviously arithmetic and algebra were important subjects for all teachers, and there is a large range of topics which may be put under these

headings. Simple questions, for beginners, modelling of a situation, resulting in equations or systems of equations from linear up to the fifth power, series, proportionality, also in mechanics, mixtures of substances, distances travelled (Krüger, 2018).

The journal may be seen as an example of informal teacher training, by experienced teachers and practitioners. It gives the impression of eagerness and a combination of learning and recreation. The journal offered problems from elementary mathematics to fairly advanced mathematics and the editors positively encouraged readers at all levels to join in.

### **Mathematics: obligatory for primary teachers**

From 1795, with the proclamation of the ‘Bataafse Republiek’ [Batavian Republic], a process of centralization was set off, also for education. The first Dutch constitution (1798) mentioned ‘national education’, there was mention of responsibility of the national government for education and in 1806 the first national law on primary education was accepted. The law and its regulations specified amongst many other matters the subjects which had to be taught (reading, writing, arithmetic and Dutch language), the required content knowledge for primary teachers and the obligation to pass an examination, also in mathematics, as a prerequisite for a teaching post. Primary school teacher was on its way to become a profession.

The teaching certificate recognized four ranks of male teachers; there was only one rank for women. For the lowest rank (4) one had to show reasonable skills in reading, writing and basic arithmetic, with whole numbers up to and including simple proportions (rule of three). For the third rank the candidate had to show for mathematics also skills in calculations with fractions and in use of calculations in problems from daily life. For the second rank the candidate should also have theoretical knowledge of arithmetic; for the first and highest rank, one had to show proficiency in mathematics and science, amongst other things. For each rank there were other requirements as well, for example level of teaching skills, knowledge of geography, etc. The mathematics exam always had a section on theory and practice of arithmetic, in whole numbers, fractions and decimal fractions and problems pertaining to daily life (for rank 1-3). As an addition one could take exams in specialist subjects, such as languages or advanced mathematics. The primary schools were ranked as well, with the salary in accordance to the rank of the school. A teaching rank 1 or 2 gave the right to be appointed at the highest ranked and best paid schools. So any primary teacher with ambition tried to reach at least second rank. The first rank was rather sparingly handed out by the regional examiners (Boekholt & de Booy, 1987, pp.109-110).

So this law put in place formal requirements on a national level for primary teachers, male and female, in order to improve education for all children. The teachers would get payment from the council and classroom teaching to groups of similar abilities was introduced. Regional school inspectors, appointed by the national government, would see to enforcement of legislation; they encouraged modern teaching methods and actively strove to improve the quality of teachers. However, it took a long time before the changes became reality in all parts of the country.

Secondary education continued to be privately organised with French schools and specialist schools. Latin schools, also called gymnasia, where mainly the classics were taught as a preparation for university, were from 1826 obliged to provide instruction in mathematics, following at least a minimal curriculum (Smid, 1997). At some gymnasia a primary teacher of first rank was engaged to

teach mathematics, as often the professors at the Latin schools looked down on mathematics and/or didn't know enough to teach the subject.

### The teachers and their journals

In order to become a teacher in primary education, the usual way still was to find a teacher with whom one could work as an apprentice, while in the evenings studying for the examinations. The assistant-teacher was now called 'kwekeling' or 'secondant'. To improve the content knowledge and pedagogical knowledge of primary school teachers, the government promoted the formation of local teacher societies [onderwijzers gezelschappen], whose members were inexperienced teachers as well as experienced teachers and school directors. They had regularly meetings to discuss the subjects and teaching methods (Boekholt & de Booy, 1987, p.111) and practiced for the teacher's exams. The teacher societies started small libraries, with textbooks and journals. Mathematics journals, which had as explicit aims improving the mathematical and pedagogical knowledge of teachers in primary and advanced education, were published from the 1820's. They can be classified into four categories: journals on general mathematics; on arithmetic; on arithmetic, algebra and geometry; on mathematics and sciences. Only the first three categories will be discussed in this paper (Table 1).

**Table 1: Dutch mathematics journals for teachers, 1820–1850**

<i>Tijdschrift ter Bevordering der Mathematische Wetenschappen (TBMW)</i> [Journal for the Improvement of Mathematical Sciences]	1823–1828
<i>Magazijn voor de rekenkunst (MR)</i> [Magazine for the arithmetic art]	1828–1835
<i>Bijdragen tot de beoefening der zuivere wiskunde (BBZW)</i> [Contributions to the practice of pure mathematics]	1829–1833
<i>Magazijn voor stel- en meetkunst (MSM)</i> [Magazine for algebra and geometry]	1830–1835
<i>Bijdragen tot de beoefening der gewone cijferkunst (BBGC)</i> [Contributions for the practice of simple arithmetic]	1831–1840
<i>Tijdschrift voor reken-, stel- en meetkunst (TRSM)</i> [Journal for arithmetic, algebra and geometry]	1839–1842
<i>Nieuw tijdschrift voor reken-, stel- en meetkunst (NTRSM)</i> [New journal for arithmetic, algebra and geometry]	1843–1847
<i>Tijdschrift der toegepaste rekenkunst voor onderwijzers en gevorderde leerlingen (TTR)</i> [Journal of applied arithmetic for teachers and advanced pupils]	1850–1852

These journals existed usually between four and ten years; often with a change of editor(s) a journal got a new or slightly different name and so became a new but very similar journal as its predecessor. For example one of the first journals in the 19<sup>th</sup> century with many teachers among its subscribers, was the Journal for the Promotion of Mathematical Sciences, or TBMW for short<sup>2</sup>, on general mathematics. It was published by J.P. Bromstring in Purmerend; the editor was Jacob (Jan)

<sup>2</sup> In this paper the abbreviations, introduced in Table 1, will be used, to save space.

van Cleeff, mathematics teacher at the Academy for Drawing, Architecture and Navigation in Groningen (Beckers, 2003, p.77). In 1823 there were 250 subscribers listed. In the last volume the readers were informed that Mr van Cleeff had decided to discontinue as an editor, due to his workload, however there would be a new journal with Hendrik Strootman, subscriber and contributor to TBMW, as editor. This new journal was BBZW, also on general mathematics; the number of subscribers had increased to about 420. Hendrik Strootman taught mathematics at the Royal Military Academy, since 1828 situated in Breda. From 1830 this journal was published in Breda. Another example is the succession of TRSM by NTRSM. The editors are unknown, but the publisher and format were the same for both journals.

All journals in Table 1 were quarterlies; they all published problems and their solutions, usually also other forms of content, such as articles and reviews of books and they encouraged subscribers to send solutions and new problems. The subscribers, usually listed in the first volume, are differentiated in four categories: educators (teachers, assistant-teachers, mathematics teachers, teacher societies and school inspectors), other occupations, including military, no occupation mentioned and booksellers. The two journals on general mathematics, TBMW and BBZW, treated similar topics as are found in the 18<sup>th</sup> century journal for teachers. However, in the 18<sup>th</sup> century the journal was aimed at teachers (and other practitioners) who were also ‘lovers of mathematics’; presenting mathematics as both useful and a pleasant pastime was usual in the 18<sup>th</sup> century in the Netherlands. This attitude shows in the interactions with the readers, which is lively and frequent. In the 19<sup>th</sup> century mathematics was less seen as a pastime, it was, for teachers, military and other practitioners, a serious requirement for their profession. All teachers had to learn at least some mathematics, whether they liked it or not, and the more the better from the point of view of career. The style of the journals was modern; the solutions of problems were clear and well formulated, the theoretical articles, if present, were usually well written. If sources were mentioned by the editors, they were from recent authors, such as De Gelder, Lacroix, Floryn and Prinsen, who were comfortable with the new, more exact style of mathematics and with modern teaching methods.

Another difference was the absence of women. In 18<sup>th</sup> century journals on mathematics most subscribers were males, but there were a few subscribers recognisable as women who occasionally sent problems and also solutions. Though the law on primary education stated that ‘primary education is taught by teachers of both genders’<sup>3</sup>, the lists of subscribers was invariably titled: ‘the gentlemen subscribers’. Mathematics was by now a very serious and consequently male business, women who wished to subscribe may have done so through a bookseller, remaining invisible.

Between 40% and 50% of subscriptions was ordered by booksellers, it is as yet not clear why so many ordered their copy through a bookseller. Of the personal subscriptions TBMW and TRSM both had around 70% working in education. TBMW aimed at practitioners and teachers, TRSM aimed at inexperienced and experienced teachers of Dutch and French primary schools. For the other journals this percentage was between 44% and 61%. It is remarkable that for all journals, irrespective whether they aimed specifically at teachers, up to 16% of the personal subscriptions was taken by other professionals (military, skippers, farmers, bookkeepers, shopkeepers, notaries,

---

<sup>3</sup> Reglement voor het Lager Schoolwezen en Onderwijs binnen de Bataafsche Republiek 1806, art. 4

etc.). The first journal on arithmetic only (MR) was very popular. It was meant for student-teachers and advanced pupils in primary schools, as was BBGC. The journals on algebra and geometry, MSM, TRSM, NTRSM, were aimed at the teachers of French schools and the advanced classes of Dutch schools, with older pupils. They also served the teachers who studied for a higher certificate. Evidently, even if there was some specialization among the journals for teachers of primary schools. TTR was slightly different: it was meant for 'teachers, advanced pupils, farmers, builders, stonemasons, carpenters, painters, shipbuilders, etc.' It contrasted the 'high level of accuracy, the rigour of calculations in school' with the situation in the professional life, in which one had to be able to give a quick approximation, to work fast and to produce useful answers in calculations. Again, both teachers (presumably of older pupils) and professionals subscribed to this journal.

## Concluding remarks

From the mid-18<sup>th</sup> century mathematics journals, primarily meant for teachers, but subscribed to by other practitioners as well, were published in the Netherlands. In the 18<sup>th</sup> century mathematics was both a respectable pastime and a means to improve the situation of those teachers, who were prepared to learn mathematics; learning mathematics was each teacher's individual choice. *Mathematische Liefhebberye* set out to disperse and enhance mathematical knowledge among teachers in the 18<sup>th</sup> century. It meant to be a support for those inexperienced in mathematics by more knowledgeable colleagues, while also offering interesting mathematics for the experienced readers. From the early years of the 19<sup>th</sup> century, one consequence of efforts by the government to improve the quality and standing of primary school teachers was the obligation for all teachers to learn at least some mathematics and preferably more. Mathematical knowledge and pedagogical skills formed from 1806 on part of the requirements for all teachers. All journals discussed above had as their aim to further mathematical knowledge and skills among their readers, primarily through encouraging them to solve problems and send new ones, just like was the case with *Mathematische Liefhebberye*. In this way the emergence of an informal learning community was facilitated, with experienced and less experienced teachers. The very diverse and active group of readers with a wide range of mathematical topics of the 18<sup>th</sup> century made place for a more narrowly defined group of readers (though still with practitioners amongst them) less topics, more specialization, in the first half of the 19<sup>th</sup> century. A common focus of the whole period discussed is the driving force of mathematics exams. In the 18<sup>th</sup> century occasionally, for some vacancies and differing very much between towns; in the 19<sup>th</sup> century compulsory for all primary teachers, probably not that different from region to region, but with increasing demands for higher ranks. All journals provided material which could be used for teaching and catered for those who practised for exams. We conclude that these journals played an important role in the professional development of teachers.

*Tractional motion is an almost forgotten theory involving machines to geometrically solve inverse tangent problems. It was at the basis of Leibniz's development of calculus and interested many important mathematicians (e.g. Euler) mainly in the 17th and 18th centuries, before its disappearance because of the decrease of importance of geometric constructions. In this work, we analyse the exploration of a tractional motion machine using the framework of Theory of Semiotic Mediation. This is just a very first work in the perspective of introducing this kind of machine to students in order to mediate the meanings of transcendental curves and infinitesimal analysis.*

*Keywords: History of mathematics, tangent, mathematical machines, tractional motion, semiotic potential.*

### Introduction.

The use of historic machines is a well-established practice to mediate mathematical meaning (Maschietto & Bartolini Bussi, 2011). Specifically, many studies have been published about the construction of geometric curves as traces of both ideal and practical machines, but most of such studies focus on algebraic curves. In this work, we deal with an approach to transcendental curves with machines, that is *new*<sup>1</sup> in mathematics education. Such an approach, called “tractional motion,” was so relevant to the conception of infinitesimal analysis (e.g. for Leibniz, who designed in 1693 a material instrument to practically solve quadrature problems). As deepened in Tournès (2009), tractional motion mixed theoretical developments and concrete constructions of artefacts for the resolution of the inverse tangent problem. Those artefacts could be interesting for STEM education. In our approach, before proposing them to students, the analysis of cognitive processes of exploration by experts is necessary. In the paper, we aim to present the first elements of this analysis for a particular tractional machine.

### Brief history of tractional motion.

As clearly exposed in Bos (2001), in 17th century Descartes proposed a class of machines tracing algebraic curves as synthetic part of his method, and polynomial algebra as an analytical tool in order to simplify the problems. That determined a dualism between “geometric” and “mechanic” curves (in modern terms, algebraic and transcendental curves), being only the first one considered acceptable in the Cartesian setting. Soon after the spreading of Descartes' canon, mathematicians got habituated to polynomials, that became no longer an extremely important step for the problem solving, but directly the solution. In that period, there were only a few curves that were considered

---

<sup>1</sup>Such approach is not in use today, but it was already adopted in Italy by Giovanni Poleni in Padua (first half of the 18th century) and Ernesto Pascal in Naples (beginning of the 20th century).

“mechanic” (e.g. the quadratrix or the cycloid), but a new general method to generate curves beyond Cartesian limits was going to emerge. The main idea underlying behind such constructions was given by a problem proposed by the architect Claude Perrault in Paris in the 1670s. The problem was easily described: *if we move the end of a chain watch along a line slowly enough to avoid inertia, what curve does the watch describe?* Cartesian tools appeared powerless to answer.

In the case of Perrault’s watch, the motion is given by the traction of a cord: that gave the name to such constructions by “tractional motion.” The described curve (called “tractrix”) is constructed given its tangents: while the watch moves, the tangent to the obtained curve is given by the direction of the chain in traction. This is a new kind of tangent problem: instead of the classical tangent problem (given a curve, finding its tangent that satisfies certain properties), known at least since classical Greek period, this time the tangent properties are given, and the curve has to be determined as the solution. That’s the rise of “inverse tangent problems.”

But how can inverse tangent problems be concretely implemented? The reference to a heavy load having friction on a plane (as the watch) involved physical problems that should be kept away from the domain of pure geometry, e.g. the unwanted role of velocity (because of the inertia that the load acquires) or the non-perfect horizontality of the plane. It was missing a clear instrumental embodiment of the theoretical concept “driving the direction of a curve” (as a pair of compasses embeds the concept of equidistance): mathematicians as Huygens and Leibniz worked on it.

To sum up, after the habituation of mathematicians to consider polynomials as solutions, which brought to a loss of interest to machines for algebraic curves, at the end of 17th-century machines got a new importance; this time to justify the construction of transcendental curves (Bos, 1988).

In the 18th century, it was particularly interesting the role of Giovanni Poleni. Mathematician, physician, astronomer and also interested in engineering studies, Poleni (1729) proposed machines for the tractrix and the logarithmic curve, that were also built and used in cabinets for exhibitions and in teaching. In 1739, he obtained the creation, at the University of Padua, of a laboratory of experimental physics (“*Teatro di filosofia sperimentale*”) which was unanimously praised by his contemporaries. He took the opportunity to set up one of the first university courses based on laboratory experiments (previously, he had students coming to his home in his personal scientific cabinet). For this reason, Poleni got a particular attention to the design of his tractional machines: they were no longer only theoretical machines but also practical instruments guaranteeing an adequate usability and accuracy. In this period, curves like the tractrix or the logarithmic were well known and generally accepted, thus it was no longer necessary to justify their introduction as solutions to certain problems, but it became important to give them concreteness (something similar to the possible needs in today classrooms). The main component behind such machine was the introduction of the “wheel” to drive the direction of the curve (as in the front wheel of a bike). Poleni’s publication (1729) made a strong impression on the geometers of his time. Leonhard Euler (1736) read it and found in it an interesting mode of construction to address the differential equations that he could not integrate in finite form by algebraic methods. Among other results using tractional motion, Euler succeeded in integrating the famous Riccati equation, which had remained unsolved for a long time. From there, an epistolary dialogue continued between Euler and Poleni for

more than four years, revealing interesting interactions between theoretical and practical concerns (Tournès 2009, p. 95-96): in particular, at Euler's request, Poleni gave the description of an instrument for drawing the tractrix of a circle.

Following on from Euler's work, Vincenzo Riccati (1752) published in Bologna a treatise in which he demonstrates that it is possible to exactly integrate any differential equation using tractional motion. From a theoretical point of view, Riccati's work is the culmination of the ancient tradition of problem-solving through the construction of curves. Descartes had shown the construction of algebraic curves by a simple continuous motion using linkages. Riccati, for his part, established that transcendental curves can also be constructed by a simple continuous motion from the differential equations that define them.

After the middle of the 18th century, the theory and the practice of the tractional motion got rapidly lost. The geometric paradigm was no longer dominant, and new mathematicians were interested in exploring only the analytical counterpart of infinitesimal analysis. However, in the late 19th and early 20th centuries, a new generation of mathematicians and engineers reinvented essentially the same solutions of Poleni, increasing just the complexity of these instruments (the "integrators").

### **The tractional machine of our study.**

One of the most interesting features of tractional motion is the deep link between its instrumental and theoretical components. Specifically, the possibility of introducing some transcendental constructions from history to classroom might be mediated by the exploration of a machine.

Out of the tractrix, the most famous construction easily given by tractional motion is for the logarithmic (or exponential) curve. As visible in Figure 1 (left and centre), for tracing this curve, a machine can implement the property of having a constant subtangent<sup>2</sup>. Poleni, who designed and build a machine tracing the exponential, also evinced that one tractional machine could generate both algebraic and transcendental curves. That was a fundamental idea while conceiving our machine: according to the notation of Figure 1, if we change the direction of the wheel in the machine for the exponential (i.e. we put the wheel direction perpendicular to the segment QS), the machine traces a parabola (Figure 1, right).

More specifically, according to Figure 2, the machine<sup>3</sup> proposed in this study is made up by a horizontal wooden table with two parallel fixed wooden guides in which a wooden frame can slide. A brass cylinder is forced to remain within the frame, free to rotate and to slide perpendicularly to the two fixed guides. Inside the cylinder, there is a wheel perpendicular to the plane. The cylinder rotation is determined by a rod that is constrained to pass through a pin fixed on the frame.

---

<sup>2</sup>In a Cartesian plane, given a curve  $C$  passing through the point  $(x,y)$ , the subtangent to  $C$  in  $(x,y)$  is the segment between  $(x,0)$  and the intersection of the line tangent to  $C$  in  $(x,y)$  with the  $x$ -axis. Referring to the Figure 1, the subtangent in  $S$  is the segment  $QP$ .

<sup>3</sup>Simulations of this machine are available online: <https://www.geogebra.org/m/zrMyFGdd> (for the parabola) and <https://www.geogebra.org/m/LXugImiH> (for the exponential). This machine was introduced by Milici & Di Paola (2012) and described with more details in Salvi & Milici (2013).

### Artefacts in mathematics education.

Basing on previous works on the use of artefacts in mathematics education (for instance, the mathematical machines in Maschietto & Bartolini Bussi, 2011; [www.mmlab.unimore.it](http://www.mmlab.unimore.it) and [macchinematematiche.org](http://macchinematematiche.org)), the analysis of the machine proposed in this paper is carried out within the framework of the Theory of Semiotic Mediation (TSM) developed by Bartolini Bussi & Mariotti (2008) in a Vygotskian perspective. In this, a teacher uses an artefact as a tool of semiotic mediation for mediating mathematical meaning to students by managing didactical cycles (composed of small group work, collective mathematical discussion and individual work). The first proposed activity is a small group work with the artefact, because its use solicits a certain semiotic activity (where the signs can be language, gestures, drawings, ...) that is the base for the teacher's intervention. The exploration of the chosen artefact related to the educational objectives is carried out following four questions (Bartolini Bussi, Garuti, Martignone & Maschietto, 2011, p.128): "How is the machine made?", "What does the machine make?", "Why does it make it?", "What

could happen if ...?”. Within this framework, the choice and the educational use of an artefact is based on the analysis of its semiotic potential. In the TSM, the distinction between meanings emerging from the practice (use of artefact) and the mathematics knowledge evoked in the expert’s mind is very important. Mariotti & Maracci (2012) specify the notion of the semiotic potential of an artefact to make that distinction explicit:

By semiotic potential of an artefact we mean the double semiotic link which may occur between an artefact and the personal meanings emerging from its use to accomplish a task and at the same time the mathematical meanings evoked by its use and recognizable as mathematics by an expert. (Mariotti & Maracci, 2012, p. 61)

Our research questions are about if and how we could use the machine as an instrument of semiotic mediation with secondary school and/or university students. As in other research on mathematical machines, we intend to propose first a material machine rather than its simulation in a DGS, because we assume the relevance of the exploration by the hand (allowing touching, decomposing the machine, perceiving the resistance to movement or not, ...). In order to answer to those questions, the first step is the analysis of the semiotic potential of the machine, considering the description of the machine by an expert that already knows it on the one hand, and the exploration of the machine by other subjects, experts in other kinds of machines or university students in mathematics. In this way, we aim to analyse what kind of semiotic activity can emerge from the exploration and use of the machine. In particular, we focus on: which are the processes of exploration of the machine? Do people identify the role and the meaning of the wheel? How?

## **Methods.**

We have videotaped two exploration processes of the machine. We chose three people that knew the mathematical machines and the TSM, and were experts in mathematics but without any knowledge of tractional motion. The first exploration was carried out by two secondary teachers, following the structure of four questions that they knew very well. In the exploration, the researcher had to often put the attention on the wheel and its way of use, thus, for the second case, we began proposing only some components of the machine. The second exploration was performed by a postgraduate student in mathematics that studied mathematical machines during a university course. In this case, the machine has been disassembled and gradually reassembled by the researcher: first the cylinder with inside the rolling wheel (cf. Figure 2, (2) and (3)) is given free to move on the table; then the rod (cf. Figure 2,(4)) is added, in the two positions (parallel and perpendicular to the wheel direction); finally, the cylinder is put into the wood frame (cf. Figure 2, (1)).

## **Findings and discussion.**

The analysis is based on videotapes and drawings produced by the people exploring the machine. More specifically, we analyse the part of the two explorations in which people detect the movement and constraints of the wheel and identify the link between wheel and the line tangent to the curve.

### **First exploration: Alberto and Bianca.**

During the first moments of the exploration of the machine (corresponding to the first question, “how is it made?”), Bianca describes the machine but she does not seem to pay particular attention

to the presence of the wheel, even if she considers it as a component of the machine. When the machine is then used to trace (intentionally, the ways of use are not suggested to her), this lack of attention is evident by how Bianca acts on the frame and on the wheel: sometimes the wheel rolls and sometimes it slips, tracing a curve or a straight line. The resistance to the slipping of the wheel is not noticed by Bianca, who raises doubts on how to use the machine until the researcher intervenes by asking it explicitly (“Don’t you feel resistance?”), by specifying the principle of operation (“[the machine] works when the wheel turns”) and by explaining the relationship between the resistance and the constraint of the machine (“you’re forcing a constraint of the machine”).

The machine doesn’t seem to offer feedback sufficiently strong to actions that force the constraints; while forcing the wheel not to follow its direction, the resistance of the tyre is mixed with friction by other structural parts, such as the frame. This certainly is an important point to take into account for paying attention to the wheel as a new element, compared to other curve drawers (such as the ones using taut threads). To foster the identification of the role of the wheel in tracing the curve, the researcher asks to specify the physical constraints of the machine allowing that tracing; he also suggests a comparison with a tracer (which corresponds to the point of a pen) (“If, instead of the wheel, there had been a tracer, would it have been the same?”). The question corresponds to “What could happen if ...?” of our educational framework. However, it is a question that can be asked to expert people. Here are some excerpts of exchanges with Bianca, Alberto and the researcher.

- Alberto: It would have been different.
- Bianca: That is ...
- Alberto: Then, the wheel...
- Bianca: Yes, it would have been different.
- Bianca: If there is a point... that is a wheel...
- Alberto: It would slip, ... it would move randomly.
- Researcher: And, so, what must the wheel do?
- Bianca: It turns [laughter]
- Bianca: It must not slip, because if it slips ...
- Alberto: Turning without slipping.

Then, they turn their attention to the geometrical property of the machine. The relationship between the wheel and the tangent to the curve appears in terms of “direction.”

- Alberto: [The properties] of the tangent line, isn’t it? But physically ... I don’t know why it is physically ... that is, the small wheel gives the direction [*gesture by the hand*] that is not ... any direction to the curve.
- Researcher: And then, what do we know ... having the small wheel this direction? ... at the drawn point.
- Alberto: The curve must have that direction.

These excerpts show that the exploration is in discontinuity with the explorations of the curves drawers that Alberto and Bianca are familiar with. This seems to confirm the deep change quoted above from the epistemological point of view. The emergence of the link between the wheel and the tangent line to the curve is fostered by the researcher. However, some questions are not immediately understood by Alberto and Bianca, as they do not link the task and their personal meanings on curve and machine. The difference between rolling and crawling seems to emphasize such a change.

### **Second exploration: Corrado.**

According to researchers' queries, Corrado moves the cylinder with inside the rolling wheel (cf. Figure 2, pieces 2 and 3) on the plane and defines some properties of the traced curve with consciousness ("It is not constrained to stay on a straight line or a circumference or a parabola or a branch of hyperbole, if we let it free it can go up and down in every place. ... It traces a continuous line, [...] can do edges but without jumps"). When asked to describe more precisely his interactions to make the machine move, he immediately defines the two degrees of freedom. In terms of the analysis of the semiotic potential, we could affirm that the task links the manipulation to Corrado's personal meanings of the curve.

Unlike Bianca, when Corrado is asked to explore the fully reassembled machine, he seems aware of the mechanical resistance to certain motions, and he is able to interpret it in relation with the constraints of the instrument. Specifically, when the wheel is put in the vertex of the parabola, Corrado notices that the machine "resists" when he tries to move along the direction of the axis of the parabola. To explain such behavior, he puts his attention on the idea of direction: "[the machine cannot move that way] because it cannot [with a gesture indicates to move along the axis direction], it is constrained here [indicates the pin, component 5 of Figure 2], it cannot invert, get comfortable [with a gesture of the hand: change the direction] and trace, it has to stay this way and it is unnatural to draw [gesture: in the direction of the axis], it cannot rotate this way [gesture of the rotation of the wheel perpendicularly to the direction of the wheel]. It [the wheel] draws only while rotating and in the direction of its rotation." Later on, he is asked to characterize the traced curve that he identified as a parabola. Corrado is able to find independently the role of the tangent for the wheel: "if we hypothesize that this [with the hand indicates the direction of the wheel] gives the direction of the tangent, the wheel is always perpendicular to this rod and so ... [he looks for a conjecture on the tangent perpendicular to something, but doesn't find any]."

Therefore, as a very early conclusion, we can suppose that disassembling the machine eases the understanding of the constraints of the machine. However, we cannot affirm that disassembling can also ease the characterization of the curve because Corrado tried to verify that the traced curve was a parabola focusing on the points traced on the plan and neglecting tangent properties. This corresponds to another aspect of the epistemological change that characterizes the machine.

### **Concluding remarks.**

At our knowledge, this is the first empirical work aimed at analysing the semiotic potential of a tractional machine. As a first result, we can evince that the passage from algebraic to transcendental constructions, so groundbreaking from a historical and epistemological perspective, recalls also

very different abilities in the exploration (the explorations were not trivial even for experts of mathematical machines). In particular, the relation between the wheel and the tangent did not appear immediately, but the idea of disassembling the machine in order to investigate simpler components appeared quite fruitful (even though it requires to be much more deepened). This suggests a possible task, but this is not enough sufficient for constructing worksheet for students. What done is only a very first step in this direction. We need other experimentations to clearly define the mathematical contents to be mediated (tangents, derivatives, integrals, differential equations) and the level of the exploration (high school, university).

*The content of Adam Ries' book (1574) with the instructions to written arithmetic fostered an enlightening for citizens at this time since they learned how to calculate themselves making it obsolete to pay a "Rechenmeister" for this task. In the early modern times algorithms entered the industrial world by mechanical automatisms intended to take away the routines from people. Nowadays algorithms hidden in many technical devices have become a part of our daily procedures often staying unaware for people. The paper discusses the historical development of the concept of algorithm and its potential for mathematics and general education today.*

*Keywords: Algorithms, enlightening, fundamental ideas, mathematics education*

### A historical view on the mathematical aspects of algorithms

The history of algorithms as part of mathematics started in the very early days since the systematic solving of mathematical problems is part of doing mathematics. For example, during the Old Greek times Euclid (300 v. Chr.) gave a rule to calculate the greatest common divisor of two given natural numbers. Another well-known algorithm is the sieve of Eratosthenes, a step-by-step procedure giving prime numbers up to a certain given natural number. Several hundred years later it was Al-Khwarizmi who presented a number of mathematical applications for traders. These were translated into Latin with the title "Algorithmi" containing the artificial word "arithmos" that is derived from "number" and the name of the mathematician (cf. Chabert, 1999).

Hundreds of years later Adam Ries (1574) wrote a booklet on basic arithmetic operations which had great influence on the German citizenship at that time. In the year 1614 the Scottish John Napier published a book on logarithms which made him look like the inventor of logarithms. Leonardo da Vinci (1452-1519) as another significant personality of the Renaissance era demonstrated with the "Vitruvian Man" his understanding of proportions blending geometric descriptions with the Renaissance art. Another hundred years later Leibniz (1646-1716) used the binary code and algorithms on that basis.

In 1815 Augusta Ada Lovelace was the first woman to program for the (technologically underdeveloped) calculator of Charles Babbage (1791-1871). 1931 Gödel destroyed the dream of many mathematicians that all mathematical theorems can be proved by algorithms by his Incompleteness Theorems:

They imply that there is no algorithm with a finite number of steps that can decide if an arithmetic statement is true or false in all cases imaginable.

Furthermore, it is impossible to prove consistency for a formal system whose complexity is the same as that of the natural numbers.

In this context we also must accept an incompleteness of arithmetic:

There is no (finite) algorithm that proves the valid statements of arithmetic on the whole. (Ziegenbalg, 2010; translated by the authors).

Later on during the 20<sup>th</sup> century von Neumann and Turing provided the mathematical basis for computing with which they started the new era of computer science (Chabert, 1999, p. 457).

During the last decades the development of “artificial intelligence” progressed so rapidly that the nature of algorithms became in immense multiple ways complex (e.g. voice recognition, decision making systems). This development was possible because of rapidly advanced technical conditions which as a consequence offered an improvement in calculating speed and storage space. As an organizational form cloud computing brought enhancements.

Concluding this very short historical view on the successive appearances of algorithms through the centuries it becomes apparent that in former days they were documented in a written form by books with the aim of becoming public to scientists and citizens. Even in the case of military purposes, namely cryptography, the secrecy of the underlying algorithm was not considered appropriate. Only the "key" that gives details of a general – even public – encryption process had to be hidden, which is the subject of Kerckhoff's principle (Kerckhoff, 1883, p. 12). Nowadays the algorithms behind apps and programs often stay hidden because they are part of a business secret often with the idea to gain money. The question arises when exactly the balance turned from transparency to its opposite and how we can deal with this new situation. One can expect insight from sociological and historical analyses that are not yet been finally concluded.

### **Today's mathematical exactification and its impact on education**

During centuries an algorithm was understood as a series of instructions. The development algorithm's understanding led to distinguished properties.

#### **Steps towards formalization**

For the longest algorithms consist of a finite series of instructions to solve a given problem like it was apparent with the sieve of Eratosthenes. Generally accepted are also the following properties which led to a general view and that can be understood as postulates for algorithms (Saake et al., 2010):

- (1) The algorithmic procedure must end up with the same outcome in case of the same preliminaries.
- (2) Any next step to take is uniquely determined.
- (3) The description of an algorithm implies a finite length of the source text which needs to consist of a limited number of signs.
- (4) An algorithm is requested to have a limited storage space at any time during its procedure.
- (5) An algorithm stops after a finite number of steps.

For didactical purposes it is therefore clear what solving procedures fall under the concept of an algorithm. Like with the concept of sets there is a naïve version of it. And after being confronted with logical difficulties (Russell, 1903) the need of exactification became apparent and was solved in form of axiomatization. The naïve perception of algorithms has its limits, exactified by the work of Turing and especially of Gödel's Incompleteness Theorems. Both topics, sets and algorithms, finally lead to questions of cardinality and self-reference.

### **Didactical perspectives for math classes**

The idea of an algorithm appears several times in school in mathematics classes. On the elementary level the four basic written arithmetic calculations have algorithmic nature and are named as such in mathematics literature. In our daily practice we do not observe a very detailed reflective attitude; neither teachers nor pupils seem to reflect on their algorithmic nature. At the beginning of the secondary I level the well-known Euclidean algorithm is subject matter in class. Very often this is the first time that pupils get aware of the concept of an algorithm. It is regarded as a prototype of an algorithm since it is named like it.

Following the spiral principle other examples of algorithms occur on the secondary I level (in the German system meaning classes 5 – 10: the methods used to solve linear and quadratic equations as well as systems of linear equations. Typical examples on the secondary II level occur with curve sketching, finding extrema, points of inflection and other properties of functions. At this stage the systems of linear equations are again subject matter with an even more algorithmic procedure (Gauß algorithm).

In school algorithms also occur using a calculator or tablets including software for educational purposes. That is for example the dynamic geometry software (DGS; GeoGebra, Cinderella) and Computer Algebra systems (CAS). Nowadays Witzke (2018) uses 3D-Plotters in math classes on different levels to not only visualize mathematical objects but to materialize graphs and geometric solids. This means that algorithms generate didactical tools not only iconical, but even haptical.

Comparing all the mentioned school examples above very few are labeled explicitly as algorithms through the names as the Euclidean and the Gauß algorithm and are therefore more obvious to the pupils. The algorithmic character of other parts of the curriculum is also not easily recognized by the pupils. Even with algorithms whose names prove to be programmatic the teaching normally emphasizes the arithmetic acting and often fails to reflect upon the concept and the meaning of an algorithm. Furthermore, the use of the recently introduced tools in mathematics classes serve didactically as technical devices to manage some type of mathematical problems. However, several of them create some kind of didactical bubble. Some calculators for the secondary level are meaningful only for math classes.

### **Algorithms as fundamental ideas – alibi or truth?**

In 1905 Felix Klein (1849-1925) claimed functional thinking as a guiding principle for mathematics education which was implemented in the German curriculum through the last decades. Already in the seventies of the last century the importance of algorithmic thinking was claimed (Engel, 1977, p. 5). This was expressed in the light of the situation 40 years ago. Nowadays, there should be no

doubt that the situation became much more prominent. The fact that the relevance of algorithms is still not in the center of educational issues is apparent with the “German Bildungsstandards” (Ständige Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland 2004, 2012): On the primary level algorithms are not mentioned at all and on the secondary I and II levels some of the well-known procedures are classified as algorithms but mostly because of their repetitive character and not in terms of their entire meaning.

We observe a simplified and shortened understanding of the notion on the part of the pupils and teachers as well, in particular relating to its potential in science, society, economy and culture in general. The latter is only recently a subject of scientific research. In the last decades algorithms and their different mechanical realizations have infiltrated our whole life in various and subtle ways. They are omnipresent in every angle of our daily routines. Social networks (like Facebook) and search engines (like Google or Yahoo) are selecting, ordering and evaluating our data, our inputs and their results. Especially the selecting part based on evaluation is a sensitive issue that the companies and institutions have not made transparent, let alone to make an enlightening out of it. On the contrary, many companies admit that they hide the conditions of their procedures, and one often gets the impression of a conscious deception of the public. Advertisements are individualized simulating or pretending that some kind of care plays a vital role. However the companies gain money by using or selling our data and neutrality and objectivity became illusions.

### **The role of algorithms for general (math) education**

Since our daily life is influenced by algorithms in the ways described above the question arises whether mathematics education can play an enlightening role. The aim here is not only the listing of typical, historically well-known examples, but the task is to elucidate about the significance of the impact on all facets of society. Heymann (2013) emphasized general education in the light of fundamental mathematical ideas. He aimed at showing that the fundamental ideas indicate the universality of mathematics and their relevance for the “entire culture” (Heymann, 2013, p. 158) and this needs to become apparent for the pupils during their school life.

Here we follow the structure of Heymann’s frame of reference. The criteria include their relevance for the mathematical development and show the essential nature of mathematics:

- (1) Preparation of life;
- (2) cultural coherence;
- (3) global orientation;
- (4) critical use of reason;
- (5) sense of responsibility;
- (6) communication and cooperation.

There can be no doubt that algorithms affect our daily life in an increasing manner. Therefore, school and especially math classes need to prepare for this fact. Although it is apparent that different countries answer with different attitudes: Europe, primarily the European Union, looks for governmental regulations while the USA care less about rules. The Far East, that is predominantly

China, responds to the situation with even stronger governmental rules. In this light cultural coherence as an aim seems to be out-of-date, and, at the same time, the developed global view is an inevitable consequence of it. Hence the critical use of reason becomes more urgent than ever before. The sense of responsibility needs to be revised and also discussed and reflected in school. And this even more since the situation became much more complex and it is not easily apparent what is for the benefit of humanity and what will harm. Of course communication and cooperation stay important in this light.

### **Towards an implementation of algorithms in math classes**

Both concepts, the set and the algorithm, are simple enough to be presented on the primary level: a set as a Venn diagram (as understood within naïve set theory) and an algorithm as a series of instructions as in a cooking recipe. Therefore both can be represented on the enactive level (Bruner 1974) and are accessible for the iconic one. Their difference lies in the fact that sets can be regarded foremost as a static phenomenon simultaneously due to time, while temporal processing is in the nature of algorithms. In this sense they are complementary. On top of it the concept of sets plays a vital role in the succession of math classes (spiral principle) as the notion of algorithms could and should also (Bruner, 1976).

Closely connected is a theory of conceptual progression of mathematical concepts (Vollrath, 1987). Vollrath presents a didactical theory of learning and teaching mathematical terms. He outlines in general what kind of various steps lead to a certain understanding of mathematical notions:

- (1) Intuitive level;
- (2) content level;
- (3) integrated level;
- (4) formal level.

On the intuitive level the pupils have an idea of a series of steps as a first access to algorithms. This may be represented by game rules or cooking recipes. On the second level they explore typical properties of algorithms. Actually on the third level a network should be recognized on the part of the pupils. In the case of an algorithm we observe that the notion itself provides a conceptual network. We distinguish two levels of formulation: Firstly, there is an exact description of certain mathematical issues through algorithms represented by flow charts or simple programming languages. Secondly, the notion of the concept of an algorithm itself is to be formulized.

It is apparent that the exactification makes the idea of an algorithm accessible for pupils already during early schooling. It became apparent that the idea of an algorithm is rich enough to be taught on all levels with a shifting emphasis. Therefore mathematics education is obliged to prove again its self-established claim for general education. This needs to be done on the conditions of the presence and how they have developed.

## **Analysis on consequences for the teaching and learning of algorithms**

In early historical times algorithms started as a scientific insight on a mathematical problem and additionally gave information for a systemized solving procedure. Paul Ernest (2004, p. 5) describes it like this:

An example is provided by algorithms. These denote precisely specified sequences of actions, procedures which are as concrete as the terms they operate on. They establish connections between the objects they operate on, and their products. They are a part of the rich structure that interconnects, and thus helps to implicitly define, the terms, and hence the objects of mathematics. This must be relativized to the solver, for what is routine for one person may require a novel approach from another. It is also relative to a mathematics curriculum, which specifies a set of routines and algorithms.

At the very end of the middle ages when Adam Ries, standing at the brink of the abacus using concrete tokens and the decimal number system using symbols on paper, the arithmetic operations in form of a booklet had an enlightening impact on the citizens; an enlightening event that is surely not often recognized in history (Deschauer, 1992). It is an example of a practice through all these times when it was mostly the aim to inform, to get insight and to support people's solution practices.

In order to simplify the solving practices and to avoid mistakes, Babbage, for instance, designed a mechanical machine (1923). And, as soon as machines came into place, the questions also involved avoiding counting errors. Later on the development continued with electronic devices aiming at more and better efficiency which first was the storages place and later the shortening of time.

We observe that the chances of an enlightening process in today's society got at least diminished as soon as commercial ambitions entered the global scene and the hiding of information was part of the business practices. And now our so called informational society is confronted with many different "black boxes".

Here, mathematics and its didactics have a long enough history to feel responsible to undertake the task to clarify the situations and to offer enlightening insights. A view into history confirms once again that we do not observe totally new phenomena. Babbage dealt with a similar situation during the early 19<sup>th</sup> century. In his "Reflections on the Decline of Science in England", first published in 1830 (Babbage, 2013), he complained about scientific mishaps: He observed that scientific results were whitewashed: by trimming (levelling of irregularities), cooking (quoting of results which fit to a theory, omitting results that contradict) and forging (inventing of scientific results which fit a conventional meaning or can be fitting to a desired doctrine).

Concluding our observations on the development of algorithms and our analyses on their position today we notice that they bear only minor enlightening character anymore compared to former times. In order to answer to this situation there needs to be a focus in math classes on prototypes of today's computers. These elementary simplifications could make apparent that the programmed algorithms are combined with money-making commercial ambitions which have to do with

evaluating, selecting and, as a result, manipulating. This goes along with Freudenthal's idea of a guided reinvention within his concept of "mathematics as a human activity" (Freudenthal, 1983).

We do not favour teaching algorithms as it developed chronologically. This might be an interesting experiment, but would be naïve to push the analogies between ontogenesis and history of science to the limit. Instead of it we support a refinement of historical awareness and instruct students to pay attention to the conditions that caused today's appearance of algorithms – one of several possible implementations of a few fundamental ideas of mankind. This is what Paul Ernest (2015) calls the "postmodern perspective". According to Lyotard (1984), postmodernism can be narrowed to scepticism towards meta-narratives. Since different fields focus on and deal with unlike sometimes divergent ideas and phenomena, their historically developed metanarratives differ enormously among each other. Therefore analysing (deconstructing) metanarratives means to retrace historical developments and the decisions made on the way. This endeavour reveals choices which were taken along the historical evolution within each field.

*In this paper, we present a proposal for problematizing activities organized in task rounds, each one consisting of three stages: a triggering task, a historical task, and reflections on teaching. This model is part of a doctoral research project and it is being tested in a module of a professional master's program for mathematics teachers. We draw from the commognition framework (Sfard, 2008), combining the mathtask model (Biza, Nardi, & Zachariades, 2007) and Kjeldsen & Petersen's approaches (2014). More specifically, we discuss how we used history to design the historical task of the first task round, based on the so-called Aha problems from Ahmes' Papyrus. History of mathematics is used in the problematizing activities to move teachers out of their comfort zone and to legitimate different ways of producing mathematical knowledge. Some episodes are presented only to illustrate our discussion.*

*Keywords: Commognitive conflict, history in teacher education, mathtask, Ahmes' Papyrus.*

### Introduction

How do teachers deal with their students' unexpected solutions? We believe that acknowledging and legitimating different kinds of mathematical reasoning in all educational levels is a crucial aspect of teachers' knowledge and professional activity, and, therefore, this discussion cannot be put aside in teacher education programs. With this motivation, we have investigated how teachers deal with students' different solutions for mathematical problems in lower and upper secondary schools.

The experience reported in this paper is part of the doctoral research of the first author, jointly supervised by the other two authors. The aim is to design activities to problematize teachers' understandings of mathematical knowledge production, in particular their own mathematical knowledge production, and how they legitimate (or not) students' mathematical knowledge production. We understand problematizing as considering different alternatives for something that is usually taken for granted, which opens ways to explore questions that are usually not even regarded as relevant. In this paper, we focus on the use of historical problems and contexts to trigger problematization. For this, we consider recent trends of the historiography of mathematics, which builds upon the perspective of social and cultural contexts within which mathematical practices are produced. Our research combines frameworks on the integration between history of mathematics and teaching of mathematics and on teachers' education.

From the historical framework, we draw from Kjeldsen and colleagues' (e.g Kjeldsen & Petersen, 2014) work, which suggests that the history of mathematics is a source of discourses governed by

different metarules. We believe that history can be used to legitimate unusual practices in specific contexts. From the teacher education framework, we consider the importance of a kind of knowledge which is developed through school practice (Tardif, 2000). For this reason, the participants in our study are experienced teachers, who were taking a professional master's program<sup>1</sup>. Our field work took place in a module, which was part of their degree. In the sessions, participants were invited to analyse solutions for mathematical problems from Brazilian school syllabuses, including students' strategies and historical approaches. This was done by combining tasks inspired by Biza et al. (2007) and Kjeldsen and Petersen's history approach (2014). The field work's methodology was designed in the light of commognitive framework (Sfard, 2008), which will also be used in data analysis. The aim of this paper is to discuss the use of history in the design of these tasks. Episodes from the sessions are reported only to illustrate our task design.

## Theoretical Background

According to Sfard, learning is understood as participating in a discourse and mathematics is a kind of discourse. For the author, discourse is a “special type of communication [...] distinguishable by their vocabularies, visual mediators, routines, and endorsed narratives” (Sfard, 2008, p. 297). She adds: “In mathematics, endorsed narratives are those that constitute mathematical theories.” (idem, p. 298) However, Sfard does not reduce narratives to formal written texts. For her, narratives correspond to a series of spoken or written utterances, whilst routines grasp a set of metarules. These rules are related to the actions of *discursants* and are historically established, changing through the different discourses. Sfard (2008, p. 260) also points out that commognitive conflict

appears when one encounters a discourse incommensurable with one's own – when familiar routines are confronted with other people's alternative ways of implementing the same discursive tasks, grounded in different metarules.

Commognitive conflicts are at the core of our research. Thus, to lead participants to discuss and reflect on different ways that mathematics can be produced, we expose them to different discourses in two ways: using historical sources, and through tasks inspired by *mathtasks* (Biza et al., 2007). Biza et al. (2007) propose *mathtask* as a situation-specific task designed to engage teachers with classroom situations, to which they are invited to discuss attitudes they would take in the actual classroom. These situations are usually hypothetical, yet data grounded and likely to occur in the actual practice. The connection between history of mathematics and the commognitive framework is inspired by Kjeldsen's work. Since history is a source of discourses governed by different metarules (e.g. Kjeldsen & Petersen, 2014), it provides different ways of approaching problems and their solutions.

Arcavi and Isoda (2007, p. 112) highlight the importance of teachers' listening capabilities, that is, “giving careful attention to hearing what students say (and to see what they do), trying to understand it and its possible sources and entailments”. This is close to our goal, since we aim to problematize teachers' criteria to legitimate (or not) students' production of mathematical

---

<sup>1</sup> In Brazil, legal certification to teach at school is granted by an undergraduate degree. So, this master program is a professional development and is also a way to increase public school teachers' income.

knowledge. In our work, history is used to reach this problematization by discussing historical solutions to mathematical problems, which may differ from the usual strategies teachers are familiar with. Thus, the *problematizing activities* we propose are designed to use historical sources that move teachers out of their comfort zones, by revealing consistent practices within specific social contexts.

## The Problematizing Activities Design

The *problematizing activities* we propose are organized in *task rounds*, each one consisting of three stages: *triggering task*, *historical task*, and *reflections on teaching*. Our field work was conducted in a module of a professional master's program for mathematics teachers. Participants were 12 mathematics experienced teachers (who teach students with ages range from 11 to 18) who were taking this module. The module comprised thirteen 3-hour sessions (organized in three task rounds), including students' assessment. In this paper, we discuss how we used history, in articulation with frameworks on teachers' education, to design the activities, with a special focus on the historical task. We address the case of one of the three task rounds – based on the so-called *Aha* problems from Ahmes' Papyrus. Some episodes are presented, in order to illustrate our discussion. It is not an aim of this paper to rigorously analyse this empirical data.

### The task rounds' structure

Each round starts with a *triggering task*, in which participants are given hypothetical student' solutions to a mathematical problem. The aim is to bring about the ways they deal with students' responses, and to which extent they are open to unusual solutions. This is followed by a *historical task*, in which participants are presented to excerpts from original sources. The aim is to shake participants' comfort zones formed by the kind of solutions they are familiar with, since the historical discourses are usually different from the ones used in the classroom. In the last stage of each round, *reflections on teaching*, participants are again given hypothetical student' solutions, which now also draw upon historical solutions.

Figure 1: Structure of task rounds

The structure of the *triggering task* and the *reflections on teaching* stages are inspired by Biza et al. (2007) *mathtask* model, namely: firstly, participants are asked to solve a mathematical problem; then they are asked to analyse student solutions to this problem, and to describe the feedback they would give to students in an actual classroom situation. In each of the three stages, participants are

first asked to write down individual responses, and then invited to collective discussion. Either by bringing historical excerpts, or by using *mathtasks*, we try to promote a commognitive conflict (Sfard, 2008). Our goal is to encourage the participants to reflect and discuss on: i) their own *routines* regarding their classroom practices, ii) how they understand mathematics, and also iii) the criteria they apply when judging their students' mathematical solutions and reasonings. For the choice of each task round's topic we take into account: potential to allow different solutions; relevance to the participants' practice; and availability of primary and secondary historical sources.

### **The first task round: context and structure**

Our first task round is built around the *simple false position rule*, according to which the solution is reached by using an “experimental number” that is adjusted by a factor. Thus, the process of finding the solution is not based on a representation for the solution, as in the case in the contemporary algebraic methods. We choose the context of the ancient Egyptian *Aha* problems (e.g. Roque, 2012; Chace et al., 1927) from Ahmes Papyrus to explore different solutions to problems modelled by linear equations nowadays, as a potential trigger of commognitive conflicts. We could consider many metarules regarding the discourse from *Aha* problems (e.g. the ones related to the Egyptian symbols, the ones related to the structure of the *Aha* problems, the ones related to the Egyptian mathematical practices), but we focus on the metarule related to the assumption of an “experimental number” to start the *Aha* problem – which considerably differs from representing the unknown quantity by a letter and operating with it. Thus, we use the simple false position rule as a means of problematizing algebraic solutions commonly used at school. The choice of this activity is also justified by the fact that the false position rule is grounded in the notion of proportionality. Despite this is a key concept in school mathematics, it is sometimes underestimated in the teacher education programs (at least in the Brazilian context). The *triggering task* consists of a *mathtask* with two hypothetical solutions to the following problem:

Marina likes to make problems for her father inspired from what she learns at school. One night she said: “Dad, find out how many Reais<sup>2</sup> I have! The tip is: if I add a quarter of what I have to what I have, I'll get R\$15,00.”

Ten participants attended this session, all of which presented an algebraic solution, as expected. A *mathtask* with two students' solutions to the problem was then discussed. The *mathtask's* context was an introductory lecture on algebra at elementary school for 12/13 years old students. The first solution uses a diagram to split the whole in 4 parts, and then add a fourth one. So, 15 is divided by 5, and the result is multiplied by 4. The second solution is a “trial and error” strategy. Aiming to set up commognitive conflicts, both student solutions were designed considering *routines* different from the algebraic solutions. The metarules behind the first solution's routine are related to the use of fraction bars, whilst the ones in the second solution routine are related to the use of a trial and error strategy.

### Designing the historical task: our methodological option

The historical task concerns two well defined moments: an immersion in original sources and a historical overlook. These approach were inspired by Arcavi and Isoda (2007)'s hermeneutic method. The authors propose a sequence of tasks aiming to

parsing the source, posing questions to oneself (or to a peer) around it, paraphrasing parts of the text in our words and notations, summarizing partial understandings, locating and verbalizing what is still to be clarified, and contrasting different pieces for coherence. (Arcavi & Isoda, 2007, p.116)

Thus, immersing in a source is the opportunity to analyse and understand different mathematical practices, contrasting them with the participants' own ones. In the historical overlook, we discuss (mathematical and cultural) contexts of the source and some aspects of the Egyptian mathematics. We adopt this approach as a means to lead participants to experiencing "other perspectives", as Arcavi and Isoda (2007) posit, which, in the context of the history of mathematics, may be the ones from the primary sources, as we used in this research. As these authors suggest, in the context of the classroom, the "other perspective" is the students' ones. So, they argue that trying to understand historical sources may lead teacher to be more receptive to students' productions, specially the unexpected ones.

The aim of the first round was to explore Problem 25 of the Ahmes' Papyrus, which states: "*A quantity whose half is added to it becomes 16.*" Firstly, we invited participants to analyse Problem 25 in Hieratic and Hieroglyphic (Figure 2), as it appears in the Ahmes' Papyrus (Chace et al., 1927). Next, they were presented to Problem 25, as it appears in Figure 3, with translation to English and to (our) Portuguese. After presenting a brief contextualization on Ancient Egypt, the role of the scribes in the society organization, and what Ahmes' Papyrus and, particularly, the *Aha* problems are about, we presented Problem 25 again as it appears in Figure 3, and invited participants to explore it. We then proposed tasks from Arcavi and Isoda's work, including: the elaboration of a dictionary of Egyptian symbols, especially numbers; a problem with Egyptian multiplication; and a set of tasks exploring Problem 24<sup>3</sup> (Arcavi & Isoda, 2007) in stages. Finally, we discussed Ancient Egyptian mathematics, especially number system, fractions and operations, using Roque (2012) as the main reference.

---

<sup>3</sup> Problem 24 is quite similar to Problem 25 and states "*A quantity whose seventh is added to it becomes 19.*"

Figure 2: Hieratic and Hieroglyphic solutions of Problem 25

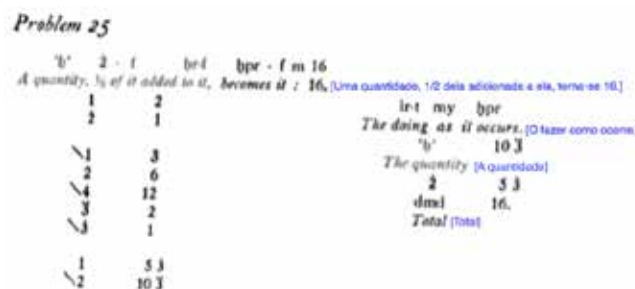

Figure 3: Modern translation of the Problem 25

We then resumed Problem 24's solution and encouraged the participants to understand the solution as a whole. As Arcavi and Isoda suggest, we asked them to try to present a solution using a different experimental number. Moreover, we invited them to try to compare the solutions for Problems 24 and 25. The solution was written in modern terms and the expression “false position rule” was presented. Finally, the questions (inspired by Winicki, 2000) were posed to guide the discussion: 1) In modern terms, to which kind of equations do the *Aha* problems correspond? 2) Present a justification for the false position rule. 3) In the false position rule, does the result depend on the experimental number? 4) Does the false position rule work for all kinds of *Aha* problems? Why? 5) Why do you think such a rule was invented? 6) Why is it anachronistic to claim that the Egyptian “solved equations”?

To conclude the historical part, we asked the teachers about simple false-position-rule rationale, that is, to explain why the method is valid. After a brief discussion, we presented a modern justification, using a linear function's graphic in order to show the proportionality between the experimental number (false position) and the solution. The *reflections on teaching* stage was guided by a *mathtask* presenting a situation in which a 12-year-old boy that doesn't know algebra yet solves Problem 25 by trial. His father wants to convince him that it is easier to solve the problem through the use of an equation. The boy tells the story to his teacher and asks her why does his dad insist on the equation. The participants were asked to explain how they would answer the boy, if they were his teacher. By the end of the task round, we had 5 different types of solutions for a linear equation: i) algebraic one, ii) using diagrams (fraction bars), iii) trial and error, iv) simple false position, and v) another one by trial presented by the boy (i.e., 3 solutions by trial). We invited the participants to compare these solutions.

During the whole first task round, we tried to promote commognitive conflicts, since the discourse of the historical Egyptian source, the discourse of the solutions presented in the *mathtasks* are modelled by different metarules (Sfard, 2008; Kjeldsen & Petersen, 2014) and are (supposed to be) different from the teachers own's discourses. This strategy aimed to stimulate the participants to reflect about the way they deal with their students' different solutions and reasonings.

### **The first task round: what happened**

The first task round took a bit more than two sessions, guided by the first two authors, and with the participation of 12 teachers (four of which attended all of the three meetings). During the sessions, we repeatedly asked the participants about how they deal with different reasonings and solutions brought by their students. Almost all participants have long-term experience in teaching mathematics at public and private schools. The sessions were audio and video recorded. There were separated audio recordings for each small group of 3 or 4 teachers, that discussed each task. The individual written answers to the *mathstasks* and to the historical task were collected. After each session, the participants were asked to write individual reflective diaries, in which they recorded their impressions of the session. Those data will be analysed in a next stage of the doctoral research project.

### **Impressions from the first activity's round implementation**

In general, the participants engaged with the tasks and discussions conducted in the first task round. We could discuss the approaches to equations and algebra teaching they use in classroom. When asked about how they deal with unusual solutions brought by their students, they acknowledge that they recognize them, sometimes sharing them with the rest of the class. However, although we tried to relativize the supremacy of algebra over other approaches, their discourses suggest that their main goal is to develop students' algebraic reasoning and writing. That is, even though they recognized some value on other approaches, they kept pursuing their goal, namely to lead students to understand that algebra makes solutions faster. For example, when we discussed solutions by trial, they repeatedly highlighted that if the numbers were bigger, they would have spent much more time, whilst algebraic solutions take the same amount of time regardless of how big the numbers are. None of them seemed to consider that experimenting with some examples could lead to an understanding of the problem, in such a way that testing all numbers would not be needed. One of the reasons for the teachers keep pursuing the algebra in classrooms might be the important role played by the algebra in the school syllabus in Brazil.

One of the participants, who we will refer to by the pseudonym Ulisses (who were present in all sessions) caught our attention in two different ways. Firstly, he told us that he used Ancient Egyptian multiplication algorithm (which had been discussed in the task round) with his students. He reported that, as his students were facing difficulties with the standard multiplication algorithm, he decided to show the Ancient Egyptian method. The students understood it and claimed that it was easier. We remark that we did not make any suggestions for the participants to apply specific approaches in their classrooms, and Ulisses did so by his own initiative. This kind of attitude is relevant to our work, since this teacher allowed himself to experiment in his own classroom with historical practices discussed during the sessions. During the discussion about Problem 25's solution, Ulisses once more surprised us: he thought of non algebraic solutions. Even though he wrote down the equation, he tried out different values. He noted that  $10+5=15$  and  $12+6=18$ . Looking to  $10+5=15$ , he noticed that 1 more was necessary, so he split 1 in three pieces  $1/3$ ,  $1/3$  and  $1/3$ , of which two should be with 10 and one with 5 – and he reached the solution.

Arcavi and Isoda (2007, p. 125) posit that

the intention to nurture attentive listening by creating a gap between our method and the Egyptian had a slightly counterproductive effect for some: the symbolic method is so powerful and efficient why bother to even consider a complicated alternative so difficult to understand.

Contrary to this, in our case, the teachers considered all methods – of simple false position and the ones that were used in the *mathtasks* – correct and valid.

## Final Remarks

The continuation of our field work included two more task rounds. The second one explores Euclid's approach to areas without numbers (quadratures) and the role of the Pythagorean Theorem's in Euclidian tradition. The aim is to problematize the teaching of areas, which is mainly based on formulas in Brazil. The third task round is designed around the development of the concept of function, and some of its historical definitions, aiming to foster the reflection of image of mathematics as an immutable science.

The episodes reported above indicate that our proposal combining *mathtasks* and historical tasks seems to be a promising way to problematize teachers' understandings of mathematical knowledge production, in particular their students' mathematical knowledge production. When data analysis from our field work is completed, we will have more evidence to deepen the understanding of our proposal's potential. Nevertheless, the episodes from the first task round indicate that at least this group have been receptive to the use of the history of mathematics. We highlight that Ulisses spontaneously tried the Egyptian multiplication out in one of his classrooms. This indicates that he problematized, at least to some extent, not only his own and his students' mathematical knowledge productions, but also his teaching practices.

## Acknowledgments

We acknowledge CAPES for the scholarship for a doctoral internship at Rutgers University under the supervision of Prof. Arthur Powell. We are grateful to Prof. Arthur Powell for the partnership, especially in the design of the field work methodology and to Prof. Elena Nardi and Dr. Irene Biza for the opportunity of working together and exchanging experience through the MathTASK project.

# The development of Thales theorem throughout history

Slim MRABET

Carthage University, Tunisia; [mrabet\\_slim@yahoo.fr](mailto:mrabet_slim@yahoo.fr)

*Keywords: Thales theorem, similar triangles, transformation.*

Thales theorem may have different functionalities when using distances, algebraic measurements, or vectors. In addition to that, the utilization of a figure formed of secant lines and parallels or a figure relating to two similar triangles.

The aim of this work is to categorize different formulations of Thales theorem and explain why in teaching we must know the appropriate mathematical environment related to each Thales Theorem statement. The analysis of many geometry books in history makes it possible to distinguish two points of view according to different forms, demonstrations and applications of this concept.

## The Euclidean point of view

The general statement of Thales theorem shows us the idea to move from one triangle to another, moreover, the link with similar triangles (immediately following it and generally with similar figures) is a characteristic of this point of view.

Proposal 2 of Book VI states that:

*"If a straight line be drawn parallel to one on the sides of a triangle, it will cut the sides of the triangle proportionally; and, if the sides of a triangle be cut proportionally, the line joining the*

Figure 1 : figure of Euclid

*points of section will be parallel to the remaining side of the triangle". (Heath, 1956).*

The demonstration is based on the surfaces method; using equalities of triangles cases and making cuts and re-compositions in order to compare surfaces.

## The point of view of transformations

This point of view is characterized by the disappearance of the link between Thales theorem and similar triangles, and, a passage from one line to another by projection appears in a figure of type: "parallels and secants".

In the seventeenth century, Euclidean treaty did not seem to satisfy some researchers. In fact, the latter prefer not to prove a result on lines using surfaces. In Thales theorem proof, Arnold rejects the detour by the surfaces made by Euclid.

For Arnold (1667), the statement of Thales theorem uses several parallels cut by secants:

*"If several lines, being differently inclined in the same parallel space, are all cut by parallel lines to this space, they are cut proportionally"*

Figure 2 : Figure of Arnold

When applying the Thales theorem, we find essentially the search of 4<sup>th</sup> proportional, and the division of a segment with a given ratio.

This type of statement is also found in Hadamard (1928) where the study of figures marks the appearance of transformations that coexist with traditional objects of geometry.

The homothety, introduced with distances, consolidates for Hadamard dynamic aspect of geometric figures. It also provides the possibility to use similarity of polygons by decomposing them into triangles.

Note that starting from the 20th century, new conceptions of geometry appeared and benefit from linear algebra. The traditional methods of Euclid and his successors were eventually set aside.

With Choquet (1964), Dieudonné (1964) and other renowned researchers, geometry is evolving in each century. For Choquet, Thales theorem allows proving the relation  $a(u+v) = au + av$ , in order to study the linearity of an oblique projection.

## Conclusion

In Thales theorem proof, Euclid uses surfaces method to avoid problems of irrational numbers. In majority of perused publications, Thales theorem proofs often use commensurable segments, thus, the transition to immeasurable segments is admitted.

In teaching, it is important for instructors to conceive the real line without holes. We also think that the two points of view of Thales theorem have their efficacy and both should have enough time to reach the students. We recommend set each one of them in the appropriate mathematical environment that can result in a better understanding of geometric themes introduced in class.

## Original sources, ICT and mathemacy

Marianne Thomsen<sup>1</sup> and Inge Marie Olsen<sup>2</sup>

<sup>1</sup> PhD student, Aarhus University & University College Copenhagen, Denmark; mtho@au.edu.dk

<sup>2</sup> Mariendal Friskole, Copenhagen, Denmark; ingemarieolsen@hotmail.com

*Keywords: ICT, original sources, hidden mathematics, mathemacy.*

The focus of our master's thesis in Mathematics Education was on how 4<sup>th</sup> grade students (10-11 years old) connect working with ICT and reading original mathematical sources in ways that support the development of a competency, *mathemacy*, "which may help students to reinterpret their reality and to pursue a different reality" (Skovsmose & Nielsen, 1996, p. 1263). Our study indicated that ICT and original sources complement each other in terms of the students' learning activities. The students' experimental activities in ICT supported their understanding of the original source. Their work with the original source supported a development of a mathematical consciousness and sharpened their awareness of hidden mathematics (Jankvist & Toldbod, 2007) and black box situations (Buchberger, 2002), which means that the students didn't just accept the results of a computer – they also questioned the mathematics behind when using ICT. Furthermore, the students' awareness of differences between working with contemporary ICT and original sources seemed to increase a balanced and critical stance towards mathematics as a universally given thing – making them see both mathematics and ICT as something that develops and changes over time.

Our research design was inspired by Skovsmose's (2006) description of critical research based on three situations: The *current*, the *imagined* and the *arranged*, as well as three processes: *Pedagogical imagination*, *pedagogical experimentation* and *explorative analysis*. The three situations and processes were used in our planning, implementation and analysis of the 3 x 90 minutes teaching session we conducted. The students were asked to carry out a final individual evaluation. We performed three types of data collection: 1) Focus group interviews prior to the first teaching session, 2) Teaching session observations, and 3) students' products from each teaching session. Data category 2 and 3 we regarded as pedagogical experimentation data helping us describe the current situation. We used this situation and our pedagogical imagination to prepare the next imagined situation. Based on the collected data we performed an explorative analysis and planned the next arranged situation and so on. The first current situation was based on data type 1. In our planning and analyses of the learning activities we were among other inspired by Jankvist's (2009) framework concerning the use of history in mathematical education as a goal (meta-issues) or as a tool (in-issues). Our study focused on history both as a goal *and* as a tool. We extended Jankvist's categorization also to deal with the students' work with ICT. The mathematical content was kept relatively simple letting the students work with only Euclid's Proposition 1, book I, *To construct an equilateral triangle on a given finite straight line* and equilateral triangles in *GeoGebra*. For the meta-issues we focused especially on hidden mathematics in software (Jankvist & Toldbod, 2007) and the fact that mathematics develops over time (Jankvist, 2009). Inspired by Jankvist and Kjeldsen (2011) and Kjeldsen and Blomhøj (2012), we used Sfard's (2008) theory of discourse and commognitive conflicts. We considered Euclid's proposition 1, book I, and *GeoGebra* as two

different discourses. Within these two discourses we saw meta-issues and in-issues as two different discourses. During the teaching sessions, we made a common ‘discourse-poster’ on which we gathered the students’ statements they agreed to during the classroom discussions. The students worked with the construction part and the proof part in relation to Euclid’s Proposition 1, book I, and equilateral triangles in *GeoGebra*. This gave rise to common discussions about the difference between proof; in terms of Euclid’s proposition and in terms of working with *GeoGebra*. One student for example compared Euclid’s proof to a game; he found one circle, then the next and so on. The students were asked to construct as many equilateral triangles as possible in *GeoGebra* and formulate their own proofs for these. The outcome of this assignment was what they called three different types of ‘proofs’ for equilateral triangles: *Measuring, the computer outcome as a proof in itself and the Euclidian way*. There were different opinions among the students about which type of ‘proof’ they found most credible, which we regarded as an in-issue discussion; understandings of different kinds of proofs within the two discourses were to some extent generating commognitive conflicts. Furthermore, the students discussed whether the computer always tells the truth and if mathematic will change in the future as well – a meta-issue discussion based on their experiences by working within the two different discourses. In addition to this, we arranged special learning activities, which focused on the meta-issues, for example asking students to write and discuss pros and cons of using Euclid’s proposition and the use of *GeoGebra* in mathematical education. Several students found that working with both Euclid’s proposition and *GeoGebra* was a good idea and had increased their learning. The students became aware of that computer outcome may contain a lot of hidden mathematics. Hopefully, this will support their reflexive use of ICT and also later in life qualify their critical stance towards the outcome of mathematical modelling.

*The present paper considers an important cultural treasure in the early Swedish history of mathematics education. After the reformation in the 16<sup>th</sup> century it became possible to study mathematics in Sweden. The first printed textbook in Swedish on arithmetic appeared in 1614, but already in 1601, the oldest known manuscript in Swedish on arithmetic was written by Hans Larsson Rizanesander. In this paper we investigate Rizanesander's manuscript in its historical context.*

*Keywords: Mathematics history, history of education, arithmetic, mathematics education.*

## Introduction

Swedish school mathematics has a history of about four centuries. During recent years there has been an increased research interest in the history of Swedish mathematics education (see, for example, Hatami (2007), Lundin (2008), Pejlare (2017), and Prytz (2007)). However, not much research has been conducted on the early history of Swedish mathematics education. The first printed textbook on arithmetic in Swedish was written by Aegidius Aurelius (c.1580–1648) in 1614 (Aurelius & Johansson, 1994). However, the oldest known manuscript in Swedish of a mathematics textbook was written in 1601 by Hans Larsson Rizanesander (1574–1646); this manuscript is the focus of the present paper. The manuscript, entitled *Recknekonsten* (*The art of arithmetic*), constitutes a significant part of the history of Swedish mathematics education. There seems to be a pedagogical idea behind the structure of the text, and it contains numerous examples with solutions. Even though it was never printed, and it is not known to what extent it was used, it can give us insights into the early history of Swedish mathematics education. Hatami and Schéele have interpreted the handwritten manuscript, and in 2018 it was, after more than 400 years, finally printed (Rizanesander, 2018). Hultman (1868–1871, 1874) wrote on the Swedish history of arithmetic, but he was probably not aware of Rizanesander's manuscript, since it was not mentioned. In his dissertation on the Swedish history of mathematics up to 1679, Dahlin (1875) summarized parts of Rizanesander's manuscript, but he did not consider it in the context of the Swedish history of mathematics education. The present paper is part of the outcome from a larger project aiming to contribute to the understanding of the early history of mathematics education in Sweden. The aim of this paper is to investigate Rizanesander's manuscript as well as possible influence on him by other authors. We conduct a content analysis on relevant parts of the manuscript and perform comparisons to other textbooks on arithmetic that he may have had access to. In order to better understand the context in which Rizanesander wrote his manuscript, we will first give an overview of the Swedish history of mathematics education (13<sup>th</sup> to 17<sup>th</sup> century).

## Swedish history of mathematics education

To better understand the cultural value of Rizanesander's manuscript and its importance for mathematics education, we will first give a summary of the history of Swedish mathematics education until the 17<sup>th</sup> century. The Swedish education has its origin in the 13<sup>th</sup> century, when education was committed at cathedral schools, convent schools and provincial schools. Through the Fourth Council of the Lateran, convoked by Pope Innocentius III in 1215, each cathedral was committed to have a school where future priests could get free education. In 1237 the Dominican Order established the first Swedish convent school in Åbo. The convent schools were oriented towards theology, but gave a higher education than the cathedral schools. In particular, those belonging to the higher states had the possibility to get educated. However, many nobles on the continent could not read or write and possibly it was the same in Sweden. During the reformation in the 16<sup>th</sup> century the convent schools were closed and the opportunity of higher education disappeared. King Gustav Vasa (1496–1560) took over the management of the cathedral schools and provincial schools, but there was no particular interest of education among the people. Not until 1842 there was a Royal decision to implement a public-school system in Sweden (Lundgren, 2015).

The oldest university in the Nordic countries is Uppsala University, which was founded in 1477, and it was the only university in Sweden until King Gustav II Adolf in 1632 founded the university of Dorpat, which today is the University of Tartu in Estonia. During the Reformation there was very little activity at Uppsala University, but during the synod of the Lutheran Church of Sweden in 1593 the Duke Charles (later King Charles IX) gave new privileges to the university, which reopened in 1595 (Pejlare & Rodhe, 2016). Until the reformation the traces of mathematical knowledge in Sweden are few; only at the end of the 13<sup>th</sup> century the Arabic numerals became known (Dahlin, 1875). At the beginning of the 14<sup>th</sup> century there probably were a few that were skilled in using the Arabic numerals in simple calculations, but at the beginning of the 16<sup>th</sup> century there were most likely very few Swedes who could perform calculations except with finger calculations or with an abacus.

The first Swede mentioned to own mathematical literature is the canon Hemming from Uppsala, who testamentated his mathematics books to a relative when he died in 1299. Among these books we find those written by two of the most well-known mathematicians of that time: Campanus of Novara (c. 1220–1296) and Johannes de Sacrobosco (John of Halifax, c.1195–1256) (Dahlin, 1875). The oldest Swedish mathematical work known is a short overview of the calendar with the title *Tabula cerei paschalis*, written in Uppsala in 1344. The first Swedish mathematician mentioned to have been relatively knowledgeable of mathematics and astronomy is King Charles VIII (c. 1408–1470), but some details of what kind of knowledge he had is not known.

When Uppsala University was given new privileges in 1593, Ericus Jacobi Skinnerus (deceased 1597), became the first Swedish professor of mathematics (Rodhe, 2002). No mathematical works by Skinnerus have been encountered. Nevertheless, he was an avid supporter of the French philosopher Petrus Ramus' (1515–1572) controversial ideas (Rodhe, 2002): Ramus questioned the Aristotelian theories that were then dominating in the academic world. Even if we cannot see any clear traces of mathematical activity during the time of Skinnerus, his interest of ramism should have provided a basis for a positive development of education.

The first Swedish professor of mathematics whose activity we know somewhat well is Laurentius Paulinus Gothus (1565–1646). He was a professor at Uppsala University from 1594 to 1601 where

he lectured on arithmetic, algebra, logic, geometry and philosophy (Dahlin, 1875). He also studied the mathematical works by Ramus, and in his spirit Paulinus struggled for the Aristotelian theories to be removed from school. Ramus preached on the usefulness of science, which for mathematics implies the search for applications to other subjects. The followers of Ramism in particular fought the mysterious and superstitious features found in the Aristotelian scholastics (Rodhe, 2002). In 1637 Paulinus became arch bishop and promulgated a program for students of theology: the demand for becoming a priest would be to have good knowledge of arithmetic, Euclid's *Elements*, Ramus' physics and in astronomy, in particular the *doctrina sphaerica* and the calendar (Dahlin, 1875).

During the end of the 16th century it became possible to teach mathematics at the cathedral schools as long as the teaching did not have a negative influence on other subjects. In the curricula from 1611, *Skolordningen 1611*, we can read that in school the children should be educated in Buscherus' arithmetic and in "*Sphaera Johannis de Sacro busto*" with the condition that no other subjects would be neglected (Dahlin, 1875). Buscherus, or Heizo Buscher (1564–1598), was a German philosopher. His book on arithmetic, *Arithmeticae logica methodo conscriptae libri duo* (1590), was an important textbook in Sweden during the early 17<sup>th</sup> century (Vanäs, 1955) and was later reedited by the Swedish bishop Johannes Bothvidi (1575–1635). Johannis de Sacro busto most likely refers to Johannes de Sacrobosco, who wrote a book on astronomy, *Libellus de sphaera*, that was widely used at universities during the middle ages.

The first known mathematics book on arithmetic in Sweden is a handwritten manuscript in Latin on the rule of three, by Peder Månsson (c.1465–1534), written in the early 16<sup>th</sup> century (Hultman 1870). In 1609 Olof Bures' (1578–1655) book on arithmetic, *Arithmetica instrumentalis abacus*, was printed. The first printed textbook on arithmetic in Swedish is Aegidius Aurelius' *Arithmetica eller Räknebook, medh heele och brutne Taal* (*Arithmetica or arithmetic textbook, with integers and fractions*), which was published in eleven editions between 1614 and 1705. But already in 1601, the first Swedish textbook on arithmetic was written: *Recknekonsten* by Hans Larsson Rizanesander. It is written in Swedish at a time when education was reserved for privileged boys with knowledge of Latin, and when mathematics education still was not generally in question.

### **Rizanesander and *Recknekonsten***

Not much is known about Hans Larsson Rizanesander (1574–1646). He studied at Vasa Akademi in Gävle – a school that had been founded by King Gustav Vasa in 1557 – and became a judge in Gästrikland, a province north of Uppsala, in 1605. Originally, he came from Rotskär in Älvkarleby. The linguistic origin of the name Rizanesander is a Greek translation of the Swedish word Rot-skärman (in English: Root-skerry-man), i.e., *Rhiza-nes-ander*.

Rizanesander wrote his manuscript in Tallinn, which during this time was a dominion of Sweden called Räfte or Reval. Today the manuscript is kept at the university library *Carolina Rediviva* at Uppsala University; to our knowledge it only exists in one copy. The manuscript is dated the 21<sup>st</sup> of August 1601. It does not have a title, but since the word *Recknekonsten* (*The art of arithmetic*) is used in the dedication this is how we will refer to the book. The manuscript consists of 147 pages, including twelve pages that may have been written by Rizanesander's son Lars Hansson. It is divided into 20 chapters: The first two chapters contain definitions and explanations of the hindu-arabic positional notation (4 pages), as well as a description of the abacus (4 pages). The following

four chapters deal with addition (11 pages), subtraction (7 pages), multiplication (10 pages) and division (12 pages), both on the abacus and with numerals. Chapters VII and VIII deal with the greatest common divisor (1 page) and the least common multiple (4 pages). Chapters IX to XIII deal with fractions (3 pages) and the four basic mathematical operations with fractions (5, 4, 3, and 4 pages, respectively). Chapter XIV deals with arithmetic and geometric series (10 pages), and chapters XV and XVI deal with the rule of three (14 pages) and reversed rule of three (2 pages). The last four chapters deal with general counting (3 pages), square roots and cubic roots (19 pages), *regula cecis* (also called *regula virginum*, 7 pages), and the rule of false position (8 pages).

The manuscript is dedicated (4 pages) to Duke John (1589–1618), son of King John III of Sweden. At this time Duke John was 12 years old. In the introduction Rizanesander claims that the art of arithmetic is indeed a glorious and useful art, since God herself used arithmetic. He also refers to Plato, who demanded that kings and princes should have the acquirement of the art of arithmetic. At the end of the introduction Rizanesander asks Duke John for financial support in order to have the manuscript printed. It is not known if there was any contact between Rizanesander and Duke John, but apparently Rizanesander never got any funding, since the manuscript was not printed. It is not known if Duke John ever mastered the art of arithmetic. However, he never became king; twice he gave up the throne and he died only 28 years old.

### ***Recknekonsten or The Art of Arithmetic***

Rizanesander begins the first chapter of *Recknekonsten* by stating that “The art of arithmetic is a knowledge of calculating well”<sup>1</sup>. He uses nine *significant* digits (1–9) and one *insignificant* (0) called *Nulla* or *Ziphra*.<sup>2</sup> The insignificant is explained to “do nothing by itself”<sup>3</sup> but it fills up the space where there is no significant digit. This means that the zero only has a meaning as an empty place indicator in the place value number system; the zero does not yet have a meaning in itself. These ten significant and insignificant digits are explained to be “the wood of the art of arithmetic of which it is built in the same way as a house is built by timber, stones, lime, clay and sand”<sup>4</sup>. It is further explained how numbers should be pronounced. Rizanesander does not have a word for numbers greater than 1000. To pronounce a great number, he uses a dot on each thousand to indicate how many multiples of thousand the digits represent. The example he gives, 13456798654321062489, should be pronounced as follows:

Thirteen thousand, thousand thousand, thousand thousand times thousand  
Four hundred fiftysix thousand thousand thousand, thousand times thousand  
[...]  
four hundred eighty nine<sup>5</sup>

<sup>1</sup> “Recknekonsten ähr een lärdom till att wäll Reckna” (Rizanesander, 1601, p. 3 r).

<sup>2</sup> In modern Swedish the word for *zero* is *noll* and the word for *numerical digit* is *siffra*.

<sup>3</sup> “förmå inthett vthi sig sielfff” (ibid, p. 3 r).

<sup>4</sup> “wirkin till Reckne konsten af hwilken hon warder vpbyggd medh Lijka såsom till itt hus att vpbyggia hörer Stocker, Stenar, Kalck, Leer och Sandh” (ibid, p. 3 r).

<sup>5</sup> Thretton tusendh, tusend tusend, tusend tusend gånger tusend fyre hundrade femtiyosex tusend tusend tusend, tusend gånger tusend [...] fyre hundrade ottotiye niyo (ibid, p. 4 v).

This method is not very efficient, but any great number can be pronounced with it. In Christopher Clavius' (1537–1612) *Epitome arithmeticae practicae* from 1583 great numbers were also marked with dots and described to be pronounced in the same way.

After presenting numbers and how to pronounce them, Ryzanesander continues to give a description of the abacus (see Figure 1) and the meaning of the lines and their spacing on it. A coin on the lines represents, from below, a unit, a tenth, a hundredth and so on. A coin in the spaces between the lines represents five, fifty, five hundred, and so on. His abacus resembles a traditional abacus but with the supplement that a coin below the bottom line represents half a unit. This is interesting, considering that Ryzanesander has not yet introduced fractions.

**Figure 1: Ryzanesander's abacus representing the number 268,957,129 (Ryzanesander, 1601, p. 6 r).**

Ryzanesander proceeds through the following four chapters by explaining the four basic operations addition, subtraction, multiplication and division, both with the abacus, and with algorithms. The abacus will only be used in these chapters; in later chapters numerical methods, only, will be considered. The chapters on the four basic operations with numbers include many examples. Most of the examples concern money, but there are also some numerical examples without a context where it is explained how to carry through the algorithms.

The algorithm for the addition of numbers is the same as the standard addition algorithm that we use today, starting from the right. However, when Ryzanesander describes subtraction with numbers, he starts the algorithm from the left, which forces him at each step to look at the position to the right in order to decide whether he has to decompose and recompose the numbers or not. For example:

One asks how many years there has been since we wrote 1574 and now write 1601? *Reliquus* 27.

Put  $\begin{array}{r} 1601 \\ 1574 \end{array}$ . Say 1 from 1 is nothing left. Draw a line through them both. Say again 5 from 6

*Reliquus* is 1, which should be written above. But the next number, 7 could not be taken from 0.

Therefore, write under :| less than one is 0 |: and keep this. Draw a line through 6 and 5. Say

again from 10 :| Since you had it in memory to do so :| *Reliquus* is 3. But write less that is 2

above, the same reason as before, draw a line through 0 and 7, and again keep one in memory;

Thereafter take four from 11 *Reliquus* is 7 which can complete be written above. Draw a line

27

through 1 and 4 and now the example is thus:  $\begin{array}{r} 1601 \\ 1574 \end{array}$ .

$\begin{array}{r} 1601 \\ 1574 \end{array}$

<sup>6</sup> Een frågar huru många år, ähre sedan thz skreffz 1574 och nu skriffwes 1601? *Reliquus* 27. Sätt såledhes.  $\begin{array}{r} 1601 \\ 1574 \end{array}$   
Sågh 1 ifrå 1 år inthz öffwer. Dragh så en linie igenom them bådhén. Sågh åther 5 ifrå 6 *Reliquus* år 1, hwilkett skulle

Ramus used the same algorithm for subtraction in his *Arithmeticae libri* from 1555, but Clavius in 1583 used the same subtraction algorithm as we do today.

Chapter V deals with multiplication, and this chapter Ryzanesander begins by presenting the Pythagorean table (see Figure 2), which he states has to be learned by heart.

**Figure 2: Ryzanesander's table of multiplication (Ryzanesander, 1601, p. 16 r).**

Interesting is that Ryzanesander uses a triangular table, where the commutative law implicitly has to be considered. This means that from the table of multiplication with 2 to the table of multiplication with 9 the length of the tables successively gets shorter. Also, other mathematicians active during the 17<sup>th</sup> and first half of the 18<sup>th</sup> century, such as for example Aurelius, but also Nils Buddaeus (1595–1653), Nicolaus Petri Agrelius (c. 1625–1681) and Anders Celsius (1701–1744), have taken the commutative law into account when they designed their multiplication tables, which makes the table triangular and compact. However, Swedish mathematics textbook authors during the end of the 18<sup>th</sup> century, such as Nils Petter Beckmarck (1753–1815), Olof Hansson Forsell (1762–1853) and Per Anton Zweigbergk (1811–1862) used quadratic multiplication tables and do not focus on the commutative law. Clavius (1583) also used a quadratic multiplication table, but Ramus (1555) only presented a multiplication algorithm and not a multiplication table.

Ryzanesander refers to the Pythagorean table when he describes division with numbers. The division algorithm with numbers he uses is a scratch method, or *divisione per galea*, which was a common method in the middle ages (Vanäs, 1955). Characteristic for this method is that the divisor is written under the dividend and is moved one position for every new quotient digit, and the quotient is written to the right. As the computation is performed, the digits belonging to the same number does not have to be written next to each other on the same line and the remainder is written above the dividend. Also, the partial products are computed from the left to the right and are subtracted as they are computed.

After the chapters on the four basic mathematical operations, Ryzanesander proceeds with finding the greatest common divisor, and the least common multiple, of two numbers. He needs this in his rendering of fractions and the four basic mathematical operations with fractions in the following chapters. Compared to the presentation of the four basic operations with numbers, the presentation of the four basic operations with fractions is different. Both presentations contain numerous

---

skriffwas offwanföre. Men her till nest föliande taal, icke kunna 7 tages vthaf 0. Derföre skriff ret vnnder :| mindre ähn eett ähr 0 |: och beholtt thz. Dragh een linie igenom 6 och 5. Och 7, och beholtt åther eet i sinnett; Tagh sidhan fyra ifrå 11 *Reliquus* ähr 7 hwilken kan fulkommeligen schriffwas offwan före.

2 7

Dragh och een Linie igenom 1 och 4 och ståår nu hele Exemplett såledhes.  $\begin{array}{r} 1601 \\ 1574 \end{array}$  (Ryzanesander, 1601, p. 14 v–15 r).

$\begin{array}{r} 1601 \\ 1574 \end{array}$

examples, but when the examples with numbers often are in a context there is, with only one exception (unit weights), no context in the examples with fractions. Also, there is no explanation of how the fractions should be interpreted: focus lies instead on how the algorithm should be carried through. However, in the following chapter XIV on arithmetic and geometric series we find examples where fractions are used in a context. One example of an arithmetic series is the following:

I would like to know how many times the bell rang since it rang at one during the night until it rang at 12 during the day.<sup>7</sup>

Many of the examples use a context with money. The money used in Sweden at this time was thaler, mark, öre and penningar (pg). The thaler was an international silver coin used throughout Europe. One thaler is four mark, one mark is eight öre, and one öre is 24 penningar. One example of a geometric series in the context of money, which resembles an example we also find in Buscherus' *Arithmeticae* (1590), is the following:

One buys a horse that is shod with 32 nails and give 1 pg for the first nail, 2 pg for the second nail, 4 pg for the third nail and 8 for the fourth and so on doubling. How expensive is the horse? Answer: 4294967295 pg, that is 5592405 thaler 1 mark 6 öre 19 pg. That was an expensive horse.<sup>8</sup>

This was indeed an expensive horse. But Rizanesander has actually made an arithmetical mistake when he changes his money: the correct answer should be 5,592,405 thaler, 1 mark, 2 öre and 15 penningar.

## Concluding remarks

Being the oldest mathematics textbook in Swedish, Rizanesander's manuscript is an important source through which we can learn more on the early Swedish history of mathematics education. The manuscript includes a rich repertoire of examples, giving students the possibility to master the art of arithmetic. However, explanations to, for example, why certain algorithms work, are not given. Regarding the algorithms, we see some similarities with both Ramus' and Clavius' books, indicating that Rizanesander was influenced by them. Also, it is indicated that he was influenced by Buscherus' book. We suggest that further investigations of Rizanesander's manuscript should be done; in particular it would be valuable to consider not only the algorithms, but also the contextualization of the examples in order to further investigate in what way he was influenced by Ramus, Clavius and Buscherus.

# I Spy with my Little Eye – Teachers’ linkages about historical snippets in textbooks

Sebastian Schorcht

Justus-Liebig-University Giessen, Germany; [sebastian.schorcht@math.uni-giessen.de](mailto:sebastian.schorcht@math.uni-giessen.de)

*The aim of this explorative survey is to identify teachers’ beliefs about tasks concerning the history of mathematics. This poster proposal will give an insightful view on a pilot study on teachers’ beliefs about historical snippets in textbooks. First results of these pilot study can be discussed at CERME11 and may help to develop the main study.*

*Keywords: History of mathematics, beliefs, textbook.*

## Research topic

Textbooks play a crucial role in most mathematical lessons (Hiebert et al., 2003). Interactions between teachers and textbooks are an active process of re-sourcing the resource (Adler, 2000, p. 207) and have an impact on mathematical lessons (Brown, 2009). If we consider that tasks concerning the history of mathematics are included in textbooks and that teachers use their pedagogical design capacity to interact with these tasks, the following research questions are formed: Which connotations do the teachers have over these textbooks’ tasks? Do teachers identify the same benefits on history of mathematics in education like researchers do?

## Theoretical framework

The presented pilot study uses historical snippets to stimulate prospective teachers’ linkages, due to the fact that historical snippets are the most founded tasks in German textbooks (Schorcht, 2018). Tzanakis and Arcavi shaped the concept of “historical snippets” (Tzanakis & Arcavi, 2002, p. 214): A Historical snippet informs students or stimulates students’ activity. The detailedness ranges from simple dates into specifics about the history of mathematics. The possible content of a historical snippet could be, for example, biographical dates, photographs, introduction into topics, etc.

The international overview shows only small variations on types of tasks over different countries. For example, Xenofontos and Papadopoulos (2015) identify two types of tasks in Greek and Cyprus textbooks: those which inform students about the history of mathematics and those which lead to students’ mathematical activity. In German textbooks Schorcht (2018) identifies similar types of tasks. In comparison with the results of the studies, the presented survey determines three types of tasks: informative type, acting type and personalization type.

## Method and Sample

The pilot study shows participants three historical snippets in an online instrument<sup>1</sup>. These tasks are selected to represent one of the three types of tasks: one informative type, one acting type, and one personalization type. The topics are Pounds and Hundredweights, Egyptian Fractions, and Sofia

---

<sup>1</sup> For a closer look into the online instrument, use the following link: <https://surveys.hrz.uni-giessen.de/limesurvey/index.php/794939?lang=de> (online available until CERME11 and in German).

Kowalewskaja's biography. All tasks are from German textbooks of grade 3, 4 and 6. The participants are German mathematics pre-service teachers studying for primary level at University of Giessen. During the online survey, the participants should name similarities of two tasks and describe a third task in a different way. For example, the first two tasks (Pounds and Hundredweights, Egyptian Fractions) deals with mathematics, the third task shows a biography of Sofia Kowalewskaja. In this way, pairs of attributes of tasks emerge by the participants (for example: "deals with mathematics" and "shows a biography"). Afterwards, the participants define their pairs of attributes (for example: "deals with mathematics" = "the task request students to do math"). This kind of method is named as Repertory grid method (Kelly, 1955). The outcome of this online instrument will be a table, where each task can be assigned to one or more attributes. These attributes allow an insight into teachers' connotations about these tasks.

## Conclusion

The poster will show some tables from participants and figures of the used tasks. The Repertory grid method may give an overview on teachers' linkages about historical snippets. The results presented at CERME11 should initiate a discussion about the research questions and the developed pilot study. The hypothesis is, teachers didn't realize the benefits of history of mathematics in education and therefore integrate historical snippets without any idea how they should exhaust the benefits for the students.

# Exams in calculations/mathematics in Norway 1946–2017 – content and form

Bjørn Smestad<sup>1</sup> and Aina Fossum<sup>2</sup>

<sup>1</sup>OsloMet – Oslo Metropolitan University, Oslo, Norway; [bjorsme@oslomet.no](mailto:bjorsme@oslomet.no)

<sup>2</sup>OsloMet – Oslo Metropolitan University, Oslo, Norway; [aifos@oslomet.no](mailto:aifos@oslomet.no)

*Mathematics has been a constant part of Norwegian primary schooling. This impression of constancy is misleading, however. In the period from 1946 to 2017, the subject ‘regning’ (calculations) had its name changed to mathematics and has gone through a long series of reforms. The goals of the subject have changed with each reform.*

*Based on content analyses of a selection of school leaving exams, we will describe how the content of mathematics has changed over time. As the demands on pupils’ language have increased, so have the demands on their ability to use different tools and handle different task formats and information presented in different ways. In summary, the knowledge and skills that pupils need to complete the exams today are very different from the skills they needed in 1946.*

*Keywords: Mathematics Education, history, exit examinations, language.*

## Background

Mathematics as a school subject has been evolving over time, and this development can be studied through the examination of curriculum documents, exams and other sources. In this paper, we will study the school subject in Norway through its exams. While this is interesting in itself, we also hope that this study may be built upon to study trends in different countries.

In 1889, ‘folkeskolen’ (‘folk school’) was established by law in Norway. Pupils would enter school at age 7 and finish at age 14. There was a difference between the urban schools (byskoler) with 40 weeks of schooling per year and the rural schools with mostly 12 weeks per year at the program’s inception (Thune, 2017). In 1890, the first ‘normal plan’ for folkeskolen was put forward; it was revised in 1922/25.<sup>1</sup>

The law was again revised in 1936 (with new ‘normal plans’ in 1939). At this time, most children aged 7–14 did attend school. In 1959, a common law for both urban and rural areas was introduced, making schooling compulsory for everyone for 7 years. It even became possible to expand compulsory schooling to 9 years (this was to be decided locally). A new curriculum for the trials with 9-year schooling was published in 1960. By law, in 1969, school was extended to 9 years for everyone. It was extended to 10 years in 1997. New curriculum documents went into effect in 1974 (M74), 1987 (M87), 1997 (L97) and again in 2006 (LK06) (Thune, 2017). The next curriculum document is expected to go into effect in 2020.

The subject was called ‘regning’ (calculation) until 1959 but was renamed ‘matematikk’ (mathematics) in the curriculum documents from 1960 onwards. The different curricula had

---

<sup>1</sup> The normal plan for rural areas was revised in 1922, the one for urban areas in 1925.

different focuses, but Table 1 suggests a clear trend: new subjects have regularly been included, but rarely have subjects been removed. The subject ‘datalære’ (computer technology) was first a subject on its own in the 1987 curriculum, and computer technology has remained part of the curriculum in some form (although not in the original form with the intention of working on algorithms). However, according to the preliminary versions of the 2020 curriculum, it seems that it will be coming back.

	1939	1974	1987	1997	2006
Numbers and calculation	x	x	x	x	x
Geometry	x	x	x	x	x
Measurement	x	x	x	x	x
Algebra and equations		x	x	x	x
Functions		x	x	x	x
Application: private economy		x	x	x	x
Problem solving			x	x	x
Statistics			x	x	x
Probability and combinatorics				x	x
IT (‘Datalære’)			x		

**Table 1: Subjects in the curriculum documents**

Such a classification can never convey the full scope of the curriculum documents; there will be nuances in which parts of these subjects are included and how they are described. For instance, in the 1997 curriculum documents, the history of mathematics was explicitly included in the description of what pupils should learn, but not as a subject on its own.

By 1939, the plan stressed the active pupil, in the sense that the pupils should ‘do as much independent work as possible’ (Mosvold, 2002, p. 12, our translation). This was adhered to in the 1960 plan. In a temporary plan in 1971, this idea was gone, and the plan was based on the New Math and on teaching the correct definitions and rules. However, by 1974, heavy criticism led to the return to the concept of the active pupil, and most of the New Math ideas were removed (Mosvold, 2002). Throughout the 1987, 1997 and 2006 documents, the focus on active pupils has remained important, even though the latest curriculum documents have been more concerned with teachers’ autonomy in choosing their own teaching methods.

## Theory and earlier research

The development and implementation of curriculum happens on several levels: societal, institutional and instructional (Goodlad, 1979). The development of the exam in Norway is currently done on the institutional level by an ‘eksamensnemnd’ (‘exam committee’) appointed by the directorate of education. The exam and the results are important for the pupils, and the results

on the school level are published and influence the standing of the schools in the community. Exams play an important part in what pupils and teachers do – what is tested influences what is considered important (Au, 2007; Niss & Jensen, 2002; Wideen, O'Shea, Pye, & Ivany, 1997). Teachers also use earlier exams in their teaching (Andresen et al., 2017). Therefore, exams are an important object of study used to investigate the implementations of the curriculum over time.

In an evaluation of the 2017 exam (Andresen et al., 2017), comparisons with the 2009 exam show that, even in such a short time, there are important developments in terms of the content tested and the language, illustrations, question formats and so on.

Andresen et al. (2017) include a summary of international research on language traits that make mathematics tasks difficult to understand. These traits can exist on the word level (long words, infrequent words etc.), on the sentence level (for instance, long noun clauses) and on the text level (such as lack of connection between sentences). They can make tasks more difficult on their own or when combined with other traits, but difficult language can also be partially offset by helpful illustrations.

Our research question is this: How has the content and form of primary school exams in calculations/mathematics in Norway changed in the period from 1946–2017?

The choice of the particular period to study is governed by the availability of full sets of exams. We would like to stress that we do not study the difficulty of the exams, as the difficulty depends on the content of the education that has been presented. Neither will this article include an analysis of the contexts used in the tasks.

## Method

To answer the research question, we performed content analysis of the selected exams. The analyses considered several different aspects of the exams: the subjects, the answer formats, the language and the illustrations. In the analyses of language, the same method and operationalization are used as in the evaluation of the 2017 exam (Andresen et al., 2017).<sup>2</sup> This means that we analyse language features that are known to contribute to making understanding mathematics tasks more difficult: the number of words, long words (>6 letters), compound words and general academic words.<sup>3</sup> In the analyses of illustrations, we are inspired by Van Den Heuvel-Panhuizen (2005) and the different roles illustrations can have, but we use a simpler categorization: illustrations that are necessary to solve the task, illustrations that are helpful and illustrations that are simply decorative.

The choice of exams has been somewhat convenience-based, as not all exams are easily available in complete versions suitable for the different analyses we plan to do. Also, we have chosen exams from different time periods. For this paper, we include the exams from 1946, 1960, 1979, 1985, 1995, 2006 and 2017.

---

<sup>2</sup> Indeed, some of the results of the analyses of the 2017 exam have been used here directly.

<sup>3</sup> According to Academic Wordlist: <http://www.tekstlab.uio.no:4000/>

The 1946 and 1960 exams were made locally, and the ones we include are from Oslo, the capital of Norway, for the entire period. The remainder of the exams are national.

Year	School	Grade	Hours
1946	Oslo Folkeskole	7 <sup>th</sup>	4h
1960	Oslo Folkeskole	7 <sup>th</sup>	4h
1979	Grunnskolen	9 <sup>th</sup>	5h
1985	Grunnskolen	9 <sup>th</sup>	5h
1995	Grunnskolen	9 <sup>th</sup>	5h
2006	Grunnskolen	10 <sup>th</sup>	5h
2017	Grunnskolen	10 <sup>th</sup>	5h

**Table 2: Exams chosen for analysis**

In some of the exams, there are tasks that not everyone is supposed to do in the same way. The 1946 exam included one task that girls could choose not to do, as they had less teaching than boys. We have included that task in our analyses. The 1985 exam was in two parts: part 1 was to be done without a calculator, but part 2 came in two versions, one for use with a calculator and one without. We have analysed the version where the calculator was allowed. In 2006, there was a considerable number of tasks (62) of which pupils were supposed to choose only some (39). While we have analysed all 62 tasks in tables and graphs, here we include only numbers based on 39 tasks.<sup>4</sup> In 1960, 1979, 1995 and 2017, every pupil was supposed to do all the tasks included in the exam. It is an interesting finding on its own that the scope of choices has varied so much through the years.

For most of the exams, it was not apparent whether all subtasks counted the same towards the result. Therefore, in these analyses, we use unweighted counts of the subtasks.

## Results and discussion

The analysis of the content of the tasks is in accordance with the general goals of the curricula. While numbers and calculations were part of all sub-questions in the 1960 exam, today they comprise about half of the tasks. There appear to be two reasons for this: partly because new topics are included in the curriculum and partly because the tasks seem to be ‘purer’, in that there are more examples of tasks that test only one topic.

---

<sup>4</sup> To be precise, we calculate the average of the numbers that would be right if the students always chose the first available option and the numbers if the students always chose the last available option.

**Figure 1: Percentage of tasks testing different topics, 1946–2017**

In addition, the answer formats have also become more diverse. In 1946 and in 1960, all exam tasks were answered with a short calculation and an answer (called ‘open’ here). In 2017, 24% of the tasks were multiple-choice items. In addition, some tasks are to be answered using a spreadsheet, some using a graphing program (Geogebra, for instance) and some (17%) were to be answered with the answer only.

**Figure 2: Answer formats in exams**

The tools that pupils have available and are supposed to master have changed through the years. In 1946, the pupils probably had no other tools than pen or pencil and paper. In 2017, pupils are supposed to use graphing software (such as Geogebra) and spreadsheets in addition to more traditional tools, such as calculators, compasses and rulers. Today, computer algebra systems (CAS) are also allowed.

Table 3 shows the number of sentences and the number of words in the exams. The amount of language has varied, with a decrease from 1946 to 1960. However, the main tendency is that the amount of language has been increasing since 1960 and that it was higher in 2017 than in any other year in our sample.

	1946	1960	1979	1985	1995	2006	2017
Number of sentences	95	62	63	113	143	111	158
Number of words	756	464	456	896	945	924	1240

**Table 3: Number of sentences and words in the exams**

In this table, the number of sentences and words that the pupils in 2006 were exposed to is understated. If we suppose that many pupils read all 62 tasks in order to choose which 39 to do, they would have to read 164 sentences with a total of 1,434 words, making the 2006 exam the most voluminous of all of these exams. Additionally, there was a 539-word information booklet which the pupils were supposed to have read in advance of the test.

More challenging than simply evaluating the number of words is trying to say something concrete about how the language has changed. In analyses of language traits that make tasks difficult to read, long words, compound words and general academic words are of interest.

**Figure 3: The ratio of long words, compound words and general academic words in exams**

In Figure 3, we see a clear tendency throughout the period of a higher proportion of long words and general academic words, while there has been no significant increase in the number of compound

words. The general academic words are noteworthy – examples of these are ‘describe’, ‘function’, ‘example’ and ‘explanation’. While pupils in 1946 were mostly asked to do something (calculate, usually), in 2017 they were asked to compare, describe and explain, which may be more demanding.

In addition to pupils having to deal with more tools and a more academic language, the exams are also visually different: there is a large number of illustrations in modern tasks. We look at which illustrations are necessary to solve the task, which are helpful, and which are only decorative.

	1946	1960	1979	1985	1995	2006	2017
Necessary	0	0	2 (2)	4 (3)	8 (8)	14 (13)	17 (15)
Helpful	0	0	2 (1)	0	0	3	7 (1)
Decorative	0	0	0	0	0	10	9

**Table 4: Illustrations in exams: necessary, helpful or decorative. In parenthesis are the numbers of illustrations that are explicitly mentioned in the text of the task**

Table 4 shows that, in our material, illustrations were not included until 1979, and at that time only as illustrations that were necessary or helpful to solve the task. In the 21<sup>st</sup> century, there have also been more illustrations that are simply decorative, and even illustrations that are necessary to solve the task are not necessarily mentioned explicitly in the text. Even though illustrations can make the tasks easier to understand, at the same time, they make more demands on the pupils – in 2017 there were 33 illustrations, and for each, the pupils had to decide if they needed to use them to solve the tasks.

While it is important to consider that the 1946 and 1960 exams were for 14-year-olds, while the rest of the tests are for 16-year-olds, most of the development noted seems to have been independent of that change.

## Conclusion

The overall picture is complex. Thematically, mathematics as a subject has become more diverse. While the exams in ‘folkeskolen’ consisted mainly of calculations, often involving measuring units and everyday economics, today they involve more topics. However, at the same time, the connections among different topics seem to be included less often – fewer tasks now include more subjects at once.

More tasks are multiple-choice, making it possible to get through more tasks in the same amount of time. Also, there is a need for speed because in the five hours allotted, pupils must demonstrate their skills with more tools than previously, including spreadsheet and graphing software and CAS.

The demands on the pupils’ language skills have also increased. The number of words has increased, and the proportion of long words and general academic words has increased as well. There are far more illustrations than before, and the illustrations serve several different functions.

Consequently, although we cannot say whether the difficulty level of the mathematics has increased or decreased, the complexity of the exams – a greater variety of topics, answer formats, tools and

greater language difficulty – means that there are many more factors that pupils must deal with than previously. At the same time, the number of questions has increased substantially, meaning that the students have far less time to consider each sub-question while handling the different complexities. Thus, speed is implicitly seen as an important value in mathematics, and while this is rarely questioned by teachers, it is often questioned by mathematics education researchers.

In conclusion, such an analysis of exams may give a clear picture of the development of mathematics as a school subject which can complement the results of curriculum analyses. To the extent that exams do not develop in the same direction as the curriculum documents, it is an open question as to whose concept of mathematics will prevail. International comparative studies would be an interesting next step to see how trends in exams are similar or different across borders.

# History of mathematics in Dutch teacher training

Desiree van den Bogaart-Agterberg

University of Applied Sciences of Amsterdam, Faculty of Education, Amsterdam, The Netherlands;

[d.a.van.den.bogaart@hva.nl](mailto:d.a.van.den.bogaart@hva.nl)

*In most teacher training programs for Dutch mathematics teachers, history of mathematics is a required part of the curriculum. The courses provide historical background knowledge of certain mathematical developments to the students. This knowledge could also affect prospective teachers' views on the nature of mathematics and the pedagogical choices they make for their classrooms. These effects have been examined in a small qualitative research project with two different groups of students from a teacher-training program in Amsterdam. The results are discussed in this paper and can be useful in describing and evaluating the relation between knowledge of history of mathematics and classroom activities.*

*Keywords: History of mathematics, teacher training, empirical study.*

## Introduction.

I have been teaching history of mathematics courses at the University of Applied Sciences in Amsterdam (in Dutch: Hogeschool van Amsterdam, in short: HvA) for the last eight years. Over time, the goals of the courses I designed have shifted from providing background knowledge of history of mathematics, to demonstrating what this could mean in terms of pedagogical choices and classroom activities. This assumes that there actually is a relation between the two. In my research I want to focus on this relation, in part to describe it and in part to evaluate it.

## Organization of the paper.

This paper is organized in three sections. First the Dutch system of teacher training is briefly described; in particular the way history of mathematics is incorporated. In the first section I will also focus on the situation at HvA, the context in which the empirical part of the study took place. Next, the aim of the study and the research method are described in the second section. Finally, the results are presented and discussed. Acknowledgements and references will conclude this paper.

## History of mathematics in Dutch teacher training.

To become a mathematics teacher in the Netherlands, there are two main options. There is the university program, which consists of a three-year undergraduate program in mathematics, followed by a two-year master's program in science education. This route leads to a teaching qualification for all secondary levels in mathematics, for pupils aged 12 to 18. This is called a first degree qualification, or a master's degree in teaching. However, in this paper the focus is on the other option, chosen by the large majority of (future) Dutch mathematics teachers. (Van den Bogaart et al., 2018)

The alternative route consists of a four-year program at a university of applied sciences. This leads to a teaching qualification for the lower secondary levels in mathematics (pupils aged 12 to 15). This is called a second degree qualification, or a bachelor's degree in teaching. Once these four years are successfully finished, teachers have the opportunity to advance in another three-year program at a university of applied sciences. This finally leads to the full first degree qualification for all secondary levels, or a master's degree in teaching.

Institutions for teacher education have autonomy in designing their curriculum, but the programs are grounded on formal 'knowledge bases' (Kennisbasis in Dutch, KB in short). Since the Dutch system recognizes two degrees of teaching, there is a separate KB Mathematics Bachelor for second degree teachers and another KB Mathematics Master for first degree teachers in programs at universities of applied sciences. I will refer to the two KBs in Mathematics as KBM2 and KBM1. In both KBM1 and KBM2, history of mathematics can be found as a specific subdomain.

The subdomain history of mathematics in KBM2 consists of eight learning outcomes, for instance "The teacher can give examples of the development of mathematics in relation to cultural and historical contexts". History of mathematics is also mentioned explicitly in the last domain of KBM2, which deals with pedagogy. "The teacher can use history of mathematics to enrich his/her pedagogical skills". (Kennisbasis Wiskunde Bachelor, 2017, p. 19)

History of mathematics is not an obligatory subdomain in KBM1, but it can be chosen as extra or can be integrated in the rest of the curriculum. For instance the history of non-Euclidean geometry can be integrated in a geometry course, (Kennisbasis Wiskunde Master, 2012). History of mathematics is not explicitly mentioned in the pedagogical domain of KBM1.

### **The curriculum at HvA.**

In the second degree mathematics teacher training program at HvA a course on history of mathematics is programmed in the first semester of the third year. The course is equivalent to 3 ECTS. Over a period of seven weeks, the students receive an overview of history of mathematics from the early ages until the beginning of the seventeenth century. There is a 100 minutes lecture once a week. Students are provided with texts (a textbook, additional articles, some primary sources), videos and exercises. To pass, students complete a written exam.

In the first degree mathematics teacher training program at HvA a course on history of mathematics is programmed in the second semester of either the first or the second year. The course is equivalent to 5 ECTS. Students learn about the history of mathematics, starting with the seventeenth century and finishing in the early 20<sup>th</sup> century. Over the course of an entire semester there are six lectures of 150 minutes each. Students are provided with texts (two textbooks, additional articles, some primary sources), videos and exercises. They are expected to perform a bit of historical research themselves on a mathematical subject of their choice. To pass, they must hand in several written assignments (individually) and a research report (group work). In both the research project and one of the other assignments they have to design a classroom activity. One of the criteria for the research report is that there has to be explicit mentioning of the implication(s) of the research project for their practices as teachers. Finally, they present the research to their classmates.

The subjects that are dealt with in both courses, either discussed in the lectures or explored in the provided materials, are chosen by me and my colleagues at HvA, with the future teaching practice of our students in mind. The subjects are closely related to subjects that they will discuss themselves with their pupils (such as preliminary algebra and Euclidean geometry in the second degree training and calculus and analytical geometry in the first degree training). Some of the exercises we do in the course are exercises that can be done in the students' own classrooms, without any modification. However, most of the texts and problems that are discussed in the course are on a more advanced level. The purposes of these activities can be different, such as: demonstrate the level of sophistication of the mathematicians and cultures of the past (and by doing so testing the level of mathematical knowledge of the students), discuss what conceptual obstacles were overcome, illustrate the circumstances under which discoveries took place and the human factor in all that. The two instructors of the courses (myself and a different colleague on either first and second degree training) both emphasize the importance of the historical knowledge for mathematics teachers on a regular basis.

### **Description of the research.**

The starting point of this research was the evaluation of the courses on history of mathematics at HvA with special interest to their effects on the beliefs and teaching skills of the students. Did the course on history of mathematics affect students' views and is there some form of transfer to their classroom activities? If the students could not identify any effects, or mainly describe the personal gain of the course they took as simply historical background knowledge with little relation to their teaching, this could serve as input for redesigning the courses.

There is very little empirical data on effects of integrating history of mathematics in mathematics education (Jankvist, 2009). The amount of empirical information on the effects of this integration in teacher training is even less. Although this research is partially set up in a quantitative way, its main goal is to gain qualitative information, as input for further research.

One can think of a number of ways in which information about the history of mathematics can have an effect on students, in particular student teachers. Literature on the use of history of mathematics in the context of teacher training provided a list of possible effects/influences, stated below.

- a) Influence on attitude and beliefs on the nature of mathematics as a subject (Schubring et al., 2000), (Charamboulous et al., 2009)
- b) Insight in the development of mathematics and its curricula (Schubring et al., 2000)
- c) Acknowledgement of processes and obstacles that can occur in developing mathematics, and thereby enhancing one's own comprehension of mathematics (Schubring et al., 2000)
- d) History is an inspirer of strategies of teaching (Furinghetti, 2007)
- e) Learning to use history of mathematics in own teacher practices (Schubring et al., 2000)
- f) Influence on self-efficacy (the degree to which a teacher considers himself as capable of affecting student learning) (Charamboulous et al., 2009)

These six possible effects were reformulated into six statements (in Dutch), to which the students were asked to react (see Table 1). Do they (partially) agree with the statement or not? Students were asked to react to the statements on a five-point Likert-scale from completely disagree (1) to completely agree (5). Statement A corresponds to effect (a), statement B to effect (b), etc.

Following the course on history of mathematics has...	1	2	3	4	5
A) affected my view on the nature of mathematics					
B) enhanced my own comprehension of certain mathematical concepts					
C) made me more aware of conceptual- or process-related obstacles that my pupils have					
D) expanded my pedagogical repertoire					
E) taught me how to use history of mathematics with my own pupils					
F) enhanced my self-efficacy as a math teacher					

**Table 1: Statements in questionnaire (transcription)**

In addition to reacting to these six statements, students were invited to comment on each statement separately. It was not required to comment on every statement, but in the instructions given by the researcher to the students upon filling out the questionnaire, the value of their additionally provided explanations, examples and/or information was amplified. For each statement there was a separate question added, to be able to connect the comments to the right statement and also provoke sufficient reactions. For instance, the additional question to statement A was: “Can you comment on the way in which your view has changed? How was it before and how is it now?”.

The group of students of the first degree training, who took the course on history of mathematics from January until July 2017, was asked to fill out the questionnaire in September. Almost the entire group had finished the course by then (some still had to hand in an assignment or do some revision work on the research project). Some students had left the teacher training program altogether, or simply were not present at the time the questionnaire was taken. Approximately 60% of the students who took the course participated in this research. In November and December 2017 the course on history of mathematics in the second degree training took place. Over 70% of the students who took this course filled out the questionnaire in March 2018.

The questionnaire was filled out in class, on paper, at the start of a lecture of another course that most students were expected to take. I chose not to combine filling out the questionnaire with the written test or peer presentations at the end of the course. This way the complete course, assessment included, could be taken into account by the participants, after the entire course had finished.

The results were imported to a spreadsheet to calculate the mean of the reactions to the statements. The open responses to the questionnaire were qualitatively categorized. The categories used were not defined in advance, but were a work-in-progress. Some categories turned out to be useful for

open responses on several statements, which show interesting relations between some of the statements. I discuss these relations in the next section.

## Results.

The results of both questionnaires are presented separately, since the students took separate courses and have different backgrounds and teaching practices. I first summarize the quantitative results on the statements, and then I address the reactions to the statements (open responses). Finally, I provide some remarks on similarities and differences between the results of the two groups.

### First degree training questionnaire.

Twenty-three students filled out the questionnaire. Table 2 shows the mean value of student reactions to the six statements and also the number of students who commented on each statement.

Statement	A	B	C	D	E	F
Mean	3.35	3.35	3.22	3.61	3.57	2.70
Comments on statement	13	12	8	15	13	7

**Table 2: Reaction to statements by first degree training group**

The calculated means were not meant to be interpreted separately, but can be used to arrange the statements from strongest agreement to weakest agreement. The statements on pedagogy and classroom activity (D and E) resonated most strongly with these students, while the statement on self-efficacy (F) received the weakest agreement. As for the comments, in what follows I briefly review the statements, specify the categories used to label them, and give examples of statements made by the students.

Comments on statement A were arranged into five separate categories. They are presented here in order of declining frequency. The majority of responding students mentioned they gained more background information (i), some started seeing mathematics more as a dynamic subject rather as a fixed set of techniques (ii), some started seeing mathematics more as a human activity (iii), some discovered more coherence within mathematics itself (iv), and finally one student realized that mathematics can be ambiguous and debated (v).

Sample student comments on statement A:

Student #M17: From abstract science to human activity.

Student #M20: I see mathematics now more as a process rather than a result (toolkit).

On statement B, most of the responses listed mathematical topics or concepts that were understood better due to the gained knowledge of their history, but some also specifically mentioned the increased insights in coherence (see also category (iv) from statement A). When asked to comment on statement C, half of the responses described in some way that their pupils should also experience mathematics as a process rather than a product, so that can be seen as a form of transfer of category (ii) to the learning process of their own pupils.

Additional remarks to statements D and E on the possible expansion of their own pedagogical repertoire and use in their own classrooms produced mostly broad topics of school mathematics such as geometry or algebra. Some students made general remarks on using history of mathematics as a way to introduce new mathematical concepts or create more variation in lesson activities.

Statement F (on self-efficacy) had the lowest average on the Likert-scale and also produced the lowest number of reactions. A number of students explicitly stated that there was no relation between their knowledge of history of mathematics and their self-efficacy as a teacher. They almost seemed offended by the suggestion. On other statements they would simply leave a blank space if they disagreed. Students who did see a positive influence formulated it in a general way, e.g., more background knowledge gives me more insights in mathematics and therefore enhances my self-confidence as a teacher. This seems equivalent to category (i) in the first statement.

### Second degree training questionnaire.

Seventeen students completed the questionnaire. Table 3 shows the mean of student reactions to the six statements and the number of students who commented on each statement.

Statement	A	B	C	D	E	F
Mean	3.65	3.88	3.53	3.76	3.29	2.88
Comments on statement	13	10	9	10	9	5

**Table 3: Reaction to statements by second degree training group**

When statements are ordered by calculated means of the Likert-scale of agreement, statement B (on their own understanding of mathematics) appears first. This seems logical, since the mathematical knowledge of this group of students in the bachelor program is obviously much less than that of the students in the master program, so there is more room for growth. Statement F also scores lowest in this group, the same as in the first degree training group, with similar comments that explicitly deny the relation. The statement on the use of history of mathematics in their own classrooms comes in second to last, which can be explained by the fact that this group consists of less-experienced teachers, which might be holding back on this type of activity in their teaching.

Comments on statement A were divided into five separate categories, which mostly correspond to the categories in the other group. Again the order is by declining frequency. Students mentioned they gained more background information (i), recognized, in particular, more different cultural contributions in the history of mathematics (ii), started seeing mathematics more as a dynamic subject rather as a fixed set of techniques (iii), saw more coherence within mathematics itself (iv), and made connections with the learning of their own students (v). The new category (ii) seems appropriate, since this course explicitly pays attention to the contribution of non-Western cultures to the development of mathematics.

Statements B and C were commented on in a rather similar way. Almost all comments contained examples of specific topics or concepts of school mathematics. Amongst those topics the concept of number (e.g., negative numbers, fractions, square roots, and zero) was mentioned frequently, as well as solving linear and quadratic equations.

Sample student comments on statement D:

Student #B3: For instance to visualize equations with geometry.

Student #B14: Introducing variables with “The thing plus the root of the thing.”

Although statement D scored rather high quantitatively and the comments on this statement produced plenty of concrete examples (like the ones on statement B and C), the use of history of mathematics in students’ own classrooms (statement E) mostly resulted in general ways of using history of mathematics, such as introduction or variation.

### **Overall remarks.**

It was surprising to see students describe effects that taking the course on history of mathematics had on them with such detail, especially in the first degree training group. Without any concrete examples mentioned by the researcher, students were able to mention words like coherence, human activity, and ambiguity. This can indicate advanced personal reflection skills on the part of students, or this may have been provoked successfully by the course.

Some of the differences in reactions between the two groups seem naturally connected to the level of their knowledge of mathematics and teaching experience. Students in the second degree training group were better at specifying the relation to the topics in school mathematics, which seems logical considering the contents of their course. Early developments of mathematics can actually be found in the curriculum for 12 to 15-year-olds, until the coordinate system of Viète and Descartes in the early 17<sup>th</sup> century, but when we discuss Weierstrass and Cantor with students in the first degree training, this has much more distance to the concepts they teach in their own classrooms.

Both groups were rather firm in their rejection to influence on their self-efficacy. One could argue that the gained knowledge, both mathematically and pedagogically, should be rather closely connected to the confidence of a teacher, but for the students who took these courses and completed the questionnaire this was a bridge too far.

### **Discussion.**

The obvious point of discussion here is the design of the courses. This was not aligned with the six effects of the use of history of mathematics in the context of teacher training which were obtained from literature. Further research is necessary to focus on one or more effects, which must be attended to beforehand in the design of the courses. In particular, the way the courses are assessed should be taken into account. Still the results of this research give us valuable information on what effects take place, by courses designed in the described manner, at least as reflected by the students themselves. This leads to another point of discussion.

It is important to note that the results are purely based on self-reported opinions of the students themselves, on their self-assessment of their knowledge, and their views ‘at the desk.’ That means: this is what they think of themselves, their views and skills, outside the classroom. To get a better picture of the effects there should be some form of ‘in action’ research in their classrooms.

The results of this pilot empirical study indicate an added value of knowledge of history of mathematics for teachers. The results can be used as input for the redesign of these courses and other activities involving history of mathematics in teacher training. They may also be useful for further research on the partnership between mathematics, history and education.

## Acknowledgements.

This research project has been made possible by the financial support of both the Research Center and the Department of Science teacher training of the Faculty of Education of the HvA. Thank you to Ron Oostdam, Monique Pijls and Andrea Haker for their support. The courses on history of mathematics that I taught in 2017, which were the context for the research in this paper, were taught together with two wonderful colleagues: Lidy Wesker-Elzinga (first degree training) and Peter Lanser (second degree training).

*With the introduction of so-called educational standards, the German government has mandated by law that German schools, universities and teacher training colleges use the language of competences as a universal language to describe, plan, test and develop teaching and learning processes. This shift to output orientation resulted in a break with the formerly internationally recognized educational tradition of the Enlightenment. In order to understand and highlight the magnitude of this, we look at different historical perspectives regarding these reforms.*

*Keywords: Democracy, history of mathematics, educational reforms.*

## Introduction

The present paper responds to a desire that several of our colleagues had expressed at the International Conference on the History of Mathematics Education (ICHME) in Utrecht in the Netherlands in 2017: To place current developments in German mathematics education in a historical context. The reasons for this request were that these colleagues realised similar developments sometimes, possibly with a time shift, in other European countries, such as output and competence orientation, the introduction of educational standards, central tests and global assessments, or the economization, centralization and digitalization of the education system. The study of the history of mathematics and mathematics education seems to support a critical view of these developments. It was pleasant to find congeniality. However, it immediately rose questions which of these issues constitute a common concern. What precisely is going on with these developments? Another aspect of this debate inspired by our lively discussions was whether and how the study of history can support the teaching of critical judgement and the safeguarding of democracy and human values in pedagogy.

In the meantime, some new perspectives such as a better understanding of the origins of competence orientation in psychology (cf. Ryan & Deci, 2000 or Gelhard, 2011) emerged from the study of the developments in mathematics education at the end of the last millennium, and from the authors' attempts to incorporate them into seminars on mathematics education. The reforms and changes we are going to discuss are, however, not specific to mathematics education. Therefore, this discourse should be relevant to the history of education, pedagogy, sociology and psychology.

However, the changes in German education policy at the beginning of our millennium were accompanied by a shift in the subjects and theoretical foundations of educational sciences towards applied psychology, empirical research and the notions of evidence and measurability. The latter had an impact on school development and beliefs and convictions about the superior importance of factors that contribute to good teaching and "effective" learning. Still, if there were to be a lecture about the history of current reforms in education, it would probably be attended by only a few people. Most students put educational sciences on a par with a general methodology (cf. Jahnke,

2008), and therefore, above all, want to receive the latest and empirically proven approaches in these subjects in order to be able to adapt themselves to the requirements of their future working situation. Here the economization of the university system and the new role of students as customers and future employees plays its part.

Why should the *history of mathematics education* be taught to future teachers and in which form can it be incorporated in mathematics education?

Learning from history does not automatically mean that history prevents us from repeating mistakes. Politicians are not supposed to be historians: Historical situations never completely recur, and therefore the future cannot be predicted from even the most profound knowledge of the past. However, on a small scale with limited demands, it is quite possible to learn from history (Geiss, 2019). The recognition of constellations and gradient patterns occurring over time plays an essential role in this. Even though it is not possible to transfer causal connections, the study of structural components, which recur and make up these constellations and patterns, can certainly contribute to sharpening political judgement. However, the tightrope between showing such patterns and indoctrination through the political or even ideologically influenced production of time references is extremely narrow (Bergmann, 2002).

Because of this, and the highly political significance of the reforms, we are going to work backwards: We start with a description of the current situation and ask the students to find differences with the practices, school subjects and events of the past, which look at first sight very similar or carry similar names to those of today. Thus, the formation of analogies does not arise through our study of historical sources, but is rather questioned by these sources.

In the implementation of educational policy requirements, teachers in Germany have a great deal of freedom in the design and application of these requirements through the legally guaranteed freedom of methods (Gasser, 1982). Dealing with the history of mathematical teaching can help to appreciate existing structures, to include experiences from the history in change processes and to relativize so-called “new approaches”.

Through taking a historical perspective on the development of mathematics education and related educational policy, our goal is to support our students’ need to question the reasonableness and necessity of political reforms and to shape them as responsible future teachers.

### **Some features of educational reforms**

The study of the history of educational reforms and their theoretical foundations is particularly relevant today. German students have experienced several reforms during their school time. The theoretical foundation of these reforms has not yet taken place. Keywords for these reforms are *output* and *competence orientation*, the introduction of educational standards and central tests, the abolition of the orientation classes and pre-school education, the reduction of upper secondary classes by one year, the digitalization of learning environments, the restructuring of secondary schools, and the overall present *inclusion*<sup>1</sup>.

---

<sup>1</sup> Political activities of the Government to implement the *UN Convention on the Rights of Persons with Disabilities*.

In particular, these political reforms have been pushed through with tremendous pace. Therefore, it is certainly worthwhile to engage in reforms, which had been prepared and installed during half a century; e.g. the *Meraner Reform* was discussed widely and implemented in small steps (Schubring, 2007). However, the current reforms have a different character. The abolition of the *orientation level*<sup>2</sup> and pre-school education, the reduction of upper secondary classes by one year, the restructuring of secondary schools, the shift from special schools for specific disabilities to integrated/ inclusive forms of schooling, the shift from the three-tier school system towards a comprehensive school: All these can be seen as structural reforms of the school *system*. Looking back at the history of German schools, it strikes us that every of the former changes in the education system was related to just one type of school and perhaps their related types, and was prepared for and carried out over a period of 200 years. The current reforms, however, took place almost simultaneously in a period of just 20 years and involved all school forms at once.

It is worth studying the history of different school types and of preschool education separately and to investigate their links to teacher training and assessment development for teachers and students (Leschinsky & Roeder, 1983). There is a large body of literature now starting from original sources like school archives, commission reports and resolutions, as well as secondary literature, which studies these reforms from the point of view of institutional history (Müller et al., 1987). Of course, the study of these sources relates institutional aspects to the biography of its main actors and of the study of political and economic contexts. It is noteworthy that it is often difficult to find historical sources with plans, programs and resolutions, but if one does find them, one knows the names of the main institutional actors. This is not the case with the present documentation of reforms. Here, the authors hide behind huge organizations and their programs. It is hard to find out who is responsible.

Another approach when looking at the history of reforms is to see the teaching community as a *community of practice*. When doing so, the importance of associations, societies, clubs, unions etc. should also be taken into account. One can also study reforms as the history of concepts, ideas and value systems as they develop in communities.

In order to describe the current changes in mathematics education as a change of value systems from input<sup>3</sup> to output orientation in terms of economization with a measurable and an only functional notion of education, we here give a short historical overview of where the notion of *competences* comes from.

### **What is the dispute about competence orientation all about?**

The concept of *education systems*, which is based entirely on economic aspects, has a long tradition in the OECD. The conference documents and the results of the discussion at the “OECD

---

<sup>2</sup> Grade 5 and 6 of secondary school were supposed to be an orientation period in order to decide about the type of school.

<sup>3</sup> Input orientation is often misleadingly referred to as the lack of qualification goals and results as well as interpreted evaluations see (Ladenthin, 2011, p.1).

Conference in Washington”, which was also decisive for the entire public discussion of educational and educational issues, showed unequivocally in 1961 the limited economic and technical view of human development and progress:

““It goes without saying that the educational system must be an aggregate of the economy, it is just as necessary to prepare people for the economy as real assets and machines. The educational system is now equal to highways, steel works and chemical fertilizers’. Thus the claim can be made ‘without blushing and with good economic conscience that the accumulation of intellectual capital is comparable to the accumulation of real capital – and in the long range may outmatch it.’” (Graupe & Krautz, 2014, p. 3)

Earlier, Graupe and Krautz explicated:

“The same conference volume states that, with regard to developing countries, it would be ‘nothing short of cutting a million people loose from a way of life that has constituted their living environment for hundreds or thousands of years. Everything achieved by these countries’ schools and education until now has served social and religious aims which have primarily allowed for resignation and spiritual comfort; things that completely go against any economic sense of progress. Changing these century-old approaches may perhaps be the most difficult yet also most important task for education to accomplish in developing countries.’” (loc. cit., p. 2)

Here, human development is reduced to economic growth and technical progress. Socio-historical, cultural and educational aspects are not only ignored, but also presented as disturbing and negative. In essence, the views expressed by the OECD have not fundamentally changed since then, but the causes of the need for unifying reforms are now general concerns, such as the growing globalization of the economy and the new requirements of a technological society.

50 years on, the OECD has in its own words, “become central, providing indicators of educational performance that not only evaluate but also help shape public policy.” (Gurría, 2011, p.318). The introduction of competence orientation is not a particularly German phenomenon. However, it seems that in Germany it leads to more radical changes in the educational system than elsewhere. The pretext for a radical change in education policy was the “moderate performance” of German students in the PISA test 2003, which was not in line with social expectations. In the media and by politicians it is referred to as the “PISA shock”.

Although the OECD had already tested in mathematics decades before, and the TIMS study had already taken place (since 1995), the second PISA test in 2003 was suddenly taken as “the truth” by German politicians and media about the German educational system and as an indicator of what students “really” know. The political goal became to improve the result of tests such as PISA or the TIMS study. Competence orientation promises, among other things, to be able to do this and turn education into a manageable system:

“Educational standards with their reference to student competences are explicitly formulated in a way that allows them to be checked with the help of corresponding questions or tests. This measurability characterizes them nationally and internationally, and with all due modesty, it is this characteristic that makes it possible to determine at certain points in time whether and to

what extent students are adequately prepared for life or whether there is a need for optimization.”  
[Blum et al. 2006, p. 9, translation by the authors]

As a measure against the PISA shock, in 2004 the German Conference of Ministers of Education adopted the so-called “educational standards” (*Bildungsstandards*) and reorganized the curricula on the basis of competence orientation.

However, is ‘competences’ really just a new word for something akin to learning goals? Has that not always been around? And, who can object to schools and universities at least formulating the goal of ensuring that graduates are fully competent when leaving? Would anyone not want them to apply this knowledge meaningfully and use it to solve “inner-mathematical problems” as well as real-world ones? Do the practitioners and theoreticians of mathematical doctrine focus on an enemy who is not actually a threat? Is it not good that requirements are standardized so that they can be taught systematically? This critical discourse may appear to large parts of a general mathematical audience as splitting hairs. The introduction of competence orientation as a universal and legally prescribed paradigm for the description and design of learning processes, however, has a very specific impact on the mathematical culture in teaching and research. The definition, which is based on the German competency orientation, goes back to Weinert:

Competences in this context are the cognitive abilities and skills available to or learnable by individuals in order to solve specific problems and the associated motivational, volitional and social readiness and ability to successfully and responsibly use the solutions in variable situations. (Weinert, 2002, pp. 27-28, translation by the authors)

The introduction to this definition in the above-cited text is rarely added:

In this context, the OECD has repeatedly suggested that the ambiguous concept of performance should generally be replaced with the concept of competence.

It is vital for mathematics teachers in schools and universities to understand these developments more thoroughly and to engage in a humanities discourse with pragmatic consequences that cannot be fundamentally clarified by empiricism and that only partially takes place within the mathematical culture. In competence orientation, we are dealing with a fundamental change in our understanding of learning. Is it about learning to understand something, or is it about convincing others on the basis of measurable output that I have understood something?

The conceptual system of competence orientation derives from applied psychology (Gelhard, 2011). For a long time it was used for the selection and adaptation of workers who were meant to meet specially defined psychological requirements in the workplace, such as patience, accuracy, speed, etc. Although competence orientation with regard to teaching was promoted on the initiative of the OECD (cf. Weinert, 2002, p. 27) and by pedagogical psychologists and educationalists working predominantly on a quantitative empirical basis, there is still no unequivocal empirical evidence to date that suggests that the competence orientation currently implemented by the state has a positive effect on the knowledge and skills of high school graduates or new students.

As of now the concept of competence, the credo of the testing industry, based on a definition by Franz Weinert, has become the central concept of the transformation of our entire education system.

It has evolved from a psychological selection tool into the guiding principle for quality control of industrial production of human capital, as the OECD has promoted for decades. After all - and this cannot be emphasized enough - competences are a psychological instrument. Modeling, collaborating, arguing and even moral competences (Weinert 2002, p. 28) etc. are elevated to context-free problem-solving activities. As they do not have to do justice to any context, they become observable and measurable psychological categories.

### **Are there developments in the past akin to competence orientation and educational standards?**

If we look at competence orientation as a promise of salvation, as a concept of being able to acquire skills applicable to any subject without learning to be an expert in that subject, then we cannot find similar developments during the last 200 years: Skills and knowledge are traditionally closely related to content, either from the perspective of vocational training or from the perspective of humanistic education.

The existence of very general concepts guiding educational reforms leads us to the reform of school geometry, driven by the slogans such as “Neue Geometrie” (new geometry) or “Los von Euklid” (away from Euclid), both in the 19<sup>th</sup> century. We may also think of the Meraner Reform and its motto of “Erziehung des funktionalen Denkens” (Education of functional thinking) or the “Neue Mathematik” (New Maths movement) (Schubring, 2014, pp. 241-257). In all these cases, the principles for the reforms were inspired by developments in mathematics such as projective and other non-euclidian geometries, descriptive and analytic geometry in the 19<sup>th</sup> century and functional analysis, algebra, logic and set theory, and probability theory at the turn of the last century.

If we think about the pretext of the reform the so-called “PISA shock”, it sounds quite similar to the “Sputnik shock” on the eve of the New Maths reforms. The Sputnik shock however, was part of world affairs whereas PISA was enacted especially to get an influence on national educational systems.

We traced the development of the notion of competences back to its original use as a psychological selection tool and its modern use to limit the notion of “Bildung” to practical usefulness and functionality. The discourses about role, extent and place of applications and modeling in today's mathematical education have also a history and can be retraced to discussions during the twenties, fifties and eighties. The current so-called modeling problems in A level tests became part of German school mathematics in the context of the PISA shock and its subsequent reforms to improve the poor performance of students in the field of modeling competences.

As we can see, there are various ways to explore the history of mathematics education: On the one hand, we went back to the roots of current educational reforms; on the other, we looked for similar patterns in the past.

## Conclusion

We did not answer the question of how to continue the discourse, which started at ICHME, but it inspired us to look for ways to include the history of mathematics education in teacher education. The current gradual shift in the fundamental principles of the German education system make reflecting on these foundations even more important.

Notably the *von Humboldt Bildungsideal* is built on two notions: the *autonomous individual* and the *cosmopolitan or Universalist (Weltbürger)* – that is, a universally interested person who cares about the important questions of humankind. The university should be – both for students and professors – a place for autonomous individuals to become such a *Weltbürger*. Student teachers, who are about to become responsible experts for *Bildung* at school, not only need to come in contact with these ideas, but should also be given opportunities to work on their own *Bildung* and personal development.

# Lucas Bunt and the rise of statistics education in the Netherlands

Bert Zwaneveld<sup>1</sup> and Dirk De Bock<sup>2</sup>

<sup>1</sup>Open Universiteit, Welten Institute, The Netherlands; [zwane013@planet.nl](mailto:zwane013@planet.nl)

<sup>2</sup>Katholieke Universiteit Leuven, Belgium; [dirk.debock@kuleuven.be](mailto:dirk.debock@kuleuven.be)

*We describe the role of Lucas Bunt at the start of the teaching of probability and statistics in the last two years of Dutch secondary schools in the early 1950s. Together with his co-authors, Bunt developed an experimental text which, from the mid-1950s on, became a regular textbook. We further sketch Bunt's other – mostly international – activities with respect to the curriculum reform movement initiated at the Royaumont Seminar in 1959. Bunt's experiment can be seen as one of the initiatives related to this reform. Finally, we present what happened with statistics teaching in the Netherlands "after Bunt".*

*Keywords: Mathematics curriculum, Probability, Secondary school mathematics, Statistics.*

## Introduction

The attention to statistics in Dutch secondary school mathematics arose in the early 1950s when a student text about statistics was developed by a group of mathematics teachers led by Lucas Bunt. The text was used in experiments in the last two years of secondary schools that prepare students for the university, initially only for the non-exact streams of these schools. Bunt's reason to develop this text was a proposal made by *Liwenagel*, one of the two associations of teachers of mathematics at that time<sup>1</sup>, to include statistics into the curriculum for these students. The proposal cannot be seen independently from the worldwide trend after World War II to include applications of mathematics into the secondary school curricula (De Bock & Zwaneveld, in press). During the 1950s the call for curriculum change was so strong that the OECD took the initiative to organize, in 1959, the Royaumont Seminar with representatives from different western countries to initiate the reform. Bunt attended "Royaumont" and many other international meetings related to this reform movement.

Although Bunt's pioneering role in statistics education is well-known in the Netherlands, a proper scientific review of his work is still missing. Moreover, his acting at the international math educational scene was not given appropriate attention so far, especially in the debates about a possible introduction of statistics at the secondary school level.

We present Bunt's role in the Dutch curriculum reform movement of the 1950s, more specifically, his activities related to the development of a statistics program as a part of it. Based on written historical sources and a few oral testimonies of contemporaries, we first provide some elements of Bunt's professional career. We then report about his experiment with the teaching of statistics in secondary school classrooms and about the actions he took to ensure that his ideas became

---

<sup>1</sup> The other organization of teachers of mathematics was *Wimecos*. Both organizations, *Liwenagel* and *Wimecos*, were the predecessors of the *Nederlandse Vereniging van Wiskundeleraren* [Dutch Association of Mathematics Teachers].

consolidated. Finally, we report what happened with statistics in Dutch secondary mathematics curricula “after Bunt” and we present some conclusions.

## Lucas Bunt

Lucas Nicolaas Hendrik Bunt (Figure 1) was born in 1905 in Edam, a small village north of Amsterdam. He studied mathematics at the University of Amsterdam where he also defended, in 1934, his PhD thesis, entitled *Bijdrage tot de theorie der convexe puntverzamelingen* [Contribution to the theory of convex point sets]. In the early 1930s, Bunt started his career as a mathematics teacher in Leeuwarden where he likely met his wife, a chemistry teacher at the same school. In the late 1940s Bunt became mathematics teacher trainer at the University of Groningen. From 1948 to 1969 he was appointed as a full-time mathematics teacher trainer at Utrecht University, a position that he combined with that in Groningen. In 1968, immediately after the retirement of his wife, he and his family migrated to Arizona (US) where Bunt became a professor of mathematics at Arizona State University. We assume that Bunt had already developed strong professional ties with the US in the early 1960s to secure this appointment, but could not verify this any further. Bunt died in 1984 in the US.

**Figure 1: Lucas Bunt (left: detail of a picture of the *Mathematics Working Group*, 1948; right: attending the public defense of the PhD thesis of his son Harry at the University of Amsterdam, 1981)**

Bunt became active at the math educational scene in the Netherlands shortly after World War II as a member of the *Mathematics Working Group*, a group that critically reflected on the existing secondary school curricula and developed proposals for new curricula (La Bastide-van Gemert, 2015). Bunt’s international career started in 1959. Recommended by Hans Freudenthal to the Dutch Ministry of Education, Bunt was one of the three representatives for the Netherlands at the famous Royaumont Seminar and he co-edited the Seminar’s Proceedings with Howard F. Fehr (OEEC, 1961). In the late 1960s, Bunt translated and adapted, in cooperation with Harrie Broekman, a series of booklets that were developed by the *School Mathematics Study Group* in the US. This resulted in a six-volume programmed instruction course for Dutch secondary school students.

Bunt was primarily a mathematician who explained mathematics to a non-mathematically schooled audience. We mention his textbook *Statistiek voor het voorbereidend hoger en middelbaar onderwijs* [Statistics for preparatory higher and secondary education] (1956), intended for Dutch students, aged 16 to 18 years, who prepared themselves for university studies in social sciences,

economics, geography, etc., based on an experiment of which Bunt published the report (Bunt, 1957). For an international audience, Bunt (co-)authored *An introduction to sets, probability and hypothesis testing* (with Howard F. Fehr and George Grossman) (1964) and *Probability and hypothesis testing* (1968).

## First experiments with statistic education at the secondary level

Bunt took the initiative to develop an experimental text about statistics in some gymnasia A<sup>2</sup>. The text was initially mimeographed, in 1956 it was printed as a textbook (Bunt, 1956). As mentioned before, one of the reasons for Bunt to start with an experiment about the teaching of statistics was a proposal of a commission established by the organization of mathematics teachers *Liwenagel*, intended to study the opportunities and possibilities of “a re-organization of mathematics education in the A-streams of the gymnasia and the gymnasium sections of the lyceums” (1950). Bunt was a member of that commission and, although it is not mentioned, likely the main author of the commission’s report.

It is worth mentioning that Bunt did not develop the experimental text and the textbook on his own, although this was a common practice in the Netherlands at that time, but in cooperation with a team of teachers. In the *Preface* of the textbook Bunt wrote (translated from Dutch):

... was an educational experiment in statistics, organized by the Department of Didactics of the Pedagogical Institute of the State University of Utrecht. The following teachers cooperated: Dr. Cath. Faber-Gouwentak, Barlaeus-Gymnasium, Amsterdam; Sr. E. A. de Jong, *Rectrix* [Headmistress] St.-Theresia-Lyceum<sup>3</sup>, Tilburg; D. Leujes, Grotius-Gymnasium, Delft; Dr. H. Mooy, Barlaeus-Gymnasium, Amsterdam; Dr. P. G. J. Vredenduin, *Co-rector* [Vice Headmaster] *Stedelijk* [Municipal] Gymnasium, Arnhem. (Bunt 1956, p. v)

At that time in the Netherlands, statistics was not a part of the official curriculum that only included algebra and geometry, topics that were also part of the final exams, organized centrally by the government. However, based on an exception rule, the Inspection of Education could allow teachers to change parts of the exam program. Such exception was obtained for the statistics experiment.

In 1957, Bunt published the report in which he describes the experiment with the student text that was used during the years 1951-1955 (Bunt, 1957). The reason why the textbook was published before this report was, as Bunt wrote in the textbook’s *Preface*: “The recent proposals of the mathematics teachers associations *Wimecos* and *Liwenagel* about the curriculum change for mathematics in the B-stream of the secondary schools, in which statistics is included as a new topic, made it desirable to make, as soon as possible, the text public” (Bunt, 1956, p. v). Bunt’s report has two parts: part A includes the motivation and explanation about the selected topics, and the way they are treated; part B is the student text (it is not included in the printed version of the report).

---

<sup>2</sup> At that time, the gymnasia in the Netherlands had two study streams: The A-stream, preparing students for university studies such as languages, economics, psychology, sociology, history, and geography, and the B-stream, preparing students for university studies in mathematics, science and technology.

<sup>3</sup> A lyceum was a school for secondary education with two sections: gymnasium and *Hogere Burger School (HBS)* [Higher Citizens School], similar to gymnasium but without Latin or Greek.

We focus on some highlights of part A. Bunt motivated the reasons for choosing statistics as follows: to students in university disciplines such as economy, psychology and sociology, an extensive study of algebra is less useful than a well-balanced treatment of the first concepts and principles of statistics. Statistics in university turns out to be very difficult and uncommon to these students. Moreover, they have to learn it in a rather short period of time. Statistics in secondary school is not only useful for the aforementioned students, but for all citizens in modern society. By reducing the algebra content, Bunt found the necessary 35 classroom hours for his statistics course. After that, he justified the chosen topics. In the first experimental text, these topics were: frequency distribution, histogram, frequency curve, cumulative frequency, average, median, quartiles, range, mean deviation, standard deviation, quartile distance, permutations, variations (without repetitions), combinations, Pascal's triangle, Newton's binomial formula, some simple theorems from probability calculus, the binomial distribution for  $p = 0.5$ , the normal curve as a limit of the histogram of the binomial distribution (graphical, not with formulae). At the end of the course, some applications of the normal curve for calculating probabilities were presented. Linear regression and correlation were left out, because of being too time-consuming. Especially on the insistence of his cooperators, Bunt drastically changed the end by including a final chapter on hypothesis testing: estimating some characteristics of a population on the basis of a sample.

Bunt extensively deals with the principles of probability calculus for which he presents an axiomatic approach. Probability is a function that assigns to an event a number in the interval  $[0,1]$ . He starts from the following two axioms: (1) If  $p \rightarrow \neg q$ , then  $P(p \text{ or } q) = P(p) + P(q)$ ; (2) If  $p$  is the sure event, then  $P(p) = 1$ . From these axioms Bunt derives the complement and product rule. He illustrates these rules with examples about rolling dice. In the textbook, however, Bunt introduces the concept of probability differently. There he starts with the definition of Laplace: the probability of an event is the number of outcomes favorable for that event, divided by the total number of outcomes (under the condition of mutually exclusive and equally likely outcomes). After having dealt with the complement, the sum and the product rule, he introduces "another" definition: if it turns out that in a large number of repetitions of an experiment,  $n$ , an event happens  $k$  times, then we are convinced that every time we repeat this experiment a sufficient number of times, this event will happen in  $k/n$  part of this number. We then state that the probability of that event equals  $k/n$ . For probabilities derived from that "new" definition, the complement, sum and product rule keep their validity. We note that Bunt's approach contrasts sharply with that of his contemporary Gustave Choquet, then president of the *International Commission for the Study and Improvement of Mathematics Teaching* (CIEAEM), who proposed at the 9<sup>th</sup> meeting of the CIEAEM a definition of probability based on the mathematical concept of measure (translated from French):

In a set  $U$ , one chooses a family  $F$  of subsets  $E$ , to each of which we attach a number  $m(E)$ , called the measure of  $E$ . These subsets have the following properties: their union and their intersection are again part of  $F$ , even if the number of  $E$ 's is infinite. In the case of probabilities, the set  $U$  has measure  $m(U) = 1$ . Each element of  $U$  represents a possible event: all favourable events constitute a subset  $E$  with measure  $m(E)$ . The probability of the favourable event is given by  $m(E)/m(U)$ . (Carleer, 1955-6, pp. 63–64)

The difference between Bunt's and Choquet's approaches illustrates the debate during the mid-1950s between the mathematics-didacticians and the mathematics-structuralists on how statistics should be introduced at the secondary school level.

Because of its innovative character, we discuss in some detail how Bunt explained the concept and procedure of hypothesis testing. He wrote about this:

On the basis of a sample of 10 marbles out of a box with 5000 white and 5000 red marbles the probabilities of 0, 1, 2, ..., 8, 9, 10 red marbles in that sample are 0.001, 0.010, 0.044, 0.117, 0.205, 0.246, 0.205, 0.117, 0.044, 0.010, 0.001. It follows that in 1.1% of all samples of 10 marbles there are 0 or 1 red marbles, and even so, in 5.5%, there are 0, 1 or 2 red marbles. And, in 5.5% of all samples there are 8, 9 or 10 red marbles. And moreover, in 1.1% of all samples there are 9 or 10 red marbles. Now suppose that the fraction  $p$  of red marbles is unknown and we take a sample of 10 marbles. We shall agree that if  $p = 0.5$  and there are 0, 1, 9 or 10 red marbles in the sample, we shall reject the hypothesis  $p = 0.5$ . If the hypothesis  $p = 0.5$  is right we have a risk of  $1.1\% + 1.1\% = 2.2\%$  that we, in spite of this, reject the hypothesis. More precisely, there is a probability of 1.1% that we reject the hypothesis  $p = 0.5$  on the strength of too small (or too large) a number of red marbles. Because, in this connection, we, for the time being, do not want to risk a greater probability than 2.5%, we stick to the mentioned agreement. This agreement, therefore, conforms to the following conditions: (a) if  $p = 0.5$ , we risk, both for too small and for too large a number of red marbles in the sample, a probability of not more than 2.5% that we reject the hypothesis  $p = 0.5$ ; (b) both for too small and for too large a number of red marbles this probability lies as close to 2.5% as possible. When we reject the hypothesis  $p = 0.5$ , we say the hypothesis  $p = 0.5$  is rejected with an unreliability of not more than 5%. (Bunt, 1957, p. 12)

The fraction  $v$  is introduced as the number of red marbles divided by the number of marbles in the sample and its values which are or are not thought contradictory to  $p = 0.5$  are represented by, respectively, dots and circles on an axis (Figure 2).

Figure 2: Axis representing values of  $v$  with dots and circles

Repeating this procedure for different values of  $p$ , one gets the two-dimensional scheme (Figure 3):

Figure 3:  $v$ -axes for different values of  $p$

By making the values of  $v$  and  $p$  “continuous”, one gets a figure on which the different boundary lines refer to different sample sizes (Figure 4). The textbook contains two of these, corresponding to unreliabilities of 5% and 10%, called by Bunt “nomograms”. From these nomograms, the student can observe that the probability of rejecting a false hypothesis increases with the sample size.

**Figure 4: Nomograms for different sample sizes (left, the unreliability is 5%, right 10%)**

### Consolidation and internationalization

In 1954-1955 a curricular commission of *Wimecos* published a report including a draft curriculum and central examination program for mathematics in HBS-B. Bunt had been a member of that commission representing the Dutch mathematics didacticians and mathematics teacher trainers. In the commission's report, it is stated that statistics had been important sources for the commission. The commission basically confirmed the conclusions of the report of *Liwenagel* (Liwenagel, 1950-1951), but now generalized to all students who prepared themselves for university studies. In 1958, the new curriculum was actually implemented, but, although it entailed a considerable change, statistics only became an optional subject for gymnasium A.

The fifth edition of Bunt's textbook (Bunt, 1968) had a slightly different title, a consequence of the curriculum reform consolidated in 1968 by a new law for secondary education. The subtitle, statistics for preparatory higher and secondary education, was changed into: statistics for preparatory scientific education. This new curriculum reform was prepared and supervised by the *Commissie Modernisering Leerplan Wiskunde* (CMLW) [Commission for Modernization of the Mathematics Curriculum]. The task of that commission was to prepare the mathematics curriculum reform in line with the ideas of Royaumont Seminar. Bunt was a member of the CMLW. The commission was officially set up in June 1961 by the Ministry of Education, Arts and Science, but already in January 1961, Bunt had proposed to the Ministry to establish such commission. However, the Inspection of Education had given a negative advice to the Ministry because the commission as proposed by Bunt was too small. In 1968 the new curriculum for mathematics, in which statistics played a clear role, was implemented in all schools for secondary education in the Netherlands: Bunt had achieved what he had started working on in 1951.

During the late 1950s and early 1960s, Bunt disseminated his ideas about the teaching of statistics. Already on May 24, 1959, he was invited to report on his experiment about the teaching of statistics at the annual meeting of the *Société Belge de Professeurs de Mathématiques* [Belgian Association

of Mathematics Teachers] and the *Société Belge de Statistique* [Belgian Association of Statistics], held in Brussels on May 24, 1959 (Bunt, 1959). The manner in which statistics became a part of the secondary-school curriculum in the Netherlands was also the topic of Bunt's paper at the Royaumont Seminar (OECE, 1961). In the period after Royaumont, Bunt had the opportunity to actively participate in meetings held in order to coordinate, monitor and refine the implementation of the Royaumont recommendations (Aarhus, 1960; Athens, 1963, Echternach, 1965).

### More recent developments

According to the law for secondary education of 1968, two types of schools could prepare students to higher education: *Voorbereidend Wetenschappelijk Onderwijs* (VWO, six grades for students from age 12 to 18) [preparatory scientific education], preparing for university studies, and *Hoger Algemeen Voortgezet Onderwijs* (HAVO, five grades for students from age 12 to 17) [higher general continued education]. The mathematics curricula of these school types were prepared by the CMLW. The curriculum of VWO included probability theory and statistics, that of HAVO only included descriptive statistics. These topics were meant to be taught in the last two years of these school types. We restrict ourselves to statistics teaching at VWO. Although Bunt's textbook was available, CMLW judged that it was better to not implement statistics immediately, but first to develop a new text and conduct an experiment with a restricted number of schools. The argument was that Bunt's textbook was only intended for students in the "old" gymnasia A, whereas statistics now had become a compulsory subject for all students. A statistics development team started in 1970, first under the supervision of the CMLW, from 1971 under the supervision of the then started IOWO, the predecessor of the Freudenthal Institute.

After a first draft the team developed the textbook (Nijdam et al., 1973) including the following content: Introduction, Probability rules, Probability distributions, Hypothesis testing and reliability intervals, Parameters of a distribution, Use of the normal distribution. The introduction contained an example with a prognosis of the number of students of VWO that should follow science or mathematics at the university, based on data of the Dutch *Central Bureau of Statistics*. From that example, terms as sample, population, random, representative, testing – for instance with respect to the quality of the production of certain items – were introduced. In this textbook the students themselves started with a probability experiment. There was a box with 1000 small marbles, 600 red and 400 black. With a kind of spoon with 20 wholes, they drew a random sample of 20 marbles. This box with the "spoon" was used to simulate various probability experiments.

### Conclusions

The mathematician Lucas Bunt played a crucial role in promoting and developing materials for statistics education at the secondary level, in the Netherlands but also at the international level. Indeed, in the post-Royaumont era, probability and statistics were seen as valuable elements of a worldwide reform of the mathematics curricula. Although Bunt explained his approach in a rather classical way, starting with some probability axioms (in pure *New Math* style), the approach in his textbook was very pragmatic. Bunt did not emphasize "theoretical aspects", accepted properties without proof and provided many clarifying examples. This pragmatic style enabled Bunt to explain the basic principles of hypothesis testing at the end of his course, in a limited number of lessons.

Nowadays in the Netherlands and in several other countries, probability and statistics are included in the mathematics programs, at least for some streams at the secondary level, but in the 1950s and 1960s, it was quite revolutionary to propose to teach these topics at that school level.

Because of his didactical work in general and more specifically on statistics, Bunt was important in Dutch mathematical education in the post-WWII period. Due to his participation to Royaumont and other international conferences, and his textbooks in English, Bunt may also have played a role in debates about the gradual introduction of statistical curricula for the secondary school level in other countries. However, this role has not yet been clarified and is a topic for follow-up research.

### Acknowledgements

We thank Bunt's son Harry for the biographical information about his father, Danny Beckers for the information about the start of the CMLW, and Harrie Broekman for his information about Bunt in the years he was Bunt's colleague at Utrecht University.

### Introduction

The Early Years Mathematics working group shares scholarly research revolving around mathematics for children aged 2-8. This includes different areas of mathematics and attention to how mathematics is approached implicitly and explicitly by children and teachers alike. The broad age range affords attention to several transitions within preschool, and from preschool to the early grades of primary school. At each CERME-conference (since CERME 6), the working group on early years mathematics has spent time considering differences in Europe (and outside Europe) regarding the organization of preschool and the cultural approaches of different countries to education at this young age. Some countries have one preschool curriculum for children aged 1-5 (6), while others distinguish between nursery and preschool. The number of children attending preschool in different countries also differs greatly, with consequences for transitions. As an example, Norway has one preschool curriculum and 91.8 % (ages 1-5) and 97.1 % (ages 3-5) of children attended kindergarten in 2018<sup>1</sup>.

Prior to the conference in Utrecht, paper and poster authors were requested to prepare and send to the leaders a brief text outlining the main points of their contribution. This helped the leaders plan the discussions and presentations, and served as a basis for this introduction. Each of the 22 papers were allocated 30 minutes for presentation and discussion. For each paper, an author of a different paper was requested in advance to prepare questions and comments for the paper presenters. The seven posters were also briefly presented in a group session, followed by a group discussion in a one-hour session.

The number of participants in TWG13 in Utrecht was greater than the number of participants in previous years. In addition to participants from Europe, there were also stimulating contributions from outside of Europe (Japan, Canada, and Malawi). In total, 38 participants from thirteen different countries attended the working group (see table below).

## A variety of topics

Several contributions to TWG13 concern classical, but indeed crucial areas in early years mathematics, such as numbers and arithmetic skills. Björklund and Runesson consider children's way of experiencing numbers, and found evidence of six different ways children can experience numbers. Bjørnebye investigates children's ability to synchronize multiple representations of numerosity in the embodiment of a counting-on-strategy. He argues that bodily experiences could support early appropriation of a counting-on strategy. Lüken highlights the role of finger use during numerical considerations, and considers how the role and use changes over time. Sprenger and Benz consider children's ability to perceive and use structures in sets. They argue that eye-tracking, as a data collection instrument, together with observations, provide strong insight into the two processes of perception and determination of the cardinality of sets of objects. Bakos and Sinclair consider the role of a digital app on the development of children's multiplicative awareness. In particular, they consider the relation between bodily movement and mathematical meaning-making. Bakos and Sinclair found two primary gestures used by children which they discuss. Müller and Tiedemann report from an ongoing study which focuses on children's development of conceptual subitizing, while Bruhn looks at first graders' creative processes when working on arithmetical open-ended problems. Tzekaki and Papadopoulou consider different levels of generalization that children can

develop in arithmetic learning by systematically adopting teaching approaches with relevant tasks and discussion.

Another branch of studies considers approaches that facilitate children's learning of mathematics during the early years. Grimeland and Sikko study children's development of mathematical literacy in a second-grade classroom working with play-coins in an inquiry-based setting. Inquiry-based settings are also the frame for the study by Skoumpourdi. However, her study is related to another area of mathematics – plane geometrical shapes. Skoumpourdi found that cooperative exploration, discussion, and justification processes were fostered in the inquiry-based setting. Pettersen and Volden look at the transition from mathematics in kindergarten to school mathematics. They argue that inquiry-based mathematics education was found to be helpful for children's ability to remember and recognize mathematical activities across the transition.

A study of Matsuo and Nakawa consider whether preschool children can improve their understanding of length and area measurement. In particular, their concern is on direct and indirect measurement, as well as measurement by an arbitrary unit. Their findings pinpoint that area measurement is found hardest to grasp, but partly in play-based settings, while direct comparison is easiest. Vanegas, Prat and Rubio characterize the learning trajectory of children aged six to eight years old when acquiring the notion of length measurement. The group also had a contribution by Bräuning that look at children's development of strategies for a combinatorial task and argues for a process-oriented view.

Palmér and Björklund focus on 2-3 years-old toddlers' ability to explore structural elements while playing "hide the toy-dragon", and pinpoint indications of emergent structural awareness among the small children. The inclusion of toddlers, as young as 2 years, within the scope of focus for TWG13 came as a result of the CERME10 conference and as an overall desire to increase insight into children's learning of mathematics (Levenson, Bartolini Bussi, & Erfjord, 2018). Nordemann and Rottmann look at how children's repeating pattern competencies can be fostered by physical activity, and report that development can be found especially for children with learning difficulties in mathematics. Nergård studies five-years-olds children's use of mathematical concepts, and found evidence of such use when they compare, explain and argue about natural phenomena.

Erfjord, Hundeland, and Carlsen characterise the mathematical discourse evolving as a teacher facilitates a mathematical activity for five-year-old children in kindergarten. Their findings indicate that mathematical discourse was characterised by engaging only one or two of the six children in longer periods and children's contributions were often of a non-mathematical nature. Gifford and Thouless address how teachers develop young children's pattern awareness.

Maffia and Mancarella consider children's interpretation of equalities represented through images, and found evidence that relational thinking can be supported when children work with number sentences containing equivalence. Maj-Tatsis and Tatsis look at characteristics of tasks that promote mathematical reasoning among young children. Tasks that required a shift from geometrical structures to numerical ones were found most difficult for children. Wernicke et al. look at social

training of spatial perception and spatial cognition in an ongoing study based on a training program of children in a day-care centre.

In two studies situated in Malawi, Gobede investigates mediation strategies used by early years mathematics teachers and Mandala explores how primary teacher education prepares pre-service teachers to teach early years mathematics. Svensson focuses on pre-school teacher students' ability to capture children's learning of mathematics in activities in preschool while Johansson, Tossavainen, Faarinen, and Tossavainen analyse student-teachers' perceptions regarding teaching mathematics for young children. Johansson et al. found evidence of different pedagogical beliefs and expectations regarding what mathematics teaching in preschool should be. Breive considers the balance between freedom and structure in kindergarten teachers' orchestration of mathematical learning activities. Tsamir, Tirosh, Levenson and Barkai investigated preschool teachers' self-efficacy for teaching patterning, with attention to why teachers report high self-efficacy before the professional program involved. Finally, Vogler focuses on the indirect processes of learning in preschool situations, which may be considered as an opportunity for children to participate and learn in what may be denoted as a "double layer structure" of every day meanings and abstract mathematical meaning".

## Methodological approaches

In TWG13, there has been an ongoing discussion regarding methodological approaches to investigating early mathematics learning. These approaches often reflect the culture of educational settings for children. In some countries in Europe, all kinds of testing and even organised activities are considered problematic when it comes to preschool. The role of play, from (total) children initiated free play to strong teacher guided play is another important discussion that has been ongoing in the group (Levenson, Bartolini Bussi, & Erfjord, 2018). In CERME 11, this discussion again arose and emphasised e.g., by Breive, who considered the balance between freedom and structure in mathematical activities for five-year-old children in kindergarten.

Most of the research reported in TWG13 follows a qualitative data collection approach, with interviews or observations, or lesson observations and video data. However, a variety of ways for analyzing the data were adopted such as: cross-case, process oriented, interpretative, and hermeneutical approaches. There are also reports from a few experiments or design research studies, with pre and post examination of children, mainly with interviews and qualitative analysis. There are also a few quantitative approaches, utilizing tests or questionnaires, and one mixed study. These differences reflect the scope of that area of research, and that different kinds of research can contribute differently.

# Pips (times) Pods: Dancing towards multiplicative thinking

Sandy Bakos and Nathalie Sinclair

Simon Fraser University, Canada; [sbakos@sfu.ca](mailto:sbakos@sfu.ca); [nathsinc@sfu.ca](mailto:nathsinc@sfu.ca)

*This paper examines the design of an iPad touchscreen application (TouchTimes), that provides children with the opportunity for direct mathematical/multiplicative mediation through fingers and gestures. We describe the explorations of a pair of third-grade students with this technology, in which engagement with number in a multiplicative sense draws on a singular interaction between the eyes and both hands. Using a theoretical perspective informed by tool use and by embodiment in mathematical thinking and learning, we seek to gain insight into the affordances of the TouchTimes app in the development of multiplicative awareness in young children, with a specific focus on the multimodal nature of their mathematical interactions.*

*Keywords: Touchscreen technology, multiplicative reasoning, primary, tangible.*

## Introduction

Multiplicative reasoning is the ability to work flexibly and efficiently with “the concepts, strategies and representations of multiplication (and division) as they occur in a wide range of contexts” (Siemon, Breed & Virgona, 2005, p. 2), concepts that include direct and indirect proportion. Among other things, such reasoning involves learners viewing situations of comparison in a multiplicative rather than an additive sense. As students progress to larger whole numbers – and then to decimals, fractions, percentages, ratios and proportions – multiplicative reasoning becomes key to a large number of mathematical situations found in upper elementary and middle school (Brown, Küchemann & Hodgen, 2010).

In the primary grades (K–3), however, the action of repeated addition is commonly used as the initial (and, for some, the sole) means for introducing and working with multiplication, and it tends to become firmly entrenched as the dominant perception of multiplicative situations, both for students *and* for primary teachers (Askew, 2018). This becomes problematic when students begin to engage with mathematics that requires a direct capacity to think multiplicatively (e.g. Siemon et al., 2005). Consequently, multiplication may prove a crucial turning point in student learning, possibly a turnstile for mathematical competence. Rather than rely exclusively on repeated addition, approaches need to be developed and implemented in the early grades that highlight the function aspect of multiplicative reasoning that can be so critical to future success with mathematics.

Since Vergnaud (1983) wrote about the conceptual field of multiplicative structures, considerable attention has been given to the comparison of quantities using multiplicative thinking. Extensive research has documented difficulties students have with employing it in middle school and beyond, which Brown, Küchemann & Hodgen (2010) claim has not improved since the 1970s. Limited student experience with different multiplicative situations is proposed as a contributing factor to this significant challenge (e.g. Downton & Sullivan, 2017). Furthermore, Askew (2018) contends that the lack of development of multiplicative reasoning in the primary grades is “a consequence of predominant approaches to teaching multiplication limiting access to opportunities through which thinking functionally can emerge” (p. 1).

## Multiplicative reasoning and digital technology

Digital technology is providing new resources and means that show promise in supporting the mathematical learning of young children (e.g. Sedaghatjou & Campbell, 2017). In particular, the multi-touch affordances of *TouchCounts* (hereafter TC) allow children to produce and transform objects directly on an iPad screen using fingers and contact gestures, providing new counting and early arithmetic opportunities that are enabled by the app's visible, audible and tangible design. Sinclair and de Freitas (2014) show how the interaction in TC between fingers and eyes—between the tangible and the visual—enables new ways of thinking about number.

*TouchTimes* (TT), a novel extension of TC, is a gesture-based, multi-touch environment for multiplication designed to improve children's flexible and relational understanding of multiplication. Multiplicative rather than additive, TT allows children to create the “visual images of composite unit structures in multiplicative situations” (p. 306) that Downton and Sullivan (2017) argue are fundamental to developing multiplicative reasoning directly. Children can produce and transform objects directly on an iPad screen, using new gestural experiences of multiplication that provide direct feedback through both symbolic and visual representations. Our research focus involves exploring the influence of TT as a gesture-based modality for conceptualizing, visualizing, experimenting with and communicating about multiplicative relationships with students in primary grades (2–4).

### Brief description of *TouchTimes*

*TouchTimes* is an iPad application, which when initially opened displays a blank screen that is split in half by a vertical bar (Figure 1a). A user can place and hold her fingers on one side of the screen to create coloured discs, which we call “pips”. (In what follows, we presume that the user has chosen the left side of the screen, but the description is also symmetric for the right side of the screen.) Each finger that maintains continuous contact with the left side (LS) produces a different coloured pip (Figure 1b). When the user taps her finger(s) on the right side (RS) of the screen, a unit of coloured discs appears. These units, which we call “pods”, are comprised of the coloured pips that correspond to those pips being created by the user's fingers in contact on the LS (Figure 1c). As each tap creates a new pod, *TouchTimes* displays the number sentence that corresponds with the pips and pods created by the user. When a finger is taken off a pod, it remains on the screen, but becomes slightly smaller, so that users can create numerous pods. As long as at least one finger remains in contact with the LS, the pips are maintained within the pods, but when the user removes all fingers, the pods disappear (“multiplying by 0”). Contact with the screen can be made either one finger at a time or several fingers simultaneously. Pods can be dragged into the trash, at the bottom of the screen.

Pimm and Sinclair (2015) note that *TouchCounts* ‘takes care of the counting’ through both symbolic and auditory means in response to the user's fingered requests. Although done in a different manner, TT ‘takes care of the multiplying’, both in terms of making sure that the pods on the RS are reflective of the number of pips on the left, and in terms of ensuring that the equation on the screen corresponds to the pips and pods that are displayed in response to the fingered requests of the user.

Downton and Sullivan (2017) argue “that the co-ordination of composite units is the core of multiplication, and that young children's (8 year-olds) concept of multiplication is based on the meaning they give to the composite units they construct” (p. 306). Thinking multiplicatively involves

the ability to simultaneously think about units of one and units of more than one. TT embodies a multiplicative model that involves the co-ordination of two quantities similar to Figure 1d below (Boulet, 1998, p. 13). One way to conceptualise this action is to see the LS touches as the number of pips which are then unitised into pods, with the pods then unitised into the product, as in the Davydovian approach (see Boulet, *ibid.*). In this view, the sentence  $3 \times 4 = 12$  is read as the multiplicand times the multiplier equals the product, which reverses the typical North American approach  $(3)(4x)$ . Of course, it is also possible to see the pods as being groups of pips, which can be understood in terms of repeated addition. However, the simultaneity of the two-handed touching retains less of the temporal, sequential sense of repeated addition. Part of the research goal is to develop tasks that promote a more multiplicative sense of multiplication.

## Theoretical Framing

The theoretical orientation of this study draws principally on theories of embodiment and the relation between bodily movement and mathematical meaning-making (see Nemirovsky et al., 2013; Radford, 2009). We take the monist, ontological position found in inclusive materialism (de Freitas & Sinclair, 2014) on the nature of body and mind, which does not subordinate sensorimotor actions to thinking, but instead recognizes the way in which new ways of moving one's body *are* new ways of thinking. For this reason, we are less interested in studying TT as a manipulative involving acts of moving structures and are more interested in the *structured acts of moving* that TT modulates. Given this orientation, and the gesture-rich design of TT, our focus will include not only verbal explanations but also gesture-based actions, as we are particularly interested in the structured acts of gesturing that arise through the use of the app. The epistemic and communicative nature of gestures has been well documented in the literature (see Sinclair & de Freitas, 2014) and warrants our attention to gestures as particularly relevant structured acts of moving. Since the multitouch environment also enables children to work together, we will also focus on jointly structured acts of moving. Therefore, we will be investigating how a pair of students' interactions with TT prompts new gestures and how these new structured acts of moving are related to multiplicative thinking.

## Methods

The data for this paper comes from an exploratory conversation conducted by one of the authors as part of an iterative design experiment aimed at refining the TT prototype and developing appropriate tasks for use with grade two and three children. After the researcher requested a pair of students who had not yet used TT (three pairs of children had already participated), the two girls, whom we refer to as Jacy and Kyra, were selected by their classroom teacher to explore TT with the researcher. This interaction occurred in an elementary school in a culturally diverse and affluent neighbourhood in

British Columbia, where the interviewer worked for approximately 30 minutes with the pair. A video-recording of this interaction was created, and the drawings produced by the girls were kept. The children were initially given time to become familiar with TT through independent exploration prior to any specific requests or questions from the interviewer. Given that this was the pair's first encounter with TT, it provided an opportunity to observe how they made sense of the app and if their interactions with TT would lead to an ability to identify certain multiplicative aspects with distinct handedness. After a period of free exploration that lasted about seven minutes, the interviewer began to use prompts to focus the attention of the children on certain features of their creations on the iPad screen. Using TT, in conjunction with the significant presence of an adult, the initial aim of this research was to understand better the impact of the affordances of TT on young children's multiplicative thinking, with a particular focus on the multimodal and joint nature of the mathematical activity of two girls working together on a single iPad.

### Data analysis

In order to account for the multimodal, distributed nature of the phenomenon seen in the video-recordings, following our theoretical tenets, we produced an *orchestral transcription* of ten-second increments involving three separate, but interacting modalities: voices, hands and the iPad screen itself (Figure 2). The top three rows were designated for the voices of each child and the interviewer, thus providing a way to sequence the speaking visually in a manner that would effectively display overlapping voices. Descriptions of what the children's hands were doing on both sides of the iPad screen, were sequenced in time with the voices transcribed in the section above.

As the importance of the iPad screen itself became apparent, additional rows were created to reflect what could be seen on the top, left and right sides of the iPad screen, supplemented by screen shots to illustrate these ideas. The orchestral transcription enabled us easily to identify patterns of structured acts of moving throughout the course of the interaction, by comparing the images.

Voices	Jacy	Laughs.....	
	Kyra	Wait, now I'll make a three.	And then... laughs They're dancing! Laughs
	Interviewer		
Hands	Left Screen	3-finger simultaneous touch (RH)	3 sequential finger touches
	Right Screen	Pointer finger touch (RH)	Hold two fingers
iPad Screen	Top of Screen	3 $3 \times 1 = 3$	$2 \times 1$ , $2 \times 2$ , $2 \times 3$
			
	Left Screen	3 pips	
	Right Screen	1 pod	1, 2, 3 pods

Figure 2: Orchestral transcription

### Results

From the orchestral transcript we chose two intervals that illuminate some of the gestures made by the girls during their exploration of TT that we see as being relevant to multiplicative thinking. Prior

to presenting these two intervals, however, we describe the pair's initial interactions with TT, which began with the researcher giving the pair permission to "play a little bit". Each girl placed and removed her pointer finger on and off the screen in what appeared to be random motions. After approximately fifteen seconds, Jacy placed her thumb on the screen in addition to her pointer finger, creating two pips. Kyra next touched the screen, creating a pod composed of two pips (Figure 3a). Jacy then began to use both hands. It is shortly thereafter that Jacy said, "How do you get those mini ones?", thus marking a transition from random tapping to more intentional actions on the iPad screen.

### Disappearing pips and 'dancing' pods

Approximately five minutes into the exploration, Jacy instructed Kyra to "Wait, just press a lot. Press your whole hand." Kyra responded by placing all five RH fingers simultaneously on the LS and waited while Jacy created pods on the RS one at a time with her index finger. The top of the iPad screen read 5x1, 5x2, 5x3, 5x4, 5x5, 5x6 until Kyra abruptly removed her hand from the screen, causing both girls to laugh. At this point, Jacy began directing the creation of pips through the placement and removal of Kyra's fingers on the LS: when Kyra returned her five fingers to the iPad, Jacy physically removed her partner's pinky and thumb from the screen, causing some confusion. Jacy tried again, telling Kyra to "Wait. Put those [indicating Kyra's RH fingers] and then take up your pinky and thumb." Kyra placed three fingers on the LS, while Jacy created one pod on the RS. This was clearly not what Jacy was after, and she further instructed Kyra to "Press your pinky and thumb away. No wait. Put your pinky and thumb down [Jacy physically presses Kyra's pinky and thumb down (Figure 3b)] and now take them away." Each time Kyra's pinky and thumb touched the screen, the resulting pips changed colour, and the composition of the pod that Jacy was 'holding' changed from three pips to five pips and back to three pips as Kyra alternated rhythmically, making the pod appear to be swinging back and forth (Figure 3c). Jacy created a second pod and at this point Kyra pointed to the pods with her free hand and declared with a laugh that "They're dancing!".

**Figure 3: (a) Two fingers; (b) Pinky and thumb down; (c) Pinky and thumb up**

Throughout this brief episode, Jacy became interested in exploring how the creation and deletion of pips on the LS affected the shape and colour of the pods on the RS, as demonstrated by both her comments and her actions. This complex interplay between the girls and TT involved a coordination of two pairs of hands, which resulted in a *joint holding and repetitive-tapping gesture*. The appeal of the 'dancing' pod seemed to draw the girls' attention to the relation between the RS and LS finger touches, which we see as significant in terms of multiplicative thinking. It involved the intentional co-ordination of two quantities: the multiplicand (three or five pips) and the multiplier (the one pod). The girls' joint gestures expressed their attention to the way in which the pods on the RS are directly affected by changes related to the number of pips controlled by the finger actions on the LS.

### Counting by fours and fives

After seven minutes of exploration, the interviewer asked Kyra to put four fingers down, which she did with a simultaneous four-finger gesture, creating four pips on the LS. Without prompting, Jacy created a single pod on the RS with her index finger (Figure 4a). When questioned about what she noticed, Jacy replied, “Four times one equals four”. She then created additional pods with her thumb while maintaining her index finger on the original pod (Figure 4b). When asked how Jacy could make five with one finger on the RS, Kyra’s thumb touched the screen to create five pips, while Jacy continued to add pods on the RS (Figure 4c). After a pause, the interviewer asked, “Are you making a five now?” At this point Jacy, who had been creating additional pods with her thumb, glanced towards the top of the screen which displayed  $5 \times 10 = 50$ , then  $5 \times 11 = 55$ . She said, “Fifty-five, sixty...” and with excitement, “Wait! It’s counting up by fives! Sixty-five, seventy, seventy-five, eighty, eighty-five, ninety, ninety-five...”. The pair were then asked what they could do to count by fours. Kyra removed one of her five fingers from the screen. Jacy said, “Count up by fours?” and physically moved closer to the left side of the screen, causing Kyra to remove her hands. While placing her thumb and all fingers except her pinky on the screen, Jacy explained that you would “Put four fingers down”. Meanwhile, Kyra used her index finger on the RS (reaching over Jacy’s arm) to create pods (Figure 4d). Jacy then said, “Two, four, six, eight, twelve” then “wait, what?” after she noticed the product displayed on the iPad screen go from eight to twelve. She silently observed the next product and then began to count aloud again: “Twenty, twenty-four, twenty-eight... We’re counting by fours.”

**Figure 4: (a) First pod of 4; (b) Second pod of 4; (c) Many pods of 5; (d) Crossover pod making**

The girls had transitioned away from single touches and were now making a *simultaneous touch gesture*, as in the four-finger gesture described above. The interviewer’s first question was meant to draw attention to the number/colour of pips in the 4-pod they had created, but Jacy described the multiplication statement instead. The interviewer then hoped to elicit the making of a 5-pod in order to prompt the unitising of five pips into one pod. With Kyra’s additional finger on the LS, Jacy did indeed begin creating 5-pods, but she did not seem to be aware of the shift from 4-pods until she noticed the multiplication statements, and that the product was increasing by five with each RS touch. This induced a particular kind of *joint skip-counting gesture* in which one girl was responsible for holding pips while the other girl’s sequential touches created pods. The pair then switched roles to skip-count by four, with Jacy holding pips and Kyra sequentially making pods. Unlike the skip-counting that occurs in many classrooms, where children count intransitively by the unit (“four, eight, twelve”, etc.), the skip-counting in TT explicitly involves gesturally expressing the unit (the pips) *and* the number of units (the pods).

Jacy’s counting self-correction seems to indicate a shift from rote counting to co-ordinating the *joint skip-counting gesture* (tangible expression) with the products (symbolic expression) that she could

see on the iPad screen. When asked how Jacy could create a 5-pod, Kyra who was in control of creating the pips, immediately added a finger to the screen and later removed a finger when prompted to count by fours. Kyra was controlling the effects of the multiplier (the pips) on the multiplicand (the pods) with her fingers. Jacy, however, did not attend to the effects of each added pod on the product until after she noticed the product changing in the equation at the top of the iPad screen. Skip-counting in TT using the *joint skip-counting gesture* involves co-ordinating two quantities (instead of one) and is therefore more multiplicative than additive.

## Discussion

The intent of the TT design was for learners to notice the relation between the number and colour of pips, and the shape and content of the pods, as this is the basis for the multiplicative operation. Although the girls created numerous pips and pods, it was not until the *joint holding and repetitive-tapping* gesture that they seemed to co-ordinate this relation. Indeed, it appeared to be the shifting pod shape, and then the changing pip colour, that initially drew their attention. The *joint holding and repetitive-tapping* gesture, which arose from manipulating the screen in exploratory ways, became a gesture for expressing the relation between pips and pods. The girls were able to make visible the effect of changing the unit through the tapping on and releasing of pips, which resulted in the changing size, shape and colour of the pods. When there was more than one pod on the screen (as in Figure 4c), the *joint holding and repetitive-tapping* gesture produced the multiplicative effect in which one new tap produced a new pip in *every* pod *simultaneously*.

In the previous section, we outlined how the joint skip-counting gesture can be viewed as more multiplicative than additive. However, we think that a gestural shift from tapping one finger at a time to create new pods, to tapping several fingers simultaneously would provide an even stronger multiplicative effect. We know from prior *TouchCounts* research that sequential tapping was more frequent than simultaneous tapping, during children's initial interactions. Since the girls rarely created several pods simultaneously, we hypothesise that such a gesture involves a more difficult co-ordination and may need to be prompted by a particular task.

Another significant aspect of the actions described throughout this paper involves the joint nature of the girls' interactions. In both of the gestures identified, the pair must co-ordinate their hand movements and there were a few instances during the 30-minute exploration in which one of the girls "took over" TT. We wonder how a situation with two children co-ordinating multiple hands would differ from one in which a single child coordinates only her own hands.

## Conclusion

Designed to support the development of multiplicative thinking, TT provides young learners with ways of thinking about multiplication that are not solely dependent upon the use of repeated addition. Two intervals were described in the 30-minute episode reported above, in which the girls created and sustained particular structured ways of moving their hands that we hypothesise as being relevant to the development of multiplicative thinking. The two primary gestures discussed were the *joint holding and repetitive-tapping* and the *joint skip-counting* gestures. The former prompted and enabled the girls to attend to the relation between the number/colour of pips and the pods, and thus the co-ordination of the two quantities. The latter enabled the girls to produce multiples of a number

determined by the number of pips. Attention to the symbolic expression on the screen was particularly salient in the second interval. We highlight that the girls primarily engaged in free exploration throughout this experiment, with few prompts from the interviewer. In future explorations, we intend to build upon the insights gathered here to design tasks that can effectively prompt and support similar types of gestures, and to link these gestures to other off-line and TT-based actions.

*This study contributes to the field of arithmetic learning a framework based on a conjecture that learning is a change in ways of experiencing numbers – decisive for what is possible to do with numbers in arithmetic tasks. 309 task-based interviews with 5-6-year-old children were used to develop the framework. To validate its use for studies on arithmetic skills development we selected 7 children who between two interview occasions developed from scoring 0 in the first interview to >75% correct answers in the second interview. Based on the results of these children's changing ways of experiencing numbers, we conclude that arithmetic skills development can be found empirically related to changes in the children's ways of experiencing numbers, which validates the framework as being a useful tool to follow and describe children's arithmetic skills over time.*

*Keywords: Arithmetic skills, early childhood education, mathematical development, variation theory of learning.*

## Background and aim

Early arithmetic development has raised an increasing interest during the last decades, providing the mathematics education field with observations of children's counting strategies (Carpenter, Moser & Romberg, 1982) and learning trajectories (Clements & Sarama, 2009; Cross, Woods & Schweingruber, 2009). Multiple studies within this knowledge area have proven that learning arithmetic is complex but most children do in fact learn to solve simple arithmetic problems during their preschool years. Nevertheless, the development of arithmetic skills is a challenge to study, not least because arithmetic computation includes knowledge and awareness of several aspects of numbers and principles (Baroody, 2016). Even if children have strategies to solve a task, their strategies may not be based on conceptual understanding of relationship between and within numbers and arithmetical principles, but rather on procedural knowledge (see Fuson, 1992). Relying on procedural knowledge alone has not shown to facilitate further learning and may even induce mathematics difficulties when encountering more advanced arithmetic tasks (Gray, 1991; Gray & Tall, 1994; Neuman, 1987). Of educational and scientific interest is thereby to be able to interpret the way a child understands numbers and what s/he can do with numbers in arithmetic tasks.

Our approach to learning and development is experiential, based on Variation theory of learning (Marton, 2015), meaning that how a child acts when trying to solve an arithmetic task depends on the child's way of experiencing numbers in the task. Variation theory explains learning failures in a specific way and spells out the conditions of learning; when learners fail to learn what was intended, they have not discerned aspects that are necessary to discern. So, the very core idea of Variation

theory is that discernment is a necessary condition of learning. Furthermore, the way a learner is experiencing numbers is expressed in the way the learner is acting in solving arithmetic tasks. This approach adds to the field of research an alternative approach to understanding development and learning as changes in ways of experiencing numbers in arithmetic tasks, that is what is discerned by the learner and what is yet to be discerned, rather than learning to use more sophisticated strategies.

The aim of this paper is to describe a framework of children's ways of experiencing numbers. To validate its use for studying arithmetic skills, we used empirical data of children's acts and utterances in interviews from a smaller sample of the whole data set and discuss to what extent these children's increased arithmetical skills can be explained in terms of different ways of experiencing numbers.

## **The study**

This particular study is part of a larger project (FASSETT) in which a pedagogical program to enhance children's number knowledge and arithmetic skills was developed. To assess this project we needed a framework to consolidate our conjecture of how children develop arithmetic skills that would allow us to study children's development and find theoretically and empirically sound explanations for their learning and possible impact of implemented teaching programs.

103 preschool children participated in researcher-designed interviews based on addition and subtraction tasks (number range 1–10). The interviews were conducted at three occasions: in the beginning of the last preschool year (5-year-olds), in the end of the last preschool year (8 months later) and after another year in pre-primary school (3 x 103 children = 309 interviews). Each interview was video-recorded, with the legal representatives' permission, to ensure repeated analyses. Ethical clearance has been provided to collect personal data for the longitudinal investigations of the children. Furthermore, we chose one group of children ( $n=7$ ) who made substantial improvements in their interview scores between interview 1 and 2 (from 0 to >75% correct answers on arithmetic tasks) for thorough analyses of their answers in the interviews.

## **Developing a theoretically informed framework**

The interview data, consisting of 3 x 103 interviews (0% falling-off), was used as empirical basis for developing a framework of the outcome space of different ways of experiencing numbers. The children's acts and utterances regarding eight items were the unit of analyses. Several researchers participated in this thorough work, both individually and collectively to fine-tune the characteristics for each category. Six different ways of experiencing numbers have been found. They are distinct in that each category forms a qualitatively different way of seeing and thus understanding what is possible to do with numbers in an arithmetic task. The framework is generated from the analysis of answers to each task, not as a general expression of a specific child. The ways of experiencing numbers are thus analysed as unique observations of each item in the interviews, which gives us a sample of approximately 2400 observations (309 interviews x 8 items).

## **Validating the framework**

The purpose of this paper is furthermore to validate the framework as a tool for studying children's arithmetic skills development. We thereby compared a group of children ( $n=7$ ) who in the first interview scored low concerning correct answers (0 of 8 possible) and high in the second interview

(>75%), eight months later. Our concern is to what extent the improvement can be explained by their different ways of experiencing numbers. These children's ways of experiencing numbers are, in line with the framework, analysed as unique observations of each item in the interviews, which gives us a sample of 56 observations (7 children x 8 items).

## The framework

The result from analysing the interviews constitutes six distinct ways of experiencing numbers (Table 1, left column). These are described in terms of criteria for inclusion (Table 1, middle column).

<i><b>Ways of experiencing numbers</b></i>	<i><b>Criteria for category inclusion</b></i>	<i><b>Strategies enacted when experiencing numbers in respective ways</b></i>
As words	<ul style="list-style-type: none"> <li>- Number words are used in quantitative contexts but without numerical meaning</li> </ul>	<ul style="list-style-type: none"> <li>- Random number words are used solely or as a sequence, <i>or</i></li> <li>- Number words from the given task are repeated</li> </ul>
As names	<ul style="list-style-type: none"> <li>- Numbers are ordered in a sequence</li> <li>- Number words describe “the <math>n^{\text{th}}</math>” object, no cardinal meaning</li> <li>- Names cannot be added or subtracted from other names, because they lack cardinal meaning</li> </ul>	<ul style="list-style-type: none"> <li>- Ascribing number names to objects</li> <li>- Saying the following number word in the counting sequence as an answer to an arithmetic task</li> <li>- Static way of representing a number with fingers</li> </ul>
As extent	<ul style="list-style-type: none"> <li>- Numbers are approximate with a cardinal meaning</li> <li>- Some sense of plausible quantities related to the task</li> </ul>	<ul style="list-style-type: none"> <li>- No attempts to count single units</li> <li>- Numbers are used to give a plausible description or comparison of quantities (however not exact)</li> </ul>
As countables	<ul style="list-style-type: none"> <li>- Strong influence of the ordinal aspect of number</li> <li>- Added units of ‘ones’</li> </ul>	<ul style="list-style-type: none"> <li>- Counting all parts and the whole</li> <li>- Exceeding the subitizing range imposes counting to determine a set</li> </ul>
As structure	<ul style="list-style-type: none"> <li>- Numbers are composite sets</li> <li>- The part-part-whole relation is constituted in the act</li> </ul>	<ul style="list-style-type: none"> <li>- Using finger patterns to structure numbers’ parts and whole</li> <li>- Operating on the relation between parts and/or the whole</li> </ul>
As known number facts	<ul style="list-style-type: none"> <li>- Numbers are instantly recognized as a part-whole relation</li> </ul>	<ul style="list-style-type: none"> <li>- Giving an instant (correct) answer</li> <li>- Retrieving from known facts</li> </ul>

**Table 1. Overview of the criteria for category inclusion and empirical expressions**

Furthermore, the way to experience numbers is conjectured to be related to what is possible to do with numbers, which means that how children use numbers and express their understanding in words and in gestures are keys to interpreting their ways of experiencing numbers (Table 1, right column).

In the following these different ways of experiencing numbers and the implications for solving arithmetic tasks will be described with examples from the interviews.

### Numbers as words

Children expressing their experiencing numbers as words say random numbers, either solely as an answer to a task, or as a sequence of words (not in an orderly fashion). This category includes instances when a child repeats one of the number words appearing in the task. Thus, numbers are words used in certain contexts but there is nothing you can *do* with numbers to solve the task at hand.

Task: Seven marbles are hidden in two hands. How many could be in each hand?

Child: Five, eight, nine [taps her finger at the right hand of the interviewer, once for each number word], ten [points at both hands], six [points at the right hand] and seven [points at the left hand]. (PFÅ09-1)

Number words are said as an answer to a question with a numerical content, but as shown in the excerpt above, there is hardly a numerical reasoning guiding the child's way of using numbers. Number words are in this sense experienced as a type of word in a certain context. They refer to quantitative situations, but the child does not know *what* numbers they refer to (Wynn, 1992).

### Numbers as names

Children seeing numbers as names have been observed by Neuman (1987), and described as a procedure of 'word tagging' by Brissiaud (1992). The child considers number words as names given to a counted item and the last uttered word denotes only that single object.

Task: You have ten candies and eat six of them. How many are left?

Child: [shows all the fingers on the left hand and the thumb on the right raised] Ate six. This is six. And then I took the thumb away. So, it's five. (ASJ10-1)

Numbers as names means that each item within a group is given a specific number name. Taking away one (the thumb) of the six fingers and answering "five" to this specific task, is a reasonable answer if the thumb is seen as "the six". Such named items cannot be added to or subtracted from anything in a true sense, since they do not have a cardinal meaning. What characterizes this way of experiencing numbers is thus the ordinal aspect, which means that for example when fingers are used to count on, each finger is given a specific number name and this name cannot be altered because the other fingers are given their unique number names. The lack of cardinal meaning of these number names is also expressed when children answer with the following number word in the counting sequence. This makes sense to the child since the order of the number words implies that the addition of a quantity will include (at least) the next word in the sequence (the  $n^{\text{th}}$  item).

### Numbers as extent

Experiencing numbers as extent means that children have an awareness of numbers in that they use quantities as approximate (Neuman, 1987).

Task: Seven marbles are divided in two closed hands, how may the marbles be divided?

Child: [points on the closed right hand] One in that one [points at the closed left hand] five in that one.

Interviewer: How did you figure that out?

Child: [points at the left hand] Eight in that one and two in that one [points at the right hand]. (PLS05-1)

To experience numbers as extent are in a sense cardinal: children give plausible approximations of smaller and larger numbers that together are close to the correct answer. The lack of ordinality means that children do not make any attempts to count in order to determine the quantity of a set. This also makes it impossible to add or subtract in other ways than giving an approximate estimation of more or less than the given numbers in the task. The answer may though be quite close to the correct answer.

### **Numbers as countables**

Experiencing numbers as countables is strongly influenced by the ordinal aspect of numbers, as children count to make a number, often using their fingers to count on. Numbers are thus seen as added units of ‘ones’ which may be difficult to coordinate in an arithmetic task.

Task: You have two shells and your friend five. How many do you have together?

Child: One, two [points at his little and ring finger] wait, I have to start over, 1, 2, 3, 4, 5 [pointing at fingers starting from long finger, index, thumb and thumb, index on the other hand. Then starts again from the little finger] 1, 2, 3, 4, 5. Five! (AVT09-1)

This child knows how to count fingers as representations for the items mentioned in the task. However, he does not seem to discern any structure that would help him solve the task in an easier way – he is able to create parts but has trouble coordinating them (c.f. Steffe, Thompson & Richards, 1982). Numbers as countables further implies that numbers are not comprehended as a composite set, they are created by adding ‘ones’. This becomes visible when using the strategy “counting all”. Some children do however experience small sets by subitizing for example three fingers (that will not be counted), but when the quantity exceeds the subitizing range the numbers have to be counted in ones.

### **Numbers as structure**

A structural approach in arithmetic problem solving is assumed to promote children in developing their conceptual knowledge of numbers (Davydov, 1982; Lüken, 2012; Schmittau, 2004).

Task: You have two shells and your friend five. How many do you have together?

Child: [puts her left hand with all fingers unfolded on the table, then the right hand with thumb and index finger unfolded, looks at her hand shortly] Seven! [with a confident smile] (HNV02-2)

The child knows the finger pattern for five and two, but needs to create the whole by seeing the parts simultaneously both as parts and as a whole, related to each other. This means that some parts may need to be counted, while other parts are experienced for example as finger patterns, but the parts and the whole are experienced as related to each other and are thus possible to handle as a triad (see Baroody, 2016). The difference, compared to experiencing numbers as countables, is the way children experience the parts as composite sets that relate to another set and/or the whole. This opens up for a different way of handling arithmetic tasks, for example in “seeing the five in the eight”. This has also shown to be a key feature of some young children’s spontaneous ways of successfully solving arithmetic problems (Björklund, Kullberg, & Runesson Kempe, 2019).

## Numbers as known facts

The last category of experiencing numbers reflects an advanced understanding of number relations. Either, the number relations are known to the child and s/he does not need to calculate, or s/he has an advanced way of reasoning and using retrieved facts to come up with the answer.

- Task: Seven marbles are divided in two closed hands, how may the marbles be divided?  
 Child: Four in that one and three in that one. ‘Cause, if you have three and one more it makes four. You have three in that one [points at the left closed hand] and three in that one and one more, makes seven [points at the right closed hand]. (HRM01-2)

In this example the child knows how three, four (seen as ‘three and one more’) and seven are related and is able to retrieve from memory known facts (‘three and three makes six’) that he can operate with to find a plausible solution. The difference between numbers as structure and numbers as known facts lies in the child’s approach to the arithmetic task. The former is focused on structuring numbers in that the missing addend will be possible to discern (it appears in the structure), while this latter category means that the child sees number relations instantly and is often able to describe how s/he retrieves the answer from known number relations.

## Validating the framework

The categories outlined above derives from the 309 interviews and 8 tasks given in each interview. Our theoretical conjecture has a pedagogical purpose, which directs our attention towards the extent to which the framework can be used to understand children’s developing arithmetic skills. Thus, we analysed the target group who made substantial improvements during an eight months period. Table 2 shows the number of observations within each category in the first and the second interview.

words	names	extent	countables	structure	known facts
10 / 0	11 / 0	10 / 6	1 / 9	0 / 22	0 / 16

**Table 2: Occurrences of ways of experiencing numbers, interview 1 / interview 2**

In Table 2 we can see that children in the first interview are with only one exception found in the three first categories: *Numbers as words*, *Numbers as names* and *Numbers as extent*. From earlier research we know that a simultaneous awareness of numbers’ cardinal and ordinal aspects are important for the child’s ability to operate with numbers. Without these aspects coordinated in the arithmetic problem solving process it is not possible to use any counting strategies or arithmetic principles (Davydov, 1982; Fuson, 1982). Experiencing numbers in these ways do not include this crucial aspect of arithmetic skills and the children’s low achievement on the arithmetic tasks in interview 1 is thereby no surprise.

The second interview includes most observations within the categories *Numbers as countables*, *Numbers as structure* and *Numbers as known facts*. Children’s way of experiencing numbers change, in this group, towards ways that allow them to handle numbers in prosperous ways in arithmetic problem solving. However, there are differences in these categories concerning what they enable the children to do with numbers. In some addition tasks the children who experience numbers as

countables manage to solve the problems by ‘counting all’ and thus working with added ‘ones’. This way of experiencing numbers stand in bright contrast to numbers as structure or as known facts, in which the parts to be added or taken away already from the beginning are seen as related to each other as composite sets. Because of this latter relational approach to a task, the child usually avoids cumbersome strategies such as working with one unit at a time. In other words, they can handle arithmetic tasks in a more prosperous way when numbers are experienced as structure.

## Discussion

The framework was developed first through qualitative interpretations of a large sample of children’s different ways of experiencing numbers in simple arithmetic tasks. In this study, we then used the six categories derived from the large data, to test the extent to which it was possible to use the framework to explain differences in arithmetic skills. The results suggest a confirmation of basic principles of Variation theory that failing to solve a task is due to the learner not being able to discern necessary aspects within the task and the strategies children use reflect what aspects they discern. Consequently, the children who score 0 on their initial interview have not discerned necessary aspects of numbers. This is also shown in our definition of the different ways of experiencing numbers. The validation of the framework further shows a hierarchical structure of the categories: when more necessary aspects are discerned there is also an advancement in what the child can do with the numbers in the tasks.

When analysing children’s ways of experiencing numbers, their strategies for solving arithmetic tasks become possible to understand, what works and why? Their ways of experiencing numbers change in most cases from primitive ways (that do not enable them to operate with arithmetic tasks) to quite advanced ways of experiencing numbers (that allow them to solve arithmetic tasks as part-part-whole relations). The framework opens for interpreting how new experiences may advance children’s arithmetic skills that does not depend on correct answers, or learnt strategies, instead it offers an alternative: what it means to learn about numbers and how to do simple addition and subtraction.

The analysis of the changes in ways of experiencing numbers seems to be solid enough to explain why some children have difficulties solving arithmetic tasks. Since our target group contained children who scored 0 points and improved to almost perfect score, we would suggest that changes in ways of experiencing numbers are possible over time and the ways to experience numbers have significant impact for children’s possibilities to solve arithmetic tasks. We would argue that more attention should be directed towards what children are able to discern in arithmetic situations, than strategies to come up with a correct answer. However, more research on a larger sample is needed to confirm our statement.

# Pre-schoolers' ability to synchronise multiple representations of numerosity in embodiment of a counting-on-strategy

Morten Bjørnebye

Inland Norway University of Applied Sciences, Norway; [Morten.Bjornebye@inn.no](mailto:Morten.Bjornebye@inn.no)

*Based on an outdoors intervention where 4- and 5-year olds were guided in articulated physical mapping of a counting-on-strategy, this study aims to examine their ability to embody a min-strategy in terms of using and cohering to multiple representations of numerosity. Video of individual post-tests of the child's interaction with the affordances are from an interpretive stance analysed from the perspective of embodied cognitive theory. Pattern analysis shows that the activity might support early appropriation of a counting-on-strategy, and the cross-case analysis reveals diversities in use and synchronisation of bodily affordances with verbalised number-space mappings. In particular, it demonstrates quality differences in the children's ability to integrate the kinaesthetic and semantic modalities with respectively tactile, visual and mental based representations of numerosity in terms of supporting fluency and solving proficiency in counting-based addition.*

**Keywords:** Embodied cognition, multimodal, addition, counting, strategies

## Introduction

Mastery of counting based addition is an important stepping-stone to the development of more mature, efficient and fluent arithmetic that involves retrieval and decomposition strategies, and the counting-on strategy is thus a critical competence in early arithmetic (Clements & Sarama, 2013). A conceptual shift occurs when the child refines informal use of a counting-all-strategy (e.g. count both addends in  $3+2$ ) into a counting-on-strategy and starts to count from the smallest or largest addend, which are termed respectively as the max- and min-strategy. The min-strategy involves stating the largest integer and count on the number of times equal to the smallest addend.

Several developmental theories (e.g. Vygotsky & Piaget) and an extensive research literature (e.g. Howison et al., 2011; Lakoff & Núñez, 2000; Seitz, 2000) suggest that children learn best through play and bodily activities, which underlines a whole-child approach that stimulates cognitive, motor and social development. Moreover, there is a rapidly growing literature within the multimodal and embodied domain which highlights the use of fingers and gestures as mediating tools for the development of arithmetic skills and concepts (e.g. Crollen & Noël, 2015). Yet, little is known about how children's informal motor skills and the use of other bodily semiotic resources might be integrated in multimodal interaction for the development of proficiency in addition. Hence, in order to address this gap, 10 pre-schoolers were engaged in a 5 weeks guided intervention. They used their body to physically map a counting-on-strategy on a 100-dotted matrix. Based on individual post-tests, this study examines the participants' ability to use and integrate multiple representations of numerosity into coherently structured articulated body-spatial mappings of an additive min-strategy. By coherence we mean the ability to integrate multimodal representations (e.g. kinaesthetic, tactile, auditory, visual, semantic) of numerosity according to the structure of the min-strategy (cf. Zmigrod & Hommel, 2013) as outlined below.

## Theoretical framework

The view that mathematical knowledge is embodied seems to meet a growing acceptance in the research domain of mathematical education (Thom & Roth, 2011). Stevens (2012) uses the notions “embodiment as conceptualist” and “embodiment as interactionist” as two complementary theoretical understandings of embodied cognition. The conceptualist stand provides a profound understanding of the nature of human thoughts and how they are organised in vast unconscious and conscious conceptual systems that are grounded in everyday activities, motion and physical experiences. An interactionist perspective of embodiment acknowledges that the body produces meaning and actions in diverse modalities. These often happen in combination and include the use of supporting means and tools such as movement, gestures, pointing, physical position and speech (Stevens, 2012). Moreover, embodied cognition holds that basic arithmetic is closely related to physical and embodied experiences (Lakoff et al., 2000). Hence, embodied actions and use of tools might follow basic laws of arithmetic and therefore possess the potential to be an integrated part of mathematical cognition that might subserve mental calculations (Johansen, 2010).

Clements et al. (2013) suggest that the understanding of counting-on strategies rests on the integration of the learning trajectories’ counting, subitising and addition. The first trajectory might be elaborated by Gelman and Gallistel’s (1978) five counting principles, which form a skeleton structure for children’s early development of counting. Applied on a multimodal scene, the one-to-one-correspondence between items of sets requires the child to relate countable units across modalities (e.g. kinaesthetic and visual tags). In counting-based addition, a prerequisite skill which addresses the stable order principle is verbal enumeration from a given number-word (e.g. “four, five, six” in  $4+2$ ). This requires the child to understand the relation between the semantic expression of the addend and the quantity (Fuson, 1988), which reflects the core of the cardinal principle. The abstraction principle is mediated via knowledge of the relations between countable items of sets with various abstract or physical modalities; for example, visual and mental units might be included in a count and in use of numerical equivalence for comparing sets across modalities. The next trajectory, subitising, refers to the immediate perception of the numerosity of small sets of items (Clements, 1999). Moreover, the term pattern recognition, which refers to direct visual perception of the numerosity of a learnt configuration (e.g. dice), is complementary and dialectical to subitising in early conceptualising of cardinality. Finally and central to the learning trajectory of addition is parts-whole relations of numbers that comprise an understanding of cardinality as an invariant property across any partitioning of a set (e.g. part-part- or part-ordinal-structure). Hence, mental fluency in additive manipulation might be mediated across modalities in the form of direct retrieval or decomposition strategies (e.g.  $2+3=5$  and  $2+3=2+2+1=4+1=5$ , respectively), whereas counting-on-strategies build on both ordinal and cardinal properties of numbers.

## Methodology

### Participants, intervention and qualitative analysis

Ten 4- and 5 year olds (4 girls, 6 boys; mean age at point of post-test 4:9) participated in a 5 weeks intervention programme, which included seven 1-hour sessions outdoors in the vicinity of their kindergarten (mean participation 6.4 sessions). Give-N-post-tests assessing knower-level of

cardinality (Lee & Sarnecka, 2010) showed that nine participants were Cardinal Principle-knowers (CP-knowers) as they mastered the use of verbal counting for exact enumeration. Moreover, one child showed consistency in the production of the maximum four objects on request and was accordingly classified as a C4-knower.

Each session integrated the min-activity as a guided part of a free construction activity. In order to get a piece for their design, they had to role two dice (e.g. 3 and 5), and outside a 100-dotted matrix ( $d = 4$  m, see Figure 1) verbalise and physically express the largest integer in a simultaneous manner (i.e. use the feet to “tag” the dice and say “Five”). Then, inside the matrix and informed by the other dice, they had to verbalise and physically tag the smallest addend in a sequential order (i.e. “six, seven, eight”). In mapping the sum, they had to hold a one-legged body-pose.

Based on an interpretive stance, a mix of pattern and cross-case analyses (Yin, 2009) were adapted to our objective to examine the participants ability to integrate multimodal representations of numerosity according to the min-strategy. First, we examined coherence in each participant’s interaction and the use of cross-modal representations of numbers across trials. Then, in order to identify differences and similarities in use and integration of modalities, a cross-case analysis was conducted. Based on this, categories of task-solution emerged and were synthesised.

### Procedure of the min-task

Individual post-testing in the 100-dotted matrix (see Figure 1) was conducted by a researcher and recorded on video. First, the participants were introduced to the min-task: “You are to do as we did in the game earlier (cf. the min-activity described above). Can you toss the dice? Which dice should you pick up? What do you do with the other dice?” If necessary, the child was guided via a practice trial. Next, in order to ensure variation in numbers to add, at least three tasks were given at each level 1 to 3: Level 1 – two dice 1 to 4; Level 2 – one dice 1 to 4, one 1 to 6; and Level 3 – one dice 1 to 6, the other set to 3, 5 and 6, respectively. During task-solution, the researcher could ask: “What did you get?”, “What do you say/do?” and “How many did you get?”

### Results

**Figure 1: A small circle outside the 100-dotted matrix**

**Figure 2: Tagging the largest addend (Stage 2)**

**Figure 3: Touch-counting (Stage 3)**

**Figure 4: Visual counting (Stage 3)**

**Figure 5: Physical expression of the final tag (Stage 4)**

The results show that five participants solved all tasks, two had one tagging error while one child developed solving abilities across trials after three errors on the first two levels. This adds up to a solution rate of 94 % (i.e. 82/87) for the eight participants who showed solving proficiency. The two remaining children, C4-knower Garth and CP-knower Hans, failed to solve the tasks (i.e. 0/19). With the exception of one-more-tasks (e.g.  $6+1$ ,  $3+1$ ), most participants showed consistency in strategy

usage. However, some children used different representations depending on whether the smallest integer exceeded the subitising range 1 to 4 or not. Basically, the children's cross-modal representations of numerosity in the min-task involved four steps or stages: 1) Place the dice with the largest addend in the small circle, pick up the other dice; 2) Articulate and physically tag the largest integer simultaneously as a whole (see Figure 2); 3) Enter into the matrix and sequentially physically tag dots and verbally count the number of units equal to the smallest addend (see Figures 3 and 4); and 4) Verbalise the sum and physically gestalt the final tag (see Figure 5). Guided by this framework, the next section provides an elaborated presentation of the general results.

Stage 1: Most CP-knowers used subitising or pattern recognition to determine the outcome of the dice. However, one CP-knower had to count dice with numerosity 6, and C4-knower Garth used verbal touch counting to perceive the numerical value of dice from 4 to 6. Regarding the more-and-less-relation, all participants shared the ability to distinguish between the two dice according to size. However, in contrast to Garth who picked up the dice with the largest addend, the rest of the children placed the dice with the largest integer in the small circle.

Stage 2: While the CP-knowers verbalised and body-tagged the largest addend in the little circle, C4-knower Garth ignored the dice on the ground. Physically, some stated the largest integer in the form of a two-legged tagging, while others integrated the tagging in gait or jumped into the circle to perform a distinct one-legged pose in parallel with an exaggerated articulation of the number word.

Stage 3: Inside the matrix, the CP-knowers mapped only one physically tagging of a dot onto one semantic expression of a number word (cf. the one-to-one principle). This transformation of units from the hand-held-dice was based on visual, tactile or mental representations of numerosity. Except for Hans who linguistically treated the two addends as separate parts, the CP-knowers showed verbal skills in counting on from the largest addend (cf. the stable order principle). C4-knower Garth also started to count from "One", but he kept on counting past the cardinality of the hand-held dice. Regarding the spatial and temporal features of the kinaesthetic modality, some participants walked in a delayed mode while others combined jumping and rhythmic moves in a rapid, precise and flexible appropriation of the spatial layout of the dots.

Stage 4: Regarding the final body-spatial tagging that stated the sum, a recurring kinaesthetic pattern for the CP-knowers was to halt in a one-legged body-pose. Some also attributed an auditory dimension as the final step was expressed in a more physically distinct way. This behaviour was often accompanied with an accentuated and prolonged articulation of the sum. Some children also attributed personal gestalts, bodily rotations and aesthetic moves to the physical tagging of the cardinal value. In contrast, C4-knower Garth continued to count and walk past the numerosity of the hand-held-dice without assigning a final tag to any physical or semantic significance. Regarding conceptualisation of the sum, participants with solving proficiency either stated the cardinal value unasked, repeated the last articulated number-word by request or via the counting-all-strategy.

The results show that major differences across solution proficiency were mediated in their multimodal use and synthesis of numerosity in the counting-on part of the min-task (cf. Stage 3). In particular, four children showed a preference for the use of tactile support, two for visual and two for mental based representations of numerosity, while two showed flexibility in a varied use of these forms of

representations in the integration with the semantic and kinaesthetic modalities. Based on this, the next section presents examples and rich description for each of these categories.

**Preference in tactile based representations of numerosity:** A shared feature for this group is the use of fingers for touch-counting the dots on the dice (cf. Stage 3, see Figure 3). Hence, tactile sensory information supported the synchronisation of articulation, visual perception and physical tagging of the configuration of the dice and the spatial layout in the matrix.

**Preference in visual based representations of numerosity:** A core feature of the “visual counters” is their use of the eyes to coordinate visual pointing and tagging of dots in the transformation of numerical information to the counting-on part of the min-task (cf. Stage 3, see Figure 4). Rich descriptions of Jon’s task solution aim to illustrate this group’s proficiency: A recurring pattern was to physically tag the largest addend as a whole, then slowly walk into the matrix and, supported by visual examination of the dice in between each tagging, continue to map the numerosity onto the semantic and kinaesthetic domain to produce the sum. However, in the following excerpt, which starts after the dice show 6 and 6, he deviates from his normal pattern:

Jon: Six and six [Jon uses a finger to touch-count the dots on both dice] One, two ... 11, 12. [He picks up a dice and tags the other using his right leg] Six. [He jumps into the matrix and without looking at the dice he continues in direct physical tagging in synchronisation with verbalising] Seven, eight ... 11, 12 [In a one-legged pose, he articulates the sum in an extended manner]

C4-knower Garth is also categorised as a “visual counter”, although incompletely compared to the proficiency described above. For example, in the 5+3- and 6+5-tasks, he counted to 10 and 22 respectively and only partially based his actions on what seemed to be “visual tagging”. Moreover, in these sequences, he lost control over the feet-dot mapping.

**Figure 6: Multimodal mapping of the largest addend (Stage 2)**

**Figure 7: Rhythmic mapping (Stage 3)**

**Figure 8: Rapid, fluent and precise physical mapping (Stage 3)**

**Figure 9: Bodily rotation in expressing the sum (Stage 4)**

**Preference in mental-based representations:** Shared features for this group comprise the use of subitising or pattern recognition to perceive numerical information from the dice (cf. Stage 1), articulated one-legged body-pose in mapping of the largest addend (cf. Stage 2) and mentally maintaining and retrieving numerical information to support the counting-on part of the min-strategy (cf. Stage 3). The smallest addends within the subitising range were most often mapped directly. However, when the smallest integer was larger than three, they could also perceive visual information from the dice one time during the process. Additional recurring patterns were in the form of precise and rapidly articulated body-spatial mapping, which was mediated as rhythmic verbalisations and

steps in between dots in expressing the ordinal structure of the counting based addition (cf. Stage 3, see Figures 7 and 8). Moreover, they often attributed an exaggerated verbalised and prolonged physical mediation of the sum with creative moves and aesthetic body-poses (cf. Stage 4, see Figures 5 and 9). Below, rich description of Oda's task solution illustrates this group's proficiency. In tasks where the smallest addend is less than and sometimes equal to four (e.g.  $5+2$ ,  $5+3$ ,  $6+3$  and  $6+4$ ), Oda showed mental fluency in the numerical mapping, as she did not look at the dice after entering the matrix (cf. Stage 3). The following excerpt exemplifies her behaviour when the smallest addend was larger and it starts after the dice show 6 and 6:

Oda: [Oda picks up one dice and tags the other with her left foot] Six. [She briefly holds the gestalt, jumps into the matrix and tags dots in a rapid motion in synchronisation with articulating] Seven, eight, nine, 10 [She halts and quickly looks at the dice before she continues in rhythmic tagging] 11, 12 [The articulation of the sum is extensive as she performs a one-legged bodily rotation]

**Cross-modal variations in use of representations:** Two participants showed flexibility across tasks in terms of a varied use of mental, tactile and visual support for modulation of numerical information in the counting-on part (cf. Stage 3). This is exemplified by Viola, who applied retrieval of mental magnitudes when the smallest addend was within subitising range and varied between using visual- and tactile based representations to solve other tasks (e.g.  $6+5$  and  $5+5$ ).

## Discussion

Based on the shared experiences of 4- and 5-year olds in a matrix to support early appropriation of the min-strategy, this study investigates the participants use and coherence of multimodal representations of numerosity in task-solution. The post-tests show that eight of the participants mastered the min-task, while two of the children lacked solving proficiency. Beyond this dichotomy, the preference for touch-counting, visual-counting or mental based representations of numerosity reflects major categories concerning the integration of modalities in the min-task.

A core signature for children with a preference to the retrieval of numerical information to support embodiment of the ordinal structure of the min-strategy is a fluent numerical interaction between the semantic and kinaesthetic modalities. This is exemplified by Oda in the  $5+3$ -task, where she projects a visual pattern recognition of the largest addend and the subitising of the smallest integer into a two-staged coherent motion in parallel with the articulation "five" and then "six, seven, eight" (cf. Stage 2 and 3, respectively). This group's ability to maintain mental magnitudes and modulate cognition of addition into compound body movements is further exemplified in the  $6+6$ -task. Based on visual pattern recognition of the numerosity, Oda's interaction suggests that she mentally decomposes the additive structure into three parts (i.e. 6, 4, 2), which are perceived and retrieved one at a time and holistically expressed as a three-staged movement trajectory reflecting a part-part-part-structure of the whole (i.e. 12). Moreover, this group's preference in mental retrieval seems to support motor creativity and verbal manipulation across the four stages of task solution. This is mediated in the form of a louder articulation and a harder physical tagging of the largest addend and the sum, rhythmic mappings of the smallest addend and in the integration of personal gestalts and bodily rotations in expressing the sum (cf. Figures 5 to 9).

The “eye- and touch-counters” are characterised by the use of visual or tactile based representations of numerosity in a resource demanding integration with the kinaesthetic and semantic modalities. Shared features include the use of the hand-held dice for cross-modal transformation of one unit at a time and this ordinal structure seems to be projected in a stiff body-spatial mapping. However, in the 6+6-task “visual counter” Jon deviates from this pattern as a pre-count enables him to mentally maintain the sum of the addition during action. Hence, he replaces visual counting and a delayed gait with a fluent multimodal mapping of the counting-on-strategy.

Regarding the children who do not solve any of the tasks, Garth is not able to follow the rules of the min-strategy, nor is he able to recognise or enact the multimodal correspondence between the spatial information of the affordances and the kinaesthetic and semantic domains. Moreover, his proficiency in exact enumeration as a C4-knower might explain his lack of the necessary abilities to embody the parts and the whole of the additive structure. By contrast, Hans demonstrates proficiency in coherent mappings of numerosity across modalities, but he is not able to use verbal skills to combine the two addends into a whole. Thus, this suggests that his mastery of the min-tasks is a linguistic matter in terms of a flexible use of the stable order principle (Gelman et al., 1978).

To sum up: The findings show cross-modal variations in the participants’ mediation of partitioning, boundaries and the interior of the additive structures. The results also suggest that the ability to apply the abstraction principle in terms of storage and retrieval of mental magnitudes supports fluency in the semantic and physical modalities of numerosity. In contrast, participants that mapped information from the dice in between each mapping seem to use their cognitive and motor resources with the complex synchronisation of eye, dice, finger, feet and matrix. These variation in strategy usage might be explained in individual differences in working-memory capacity (Noel et al., 2003), the participants’ competences in applying bodily semiotic resources and their proficiency in the learning trajectories counting, subitising and addition (Clements et al., 2013).

### **Summary and concluding remarks**

Countering a view of cognition which sees mathematics as a fixed disembodied phenomenon, this study presupposes that arithmetic structures must be embodied by each child, as the body with its motor system is an integrated part of thinking that works dialectically with and under the guidance of both external factors and cognitive processes (Seitz, 2000). Thus, by grounding the additive structure in the body language of 4- and 5-year olds, we examine their use and coherence of multimodal representations of numerosity in counting-based addition. The findings show that mediation of the min-strategy rests on the children’s ability to structure and synchronise cross-modal and mental based partitioning of numbers and manipulation of the interior and the boundaries of sets. Hence, this study contributes to embodied cognitive theory, which regards the body as an open and available resource for thinking, learning and social activity (Stevens, 2012). In particular, it demonstrates how embodied experiences in ecological rich milieus might conflate with arithmetic structures (Lakoff et al., 2000). However, the study is limited in the sense that we cannot make any claims of strategy generalisation (Siegler & Jenkins, 1989). Yet, even though some participants have problems to discern the additive structure embedded in the complex scene, our overall results suggest that the min-activity might

facilitate 4- and 5-year olds ability of to synchronise multimodal representations of numerosity in a manner that reflects coherence of the min-strategy.

# Development of strategies for a combinatorial task by a 5 year old child

Kerstin Bräuning

University of Halle-Wittenberg, Germany; [braeuning.kerstin@gmail.com](mailto:braeuning.kerstin@gmail.com)

*The transition from kindergarten to first grade is a very special time for children. In a longitudinal research project over two years, we interviewed children up to 6 times individually. They solved several tasks from different mathematical areas. In this study, I will present one combinatorial problem and analyze approaches to solve it by one child over two years as a case study using the strategies of Hoffmann (2003). How does this child solve the combinatorial problem before school, just after the school start and at the end of grade 1? What kind of different information do we get if we analyze the data product-oriented or process-oriented? Observing and analyzing the child's approaches and development over time will be at the heart of this paper.*

*Keywords: combinatorics, combinatorial reasoning, Piaget, preschool education, elementary school*

## Introduction

The domain of combinatorics is a very interesting and fertile field for research in mathematics education. Even young children can discover the rich mathematical structure and can become acquainted with mathematics as the art and science of patterns (Devlin 1995). Still this topic is not the best recognized one in elementary school, as English (1991, p. 451), almost 30 years ago mentioned. Hoffmann (2003, p. 3) indicates that combinatorial problems are interesting because previous knowledge is not necessary. It is possible to solve combinatorial problems in an activity-oriented and material-oriented fashion; it is easy to build analogous problems on a higher level; one can choose different ways to arrive at the solution. Furthermore, problem-solving approaches can become apparent and children are encouraged to mathematical communication and argumentation skills.

## Theoretical background

Piaget and Inhelder (1975) investigated in their studies the development of a combinatorial system connected to the Piagetian developmental stages. They find out that children in the preoperational stage search without a system, in the concrete operational stage they search for a system and in the formal-operational stage, they search systematically and use the odometer strategy. Their ability to reason and argument is increasing similar to their search for a system. Combinatorial problems play not only an important role in cognitive development but mathematics education researchers like Piaget and Inhelder (1975) found that they may promote students' reasoning and generalization processes. Further research showed that there are first steps to a systematical search and that the task should be in a more suitable and meaningful context and material should be more child appropriate (English 1991, p. 453).

Further studies investigated the strategies of the children when solving a combinatorial task. I refer to two studies explicitly because in my study I deal with almost the same age range and videotapes like English (2005) and with a case study like Martino (1992). English (2005, p. 129) videotaped 50

children between 4.5 and 9 years, solving combinatorial tasks. She analyzed the video material without transcripts. In comparison to English, I observe the children several times over two years. I use transcripts to reconstruct the approach of the child when solving the combinatorial task. Martino (1992) dealt with the understanding and development of mathematical ideas using combinatorial tasks as one example. She looked at three case studies. She observed children in grades 2, 3 and 4 in pairs or a group of three without the intervention of a teacher. I observe children from 5 to 7 years old in one-to-one-interviews with an interviewer, as an observer, and so I examine a younger group of children. Looking at younger children is especially interesting because combinatorial problems also “facilitate the development of enumeration processes, as well as conjectures, generalisations, and systematic thinking” (English 2005, p. 122) and these are key components of mathematical understanding.

Hoffmann (2003), based on the two studies mentioned above, worked out that there are macro and micro strategies. Macro strategies are guiding actions for a structured finding of all combinations. One strategy is the odometer strategy, “holding one item constant while systematically varying each of the other items” (English 1991, p. 451). Other strategies are, the entire counterpart construction, and looking for the solution in phases. Micro strategies describe patterns of action to find the next combination or find some of the combinations. For my study, only the following seem relevant: 1- and 2-constant-principle, stair formation, counterpart construction and turn around. In the analysis part, I will describe them on more detail.

The study reported here made use of two levels of manipulative materials. The concrete external representation enables the children to handle the material and keep their focus on the solving process without representing their solution on paper. English (1991, p. 453) stressed that young children would display more sophisticated combinatorial approaches than suggested by the Piagetian studies. Further on English (2005, p. 128) assumes that preoperational children (like the children in my study) “generate combinations only in an empirical manner by randomly associating elements” and her conclusion is that “there is a lack of systematic method”. This study addressed this assumption in the course of a longitudinal study over two years where each child solved the same combinatorial task up to six times in a one-to-one-interview. The idea of repeating always the same task without teaching is that the children need time to become acquainted with this task. In addition, the verbalization competence is restricted with young children, but they have the possibility to show their thinking by using materials, gestures, deictic expressions (Werner 2018) and also by us observing their actions in process. Previous studies looked at the products children developed when they solved combinatorial tasks and because of the young children, I take a process-oriented view on the children’s actions. Even more, I could not find any studies, which had a longitudinal view on the solving of combinatorial tasks of young children. English (2005, p. 130) observed the learning across the set of tasks dealing with combinatorics at one interview point.

The present report examines the following research questions focused on one case study for a first small analysis of all collected data:

What kind of approaches does a child, aged 5 to 7 years, use in solving the same combinatorial problem several times over two years?

To what extent does the analysis method, product-oriented or process-oriented, show a different view on the way of finding all combinations for a combinatorial task of one child (5-7 years)?

## Research project

### Sample

The study is called “mathematics and first day at school – talking with children in the transition from kindergarten to primary school” (MaScha). The key aspect of this study is to investigate the (re)interpretation and strategy diversity of children from the last year of kindergarten (preschool) to the end of grade one in several different mathematical areas. It includes finger patterns, one problem solving task, one combinatorial task and the attitudes of children to mathematics teaching and mathematics as a teaching content. In this paper, I will only focus on the combinatorial problem.

The study involved 14 children (8 boys, 6 girls) from a rural area. They all attended the same kindergarten and the same class in primary school. At the beginning of the study, they are all in their last year of kindergarten (5 or 6 years old). The end of the study is at the end of first grade and they are almost all 7 years old. Surveys were conducted every three months in the last year of kindergarten (December 2015, February 2016, May 2016) and every 5 months at the beginning, in the middle and at the end of the first school year (September 2016, February 2017, June 2017). Each child is interviewed for about 30 minutes in a one-to-one-interview. The interviews are all video documented and interesting parts are transcribed for analysis. The interviews take place during school time but are additional to teaching. The interviewer is either a pre-service teacher who attended a seminar on talking with children about mathematics or the researcher. It follows a semi-structured interview guide, which is competence-oriented and can be widened with questions to better understand the comprehension of the child and with additional analogous tasks if necessary. The semi-structured interview guide remains the same over the two years because I can only recognize changes or process of development in the (re)interpretation and strategy use of the children when they were familiar with the task and knew what to do. Especially the assisted problem solving with the interviewer could help the children, and like Freudenthal (1973, p. 110) said, “the best way to learn an activity is to perform it”. On the other side, the tasks have to be sufficiently challenging so the children have to solve the tasks every time from scratch and cannot remember the solution like an easy calculating task.

The competence of the interviewer influences the results of the interviews with the children. Therefore, the same interviewer interviews most of the children over the two years to keep the influence constant. The interviewer sometimes gives instructions or intervenes (Bräuning & Steinbring 2011) to establish a “common base of understanding” (Bräuning & Steinbring 2010) between the child and the interviewer and to give the children the chance to deal with unfamiliar tasks. The kindergarten teacher and the primary teacher were only told that the interviewer is talking with the child about mathematics for around 30 minutes. They were not given the tasks so that the teacher is not able to train the children and cannot intervene.

The combinatorial task called bears task is: “You have three bears, a yellow, a blue and a green bear. They move into a tower. Each bear lives on one level. How many different ways can they live in the tower?”. The children were given eight towers (without a roof to avoid confusion) drawn on paper and several yellow, blue and green plastic bears (more than 20 bears).

**Figure 1: Solution of the bears task interview 1 with Lena final product**

We offered the children more material than needed so that they have to decide if they found all combinations on their own. Similar to the bears task the problem is often presented with blocks which the child puts together. The advantage for the bears task is that through the tower on paper and the placing bears, two dimensions for representing the child's approach are available. Especially if a very detailed process-oriented view on the approach is taken the researcher can identify on which level at what time the child is placing a bear and where the child is looking at to find a new combination. Through the video documents and the transcripts, eye and head movements are observed. This would be easier using eye tracking, but it probably would be an artificial situation for the child, therefore we did not use it.

### **Realization of the interview**

When the child solved the task with material there was preferably no inquiry. At the end the question, "How many ways did you find" is posed. If the child found the same combinations several times, or less than three combinations the interviewer asked: "Can you find double combinations in how you have bears living in towers? Can you find additional combinations? How often can you find yellow (blue, green) on the lower (middle, upper) level?" I think these questions are very important because during the analysis there occurred the phenomena that some children had a lot of trouble with understanding equality. Some of them interpreted equal as identical so that every tower constellation even with the same order of colors was a new combination for the child.

In the reflection phase, the children were asked: "What can you notice if there is yellow twice on the lower, middle and upper level? Are you sure you found all combinations? Please explain". Hoffmann (2003, p. 260) observed that her youngest participants (7-9 years old) could not justify repositioning their combinations. As this challenge was too much for them, I decided for the 5 to 7 years old children not to pose this demand. Instead, we asked them to explain why they think that they completed the task. Some of the children developed their argumentation skills and were able to explain their approach. By means of these explanations, the macro strategy can probably be identified.

### **Analysis of one case study**

I will present as a case study Lena. She is interviewed six times. I chose her because five interviews were conducted by the same interviewer, and only the fifth interview was by another interviewer. Therefore, the influence of the interviewer is kept almost constant. This is especially important because the interviewer posed different questions, which I distinguish in subject-specific questions and non-subject-specific questions. In another paper, I will analyze the influence of these two types of questions for the explorative investigation of the child's thinking. I will present the analysis of three interviews of three specific moments. The analysis of her first interview represents the first contact of Lena with this task. Her fourth interview is just one month after the first day of school and

so she is still getting used to this new institution. At the end of first grade, the sixth interview shows the end of development in her approaches because it is the final interview of this study.

In the product-oriented analysis, I always present the final product of the solving process in the interview and in the process-oriented analysis I describe each change and the whole process precisely in order the child placed the bears in the tower and the order of the towers. The eight towers on paper are represented in two rows of four towers. The researcher when transcribing the video document writes down the order. In the coding table, you will find the order of towers with T1, T2, etc. and the order of placed bears in an extra column for each tower. The researcher and his team watch the video several times to identify each hand and eye movement and analyse the transcript qualitatively.

The following micro strategies referring to Hoffmann (2003) are identified in the previous analysis:

1-constant-principle: the color of one level will be fixed. For three-dimensional combinatorial tasks, an implicit 1-constant-principle occurred in the process-oriented analysis where at first two colors will change places and then the constant will be placed implicitly or automatically the third color keeps constant.

Stair formation: the colors “walk” through the levels (entire or single stair formation)

Counterpart construction: changing the two possible colors between two combinations (only for multiples of two-dimensional combinatorial tasks). With three-dimensional combinatorial tasks, this corresponds to the 1-constant-principle or the implicit 1-constant-principle.

Turn around: two combinations are the same when rotated 180°.

The macro strategy is reconstructed out of the most frequent occurrence of micro strategies and the verbal justification of the child.

In the first interview with Lena in December 2015, she found six combinations. Tower 6-4 means that Lena found this combination after rejecting three other possibilities. I present the solution in this table because I want to compare Lena’s solutions at different interview points and to give more consistency (you can see the real picture in Figure 1).

T5 Blue Yellow Green	T6-4 Yellow Blue Green		
T4 Green Yellow Blue	T3 Yellow Green Blue	T2 Green Blue Yellow	T1 Blue Green Yellow

**Table 1: Solution of the bears task interview 1 with Lena final product**

From T1 to T2 yellow remains constant and so the 1-constant-principle can be identified. The 1-constant-principle also occurs as from T3 to T4 blue is constant and from T5 to T6-4 green is fixed. T2 to T3 is an entire stair formation. T4 to T5 is a “turn around” or a 1-constant-principle where yellow remains in the middle. In consideration of the identified micro strategies, a kind of odometer principle is inherent, because Lena uses a lot the 1-constant-principle. Analyzing the same approach with a process-oriented view provides another insight into strategies Lena used.

T5 Blue Yellow Green	3 2 1	T6-4 Yellow Blue Green	10 9 8 (I)				
T4 Green Yellow Blue	3 1 2	T3 Yellow Green Blue	2 3 1	T2 Green Blue Yellow	3 1 2	T1 Blue Green Yellow	1 2 3
		T6-1 Blue Green Yellow	3 1 2	T6-2 Green Blue Yellow	5 4 -	T6-3 Green Yellow Blue	- 7 6

**Table 2: Solution of the bears task interview 1 with Lena process**

From T1 to T3 there is a single stair formation and between T2 and T3 even an entire stair formation. T3 to T4 is not identified and T4 to T5 is a “turn around”. T5 to T6-1 is an implicit 1-constant-principle and T6-1 to T6-2 a 1-constant-principle where Lena detect the identity to T2 and rejects this combination. T6-2 to T6-3 is also the 1-constant-principle and identical to T4; Lena also rejects this combination. From T6-3 to T6-4, there is an implicit 1-constant-principle. In consideration of the identified micro strategies we can recognize that Lena’s approach is very inconsistent and cannot identify a macro strategy. English (1991, p. 458) named this strategy trial-and-error-procedure with random item selection and rejection of inappropriate items whereupon in this study the interviewer asked the child if there are identical combinations. In addition, I present some of the interviewer’s questions posed to Lena. “Are they all different (the towers) which you posed here?”, “How often does a yellow bear live in the lower level?”, “Compare these two (towers)”, ... These questions influenced of course the way of Lena’s solving process, but these affects occur in the product-oriented and process-oriented analysis and nevertheless there is a difference. Even more the interviewer wanted to give stimuli to deepen the mathematical thinking of the child.

	Product	Process
Micro strategies	T1/T2: <i>1-constant-principle</i> T2/T3: <i>entire stair formation</i> T3/T4: <i>1-constant-principle</i> T4/T5: <i>turn around or 1-constant-principle</i> T5/T6-4: <i>1-constant-principle</i>	T1-T3 <i>single stair formation</i> T2/T3 <i>entire stair formation</i> T3/T4 ? T4/T5 <i>turn around</i> T5/T6-1 <i>implicit 1-constant-principle</i> T6-1/T6-2 <i>1-constant-principle</i> , identical to T2 T6-2/T6-3 <i>1-constant-principle</i> T6-4 <i>implicit 1-constant-principle</i>
Macro strategies	Mainly 1-constant-principle -> odometer principle	???

**Table 3: Comparison of the product-oriented vs. process-oriented analysis of Lena’s solution 1**

I will only present the comparison of the product-oriented vs. process-oriented analysis of Lena’s solution 4 and 6.

	Product	Process
Micro strategies	T1-T3: <i>entire stair formation</i> T4-T5: <i>entire stair formation</i>	T2/T4 <i>1-constant-principle</i> , yellow remains in the middle, blue and green change T3/T5 <i>1-constant-principle</i> , yellow remains in the lower, blue and green change

	T6/T7 identical to T3 T8 identical to T1	T4/T6 <i>1-constant-principle</i> , green remains in the middle then see identical to T1 T5/T6 <i>1-constant-principle</i> , yellow remains in the lower, then blue and green change T6/T7 identical to T3 T8 identical to T1
Macro strategies	Mainly stair formation -> odometer principle	Mainly 1-constant-principle -> odometer principle

**Table 4: Comparison of the product-oriented vs. process-oriented analysis of Lena's solution 4**

In September 2016 some weeks after the first day of school, Lena had her fourth interview. She already used an emerging pattern in item selection. Interesting is that it is the same micro strategy for the whole solution process but a different one for product-oriented or process-oriented analysis. Lena did not identify the identical ones and she could not justify her approach.

	Product	Process
Micro strategies	T1/T2 turn around T2/T3 stair formation T3/T4 1-constant-principle, yellow remains in the upper level, green and red change T4/T5 stair formation T5/T6 1-constant-principle	T1/T2 implicit <i>1-constant-principle</i> T1/T2/T3 green in every level, <i>single stair formation</i> T3/T4 <i>1-constant-principle</i> T5/T3 <i>1-constant-principle</i> T6/T1 <i>1-constant-principle</i>
Macro strategies	???	Mainly 1-constant-principle -> odometer principle

**Table 5: Comparison of the product-oriented vs. process-oriented analysis of Lena's solution 6**

In the sixth interview with Lena in June 2017, the product-oriented analysis cannot find a macro strategy but if we look at the process-oriented analysis, there is evidence that Lena uses the odometer principle without rejecting any combination. She does not use the odometer principle visibly from the beginning but if she checks her solutions, one can observe it. Even more she justifies her approach after the question “how can you quickly check that they are all different?” with “these two have to change all the time (points to T6 and T1) and these also (points to T5 and T2) and also those (points to T3 and T4)”. Looking at Lena's progression from the first to the sixth interview, she developed a more efficient solution procedure, which is only observable with the process-oriented analysis and is confirmed by Lena's verbal justification of her approach.

## Closing remarks and outlook

To answer the posed research questions, I refer to the studies of English (1991, 2005). English (2005, p. 128) assumes that preoperational children (like the children in my study) “generate combinations only in an empirical manner by randomly associating elements” and her conclusion is that “there is a lack of systematic method”. Looking at the analysis of the case study, Lena uses quite different strategies when analyzing her approaches product-oriented or process-oriented. In her first interview in the product-oriented interview, it seems that Lena is already “emerging pattern in item selection, with rejection of inappropriate items” (English 1991, p. 458). This could be traced back to the interviewer's questions. If you compare it to the process-oriented analysis you can see that Lena uses the trial-and-error-procedure with random item selection and rejection of inappropriate items. In the sixth interview the interviewer does not pose any questions and in the process-oriented analysis it

seems evident that she uses the “odometer principle without rejecting any combination” (English 1991, p. 461). There is an obvious development in Lena’s solving approaches when using the process-oriented analysis. It seems that the process-oriented analysis method is more appropriate to this young child and probably to all young children with restricted verbalization possibilities. So probably preoperational children are already able to evolve strategies from dealing several times with the same task and an explorative supervision of the interviewer. In the sixth interview, Lena is able to justify her conclusion by making the following statement: “these two have to change all the time (points to T6 and T1) and these also (points to T5 and T2) and also those (points to T3 and T4)”. Hoffmann (2003, p. 260) observed that her youngest participants (7-9 years old) could not reposition their combinations with justification. There will be further analysis of the children’s development over two years especially qualitative interpretative analysis of the communication and interaction between child and interviewer (Bräuning & Steinbring 2011). The possibilities of young children to express their mathematical thinking is quite different to that of older children and adults. Looking at the approaches of young children, researchers should seek methods to observe and to analyze strategies of children who have limited possibilities to verbalize their thinking.

# Kindergarten teachers' orchestration of mathematical learning activities: the balance between freedom and structure

Svanhild Breive<sup>1</sup>

<sup>1</sup>University of Agder, Norway; [svanhild.breive@uia.no](mailto:svanhild.breive@uia.no)

*This paper reports on a multiple-case study which focuses on four kindergarten teachers' orchestration of mathematical learning activities with respect to the degree of freedom, and what impact their orchestration has for children's mathematical learning possibilities. The study draws on Valsiner's (1987) zone theory to investigate the relationship between zone of free movement (ZFM) and zone of promoted action (ZPA) which the kindergarten teachers set up to canalise children's actions and thinking and thus development. The results show that in the kindergarten where the ZFM is gently set up and limited to mathematics, and where the kindergarten teacher sensitively sets up the ZPA and promotes children to share, argue for and explain their mathematical ideas, and explicitly promotes the children to collaborate, is where most problem-solving interaction occur and thus facilitate children's learning possibilities the most.*

*Keywords: Kindergarten, mathematics, orchestration, zone of free movement, zone of promoted action.*

## Introduction

This paper reports on a multiple-case study which aims to investigate four kindergarten teachers' (KTs') orchestration of pre-designed mathematical learning activities and what impact their orchestration has for children's learning possibilities. The current debate about mathematics in kindergarten is seldom about whether or not mathematics should be part of the curricula in kindergarten, rather on how mathematical activities in kindergarten should be orchestrated<sup>1</sup> (Gasteiger, 2012; Hirsh-Pasek, Golinkoff, Berk, & Singer, 2009; van Oers, 2010). Children's opportunities to take part in mathematical discourses are important in learning mathematics, but in activities where the kindergarten teacher has a pedagogical aim, it may be difficult to balance teacher-talk and child-talk (Dovigo, 2016). The study reported here focuses on four KT's orchestration of mathematical learning activities with respect to the degree of freedom<sup>2</sup> and aims to:

- Investigate the characteristics of four kindergarten teachers' orchestration of pre-designed mathematical activities with respect to the degree of freedom, and;
- Investigate what impact the four kindergarten teachers' orchestration of the mathematical activities has for children's mathematical learning possibilities.

---

<sup>1</sup> The term 'orchestration' is used in accordance with Kennewell (2001), as a broad metaphor for how the KT's structure or organise the activity through use of questions, cues, prompts, information, demonstrations etc.

<sup>2</sup> The term 'degree of freedom' is used in accordance with van Oers (2014) as a characteristic of the way an activity (in cultural-historical activity theory) is carried out and refers to the "degrees of freedom allowed to the actor in the choice of goals, tools, or rules" (p. 113, emphasis in origin), which in turn initiates the actor's choices of actions.

## Theoretical framework

The study reported here draws on Valsiner's (1987) zone theory to investigate the relationship between freedom and structure in four KT's orchestration of mathematical learning activities. The balance between freedom and structure is the main focus when Hirsh-Pasek et al. (2009) and Weisberg, Kittredge, Hirsh-Pasek, Golinkoff, and Klahr (2015) discuss 'playful learning' as an educational approach in kindergarten. Playful learning captures both 'free play' where children play without interference from adults, and 'guided play' where the KT organises the learning environment and guides the play in desired directions with respect to a learning aim. Weisberg et al. (2015) argues that, although the KT's initiate and guide the activity in guided play, the KT's must make room for children's self-directed exploration, and it is this balance between freedom and structure that makes guided play such an effective teaching tool. Similar van Oers (2014) argues that playful learning activities should contain some elements of instruction. "The nature of the actions embedded in play can vary with respect to their degree of freedom allowed, as long as the activity as a whole remains a playful activity" (van Oers, 2014, p. 121). The learning activity must be engaging and give possibilities for the players freedom to explore the (mathematical) objects in their own manner.

In his study on preschool children's argumentation, Dovigo (2016) investigates children's learning opportunities in different types of conversations (peer-talk and child-teacher talk). Dovigo found that children had richer opportunities to participate and asked more questions in peer-talk than in child-teacher talk. It was a clear tendency that in child-teacher talk, the KT talked more than the children. However, the children's abilities to build arguments were limited in peer-talk and were facilitated in child-teacher talk. The KT's facilitated children's explanations and helped them to elaborate their argumentations, which again improved children's critical thinking and abilities to collaborate.

Through his zone-theory, Valsiner (1987) explores the development of children's actions and thinking through organisation of person-environment relationships. The physical environment of the child is the cultural frame which the child is acting within and thus develop its thinking. Valsiner's theory emphasises that both the developing child and the environment are structurally organised, however the structuring nature of the child and the environment is continuously and dynamically transformed. Valsiner (1987) uses three zone concepts to conceptualise the dynamic environmental structures that organise the child's development: Zone of Free Movement (ZFM); Zone of Promoted Action (ZPA); and Zone of Proximal Development (ZPD). The ZFM is co-constructed by the child and the adult and organises the "child's (1) access to different areas in the environment, (2) availability of different objects within an accessible area, and (3) ways of acting with available objects in the accessible area" (p. 97). Within the ZPA there may be activities or objects which the child is promoted to engage with. An important characteristic of the ZPA is its non-binding nature: The child does not need to follow the ZPA and can act with other objects (in other ways) within the ZFM. The child cannot be 'forced' to accept the ZPA unless the ZPA is turned into ZFM. The ZFM and ZPA must be considered as a unit and Valsiner (1987) labels it the 'ZFM/ZPA complex'. The ZFM/ZPA-complex work as a mechanism to canalise the child's actions and thinking and thus development in culturally accepted ways. In addition, Valsiner (1987) discusses how ZPD relates to the ZFM/ZPA-complex, but due to space limitations, this study focuses primarily on the relationship between ZFM and ZPA in four kindergartens with respect to mathematics.

## Methodology

The study reported here is a multiple-case study (Yin, 2014), which aims to characterise four KT's orchestration of pre-designed mathematical activities and its impact for children's mathematical learning possibilities. It is part of a larger study on mathematical teaching and learning in kindergarten and situated within a Norwegian research and development project called the Agder Project<sup>3</sup> (AP). The intervention of the AP was based on mathematical activities which were pre-designed in collaboration between researchers (including myself) and the KTs in the focus groups of AP. The mathematical activities suggest how to organise learning sessions, what materials to use and suitable questions to ask etc. in order to promote a playful and inquiry-based approach to the teaching and learning of mathematics. The activities were meant as suggestions not as scripts which the KTs needed to follow to the letter and this was communicated both verbally and in written form to the KTs before the intervention. The activities are described in Størksen et al. (2018), a book containing one-page outlines of the activities. This study takes a qualitative approach to data collection and data analysis and the empirical material was collected over two observation periods (autumn 2016 and spring 2017) during the intervention of the AP. Observations were conducted of approximately 40 minutes sessions where the four KTs, who were part of the focus groups of the project, implemented the pre-designed activities. Interviews were conducted in each kindergarten after each observation period. Overview over data sets (observations and interviews) in each kindergarten is illustrated in Table 1 below. All four KTs have at least 15-years working experience.

	KT1	KT2	KT3	KT4
Autumn 2016	5 obs. + 1 interv.	4 obs. + 1 interv.	5 obs. + 1 interv.	3 obs. + 1 interv.
Spring 2017	6 obs. + 1 interv.	7 obs. + 1 interv.	0 obs. + 0 interv.	4 obs. + 1 interv.

**Table 1: Overview over data sets (observations and interviews) in the four kindergartens**

The empirical material was collected through ethnographic field notes (Emerson, Fretz, & Shaw, 2011) from observations and interviews. Field notes were written during and/or straight after each observed session and were supplemented when having conversations with the KTs after each session. Field notes from the interviews were made straight after the interviews and were extended when the video-recordings of the interviews later were watched. Field notes should not, ideally, include interpretations of the observed interaction (Emerson et al., 2011). However, as Emerson et al. (2011) argues, when the fieldworker starts to work with the field notes, he/she orders patterns of interactions and decides what to include and leave out from the field notes. In this research study the research questions were made before conducting the field work, which guided what I was especially looking for and thus what I included and left out from the field notes. The field notes must therefore, to a certain extent, be regarded as interpretative or analytical.

---

<sup>3</sup> The Agder project is funded by the Research Council of Norway (NFR no. 237973), The Sørlandet Knowledge Foundation, The Development and Competence Fund of Aust Agder, Vest Agder County, Aust Agder County, University of Agder and University of Stavanger.

Processing and analysing data went through an iterative process. Instead of using the field notes as ‘raw material’ from which I started a coding process, I worked directly with the field notes and carefully contracted them into profiles of the KT’s orchestration and their interaction with the children. Since the field notes were already to some extent analytical, they served as a useful starting point for this purpose. The profiles concern four key points: (1) Children’s access to different areas in the environment; (2) children’s freedom to act (physically) within the accessible area; (3) children’s freedom to contribute with questions, mathematical ideas and argumentations etc.; and (4) the degree to which problem-solving interaction was promoted (that is the degree to which the children were promoted to ask questions and explain and argue for their ideas to solve mathematical problems). Key points 1-3 concern the KT’s orchestration of the mathematical activities with respect to the degree of freedom and intends the ZFM. Since the ZFM is co-constructed by the child and the adult, children’s eagerness to participate and take initiative are also used to identify ZFM. Key point 4 concerns how the KT’s promote children to ask questions, explain and argue for mathematical ideas to solve mathematical problems, which intends the ZPA. As Valsiner (1987) argues, ZFM and ZPA are related and work as a unit to canalise children’s development, and in this case, learning and development related to mathematics. In this study I identify learning possibilities whenever the KT’s and the children together solve mathematical problems through questions, explanations and argumentations.

The profiles, which will be presented below, are of course tendencies not absolute characteristics. The KT’s orchestration with respect to the degree of freedom changes dynamically during each session and from session to session. In addition, the profiles are relative, which means that the degree of freedom in one kindergarten is relative to the three other kindergartens and cannot provide an indication for how it relates to other KT’s orchestration in other contexts.

## **Profiles of four kindergarten teachers’ orchestrations**

### **Kindergarten teacher 1**

KT1 orchestrated the mathematical activities with a relatively high degree of freedom, which is based on the way that the children were allowed to move around in the room (and even walk out of the room) and to talk about almost whatever they wanted, like birthday parties or their parents’ occupation etc. The KT never told the children to sit down and pay attention, instead she promoted the children to do so by the way she enthusiastically presented the activities, which captured the children’s attention. For example, in an activity about reflection symmetry, the KT introduced the activity having diverse reflection symmetrical objects in a plastic bag without telling what was inside. She shook the bag and whispered, “Listen!”, which made the children curious and created joint attention. Another characteristic of the KT’s orchestration was that the KT listened to almost every child’s contribution (not only related to mathematics). In one of the conversations with the KT, she expressed that her desire to listen to and appreciate every child’s contribution could be a hinderance for her, because her attention became very shifty. She rapidly turned her attention from one child to another. The children eagerly participated in the activities, however, as mentioned above, they often contributed with other ideas than mathematics. The KT expressed that she had a challenging group of children but their ability to pay attention to mathematics grew during the intervention. There were a lot of ‘golden moments’ for problem-solving interaction. The KT and the children initiated a lot of

interesting ‘topics’ for investigation, but very few ideas were thoroughly discussed. Mathematical questions were often (not always) considered briefly, and the children seldom had to ponder about problems and to express mathematical ideas, argue for and explain their ideas in order to solve the problem. Because the KT gave the children a lot of freedom to talk and payed attention to almost every contribution, the conversations moved very quickly from one topic to another.

### **Kindergarten teacher 2**

KT2 gave the children a relatively high degree of freedom to talk, however she often restricted children’s talk to mathematics by ignoring some of the contributions that were about the children’s everyday experiences. The KT also restricted the children’s freedom to act (physically) to areas or with objects relevant to the mathematical activity. Although the KT for the most part focused attention to mathematics, she gave the children freedom to suggest other mathematical issues than what she initially introduced. Similar as KT1, the KT2 presented the activities in an exciting way, by use of for example excited face expressions and whispering, which captured the children’s attention and promoted the children to contribute. But sometimes she also asked questions directly to children to capture their attention. For example, when Carl was distracted by something else, she said: “Carl, do you know how many building blocks there are in the red tower?” When Carl said that he didn’t know, the KT further asked “Would you like to help me count?” This helped Carl, who often had difficulties paying attention, to focus his attention on mathematics. The conversations between the KT and the children were almost always mathematical, and sometimes the KT and the children had longer conversations about mathematical problems. The children had to argue for and explain their ideas in order to solve the problems, and the children eagerly participated with mathematical ideas and explanations. In addition, the KT seemed to focus on collaboration. For example, the KT had a conversation with the children about the meaning of collaboration, and the KT promoted the children to help each other if needed. She also promoted the children to listen to each other by for example asking the group of children: “Did you hear what Ada suggested?”.

### **Kindergarten teacher 3**

KT3 was a football trainer in his spare time, which was somehow recognisable from his orchestration of the activities. He gave the children a relatively high degree of freedom to act (physically) and focused on ‘doing’ mathematics, which for him was when the children got opportunities to use their hands, their body and various artifacts to solve mathematical tasks. In one of the conversations with the KT he expressed that ‘doing’ mathematics was for him an important feature of mathematics in kindergarten and therefore he especially liked physical outdoor activities. In addition, he was giving short ‘missions’ for the children to perform. For example, in the ‘Sorting Shoes’ activity, when the children had to figure out how many shoes there were in each category, the KT gave each child a ‘mission’ to draw equally many lines in the bottom of the diagram as there were shoes in each category. The KT expressed several times that it was important to give the children challenging but manageable tasks, so they felt they succeeded. He often encouraged the children, in an enthusiastic manner, with comments like “good” or “great” etc. It seemed that the children enjoyed the activities and the way that the KT encouraged them. The children eagerly participated and seemed to have fun. There was relatively little problem-solving interaction and the children often solved tasks without

having to explain or argue for their ideas. For example, in the activity called ‘Tripp, Trapp’, where the children should count stairs in a staircase and find out what number each stair had, the KT made A4 papers with numbers from 1-24 on and the children, one by one, had to pick an A4 sheet and place it on the correct stair. (Stair number 15 should have the A4 sheet with the number 15 on). The children just performed the tasks, without having to explain what they did, and why they did what they did. Sometimes the KT promoted the children to reflect on their solution strategies in retrospect, however the children’s explanations were seldom helping them to solve problems in the first place.

#### **Kindergarten teacher 4**

KT4 gave the children relatively little freedom to act (physically) or talk which is based on the way that she, to a large degree, controlled who was going to talk (or ‘do’ something) and when. For example, in an activity called ‘The Farm’ the children were, at one point in the activity, supposed to find how many animals there were on the farm. First the KT asked a girl, “Helene, can you figure out how many animals there are all together?”. After Helene had counted and answered the KT asked a boy, “John, can you find how many different animals there are?”. The KT continued to give similar ‘missions’ to each child. The KT made sure that each child got the opportunity to answer or ‘do’ something mathematically, and she appreciated children’s contributions by comments like ‘that’s correct’, ‘very good’ etc. The KT expressed in one of the conversations that it was important that the children learnt to respect the other children and to wait for their turn in an activity. The KT also expressed that some activities were difficult to implement as outdoor activities, because the children often got disturbed by other things. These characteristics are of course tendencies, and sometimes the activities were a lot more open where the children had a lot more freedom to act. But, as she also expressed in one of the interviews, she thought it was difficult to ‘hold back’ and give room for the children to figure out the problems themselves without too much interference. It is difficult to state how ‘eager’ the children were to participate, because they seldom answered or did something without being asked. They accepted the KT’s request to sit and wait for their turn. In some activities, like when they measured how much water there was room for in a tank, the children laughed and were having fun and showed eagerness to participate. Still they were asked to wait for their turn and respect that each child got the same opportunity to fill water. There were few incidents where the children together solved problems by expressing ideas and arguing for solutions. The children were waiting for their turn to answer or to perform ‘missions’. The KT sometimes asked the children to explain what they did when they solved a task, but this explanation did not help the children to solve the problem, but to reflect on their strategy in retrospect.

#### **Discussion**

From the results above, it seems that KT1 is very concerned about freedom, and the ZFM is relatively wide compared with the ZFM the other KTs set up, both with respect to what the children are allowed to talk about and what they are allowed to do (physically). The children are even allowed to walk out of the room if they want to, and they can talk about whatever they want. KT2 restricts the ZFM to mathematics, both what the children can physically do and what the children are allowed to talk about. However, KT2 gives the children freedom to talk about and work with other mathematical objects than what she initially promotes. KT3 restricts the mathematical talk to specific mathematical areas,

however the ZFM is relatively wide when it comes to what the children are allowed to do (physically). The KT3 gives the children freedom to move physically and to make loud voices when they solve the mathematical tasks. KT4 is the most controlling of the four KTs, and the ZFM is relatively narrow both with respect to what the children are allowed to do (physically) and what the children are allowed to talk about. KT4 decides, to a large degree, who is allowed to talk (or 'do' something), when the children are allowed to talk (or 'do' something) and what the children are allowed to talk about.

Considering the ZPA, the results illustrate how the KTs promote children to ask questions, explain and argue for their ideas in order to solve mathematical problems. The children do not need to accept the ZPA set up by the KT, but instead of turning the ZPA into ZFM the KT may, I hold, 'advertise' for the ZPA to promote the child to act in a desired manner. In K1 the KT promotes children to act mathematically by acting in an exciting way, and by introducing the activities in a manner which makes the children curious. The children sometimes accept the ZPA, but sometimes they do not. The KT1 is carefully promoting the children to think mathematically, but the ZPA (related to mathematics) is never turned into ZFM. The KT2 also promotes children to think mathematically by acting in an exciting way. The ZPA is related to specific mathematical areas, however the ZFM is related to mathematics in general. Sometimes, especially related to some children, the KT2 carefully turns the ZPA into ZFM, that is the KT limits the ZFM to specific mathematical tasks whenever the children do not pay attention. In addition, the KT explicitly promotes the children to help each other and to collaborate which, I hold, is important for the way that the children solve problems together. KT3 promotes children to think mathematically or 'do' mathematics by a quite tight ZFM related to mathematics. The ZPA is often turned into ZFM by asking the children to perform 'missions'. However, the ZFM is relatively wide related to physical actions. KT4 almost always turns the ZPA into ZFM. What the KT promotes the children to do is also what the KT allows the children to do.

Considering the characteristics of ZFM/ZPA complex in each kindergarten which according to Valsiner (1987; 1997) canalise children's actions and thinking and thus development, it seems that the KTs who limit children's actions to mathematics, but where the children's freedom is relatively wide related to what the children may talk about within mathematics and who is allowed to speak, promotes most problem-solving situations (KT2), and thus children's opportunities for learning. How the ZFM/ZPA complex canalise children's development is not only related to the boundaries of the zones itself, but *how* the ZFM and ZPA are set up. The KT2 is relatively mild in her way of setting up the ZFM, and instead of turning the ZPA into ZFM she acts in an exciting way which promotes the children to accept the ZPA. The KT2 'advertise' for the ZPA by the way she presents the mathematical problems and makes the children want to pay attention and accept the ZPA. The KT4 is not that enthusiastic, and perhaps that is why she must turn the ZPA into ZFM to make the children pay attention and to accept the ZPA. The KT1 is also enthusiastic in setting up the ZPA, but since the ZFM is relatively wide, the children often choose to act in other ways than what the KT promotes. The results support Hirsh-Pasek et al. (2009), Weisberg et al. (2015) and van Oers (2014) who emphasise that playful learning activities should have some structure as long as the activity as a whole remains a playful activity and as long as the KTs gives freedom for children's self-directed play, so they may explore the content in their own manner. The results also supports Dovigo's (2016) results in the sense that whenever the KT is structuring the environment around mathematics, but opens up

for children's own exploration around mathematical ideas, the children are canalised into more problem-solving activity and thus create possibilities for children's mathematical learning.

The results indicate that instruction which structures children's actions around mathematics but introduces the mathematics in an 'exciting' way and allows and promotes children to contribute with various mathematical ideas not necessarily related to the aimed subject area, captures children's attention and promotes their voluntarily participation in the problem-solving activity and thus facilitates children's possibilities for mathematical learning.

### Limitations of the study

This study focuses on the KT's orchestration and its consequences for children's learning possibilities and does not consider how the children, in light of for example their background, influence the KT's orchestrations and the nature of interaction in each kindergarten. Moreover, in this study the ZFM/ZPA complex is considered on a group level. It would be interesting to investigate the ZFM/ZPA related to each child in the groups, to see which children benefitted the most from the KT's different orchestrations.

# Creative processes of one primary school child working on an open-ended task

Svenja Bruhn

Bielefeld University, Germany; [svenja.bruhn@uni-bielefeld.de](mailto:svenja.bruhn@uni-bielefeld.de)

*A lot of mathematical tasks challenge primary school children to be mathematically creative. But how exactly is mathematical creativity embedded in primary school education? And: How are the mathematical creative processes of one first grader working on an open-ended task displayed? Therefore, two creativity patterns are analyzed. The first illustrates the flexibility within the free working process. The second depicts the child's ability to structure and describe her solutions during the elaboration process. Purposeful and adaptive prompts support the child in both creative processes. The results of this pilot study show, that the child develops a qualitative new structure of her solutions and, therefore, is able to expand her solution space.*

*Keywords: Mathematical creativity, primary school children, open-ended tasks.*

## Introduction

In most standards for mathematics education (e.g. MSB NRW 2008; NCTM 2003) creativity is part of the competences children from the early years onwards have to exercise and develop in their mathematical education. However, the construct of creativity is often sparsely characterized but rather all process-oriented abilities in mathematics implicate creative behavior as a fundamental competence. Already Vygotsky (1930/1998) described creativity as “one of the basic mechanisms that facilitate development of new knowledge” (Leikin & Pitta-Pantanzani, 2013, p. 162) Therefore, it is necessary to define creativity more precisely in a content-specific way to make this term more adaptable for mathematics instruction.

In this paper, I present my research project on the creative processes of primary school children in Germany. I illustrate my working definition of mathematical creativity at school based on various studies within the psychological and mathematical research sphere. Additionally, a case study of one child at the end of the first grade from the pilot study I have realized so far is presented. Therefore, my greater research question is: How are creative processes of a primary school child displayed?

## Theoretical Background

### Mathematical creativity

Creativity is nothing mystical (Sternberg & Lubart, 1999) but rather a construct that is being researched not only in psychology but also in various other disciplines like e.g. arts, language, mathematics, and pedagogy (Torrance, 1966). Logically, there is no coherent definition of creativity in general. Also in the particular field of mathematics education “the word creativity is ‘fuzzy’ and lends itself to a variety of interpretations” (Sriraman, 2005, p. 20). Thus, there is a large body of research discussing the different approaches on defining mathematical creativity (e.g. Leikin & Pitta-Pantanzani, 2013).

Kwon, Park, and Park (2006) state that, when analyzing all different approaches, there are overall only two main positions: The first one is the definition of mathematical creativity as “the creation of new knowledge” (Kwon et al., 2006, p. 52). The moment, a student finds a new, adequate, and – more important – insight-based and therefore mathematically adaptive solution to a mathematical problem, the person acts creatively (Liljedahl & Sriraman, 2006; Silver, 1997). In contrast, the second position focuses on the “flexible problem-solving abilities” (Kwon et al., 2006, p. 52) that every child is supposed to develop at school (NCTM, 2003). Children show flexible competences by finding not only one but various differing solutions to a task (also called *divergent thinking* (Guilford, 1967)). In doing so the children act creatively. Therefore, the definitions of mathematical creativity referring to the first position mainly focus on the creative product, while the ones referring to the second position analyze the individual creative processes that students show. I locate my research at the second one because my motivation is to observe, illustrate, and appreciate the creative process of primary school children in detail.

### **Creative person, product, process, and press**

When talking about creativity there are four creative domains which constitute the specific mathematical creativity: *person*, *product*, *process*, and *press* (Leikin & Pitta-Pantanzi, 2013). Every domain has an overlap to the other three so that complex connections within these aspects occur. Haylock (1987) postulates that in many research studies product and process are focused and connected. This connection results from reconstructing the creative process by analyzing the child’s creative product as well as the child’s procedure in finding the solutions. I follow Haylock’s assumption in this pilot study and focus on the creative process, while analyzing the creative product.

To think of the other two domains, the situation in which the child solves the task marks the creative press. However, I do not concentrate on details of the creative environment or person itself. In contrast to many definitions that link mathematical creativity to giftedness (e.g. Sriraman, 2005) or advanced mathematical thinking (e.g. Ervynck, 1991), I assume that every primary school child has the ability to be a creative person. It has to be considered, though, that “creativity in school mathematics differs from that of professional mathematicians” (Leikin, 2009, p. 131). Referring to Vygotsky’s “division into subjective and objective imagination” (Vygotsky, 1930/1998, p. 164), the term of *relative creativity* in contrast to *absolute creativity* in the work with children is suggested. Relativistic creativity means that the creativity level is not compared to the ability of a professional mathematician. Instead, a person’s creativity is compared within a specific peer group. That is why every student can be creative and thus shows a creative process (Liljedahl & Sriraman, 2006).

### **Characteristics of the mathematical creative process**

There are as many different approaches to characterizing the creative process as well as definitions of mathematic creativity itself. Due to the assignment of this study to the second definition position presented before, the characterization of the creative process is based on the student’s ability to think divergent. Following Guilford (1967), Torrance (1966) defines for his psychological test four categories of creativity: *fluency*, *flexibility*, *originality*, and *elaboration*. These “characterize students’ creative process” (Leikin & Pitta-Pantanzi, 2013, p. 163). Many recent studies on mathematical

creativity use these characteristics for their research, whereas the most of them only use the first three concepts, excluding elaboration, and investigating on students grade 6 and higher (e.g. Leikin, 2009).

Leikin's (2009) and Silver's (1997) concept on creativity are based on Torrance's categories but fit to mathematical tasks: Fluency means the total number of solutions and thus, focus on the quantity. In contrast, to depict the quality of a creative process, flexibility measures the number of solution strategies which are "based on different representations, properties (theorems, definitions, or auxiliary constructions), or branches of mathematics" (Leikin, 2009, p. 137). Hence, if the child finds a vast number of solution this does not automatically mean that he/she shows a high flexibility score. Originality in Leikin's understanding evaluates the relativistic singularity and novelty of an idea. Leikin showed in her study on mathematical creativity that only a few children had higher originality scores. Based on her results, she attributes originality to gifted students (Leikin, 2009). In contrast, Silver (1997) defines originality (or novelty) as the ability to explore many given solutions to a mathematical task and then generating a new, different one. The production of a novel solution refers to Leikin's concept of original ideas, because the child has to find a solution, which was not stated in the solution space before. While exploring the given solutions the child has to describe, illuminate, and generalize the solution strategies, which relates to Torrance's (1966) characterization of the category elaboration: The elaboration displays the amount of detail in the responses and shows the ability to describe, illuminate, and generalize the responses.

I aspire to illustrate the quality of the creative process of primary school children in a neutral, not judging way. In contrast, many studies aim to evaluate the mathematical creativity of children or adults (e.g. Leikin, 2009). This is why I mainly and directly focus on the aspects of flexibility and elaboration, and only indirectly on fluency and originality:

*Flexibility*, in my research, means that children find solutions by different changes of ideas. An idea either can be structurally inferred from the idea before or is newly generated. The concept of fluency is considered by the total number of the solutions.

*Elaboration* means the children's ability to describe and structure their own solutions to find additional solutions, and thus to expand their solution space. The new found solutions could be considered as original following Silver's definition, and therefore the concept of originality is implicitly included.

### **Open-ended tasks**

Hashimoto (1997) outlines that at today's schools children do not have to be creative, because most tasks prompt the students to find only one correct solution. He states that a good mathematical education needs appropriate tasks to allow children to explore and develop their creativity. There are many notations in the international references, which describe these tasks: e.g. multiple solution tasks (Leikin, 2009) or open-ended problems (Silver, 1997). It is essential that in my study the creativity fostering tasks have to allow the students to demonstrate their fluency, flexibility, originality, and elaboration abilities. Therefore, I characterize an *open-ended task* as a task that invites the children to find various solutions and has no verbalizations like "Find all solutions...". In addition, the task has no limited number of solutions and challenges every student. Most important, the tasks entail quantitative and especially qualitative differences of the solution spaces.

## Prompts

Fostering children's ability to show creative processes working on open-ended tasks, the children can be supported by instructional prompts. Prompts are "recall and/or performance aids, which vary from general questions to explicit executions instructions" (Bannert, 2009, p. 139). Based on the research results on instructional prompts, the combination of *cognitive prompts* (explanation) and *metacognitive prompts* (regulation) has a high effectiveness on supporting children's self-regulated learning (Wichmann & Leutner, 2009). Cognitive prompts "directly support a student's processing of information for example by stimulating memorizing/rehearsal, [or] elaboration" (Bannert, 2009, p. 140). This relates to the two in this study primarily focused characteristics of creativity: flexibility and elaboration. Metacognitive prompts in general tend to support children's monitoring and controlling when working on specific tasks like mathematical open-ended tasks (Bannert, 2009).

## Research questions

My research aim is to illustrate the individual creative processes of a primary school child working on open-ended tasks. Considering the theoretical background, I attempt to answer the following detailed questions in the case study:

1. How is the child's individual flexibility displayed in her solutions?
2. How does the elaboration and the prompts support the child to find additional solutions?

## Method

The intention of my first pilot study was to try out various ideas concerning the tasks, interview design, procedure and material, the interview guideline, and the instructional prompts. Below these decisions are illustrated and the results of the presented case study are discussed.

## Participants

In July 2018, I realized a first pilot study with three children at the end of first grade (age: 6;11, 7;0, and 7;9). They are primary school children of a municipal primary school in a large German town. The children were chosen because I expect first graders to be more open-minded and less affected from in school thought mathematical structures and strategies than older school children. Thereby, it is more likely to accurately reconstruct the creative processes of these children. The primary school teacher selected these three children due to their current mathematical development. In this paper, I present as a case study the creative processes of Maria (7;9 years), who shows an age-based mathematical development.

## Design, materials, and procedure

During an individual interview, the first grader worked on the following arithmetical open-ended task, because arithmetical ideas can explicit be categorized and thus, flexibility can be analyzed:

*Find different tasks with the number 4. [Finde verschiedene Aufgaben mit der Rechenzahl 4.]*

The interview was divided into two creative working phases that built on each other and used different sort of materials:

1. *Free working process*: The child found as many different solutions as he/she could and, at the same time, produced his/her own documentation of the solutions. I offered the first graders blank filling cards to write down each solution and arrange them on the table.
2. *Elaboration working process*: Afterwards I asked the children to explain their solutions and the process of generating them. Then I invited them to restructure their solutions and explain this arrangement of the written cards for me. This procedure was supposed to help the children in finding additional solutions and adding them to the arrangement.

Furthermore, I gave adaptively cognitive and metacognitive “just-in-time-prompts” (Bannert, 2009, p. 142) during the elaboration working process to support the child in his/her creative processes. The used metacognitive prompts tended the first grader to follow the open-ended task in the working processes. The explicit questions was e.g. “Can you find further solutions?”. For cognitive prompts, I used to write a new solution on a card and asked the child to explain, whether this solution match to his/her solutions, and if so, if he/she can find further solutions. Thus, children with a very systematic approach might be encouraged to admit new ideas and conversely, children who found many new ideas might be motivated through a prompt to structure their solutions in a systematic way.

### Analytical tool

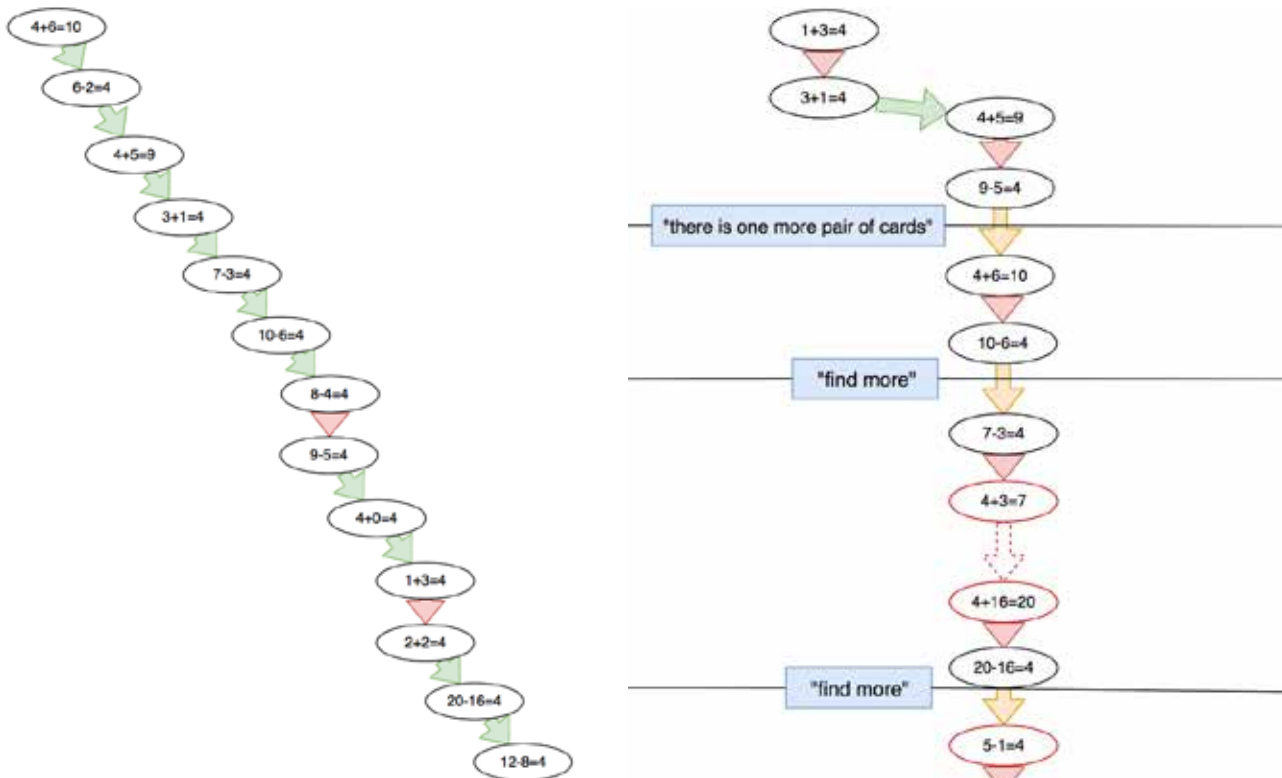

To illustrate the flexibility and elaboration in the two working processes I conducted a category-lead analysis for each child. I deductively constituted a catalogue of categories for the changes of ideas children can use in their solutions. There are three main categories of changes of ideas: *new*, *inspired*, or *structured ideas*. A new idea has no connection to the idea before (e.g.  $3 + 4 = 7$  followed by  $20 - 16 = 4$ ). A structured idea connects two consecutive ideas by a mathematical structure like the sub-category law of constancy (e.g.  $3 + 1 = 4$  followed by  $2 + 2 = 4$ ) or the complement principle (e.g.  $3 + 1 = 4$  followed by  $4 - 3 = 1$ ). An idea is inspired either if it was used in a former structure and is picked up again in another structure (e.g.  $3 + 1 = 4$  followed by  $2 + 2 = 4$  (law of constancy) and by  $4 - 3 = 1$  (complement principle)), or if a previously used structure is resumed.

Thus, I got two *individual creativity patterns (ICP's)* which I represented graphically in a sort of a sequential tree diagram. Afterwards I contrasted the two patterns to show how they differ and how the new structure extends the solution space. Due to the lack of space in this paper, I present the ICP's in a reduced schema only concentrating on the main categories – new (green), inspired (orange), and structured (red) ideas – but categorizing them in detail in the description.

### Results

Maria generated 13 solutions during her free working process on the open-ended task “*Find different tasks with the number 4*”. She wrote every solution on a single card and placed them randomly on the table. She did not look back on the inscribed cards but only on the blank cards in front of her. I was not able to see any system in the arrangement of the cards. Moreover, her ICP illustrates that she found her solutions by generating mainly new ideas. I analyzed ten new and two structured ideas. First, Maria produced six different tasks, which differed in the used operation – addition or subtraction – and in the placement of the number 4 either as the first summand or as the result. Afterwards she showed one of the two structured ideas by inferring a solution from the one before by the law of constancy:  $8 - 4 = 4$  followed by  $9 - 5 = 4$ . Maria generated the second structured idea in the same

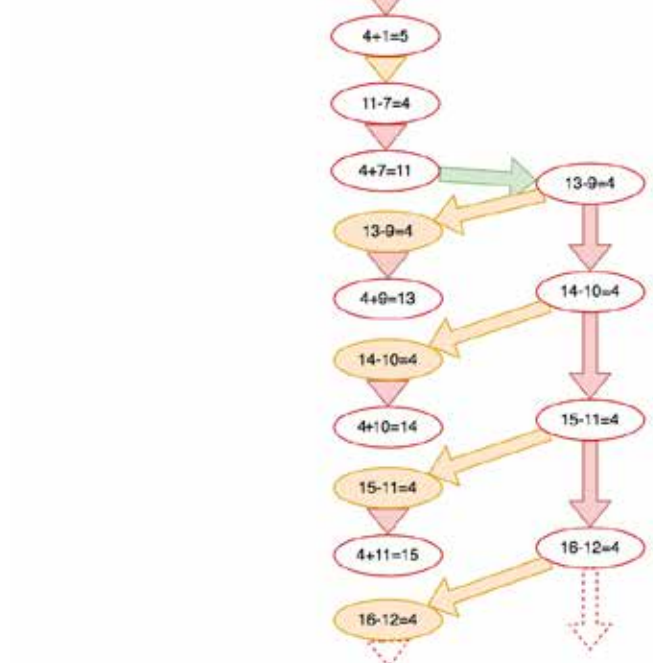

way but with the operation of addition:  $1 + 3 = 4$  followed by  $2 + 2 = 4$ . In between and after these structured ideas Maria produced constantly new ideas with the number 4 as the result of the task. The following schema illustrates Maria's complete first ICP (see figure 1):

**Figure 1: Maria's ICP of the free working process**

Figure 2 shows the schema of Maria's second ICP. The red lined tasks are the tasks, which Maria produced in addition to her free working process. The dotted arrows symbolize that she produced more solutions in the prior pattern.

Maria's second ICP, illustrating her elaboration process, differed widely from her first one. She expanded her first solution space from 13 to now 31 solutions consisting of two new, four inspired and 18 structured ideas. First, she picked up her two written cards  $1 + 3 = 4$  and  $3 + 1 = 4$ , arranged them side by side and labeled them *turn arounds* [Tauschaufgaben]. This structured idea is based on the additive commutative law. She then displayed a new structured idea – the complement principle – by connecting the two cards  $4 + 5 = 9$  and

**Figure 2: Maria's ICP of the elaboration working process**

$9 - 5 = 4$ . I gave her a metacognitive prompt by saying that there is one more pair of matching cards based on the complement principle. She found them and placed them near the first pair. Hence, Maria reconsidered the previously used structured idea and thus, showed an inspired idea connecting the task  $9 - 5 = 4$  with the tasks  $4 + 6 = 10$  and  $10 - 6 = 4$ . Subsequently, she thought for a while and after a metacognitive prompt, if she could write more solutions, she wrote the matching tasks within the complement principle to all previously found solutions. This means that Maria was able to respond to the given prompt and produce seven additional solutions by following a structured idea. After one more metacognitive prompt, if she could find further solutions, she generated in the previous used focus four new solutions, thus, two additional pairs. Finally, and without a prompt, she showed a new idea by writing the solution  $13 - 9 = 4$ . For this solution she combined two different structural ideas. Primarily, Maria interpreted her solution in the previously used structure based on the complement principle, and wrote  $4 + 9 = 13$ , and thus, showed an inspired idea. Then she focused on the law of constancy and derived  $13 - 9 = 4$  from the solution  $14 - 10 = 4$ . Maria repeated this pattern twice with the tasks  $14 - 10 = 4$  and  $16 - 12 = 4$ . Then she stopped the production but was able to explain how she could find further solutions in this way.

## Discussion and Outlook

The case study gives an insight into the potential of a high-resolution view on the first graders' creative processes when working on arithmetical open-ended problems.

Referring to the first research question the analyzed processes of the first grader Maria exhibit that there are interesting differences in the flexibility (and fluency) of the two ICP's from the two processes themselves and in the transformation. She first produced mainly new ideas and then completely changed her ICP when elaborating and expanding her own solution space. Especially her last composition, the combination of the complement principle and law of constancy, is stunning. Thus, a qualitative view at and analysis of the four characteristic of mathematical creativity seems to be necessary to define this term more precisely in a content-specific way. The second research question tended on the expanding of the child's solution space through elaboration and prompts. In the case study, Maria was able to react to the given prompts, and thus, the level of support of the metacognitive prompts themselves were high. Maria did not need any sort of cognitive prompts to expand her solution space. Thus, the following assumption can be made: The higher the ability of elaboration (and originality) of the child, the lower the need for various instructional prompts.

Following the previous presented insights of this case study from the pilot study, there have to be two implication for my future main study from March to July 2019:

First, an interview design needs to be developed in which all characteristics of mathematical creativity – still focused on flexibility and elaboration – can be analyzed in one first grader's creative process working on an arithmetical open-ended task. Looking at more such creative processes may lead to additional and complex ICP's.

Second, the prior stated assumption about the relationship between the elaboration abilities and the reaction to the instructional prompts has to be researched precisely. Furthermore, the effectiveness of the prompts itself must be considered in more detail. Therefore, all participants in my main study will be interviewed twice with two arithmetical open-ended tasks but the same instructional prompts.

[per.s.hundeland@uia.no](mailto:per.s.hundeland@uia.no)

*In this study we investigate the mathematical discourse in a kindergarten. The mathematical learning activity engaged with was initially designed by researchers for 5-year-olds, and the kindergarten teacher orchestrated the mathematical activity. Observational data was quantitatively analysed by measuring how time and talk were distributed between the kindergarten teacher and the children. We also analysed whether the talk was focused on mathematics or not. Our analysis shows that the time elapsed during the activity was distributed unequally, the nature of the participants' utterances shared both similarities and differences, while the engagement nurtured upon the kindergarten teacher's request varied from each of the requests. Based on these results we characterise the mathematical discourse and hypothesise about the children's potentials for mathematics learning.*

*Keywords: Discourse, inquiry, kindergarten, mathematics, playful learning.*

## Introduction

Researching teaching and learning of mathematics in a kindergarten setting has been gaining improved focus over the last decade. Since the establishment of the early years mathematics research group at the 6th Congress of the European Society for Research in Mathematics Education in Lyon in 2009, a multitude of research foci have been launched and 50-100 research studies have been conducted (see CERME proceedings, [www.mathematik.uni-dortmund.de/~erme](http://www.mathematik.uni-dortmund.de/~erme)). This is not to neglect journal articles published in the same period as well as before 2009. Early years mathematics has gained its place as a research field with mathematics education research also due to the four POEM conferences we have seen so far (POEM - A Mathematics Education Perspective on early Mathematics Learning). A huge portion of the conducted studies have been qualitative in nature, as case studies have been conducted, observations and interviews have been made (Levenson, Bartolini Bussi, & Erfjord, 2018). This study is an attempt to broaden the qualitative research scope and include quantitative aspects of mathematics discourse in a kindergarten context.

The aim of the analyses made in the current study is thus to quantitatively characterise the mathematical discourse evolving as a kindergarten teacher (KT) orchestrates a mathematical activity for her five-year-olds. In the analysis we seek to develop an analytical approach which quantifies the collected qualitative data. We use the term mathematical discourse in line with Sfard (2007), as a type of communication featuring mathematical words that “bring some people together while excluding some others” (p. 573). According to Sfard, a mathematical discourse has the features called visual mediators, narratives, and routines as well. However, in the current study we focus at the verbalisations made by the KTs and the participating children. The results of our analysis will be discussed in light of the framework of mathematics discourse in instruction (MDI), developed by Adler and Ronda (2015), which heavily build on Sfard's (2007, 2008) work. For the present study we have formulated the following research question:

*What characterises the mathematical discourse in a kindergarten in which a kindergarten teacher and five-years-old children engage with a planned mathematical learning activity?*

In our analysis we have particularly focused at three dimensions: (1) the distribution of time in the activity; (2) the nature of the participating persons' utterances; and (3) the engagement nurtured through the KT's initiatives, requests, and prompts. Our focus at adult-child interactions has been studied elsewhere (e.g. Carlsen, Erfjord, & Hundeland, 2010; Dovigo, 2016; Vogel & Jung, 2013). Dovigo (2016) studied argumentation as a basis for collaborative learning and problem solving in a preschool setting. Dovigo adopted a sociocultural approach in his analysis, compared teacher–children talk and peer-talk, and investigated the role of argumentation in empowering children's collaboration and problem solving through discursive practices. Results from quantitative and qualitative analyses show that argumentation is effective in cultivating shared and critical thinking amongst the children.

The mathematical activity that was orchestrated by the KT (one of many) was designed by researchers in mathematics education (the authors of this paper among others) in collaboration with the KT (among others), as part of the research and development project called “The Agder project”<sup>1</sup> (AP). This is why we use the term planned mathematical learning activity in the research question.

These planned mathematical activities were designed based on the principles of playful learning and inquiry approach to the learning of mathematics. Playful learning as a construct comprises free play (child-initiated and child-directed play) and guided play (adult-initiated and child-directed play). In AP we drew on the principle of guided play as the KTs were empowered to orchestrate and guide the children's play in the mathematical activities in purposeful directions in order to plausibly reach aims for the activities. Furthermore, The KTs functioned as catalyst for the interest, curiosity, engagement, and mathematical sense-making of the children (cf. Weisberg, Kittredge, Hirsh-Pasek, Golinkoff, & Klahr, 2015). Adopting inquiry as an approach to the learning of mathematics is in accordance with Jaworski's (2005) inquiry as “a way of being in practice” (p. 103). Inquiry as a way of being is empowering when five-year-olds and their KT interact to achieve insights in mathematics. By seeking answers to mathematical prompts and questions, the children's curiosity and excitement are nurtured and met.

## **Mathematical Discourse in Instruction**

Adler and Ronda (2015) developed the MDI framework to analyse the mathematics made available for students to learn in the classroom. The framework was developed for a South African classroom setting, deviating from a Norwegian kindergarten context. We have thus slightly adapted the framework in order for us to purposefully employ this framework in our analyses of orchestrations of mathematics activities. However, the main components are adopted in our use of the framework. But as will be seen, we have adapted the definitions of these components to also encompass a Norwegian kindergarten context.

According to Adler and Ronda (2015), it is important to focus on what mathematics students are supposed to learn, when analysing teaching. Thus, the object of learning, e.g. a concept, procedure,

---

<sup>1</sup> The Agder project is funded by the Research Council of Norway (NFR no. 237973), The Sørlandet Knowledge Foundation, The Development and Competence Fund of Aust Agder, Vest Agder County, Aust Agder County, University of Agder and University of Stavanger.

algorithm, is the starting point for the MDI framework. In our context and analysis, acknowledging and accommodating the social pedagogy tradition of Norwegian kindergartens' enterprise, we use the concept of intention to address what the children are supposed to meet and make experiences of in the mathematical activities. Further, Adler and Ronda (2015) argue that the mediational means used in teaching to reach the object of learning, are exemplification (examples and tasks), explanatory talk (naming and legitimations), and student participation. We believe learning takes place in social, communicative settings, in which children and adult(s) actively participate, engage, and argue in interaction. Hence, it is of importance to consider children's possibilities to talk in the orchestrations, their opportunities to "speak mathematically and to verbally display mathematical reasoning" (Adler & Ronda, 2015, p. 245).

The mediational means of exemplification manifests itself as examples and tasks. Examples used in mathematics teaching/orchestration serve the purpose of being a representative of a larger class, one particular case of that class from which it is possible to generalise (Zodiak & Zaslavsky, 2008). Deliberate use of examples is important to reach the intention/object of learning. Tasks are also commonplace constituents of mathematics teaching/orchestration. Tasks are given by the teacher/KT to bring to the fore certain mathematical properties, actions etc. Tasks are thus what the children are supposed to do with the examples given (Adler & Ronda, 2015).

The mediational means of explanatory talk comprise what is to be done and known, that is to name and legitimate the focus and content of the talk between the teacher/KT and the children. To address this, Adler and Ronda (2015) coin the terms naming and legitimation. Naming is "the use of words to refer to other words, symbols, images, procedures or relationships" (p. 244). Naming may be either colloquial, non-mathematical everyday language, or mathematical, either mathematical words used or reading strings of symbols (Ms) or formal mathematical language used (Ma). Legitimation comprises four domains: mathematical, non-mathematical, curriculum and teacher. Within the mathematical domain there are local (L) criteria (specific case, convention) and general criteria (partial (GP) and full (GF) that give authority. Within the non-mathematical domain there are also criteria that give authority, called visual (V), positional (P), assigning the authority to the speaker, and everyday (E) knowledge and experience. The significance of addressing all these criteria is, according to Adler and Ronda (2015), "the opportunities they open and close for learning" (p. 244).

The KT's utterances will be analysed according to the levels in the MDI framework (cf. Adler & Ronda, 2015), where level 1 is a type of mathematical discourse in which the children contribute with answers to yes/no questions or single words to the KT's unfinished utterances. Level 2 is a type of mathematical discourse in which the children contribute with answers to what/how questions in phrases/sentences. Level 3 is a type of mathematical discourse in which children contribute with answers to why questions and present ideas and where the KT revoices/confirms/asks questions (cf. Adler & Ronda, 2015).

In our discussion we adapt the MDI framework in order to analyse the KT's orchestration of mathematical activities. Thus, not all facets of the MDI framework will be used in the discussion. The reason for our adaptation is that the MDI framework is developed to analyse mathematics teaching in (South African) schools. The Norwegian kindergarten context differs significantly from that school context. As will be seen in the analysis, to approach the intention/object of learning of the mathematical activity, the KT exemplifies by the use of examples, use of tasks made explicit

through questioning, and explanatory talk. The children participate in the interaction with the KT, question and argue for their opinion(s).

## Our analytical approach

In this study we collected video data from the orchestration of a mathematics activity by one kindergarten teacher. The activity involved five five-years-old children in this kindergarten who participated in AP, selected by the KT. The studied KT and children were chosen out of convenience, based on the consideration that the only criterion for selection was that the observed KT and children had to participate in AP and voluntarily participate in this specific study.

In order to analyse the mathematical discourse emerging from the KT's orchestration of a mathematical activity, we developed an analytical tool that fitted our purpose of quantifying qualitative data. Quantification of qualitative video data has also been studied by Vogel and Jung (2013), however from a slightly different perspective. The first step of our analytical process was that we agreed upon making 'quantification of qualitative' data the main focus of our analysis. With this idea in mind, the second step of our analysis continued as two of the researchers met and discussed ways of making this quantification. These two researchers agreed that use of time was a critical element in the orchestration, who had the floor? Were any questions asked, and by whom? Were the questions mathematical ones or not? What other comments were made, and by whom? Were these comments mathematical or not? etc.

The result of that meeting was submitted to the third researcher, who had not been taking part in the discussions so far, comprising a third step in our analysis. This researcher critically scrutinised the preliminary analytical tool, asked critical questions and made modifications to the tool.

All three researchers met for the fourth step of our analysis as we refined the analytical approach, agreed upon the various dimensions necessary to scrutinise in order to analyse the mathematical discourse in the kindergarten, as well as pinpointed sub-categories within the three dimensions. The idea behind our analytical approach is to steadily funnel down to the core of our analysis. The distribution of time is seen as a first attempt to separate the various elements of the activity. Secondly, we discriminate between what we call verbal mathematical contributions and non-mathematical or colloquial contributions. Thirdly, we have chosen to make a deeper analysis of those verbal contributions in which mathematics is focus, what Sfard (2008) would label a mathematical discourse. Our analytical approach is summarised in the following table (Table 1):

<b>Distribution of time between the KT and the children</b>		
<b>Who</b>	<b>Number of minutes</b>	<b>Description of category</b>
KT active		Informing, Demonstrating, Explaining, Exemplifying
Dialogic communication		Questions and prompts from KT and answers from children
Children active (KT interference tolerated)		The children work with concrete materials, explore mathematical relationships «on their own»
<b>Verbal utterances</b>		
<b>Who</b>	<b>Mathematical (#)</b>	<b>Non-mathematical (#)</b>
KT		
Children		

<b>Mathematical engagement nurtured</b>					
<b>Initiatives from KT</b>	<b>Child 1</b>	<b>Child 2</b>	<b>Child 3</b>	<b>Child 4</b>	<b>Child 5</b>
1					
2					
...					
N					

**Table 1: The analytical approach to quantification of qualitative data**

## **Analysis of the mathematical discourse associated with ‘The secret bag’**

The mathematical activity called ‘The secret bag’ was orchestrated by the KT Tone (pseudonym). The activity addresses geometrical shapes of both two and three dimensions and an in-transparent fabric bag. The KT and the children talked about and discussed the various geometrical shapes, and they talked about the connections between two-dimensional shapes and three-dimensional shapes, as some two-dimensional shapes may be turned into three-dimensional ones and vice versa. Continuing from this, the KT put all the shapes in the in-transparent bag, and let one child at a time, hold his/her hand into the bag, pick one of them and tactilely reason what shape the picked one has. As seen in Table 2, the KT holds the floor for approximately 1/3 of the total time used, the children are active discussing more or less on their own for about 15 % of the time. About 50 % of the time was used for dialogic communication between the KT and the children.

<b>Category</b>	<b>Distribution of time</b>
KT active	00:07:16
Dialogic communication	00:10:54
Children active (KT interference tolerated)	00:04:11

**Table 2: Distribution of time between the KT and the children**

Concerning the verbal communication going on in the activity, we found that the KT made 125 mathematical utterances and 99 non-mathematical utterances. The children contributed with 103 mathematical utterances and 86 non-mathematical utterances. An utterance is here viewed as an instance of speech. However, the non-mathematical utterances enable the mathematical utterances to emerge. Thus, all utterances contribute to the ongoing mathematical discourse (cf. Sfard, 2007, 2008).

<b>Verbal utterances</b>			
<b>Who</b>	<b>Mathematical (#)</b>	<b>Non-mathematical (#)</b>	<b>Sum</b>
KT	125	99	224
Children	103	86	189

**Table 3: Categorisation of utterances**

In this study we are occupied with the KT’s utterances that we characterise as mathematical and the verbal engagement nurtured amongst the 5 children involved. Upon the KT’s verbal utterances, we counted the number of contributions of the various children, see Table 4.

	<b>Erik</b>	<b>Ivar</b>	<b>Ida</b>	<b>Mari</b>	<b>Nina</b>	<b>&gt;1</b>	<b>Sum</b>
Number	62	29	23	24	22	29	189

**Table 4: Number of verbal contributions distributed over the children**

We further registered the number of children responding to the KT's questions and prompts, thus we see this number as a measure of the mathematical engagement nurtured, see Table 5. Three questions from the KT were not responded to at all, and none of questions/prompts engaged all five children. At 46 occasions it was only one child responding to the KT's question/prompt. However, each child might contribute with several responses to the initial question/prompt. Thus, the total number of responses in Table 5 (120 responses) is less than the 189 verbal contributions mentioned above.

# of children engaged	0	1	2	3	4	5	Sum
Frequency	3	46	23	4	4	0	77
# of children responding in total	0	46	46	12	16	0	120

**Table 5: Children responding to the KT's questions/prompts**

Adopting an inquiry approach to the orchestration of mathematical activities in kindergarten, will plausibly create mathematical engagement amongst the children. We thus further scrutinised each of the 77 contributions of the KT that engaged the children mathematically, and we analysed the mathematical discourse that these contributions initiated according to the levels of discourse in the MDI framework (cf. Adler and Ronda, 2015). From this analysis we found that 49 mathematical discourses were at level 1, 24 of the discourses were at level 2 and four discourses were at level 3, see the right-hand column of Table 6.

# of children engaged	1	2	3	4	Sum
# of mathematical discourses at Level 1	31	14	2	2	49
# of mathematical discourses at Level 2	14	8	0	2	24
# of mathematical discourses at Level 3	1	1	2	0	4
<b>Total</b>	46	23	4	4	77

**Table 6: Number of children involved versus the levels of mathematical discourse**

Amongst the 49 mathematical discourses at level 1, 31 engaged only one child, 14 of those 49 discourses at level 1 engaged two children, 2 discourses engaged 3 children and 2 discourses engaged four children. From Table 6 we also observe that approximately 64 % of the mathematical discourses were at level 1, and 36 % were at level 2 & 3. We also observe that rarely more than 2 children were engaged by the KT's questions and prompts, 69 (46 + 23) out of the 77 mathematical discourses, and in those occasions 45 were at level 1 and 22 at level 2 and only two discourses were at level 3.

Examples of the KT's questions and prompts that we analysed as initiating a mathematical discourse at level 1 were: "Are all the edges (of the rectangle) of equal length?" and "Is it (the rectangle) two dimensional?" Examples of the KT's questions and prompts that we analysed as initiating a mathematical discourse at level 2 were: "What is this (a sphere)?" and "What is your thinking with respect to that one (a cone)?" Examples of the KT's questions and prompts that we analysed as initiating a mathematical discourse at level 3 were: "Why is that a rectangle?" and "Why does this quadrilateral (a square) have another name?"

## Discussion

We have addressed the question: What characterises the mathematical discourse in a kindergarten in which a kindergarten teacher and five-years-old children engage with a planned mathematical activity? *Firstly*, the mathematical discourse analysed is dominated by the KT. She holds the floor

on individual basis for about 1/3 of the elapsed time for the whole activity. She is also dominating the dialogic communication going on, a category comprising approximately 50 % of the elapsed time. This result is also documented by Dovigo (2016). *Secondly*, we observe that the distribution of verbal utterances amongst the KT and the children is fairly equal, both regarding utterances categorised as mathematical and utterances categorised as non-mathematical. However, we also observe that the children do not contribute equally to the mathematical discourse. Erik is dominating and the other four children are contributing approximately at the same level. *Thirdly*, the mathematical discourse is characterised by engaging only one or two children. Additionally, 64 % of the mathematical discourses were at level 1 and 36 % at level 2 and 3 according to Adler and Ronda (2015).

The sparsity of occasions where three or four children were engaged, and at the same time engaged in a mathematical discourse at level 2 and 3, we hypothesise has consequences for the mathematical learning potential in this orchestrated mathematical activity. According to Sfard (2007), “Learning mathematics may now be defined as individualizing mathematical discourse, that is, as the process of becoming able to have mathematical communication not only with others, but also with oneself” (p. 573). We thus hypothesise that the children in this activity have limited opportunities to individualise the mathematical discourse occurring.

We took the KT’s questions and prompts as point of departure in our analysis, and scrutinised the mathematical discourse associated with these various questions and prompts. The mathematical discourse was then analysed according to the levels of Adler and Ronda (2015) regarding children’s participation. From this analysis, we came to the result communicated in Table 6 above. Our initial hypothesis was that it seems reasonable to argue that the levels of children participation comprise an increasing opportunity for learning. Thus, the potential of learning associated with a level 3 mathematical discourse is more promising than mathematical discourses at level 2 and level 1 respectively. Our analysis shows that most of the mathematical discourse was at level 1 (64 %). From the analysis we argue that the KT often initiated a mathematical discourse at level 1 through asking a yes/no question. However, these mathematical discourses evolved into mathematical discourses at level 2 and level 3 in several occasions. Thus, mathematical discourses that from the outset may seem to have a limited learning potential evidently may improve into mathematical discourses at levels comprising a higher mathematical learning potential.

We also find that the KT adopts an inquiry approach to mathematics teaching and learning (cf. Jaworski, 2005), due to her mathematical questions and prompts. However, how to engage the children in mathematical inquiries is a different matter. An implication from our study is thus how to empower the children’s inquiry by discussing more between themselves. More research regarding what characterises mathematical activities that empower children’s own inquiry into mathematics is needed.

# Paper plate patterns: teachers developing patterning in pre-school

Sue Gifford<sup>1</sup> and Helen Thouless<sup>2</sup>

<sup>1</sup>University of Roehampton, United Kingdom; [S.Gifford@roehampton.ac.uk](mailto:S.Gifford@roehampton.ac.uk)

<sup>2</sup>UCL-Institute of Education, United Kingdom; [h.thouless@ucl.ac.uk](mailto:h.thouless@ucl.ac.uk)

*Keywords: Early childhood education, cooperative learning, mathematical activities.*

## Introduction

Young children's patterning, defined as "finding a predictable sequence", has been identified as significant for later mathematical achievement, with promising intervention research (Rittle-Johnson, Fyfe, Hofer & Farran, 2017, p. 3). Two years ago we began a collaborative project with English teachers of three to five year olds, drawing on the work of Papic, Mulligan and Mitchelmore (2011) and Mulligan and Mitchelmore (2016). Our research question is: How do teachers develop young children's pattern awareness? We analyse our findings as learning in a 'community of practice' (Wenger, 1998), focusing on a teacher innovation of paper plate patterns.

## Methodology

Wenger (1998) identifies a community of practice as a group whose members have a joint enterprise, are mutually engaged in an activity and have a shared repertoire of customs of practice. Accordingly, learning is defined as a change in participation in the community of practice. Bannister (2018) identifies benefits of teacher communities of practice as providing better outcomes for teachers in terms of opportunities to learn and improved working conditions. Our group was formed of 12 experienced nursery and reception teachers who volunteered to trial teaching patterning, working in six socially diverse state-funded schools in London, UK. We offered number and pattern assessment activities, and a core teaching sequence, which we encouraged teachers to adapt for their children and settings. In total we held 14 after-school meetings, where we introduced the next month's topic and teachers shared how they had been teaching pattern, with photos and accounts. We visited three times to assess focus children with teachers and three times to conduct informal interviews about teachers' work, discuss records of children's progress and once to observe teaching and learning. The data reported here derive mainly from three sources: field notes from teachers' reports at project meetings and informal interviews, our observations of teaching and learning and semi-structured group exit interviews. We analysed notes and transcriptions to identify common themes in relation to our focus on learning in a community of practice.

## Findings

As a community of practice, the teachers developed convergent pedagogical approaches, such as integrating patterning into whole class routines and encouraging children's independent 'co-working', including challenging each other to continue patterns or spot errors. In Bannister's (2018) terms, teachers reported benefits for themselves in increased subject knowledge of patterning progression and in improved working conditions through peer support for 'marginalised' early years teachers in primary schools. One example of learning was a teacher's innovation of circular repeating patterns as an interim stage before Papic et al.'s (2011) border patterns. The latter present the

challenges of making a continuous pattern, turning corners (by rotating the frame or carrying the pattern mentally through a rotation) and fitting the unit of repeat into a fixed number of squares. During the second year, Sam reported that paper plates enabled children to make continuous patterns by adjusting the size of the unit to fit, which allowed discussions about whether a pattern ‘worked’. The other teachers took up this idea in their practice and in subsequent meetings Tess and Pam agreed that their children found it easier to make a pattern around a circular border than a square one since this avoided turning a corner. Several teachers noted disadvantages in using plates and made adaptations: for example, Pam said, “Dave wanted to put another circle inside the first one, maybe because he thought that he had to fill in the plate. He wanted to match the inside and outside circle but didn’t realise that the numbers couldn’t match. So I coloured the inside of the circle so that the children didn’t feel like they had to fill in the middle.” Two other teachers developed a further interim stage of making a border around the outside of rectangular shapes, which involved turning corners, without a fixed number of squares. We observed two children fitting pom-poms around a rectangular border by changing the pattern unit from “white, white, white, yellow, yellow, blue” to what they jointly described as “white, white, white, 3 whites” and “yellow, blue and start over and over”. The refinements made by the teachers seem to enable these children to analyse and identify the unit of repeat in a continuous pattern.

## Conclusion

The teachers’ learning in this community of practice was evident in changes in their participation as they took up the research and applied it to their teaching, developing new activities based on children’s responses and mutually engaging in sharing and refining each other’s ideas. The strength of this community of practice lay in participants’ willingness to share and develop their pedagogy, which resulted in the teachers creating significant interim stages in the trajectory of developing pattern awareness.

## Acknowledgement

We are grateful for the contribution of the teachers and children in our participating schools.

# Investigating mediation strategies used by early years mathematics teachers in Malawi

Fraser Gobede

University of Malawi, Malawi; [fgobede@cc.ac.mw](mailto:fgobede@cc.ac.mw)

*Keywords: Early years mathematics, mediation, Malawi*

## Introduction

Teaching mathematics to children in their early years of primary schooling is a very challenging undertaking. Teachers usually find it difficult to design tasks that can keep young minds engaged and motivated throughout the lesson. In Malawi, the task is even more difficult considering that 60% of learners do not have the opportunity of attending some form of pre-school education; hence most children are formally introduced to concept of number in grade 1 at the age of six, or more (Robertson, Cassity, & Kunkwenzu, 2017). If number sense is not properly introduced to learners, the result might be a wide gulf between school mathematics and their everyday experiences of actual mathematics, making them disengage their minds in the subject despite efforts of the teacher (Boaler, 2016). For children in Malawi, the problem of lack of understanding Mathematics is often observed from the perpetual low scores attained by learners during standardised national examinations and international assessments in mathematics and numeracy. As such, this study seeks to understand ways in which early years mathematics is taught in Malawi and assess the opportunities of learning offered through their approaches. The study will seek to answer the question: How do Malawian teachers mediate mathematics during lessons in the early years of primary school? The main question will be answered through the following subsidiary questions: How do teachers in early years work with tasks and examples during lessons? How do mathematics teachers use artifacts during early years of primary school? In what ways do teachers use inscriptions to represent mathematical processes in early years? What talk/gestures do teachers use to generate solutions to problems, make mathematical connection, and advance learning connections?

## Theoretical Framework

This study is guided by the Mediating Primary Mathematics (MPM) framework developed by Venkat and Askew (2018). The framework focuses on the nature of the mathematics that is made available to learn and enables a detailed exploration of the quality of primary mathematics instruction. The MPM framework applies variation theory to understand teachers' use of example spaces during instruction (Kullberg, Kempe, & Marton, 2017). It is grounded on Vygotskian concept of mediation as the major requirement for learning and adopts sociocultural theory to understand the teacher's role as the sole mediating agent in the classroom, determine the goals in mathematical instruction, and determine sociocultural materials and practices for mediation. The framework identifies four overarching means of mediation (called strands), which are: Tasks/examples, artifacts, inscriptions, and talk/gesture.

## Research Design and Methodology

The research will adopt a qualitative exploratory case study design. One rural primary school in a remote village will be purposively selected as a paradigmatic case of exemplary performance during standardised national examinations, despite having limited teaching and learning resources. Lessons will be observed from four outstanding mathematics teachers (one in each of the first four early years classes), identified by the school authorities. The classroom observations will be followed by video-stimulated recall interviews (VSRI) with each teacher to elicit their thinking behind the choices made during the lesson. Document analysis will also be done on learners' notebooks, textbooks, mathematics syllabi, teachers' guides, lesson plans, schemes and records of work. Recorded videos of lessons will be analysed using MPM's tool for lesson analysis (Venkat & Askew, 2018).

## Pilot Findings

The study was piloted with a grade 2 teacher at another well performing rural primary school. The findings from the pilot study indicated substantial use of artifacts to explain new concepts during lessons. Single-use artifacts were mainly developed by the teacher while multiple-use artifacts, such as counters, were brought by children in collaboration with their parents. Chalkboard inscriptions were also used to reify the artifacts when representing concepts during lessons. Highest levels of abstraction were achieved with talk and gesture that corresponded with the tangible artifacts and the written inscriptions. This shows that highest opportunities for learning are afforded when artifacts, inscriptions, talk and gestures are used concurrently to represent a single concept.

## Acknowledgment

This study will be carried out with support from Norwegian Programme for Capacity Development in Higher Education and Research for Development (NORHED) programme through the *Strengthening Numeracy in Early Years through Capacity Development of Teachers* project based at the University of Malawi in collaboration with the University of Stavanger.

# Developing mathematical literacy in an inquiry-based setting working with play-coins in a second-grade classroom

Benedikte Grimeland and Svein Arne Sikko

Norwegian University of Science and Technology (NTNU), Norway;

[benedikte.grimeland@ntnu.no](mailto:benedikte.grimeland@ntnu.no) , [svein.a.sikko@ntnu.no](mailto:svein.a.sikko@ntnu.no)

*In this paper we discuss how focusing on inquiry-based learning may contribute to the development of mathematical literacy in the early grades. We analyze a grade 2 lesson with play-coins with a particular view on what it means for students to have a critical orientation.*

*Keywords: Mathematical literacy, Numeracy, Elementary school mathematics, Number concepts, Inquiry-based learning*

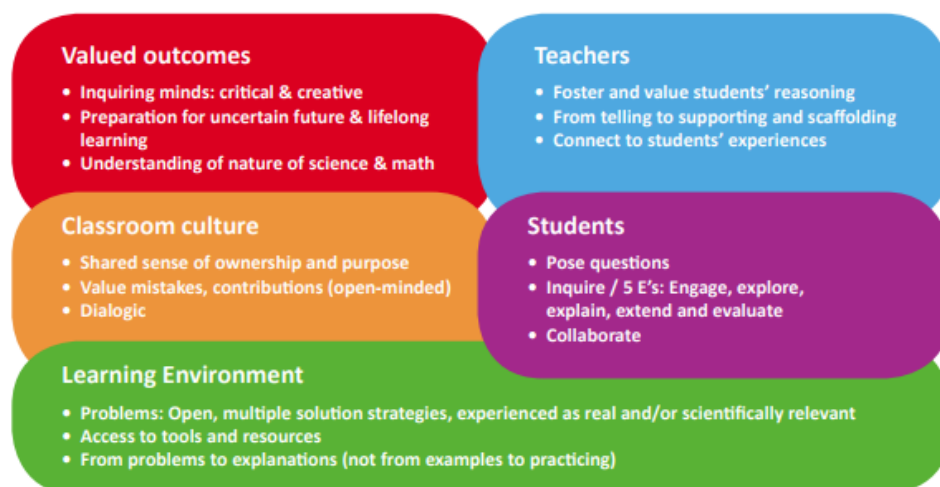

## Introduction

The work reported in this paper is part of a longitudinal study on mathematical and scientific literacy and inquiry-based learning in two Norwegian primary schools. The project group consisted of university didacticians from both the mathematics and the science sections of the teacher education department working together with teachers at the two schools. At the start of the project, the students were in grade 1. The data analyzed in this paper was collected when the students were at the start of second grade, at ages 6- and 7-years old. Using data from an IBL-inspired lesson with students at their start of second grade, we explore affordances for students' critical meeting with mathematics in a 'realistic' context. While a lot has been said and written about literacy in general and also the particular topic of mathematical literacy, what mathematical literacy constitutes in the earlier grades has been less discussed (e.g., Askew, 2015, p. 708). In this paper our research question is: Which opportunities do students have to be critical in mathematics in a second-grade classroom, and how can an IBL approach foster this?

## Literature review

The use of more inquiry-based learning has been launched as a way to make mathematics and science more relevant to students, preparing them for an uncertain future where the ability to ask questions, to reason, explore, explain and develop a creative and critical mind is seen as essential (e.g., Maaß & Artigue, 2013). Also for early years mathematics inquiry-based activities has been launched as beneficial to develop critical and creative thinking (e.g. Skoumpourdi, 2017). Through working inquiry-based, teachers will expand their teaching repertoire and will also be better able to meet different types of students, including students who struggle with mathematics. Inquiry-based learning has been shown to be effective in rich and real-life contexts and may have a positive effect on students who otherwise perform poorly (Kogan & Laursen, 2013). Through context-based approaches, students gain insight into meaningful use of mathematics and this results in improving students' motivation and attitudes towards learning, which in turn affects academic achievement (Bruder & Prescott, 2013). In this way, IBL appears as a framework that is productive in terms of building mathematical literacy. There is no universally agreed upon definition of inquiry-based learning. Core elements of IBL include developing a questioning mind and a scientific attitude. In the EU funded

Primas project (Maaß & Reitz-Koncebovski, 2013), aspects related to students, teachers, classroom culture, valued outcomes and learning environment were identified and summarized, see Figure 1.

**Figure 1. The multifaceted understanding of IBL (Maaß & Reitz-Koncebovski, 2013, p. 8)**

Whereas mathematical literacy has been propagated by policy makers and educational authorities, the term is not well defined within the scientific literature. Terms like numeracy and quantitative literacy have been used, more or less synonymously with mathematical literacy, without any determinate definition of what the term entails (Geiger, Goos, & Forgasz, 2015). Niss and Jablonka (2014) pointed out that researchers from non-English speaking countries may have reservations towards the use of the term based on the fact that it is not easily translated and lack counterparts in many languages, including German and the Scandinavian languages. For the PISA assessments, OECD made a working definition that has been slightly amended through the years. In its latest version it reads

Mathematical literacy is an individual's capacity to formulate, employ and interpret mathematics in a variety of contexts. It includes reasoning mathematically and using mathematical concepts, procedures, facts and tools to describe, explain and predict phenomena. It assists individuals to recognize the role that mathematics plays in the world and to make the well-founded judgements and decisions needed by constructive, engaged and reflective citizens. (OECD, 2017, p. 4)

An aspect that is downplayed by this definition is the critical aspect. Some authors see the development of a critical disposition as a primary aspect of mathematical literacy. In the model developed by Goos, Geiger and Dole (2014) a critical orientation is seen as an overarching element. D'Ambrosio (2003) used the term matheracy along with literacy and technoracy as essential for the "providing, in a critical way, the communication, analytical, and technological instruments necessary for life in the twenty-first century" (p. 237). Matheracy is not about counting or measurements, but about thinking and philosophy, about the ability to derive, suggest hypotheses and draw conclusions from data. Literacy, according to D'Ambrosio, is the ability to process information, such as the use of spoken and written languages, of characters and gestures, of codes and numbers. Ole Skovsmose (1998) introduced the term mathemacy as a parallel to the way Paulo Freire has used literacy, namely by linking it to being able to function in society, and thus not only to number sense or basic skills in arithmetic (p. 199). To Skovsmose, mathemacy is about the competence to be able to function in

society structured by mathematics. Against this we can ask to what extent mathematics education educates students to become critical citizens who can challenge the authorities. Askew (2015, p. 708) argued that being critical can be addressed in at least three ways: 1) being critical within a particular mathematical model; 2) being critical of the choice between mathematical models; and 3) being critical of what is modelled mathematically. Askew emphasized that these three forms of being critical are not to be seen as separate to each other or mutually exclusive, but rather “co-construct each other” (p. 709). Being critical within a particular mathematical model is the approach in most papers about young students, this is about reflecting on the chosen methods/approaches used by the students towards finding the required answers or results. It is less clear what being critical to the choice of mathematical model or being critical to what is being modelled may constitute in the lower grades. Does being critical presuppose mathematical knowledge to a certain degree? And which comes first, Askew asked, the mathematical knowledge that enables you to be critical, or the critical orientation towards practice? The problems posed in mathematics classes has a long tradition of being ‘made up’ to look like real problems, and posed to be solved by the algorithms of mathematics. On the other hand, “real-life problem solving is pragmatic and seeks effective solutions to particular problems, rather than the generality and abstraction sought in formal mathematics” (Askew, 2015, p. 709). There are, however, no quick fixes according to Geiger et al. (2015): “The question of how to best promote numeracy capabilities remains an open question. (...) there appears to be little research that outlines the characteristics of effective numeracy tasks or how these tasks promote student learning” (p. 544).

## Methodology

The data was collected as part of a seven-year longitudinal study where four groups/classes in two different primary schools and their teachers partake in lesson study cycles focusing on inquiry-based approaches to mathematics and science. Each group of children with their teachers partake in two lesson study cycles each year, in science or mathematics, starting with the children’s first year in school and until they leave primary school after 7th grade. At the time of the lessons reported on here the students were at start of their second year at school. Skoumpourdi (2017) pointed out that “it is not easy for teachers to design inquiry-based activities and implement them in the classroom” (p. 1906). To implement new pedagogical and didactical ideas, it is beneficial for teachers to work collaboratively and with support from outside ‘experts’. Lesson studies in the form of planning lessons together and observing each other’s teaching in cyclic processes of design and redesign is a particular efficient way of professional development (e.g., Yang & Ricks, 2013). In our project, each lesson study cycle is initiated by the in-service teachers choosing a topic or teaching goal, building on the national curriculum, in either mathematics or science. The research group and the teachers meet to develop a detailed lesson plan for the teaching. The planning meeting is audio-recorded. One of the in service-teachers then conducts the lesson, which is video-taped, while the other teachers and researchers observe the lesson, using observation sheets that have been developed as part of the planning sessions. In addition, the teacher wears an audio-recorder, and additional audio-recorders are placed among selected groups of students. After the lesson the researchers and the in-service teachers meet to reflect on the lesson and redesign it. A (possibly different) teacher conducts a new lesson with the new redesigned lesson plan in another group/class. A new reflection and redesign

meeting is held after this second run-through. This is also audio-recorded. In addition, annual interviews are conducted. Students are interviewed in groups of 3-4, while teachers are interviewed individually and respond to questionnaires. For this paper the data analyzed comes from two lessons in the lesson study cycle. The first group of students comprised 16 students and the second 14 students. The same teacher, who is one of the two regular teachers sharing these two groups, conducted both lessons. The underlying mathematical goal concerned addition with natural numbers up to twenty. The mathematics was introduced in a context that involved Norwegian coins (values 1, 5, and 10 kroner), bringing the 'real' world into play. We use the word 'play' here deliberately to emphasize that the real world for children is as much a world of playing games and not only the real adult world. At the same time, using coins relates to the adult world and prepares students for meetings with, and they may already relate to, money in the real world. Thus, the tasks were partly presented as small 'mysteries' where the students were supposed to find solutions, as if solutions to real problems and not pure mathematical tasks. A particular aim in the design of the tasks was to focus on the different types of number of solutions a mathematical problem may have: one unique solution, several or infinitely many solutions, or no solution at all. For the students, working collaboratively, in pairs, was an explicit goal for the lesson. Students had access to number lines, play coins similar to Norwegian 1, 5 and 10 kroner coins, and A3-size sheets of paper, pencils and crayons. Each lesson was divided in three parts: 1) plenary gathering around the smartboard, where the topic was introduced; 2) students working in pairs with up to five different tasks. The tasks were printed on laminated A5-size paper sheets and handed to the students as they asked for it. 3) plenary session where students were asked to present their findings. Data sources used for the analysis in this paper are the audio- and video-recordings and transcripts of the lessons, observation sheets filled in by the authors during the lessons, and copies of the A3 sheets filled in by the students. The multiple data sources enhances the construct validity (Yin, 2018, p. 43). Data analysis started by the two of us watching the video recordings together. Whenever anything in the video was unclear, the audio recordings were consulted, and sometimes also copies of the student work sheets. Together with the lesson plan and the observation sheets this gave us an overview of the lessons. Subsequently, the transcripts were analyzed by each of the authors with respect to two lines of inquiry: 1) are any of the aspects of IBL as identified by Maaß and Reitz-Koncebowski (2013) apparent? and 2) are any of the three ways of being critical as identified by Askew (2015) apparent? We then sat together to exchange scripts and discuss our findings to enhance inter-rater reliability. Part of this also included consulting the video- or audio recordings or the students work sheets whenever anything needed to be clarified.

## Findings

All together there were six available tasks for students to work on, labelled 1a, 1b, 1c, 2a, 2b, 2c. All students were able to work with at least the two first ones, and some students were able to finish all tasks. We arrange our findings according to the tasks, with an analysis of student answers to the first four tasks. The students started out on task 1a), that had a unique solution, namely: *Jens has four coins in his pocket. The value of the coins are 17 kroner. Which coins is it?* In the conversation below we see an example where the students have already solved the mathematical problem by representing the answer with play-coins but without writing or drawing. The teacher asks them to write and draw the answer, and the calculation. They found a short plenary talk where the teacher reminded the class

that they should collaborate and use the available resources when needed, as something that disturbed them:

- 24 Student 2: We are already finished with these coins. We managed to find out before you began with your talking-thing
- 30 Teacher: But, you, can't you say how you were thinking, and write it? Draw coins, write the addition? Write the answer!

In this interaction with the teacher the students have a solution, and rather than giving the students an opportunity to explain their thinking with the play coins, they are encouraged to make a written record on paper. The teacher does ask them to draw the coins, while in the video it is clear that the students have used the play-coins to solve the problem. We see here that there is some discrepancy between the students' and the teacher's ideas about how to solve the problem. This can be interpreted as the students being critical within the mathematical model, the first of Askew's (2015) three ways of being critical.

*Task 1b): Jens has 17 kroner in his pocket. Which coins can that be?* This task has several solutions, however only a finite number using Norwegian coins.

- 66 Student 1: OK. 17 kroner. OK. One ten, one five, plus two. Like that. You can write it.

Student 2 asks whether to write the same answer as in 1a), but Student 1 says

- 70 Student 1: No, no, no. You do different ways.

The students explore different ways to make a sum of 17 kroner from the Norwegian coins, realizing that there are lots of solutions.

- 104 Student 2: Maybe we can fill the whole sheet only with b).

This type of task, with several solutions, is not very common in Norwegian text-books and classrooms. In their conversation, Student 1 sees only one possible solution, however Student 2 points out that there are in fact many solutions, and they continue to explore this together.

*Task 1c): There are 4 coins in the bag. Which coins can it be and how many kroner?* This task poses the same challenges as the previous one, as there are several solutions, though only a finite number using Norwegian coins. Many of the students did not realize that the coins did not need to hold the same value in this task. Several were happy with the solution  $1+1+1+1$ , and needed prompting from the teacher to realize that there were other possible solutions. Two of the students found several possibilities and started discussing whether there are more than already discovered. Further in the discussion a question arises:

- 416 Student 2: Is it allowed with minus? Because there are no more numbers.

This can be interpreted as the student questioning the choice of model in this setting, which is the second way of being critical according to Askew (2015). It is not within the model or given context natural to consider that you add some of the coins in the pocket and subtract any. These students are in the early stages of learning addition and subtraction and so it is natural to also question which mathematical operation that is valid in a given situation. And indeed, considered as a purely mathematical problem, subtraction is also part of the additive context.

*Task 2a): Kari has 5 coins in her pocket, in total 20 kroner. Which coins does Kari have in her pocket?* This task does not have any solutions using Norwegian coins. The students' first reaction was

468 Student 1: OK, that is easy. No, what?

The two students discussed it, trying out possible solutions.

511 Student 1: We need one ... It doesn't work

513 Student 2: Yes, but it has to work, Hm ...

515 Student 1: This also does not work. Definitely not this. Kari has five in her pocket ...

527 Student 1: It would have worked if there was a 2-coin.

529 Student 2: OK. Oi, oi, oi. This is totally ... Hm ... Five ..

537 Teacher: What are you doing?

539 Student 2: We are working with this one, with 5 coins, it is not possible to divide in twenty or something. Ones, too few. All of them, too little. And fivers, too much, and tens, too much.

567 Student 2: Four. If we need, then,... If it was supposed to be 19, then we would have found the answer immediately. There should have existed 2-coins.

Not all mathematical tasks have a solution, and quite a few mathematical tasks do not have a solutions within the number set you are working with; e.g.  $3 - 5$  does not have a solution in the natural numbers,  $3 : 5$  does not have a solution in the integers, a set of linear equations represented by non-identical parallel lines does not have a solution; etc. In this case this fact is discovered by the students, when they realize that if you had a coin with value 2 kroner then the problem could be solved. Two other students, Student 3 and Student 4, also working with 2a), turned critical to the idea of having this type of tasks. Their relationship with the teacher is one of confidence and trust, allowing expression of honest opinions of frustration without being interpreted as rude or angry.

445 Student 3: So this is a nonsense task?

447 Teacher: Or an impossible task?

449 Student 3: Did you make this so that we should not be able to solve it, just sit there struggling and struggling?

These students questions the teachers motivation for choosing a task that does not have a solution. This can be seen as the students being critical to what is being modelled mathematically, the third way of being critical as identified by Askew (2015).

## Discussion

The multi-faceted understanding of IBL consisting of five related areas displayed in Figure 1 was used as a guiding map during the planning of the lesson, and the analysis shows that several characteristic aspects of IBL could be discerned in the lessons. The learning environment was characterized by problems that afforded diverse possible solution strategies, and apart from task 1a) they all had a number of possible solutions. Furthermore, the problems could be experienced as real for the students, and there was access to tools such as play-coins, number lines, paper and pencils. Explanation of solutions were encouraged, as made clear by the teacher both at the start of the lesson and during the students' problem solving. The realistic restrictions to the coin-problems by using only

Norwegian coins afforded the students opportunities to discover firstly that not all problems are solvable with these restrictions, secondly that if there were other coins such as a coin with value 2 kroner the problem could be solved, and thirdly, in the real world there is actually no coin in Norway with value 2 kroner. Understanding what a solution means, under what circumstances and limitations solutions can be found, and being able to see that changing conditions may lead to other solutions, is an important part of learning mathematics, and in particular an important part of developing a critical orientation in mathematics, e.g. as identified by Goos et al. (2014) and Askew (2015). Additionally, it is certainly also an important part of being able to solve problems in the society. This brings us closer to those aspects of learning mathematics that are proposed by D'Ambrosio (2003), Skovsmose (1998) and which are some of the underlying ideas and valued outcomes of IBL (Maaß & Reitz-Koncebovski, 2013). For some students, such as students 1 and 2, we observed that they had to be encouraged specifically to do writing and drawing by the teacher. They had already solved the problem using play-coins but not made a written record. Learning to communicate your solution, making your thinking visible to others in a multitude of ways, is an important part of building mathematical literacy. At the same time, forcing children to represent their answers in particular ways may distract from their learning of the mathematical content, and prevent them from going into deeper thinking. One risks, as D'Ambrosio (2003) pointed out, to emphasize manipulation of numbers and symbols rather than developing math literacy. We believe that this tension between steering children towards particular representations and letting them explore more freely, is something we have to live with. By emphasizing the importance of writing or drawing as representations and as means for communicating results, one risks downplaying the importance of other, for instance oral communication (which is also something one would like to foster). From the empirical data we also see that the students engaged in the inquiry cycle with the five E's, engage, explore, explain, extend and evaluate while working collaboratively in pairs. The teacher encouraged students' reasoning by asking students about their ways of thinking, both in plenary and when students were working in pairs. From the data it is evident that it was necessary for the teacher to prompt students to collaborate and inquire, even if this prompting when done in plenary was seen as 'disturbing' for some students, as evident from transcript line 24 above. Developing a classroom culture that values questioning, exploration and where mistakes are seen as a necessary part of learning mathematics is emphasized as important in IBL (Maaß & Reitz-Koncebovski, 2013) and is essential for students to develop a critical disposition that is essential in being mathematically literate. In our data it is evident how the teacher tried to achieve this, both by her innate experience as a teacher and by using the IBL oriented lesson plan. The start of the lesson with the students all gathered around a smart-board where the coins and the problems were introduced, was used to create a classroom culture of shared ownership and purpose, and where the students were encouraged to explore and work together. Valued outcomes in an IBL setting include developing critical and creative inquiring minds. This echoes some of the ideas proposed by D'Ambrosio (2003) and Skovsmose (1998) and also the critical orientation underlined by Goos et al. (2014). It is not straight forward to answer the question about what it means to be critical in a mathematics lesson, in particular at the lower grades of primary school. Our data shows that it is possible to identify the three ways of being critical (Askew, 2015) even in 2nd grade, if the setting and atmosphere in the classroom is encouraging, e.g. the classroom culture and learning

environment are as described in the IBL model. Planning a lesson using an IBL model like the one used here may help fostering mathematical literacy, including developing a critical disposition.

### Acknowledgement

The authors would like to thank participating teachers, the schools and our colleagues from NTNU.

*This article reports on how a group of preschool and primary student teachers define the concept “teaching mathematics in preschool” in the beginning of their studies. The background for this pilot-study is the recent change in the Swedish curriculum, which means a shift from play-based to more teaching oriented activities, and the actual Swedish debate on the role of teaching in preschool.*

*Keywords: Young children, Teaching, Learning, Mathematics, student teachers, preschool.*

### Introduction.

In 2011, a new national curriculum for Swedish preschool was implemented. In this text, and also in the previous curricula for preschool, the concept of teaching is not discussed. Instead of that, the guidelines for preschool teachers highlight the learning opportunities that should be provided to children, and these indicate indirectly what kind of mathematics preschools should provide to children (Swedish National Agency for Education, 2011). The concept of teaching is however used in the Swedish educational act (SFS, 2010:800). According to Öqvist and Cervantes (2017), this was the first time the concept of teaching was used in a steering document for preschools in Sweden. On the other hand, it seems to be important for preschool teachers not to work in the school-like way and, hence, they tend to avoid using the word “teaching” to describe their professional work (Hedefalk, Almqvist, & Lundqvist, 2015).

In Sweden, there is an ongoing discussion about what teaching in preschool means (Rosenqvist, 2000; Doverborg, Pramling, & Pramling Samuelsson, 2013; Hedenfalk, Almqvist, & Lundqvist, 2015; Jonsson, Williams, & Pramling Samuelsson, 2017). Palmér and Björklund (2016) provide an overview of eight Nordic articles which show a large diversity of aims and goals within preschool mathematics. There is not a common understanding or view of what teaching in preschool is, could or should be. Quite recently, this question was raised when the Swedish National Agency for Inspection (2017) reported that there is a lack of teaching in the Swedish preschools and that there is uncertainty about what the concept teaching in preschools is. This debate is our primary motivation for the present study.

Secondly, according to Clarke, Clarke and Cheeseman (2006), the research into mathematics in preschools has often been driven by the school curriculum with its emphasis on number knowledge. Researchers have investigated various aspects of children’s learning of mathematics and numerous theories concerning children’s mathematical learning exist. Yet the everyday of the teaching of early mathematics has received much less attention in Nordic countries (Saebbe and Mosvold, 2016; Vallberg Roth, 2018).

A third motivation for this study is the fact that the views and beliefs of student teachers (and teachers) affect the way they plan their teaching, what kind of materials they use, and their performance in mathematics during their teacher studies (Wilson & Cooney, 2002; Tossavainen, Väisänen, Merikoski, Lukin, & Suomalainen, 2015). Hannula (2002) emphasises, in his widely applied framework for analysing individuals' attitude towards mathematics, the role of expected consequences and relating the attitudes to personal values. So, by surveying prospective preschool and primary teachers' views of the teaching of mathematics for small children we hope to get knowledge about their personal values and what they expect the outcome of their own mathematics education during teacher education and mathematics education in preschool will be.

### **Theoretical perspective**

Benz (2016) synthesised the professional competences needed for supporting children's early mathematical thinking. These competences are also important for teacher education and hence can contribute to the understanding and the impact of beliefs on the teaching of mathematics. She specified three categories of competences found in previous research: (a) content knowledge, pedagogical content knowledge, and knowledge of children's development, (b) action competencies, and (c) attitudes and beliefs. In this article, we will focus on the third point, the attitudes and beliefs. These play an important role when it comes to providing learning opportunities for children in mathematics in preschools. Indeed, teachers' view of what counts as mathematics and what mathematics teaching for young children is have a remarkable effect on their everyday practice.

Hannula (2002, p. 30) defines attitude as a category of behaviour that is produced by different evaluative processes which concern emotions, values and expectations. These processes are influenced by the social setting and former experiences. In the present paper, we are interested especially in students' values and expectations.

Concerning the beliefs, we use the following definition: "...teachers' pedagogical beliefs refer to pedagogical attitudes and values such as educational goals and norms, the definition of their own pedagogical role, beliefs about developmentally appropriate practices, as well as the educational goals of preschools" (Anders and Rossbach, 2015, p.308). More specifically "mathematics-related beliefs, which include the implicitly and explicitly held subjective conceptions about mathematics education, the self as a mathematician, and the social context, i.e., the class-context" (Op't Eynde et.al. 2002, p.14). In this paper, we focus on the explicitly held subjective conceptions about teaching in mathematics education.

Our research questions are:

- (i) *How do student teachers describe mathematics teaching in preschool in the beginning of their university studies?*
- (ii) *Are there differences between the different groups of students, and if there is, how can they be described?*

## The study

This study aims to investigate student teachers' beliefs about the concept of teaching in mathematics education for young children, specifically in preschool. In order to do that, we collected data from three different groups of students by using a printed questionnaire. The participants of the study (N=94) represent Swedish university students from three different teacher education programs. The first group studies (N=27) to become preschool teachers, the second (N=42) to lower primary teachers (Swedish classes F-3) and the third group (N=25) to upper primary (Swedish classes 4-6) teachers. All of the respondents were in the beginning of their university studies and had therefore not yet taken any mathematics courses contained in their university program.

The motivation for including these three different groups is the fact that the primary teachers continue the work of the preschool teachers, so, it is important to see if they share the same ideas and goals related to mathematical education. Another reason for the three groups is that we want to see whether students' views on teaching arise during the teaching education programme or are they based on their earlier beliefs. Therefore, we need to examine whether or how these groups' views differ from one another already in the beginning of university studies.

The first part of the questionnaire surveyed the participants' educational background concerning mathematics. In the second part, the participants were asked to make a concept map of their definition of mathematics education in the Swedish preschool. The third part contained a set of statements related to teaching of mathematics for young children with the seven-point Likert-type scales. In this article, we focus on the participants' concept maps i.e. the second part of the survey. The task was presented in the questionnaire as follows: "The definition of mathematics teaching in preschool: Spend a few minutes on reflecting teaching mathematics to young children and what it brings to your mind. Then, using a concept map, define what mathematical teaching in preschool education in Sweden should in your opinion be. Focus on the essential features, more detailed questions follow on the next page."

The students then provided concept maps where they had a centre of the map and then added essential features of the question around this centre. Using a concept map may provide other information about teachers' views and beliefs than open questions and Likert-type scale questions. This method is mostly used for investigation concept understanding (Rosas & Kane, 2012) and, hence, we found that it might be a way also to investigate beliefs and views on the concept of teaching mathematics in preschool since this is in line with the definition and focus of the paper, the conceptions about teaching of mathematics. When analysing the students' concept maps we realised that they often had more features of a mind map than a concept map. According to Davies (2011), one important difference between a mind map and a concept map is that a concept map has a hierarchical structure with several levels. This was not the case with these students, most of their maps had only one level.

We used content analysis in order to find the essential categories of sub-concepts that occur in the students' concept maps. The analysis focused on qualitative differences in students' values and expectations. It did not however take into account at what levels in the concept maps these sub-concepts were mentioned. The categories were derived purely from the data, i.e., the words found in

the maps are grouped and after the grouping the categories are defined. When it comes to the written answers (a few students gave a written response instead of drawing a concept map), they were added to the categories after the grouping of the words.

## Result

In this section, we first present the categories found in the concept maps and then give examples of different categories and their content. Secondly, we discuss the differences or similarities that can be seen between the three different groups.

The following categories were found in the concept maps: Motivation, Methods for teaching, Children-centred, Everyday, and Content.

*Motivation* is the first one of these categories. Here we have words like fun, enjoyable, meaningful, play based, play, inspiring, interesting and creative. We interpret these words as describing how mathematics teaching should be for young children. They focus on feelings as a tool for motivation. We also attached play and play-based to this category even though they could be placed also in the category methods for teaching.

The category *Methods for teaching* also answers the question how mathematics teaching should be for young children, but with a focus on the organization of the teaching or learning rather than the motivational aspects. Here we find words like practical, concrete, concrete materials, games, digital tools, mathematics in all activities, variation, exploration and group work.

The next category can also be seen to answer the question how, but it focuses on children and their world. Therefore, we call it *Children-centred*. Here we find words like draw on children experiences, on the child's level, and suitable level.

*Everyday* is another category putting a child in the centre. In this category, we find words like everyday situations, connect to the everyday, connected to reality and use the everyday.

*Content* is the last of the categories and here the students have given examples of mathematical content that the children should meet in the preschool. Here are words like numbers, counting, shapes, develop concepts, space, symmetry, geometry, arithmetic, problem-solving and sorting. This category is not analysed in detail here due to limited space but it is of interest for further investigations.

	Motivation	Children-centred	Everyday	Methods for teaching	Content
Preschool N=27	17 64%	12 44%	4 15%	5 19%	17 63%
Lower Primary N=42	26 62%	7 17%	9 21%	16 38%	18 45%
Upper Primary N=25	7 28%	1 4%	3 12%	11 44%	21 84%

**Table 1: Distribution of the categories for each group**

In Motivation, we have few (7) response from upper primary student teachers, and of these seven, six mentions play. On the other hand, play is not mentioned at all by the preschool student teachers, this is surprising given that play as a base for learning is a foundation for the Swedish curriculum for preschool. For the preschool student teachers, we have 17 responses and for the lower primary student teachers we have 26 responses in this category. To conclude this category seems to be important for preschool student teachers and for lower primary student teachers.

The category Children-centred seems to be important for the preschool student teachers but not so important for the other groups, only one of the upper primary student teachers has a word in this category, and there are only few words from the lower primary student teachers and then even less for the upper primary student teachers.

Surprisingly, Everyday does not have that pattern. Here the lower primary student teachers have the mode while preschool student teachers and upper primary student teachers only have 4 and 3 responses, respectively.

In Methods for teaching, the preschool student teachers have few words in this category and they all say variation. This is in contrast to lower primary student teachers group where they have 16 and upper primary student teachers have 11 and gives a variety of methods.

Content is the largest category overall and seems to be important for all the groups, and it will be a subject to a separated analysis later on. It is the only category that is almost the same in all three groups and almost all student teachers have words in this category.

One important thing that was noticed in the analysis was the fact that the students had different words in the centre of their concept maps. The formulation of the task mentioned explicitly “The definition of mathematics teaching in preschool” and from this expression the students had chosen different centre words for their maps. This may have had an impact on the concept maps and, hence, it is important to present the different centerwords as well. They are: mathematics, mathematics learning, mathematics teaching and mathematics in preschool. The remaining 19 students either does not have a centre word, have written a short text describing, or it is not obvious what the centre word is.

	Mathematics	Mathematics in preschool	Mathematics learning	Mathematics teaching
Preschool N=27	7 26%	3 11%	9 33%	1 4%
Lower Primary N=42	8 18%	17 39%	0	14 32%
Upper Primary N=25	9 39%	6 26%	0	1 4%

**Table 2: Concept map centres across the student groups**

As we can see in Table 2, only one of the student teachers for preschool has written about mathematics

teaching. This is not surprising since we know from previous research that this is typical for in-service preschool teachers (Hedefalk, Almqvist, & Lundqvist, 2015). So, the fact that the same pattern appears for upper primary student teachers is more interesting. On the other hand, none of the primary student teachers has used the mathematics learning in their centre. The lower primary student teachers have focused on mathematics in preschool or mathematics teaching and the upper primary student teachers on mathematics and mathematics in preschool. The difference between the groups is noticeable and can only partly be explained by the fact that they have started their studies. They are, as mentioned before, in the beginning of their studies and have not yet taken the mathematics course.

## Discussion

As mentioned above, this is just a pilot study with a relatively small group of students, and the results discussed in this article are only due to an analysis of one of the parts of the survey. The next step would be to investigate how these results are connected to the students' responses to the statements measures on a Likert-type scale; some preliminary results have been reported by Tossavainen, Johansson, Faarinen, Klisinska and Tossavainen (2018). Nevertheless, the above results give us an overview of what prospective preschool and primary teachers expect mathematics education in preschool to be and what they value in the teaching of mathematics for small children.

One point that needs to be addressed here is that the students had chosen different words in the middle of their concept maps. The formulation of the task mentioned explicitly “The definition of the teaching of mathematics in preschool” and it seems that, from this expression, the students have chosen different centre words for their maps. This may have impacted the concept maps and, hence, it is important to present the different subcategories as well. They are: mathematics, mathematics learning, mathematics teaching and mathematics in preschool. The fact that most students have mathematics learning as the concept centre is compatible with previous research (Hedefalk, Almqvist, & Lundqvist, 2015) but a new finding is that this view is already present when they start their studies at university. Similarly, it is surprising that their concept centres differ already at this stage.

The lack of the word *play* in the preschool student teachers' concept maps is another point is worth more investigations. One way to interpret this is that, for this group of students, play is so obvious that it does not have to be mentioned, yet this is not self-evidently supported by our data.

The fact that the lower primary student teachers seem to have a broader view than the other groups would be even more evident if we studied the students' concept maps at individual level.

To answer our research questions, the three groups of students give different descriptions about what teaching in mathematics in preschool is, and they focus on different parts of the teaching of mathematics. We can say that they in fact have different pedagogical beliefs and expectations regarding at least what mathematics teaching should be in preschool, how it should be provided, and also which focus the teachers should have. The category Content gives us some indications of attitudes and values regarding their educational goals. Since this category is shared by all groups and is the largest one, we can conclude that this is an important base for all the teachers' pedagogical beliefs. The categories Everyday and Children-centred give information regarding expectations and

values concerning the teachers' pedagogical role. Here the focus for the preschool student teachers is on the child and the focus for the lower primary student teachers is on the everyday. These are not so important for the upper primary student teachers, and this could possibly be explained by the fact that they have not thought about the pedagogical role of the teacher since they will not teach themselves. Methods for teaching and Motivation give information about attitudes and values about appreciated practices. These can be found in all the groups but with different focus. For the preschool student teachers, the focus is on motivational issues and, for the primary student teachers, on the methods. This is one of our main results since it gives us information about the preschool student teachers' beliefs that teaching in preschool is not their main interest but they prefer to focus on other parts of the educational practice.

## Using finger patterns – the case of communicating age

Miriam M. Lüken

Bielefeld University, Germany; [miriam.lueken@uni-bielefeld.de](mailto:miriam.lueken@uni-bielefeld.de)

*Young children spontaneously use their fingers to represent numerosities. However, there has been relatively little research on how and in what contexts young children use finger patterns, which is critical to understanding the role fingers play in early numerical development. This study examines a very common situation in which young children use finger patterns: answering the question “How old are you?” In one-on-one interviews 158 children age three to five were asked their age; additional tasks to measure the child’s early number development were administered. Results show a decrease in the spontaneous use of finger patterns for older children. Interestingly, all finger patterns for four and five were shown canonically and produced statically. This hints at the fact that finger patterns might function symbolically. Furthermore, older children who spontaneously used finger patterns vs. verbally said their age differed according to their early number development.*

*Keywords: Finger pattern, numeracy development, number representation.*

### Introduction

The use of fingers during numerical considerations is a frequently and cross-culturally observed action in early childhood. Children use their fingers in different ways and for various purposes: Fingers are used to point at objects that are being counted (*pointing gestures*; Gelman & Gallistel, 1978). Fingers themselves are counted or rather raised consecutively to accompany the recital of number words (*finger counting*; Wasner, Moeller, Fischer, & Nuerk, 2014). Over the last couple of years, a growing body of research has shown that the ability to represent one’s fingers mentally is correlated with math skills (*finger gnosis*; Noël, 2005). Later, fingers are used in solving arithmetic problems (*finger arithmetic*; Butterworth, 1999). The research presented in this paper focuses on yet another purpose of fingers in early mathematical development: Like number words and written numerals, fingers can be used to represent numbers, for example holding up a certain number of fingers to represent a set size. Various terms like *finger pattern* (Butterworth, 1999), *finger montring* (Di Luca & Pesenti, 2008), *finger numeral configuration* (Di Luca & Pesenti, 2008), *cardinal number gesture* (Gunderson, Spaepen, Gibson, Goldin-Meadow, & Levine, 2015), or *finger symbol set* (Brissiaud, 1992) are used in this context. Coming from mathematics education, in particular a pattern and structure background, I use the term *finger pattern* throughout this paper.

Children from most cultures spontaneously use their fingers to represent numerosities, and, on some occasions, adults still use their fingers to communicate with other people about numerosities (Di Luca & Pesenti, 2008). Despite their ubiquity across cultures, there has been relatively little research on how and in which contexts young children use finger patterns, which is critical to understanding the role fingers play in early numerical development (Gunderson et al., 2015). And, although I personally have observed children spontaneously produce finger patterns as early as two years of age, most of the existing research has focused on adults’ use of finger patterns (e.g., Di Luca & Pesenti, 2008). This research, therefore, specifically looks at how young children use finger patterns. To start with, a very common case was chosen: children communicating their age by showing a finger pattern.

## Theoretical Background

### “Finger dialects” and canonical configurations of finger patterns

Although the use of finger patterns to show numerosities can be found in most cultures (Ifrah, 1981) there are no universal finger patterns; instead, they differ by culture. Butterworth (1999, p. 221) calls this phenomenon “finger dialect”. The finger pattern that represents *three* would be for most Germans and Southern Europeans the raised thumb, index, and middle finger, for most Northern Americans and Northern Europeans it would be the raised index, middle, and ring finger (Butterworth, 1999; Pika, Nicoladis, & Marentette, 2009). For these kinds of finger patterns the term *conventional gesture* is used to emphasize that their form and meaning are established by the conventions of specific communities (McNeill, 1998). Di Luca and Pesenti (2008) used the term *canonical finger numeral configurations* in their study with young adults when evaluating the understanding of canonical and non-canonical finger patterns. Subjects were instructed to say as fast and as accurately as possible how many fingers they saw. Canonical finger patterns included only those that would occur during cardinal finger montring (showing a finger pattern to others), whereas non-canonical finger patterns showed an assembly of random fingers (e.g., index, ring, and pinkie finger raised to mean *three*). Results showed that subjects were better in naming the correct number when a (for the individual) canonical (and not a random non-canonical) finger pattern was presented. Furthermore, canonical finger patterns, but not non-canonical, prime nearby numbers based on their proximity to the target in the same way that Arabic numerals do (Di Luca, Lefèvre, & Pesenti, 2010). These findings suggest that adults’ finger patterns function symbolically and possess semantic meaning based on their canonical configuration, rather than deriving their meaning merely from the number of raised fingers. Using finger patterns might even be a form of pattern recognition in which well-known patterns are recognized and employed, similar to the dot-patterns on dice.

In the context of mathematics education it is important to look at the way, i.e. *how* a finger pattern is produced. Finger patterns can either be constructed by raising the fingers successively (by counting) or simultaneously (Gaidoschik, 2007). The first would be called a dynamic, the second a static finger pattern (Lorenz, 1992). If a child produces a static finger pattern it might be supposed that it has the pattern for the specific number memorized and does not need to count up to the specific number (pattern recognition). However, it possibly might be that lacking fine-motor skills hinders a child to simultaneously raise his/her fingers and instead the child raises the fingers one by one until the produced finger pattern matches the one he/she has memorized for the specific number. In this case, the dynamically produced finger pattern is not a result of a counting process.

### Finger patterns as number representations

Fingers are an easily accessible, concrete, and always available device that can aid children in the development of number concepts. Fayol and Seron (2005) see finger-based representations and finger use as a link between concrete numerosity and abstract number. Fingers themselves are concrete but at the same time, “finger representations exhibit an iconic relation to numerosities, since they preserve the one-to-one matching relation between the represented set and the fingers used to represent it” (p. 29). Furthermore, fingers have an additional abstract dimension. Similar to number words they can stand for various different objects: “[...] the same pattern of raised fingers can equally well represent

three giraffes, three toys, or three elements in an argument.” (p. 29). By this dual capacity, fingers moderate the transition from an understanding of concrete numerosities to an understanding of abstract number (Rösch, 2016). The use of specifically *finger patterns* has a lot of theoretical potential to support children’s development of number concept, namely the cardinal principle, subitizing, part-whole concept (Resnick, 1983), and the concept of base (Fayol & Seron, 2005). As the first two are relevant for this research, they are explicated further in the following. One of the basic number concepts, young children acquire, is that numbers are not only represented as sequences of single units (e.g., fingers, finger counting; *ordinality*) but that number also corresponds to the whole set of fingers (finger pattern; *cardinality*). Finger patterns directly reflect the cardinal aspect, i.e. the quantity of number; a specific finger pattern is associated with a particular number. Thereby, each number between 1 and 10 has its own culture-specific finger pattern. Considering fingers as manipulatives they can be used for exercises in quickly and simultaneously determining quantities (*subitizing*; Schipper, 2005). Because of their base-five structure it is possible to conceptually subitize quantities bigger than four (Butterworth, 1999). Closely connected with subitizing is the pattern recognition of canonical finger patterns. Similar to dice-pattern, the specific arrangement is recognized and connected to the corresponding number word.

### **Research on young children’s competencies for labeling set sizes with finger patterns**

Current research with young children on their use of finger patterns when labeling sets shows somewhat contrary results. Nicoladis, Pika, and Marentette (2010) assessed the correctness of 44 preschoolers’ (aged two to five) answers in determining set sizes when using number words vs. finger patterns. They found that children perform better on verbal than on gestural (finger pattern) number tasks. They conclude that children’s early understanding of number words is not aided by finger patterns. Gunderson and colleagues (2015) examined the number words and finger patterns 3- to 5-year olds ( $n = 155$ ) used to label set sizes. They found that young children who had not yet mastered the cardinal meaning of number words performed significantly more accurate in labeling set sizes when giving a gesture response (finger pattern) than a speech response. They conclude that finger patterns may play a functional role in young children’s development of number concepts.

Understanding of number and the use of finger patterns do not only occur in situations in which set sizes are labeled. Therefore, when trying to assess finger patterns contribution to young children’s development of number concepts, study designs should take alternative contexts into account.

### **Research questions**

This research aims at contributing to our understanding of the role, finger patterns play in children’s development of (cardinal) number concept. Therefore, I take a closer look at children’s use of fingers in a common, everyday situation, namely young children conveying their age. I specifically address the following questions:

How do 3-, 4-, and 5-year old children spontaneously communicate their age?

- If children show finger patterns, do they use a canonical or a non-canonical pattern? How do they produce the finger pattern (dynamic vs. static)?

Does the way in which children convey their age relate to their early number development?

## Method

### Participants

Consent was obtained for 158 children attending 14 kindergartens<sup>1</sup> in a metropolitan area in the northwestern part of Germany. The kindergartens were chosen to cover a broad range of socio-economic backgrounds. The sample consisted of 54 children aged 3 (30 girls,  $M_{\text{age}} = 3$  years 6 months,  $SD = 2.7$  months, range = 2 years 11 months – 3 years 11 months, 43% with a migration background<sup>2</sup>, 76% speaking German as family language), 64 children aged 4 (33 girls,  $M_{\text{age}} = 4$  years 5 months,  $SD = 3.2$  months, range = 4 years 0 months – 4 years 11 months, 36% with a migration background, 81% speaking German as family language) and 40 children aged 5 (15 girls,  $M_{\text{age}} = 5$  years 4 months,  $SD = 3.9$  months, range = 5 years 0 months – 5 years 11 months, 58% with a migration background, 80% speaking German as family language). Children participated voluntarily and with informed consent of their parents.

### Design, Materials, and Procedure

Using a clinical format, individual interviews with each participant were conducted. After being asked for their age, children completed several patterning tasks, followed by tasks on early number development. The patterning tasks are not object of this paper. Interviews were conducted by four members of the research team and were videotaped.

*Task on finger pattern (asking for age).* Right at the beginning of the interview the child was asked “How old are you?”. If the child indicated his/her age by showing a finger pattern the child was then asked if he/she could also tell the age using a number word (“Please, also tell me with words how old you are!”). If the child used a number word in the first place the child was prompted to also show his/her age with fingers (“Please, also show me your age with your fingers!”).

*Tasks on early number development.* To explore a possible relation between children’s use of finger patterns and their number development in early childhood, children’s rote counting, enumeration, and subitizing skills were measured. I adapted the tasks from the Australian “Early Years Numeracy Interview” (DEET, 2001). They included counting forward from 1 (total possible score was 5 points), counting onward from 4 and 8 (max. 4 points), counting backward from 7 (max. 3 points), and identifying the number before/after 4 and 8 (max. 4 points). For enumeration the children were asked to enumerate 4, 7 and 12 object sets (max. 7 points), counting out 3 objects (max. 1 point), and compare sets of 3 and 4 objects (max. 1 point). Materials were red, yellow, and blue little plastic bears (see DEET, 2001). During enumeration children’s abilities regarding the counting principles were observed (Gelman & Gallistel, 1978), including the one-one principle, the stable-order principle, the cardinal principle, and the order-irrelevance principle (max. 5 points). For subitizing children were presented with seven 9x9cm cards with sets of 2, 5, 4, 1, 9, 3, and 6 dots placed regularly on each

---

<sup>1</sup> German kindergarten comprises the three years before school entry, i.e. children start kindergarten when they are three years old.

<sup>2</sup> Migration Background is defined here as: the child or one parent or both parents not born in Germany.

card. The cards were displayed for two seconds each in the above order (max. 7 points). The total possible score for all items on early number development was 37 points.

## Analysis

Children's initial reactions to the question "How old are you" were inductively categorized according to their way of communication. Furthermore, the correspondence of finger pattern and number word was assessed. I also looked at how the finger pattern was produced (dynamic vs. static) and at the produced finger pattern itself in terms of canonical vs. non-canonical use. For Germany (see German Math textbooks and finger pattern based intervention programs, e.g., Claus & Peter, 2005), a canonical finger pattern would be for *three* the raised thumb, index, and middle finger. For *four* two different versions are common. Depending on the children's fine motor abilities they would either raise thumb, index, middle, and ring finger (pinkie finger folded) or raise index, middle, ring, and pinkie finger (thumb folded). The canonical finger pattern for *five* is the raised fingers of one complete hand. The answers to every task on early number development were coded by correctness; the scores were added for each child.

## Results

The three main ways children communicated their age was by either naming a number word (category 1), showing a finger pattern (2) or doing both, i.e. uttering a number word and showing a finger pattern simultaneously (3). Only three 3-year olds were not able to convey their age at all. As number words only whole numbers of years were used by all children. The distribution of frequencies (see Table 1, left) shows a distinct pattern: the older the children, the more frequently they used verbal number words and less frequently their fingers to spontaneously indicate their age. Comparing the children's mean scores for the number tasks regarding their way of communicating their age revealed some significant differences. The 4-year olds who answered by saying the number word (1) scored significantly higher on average for the number tasks than the 4-year olds who were showing their fingers (2) ( $t(48) = 2.43$ ;  $p < 0.05$ ;  $d = 0.7$ ). This difference did not apply for the 3-year olds. As the sample size for the 5-year olds who were showing a finger pattern was too small ( $n = 5$ ) a t-test was not executed. For comparison purposes it has to be said though that the difference between the 5-year olds answering by number word (1) and the 5-year olds doing both (3) was significant ( $t(33) = 2.49$ ;  $p < 0.05$ ;  $d = 0.87$ ), with the former scoring higher on average. As the sample sizes of the sub-groups are quite small these results should be treated carefully.

All 4- and 5-year olds (except one) who communicated their age by spontaneously showing a finger pattern were able to verbalize their age when asked to do so, and vice versa. This was different with the 3-year olds. Additional to the three who were not able to communicate their age at all, four were merely able to show a finger pattern and not name the number word, and three could not show the finger pattern for their age (plus one missing data: one 3-year old was not asked the second question). When children were able to use both ways in communicating their age, the finger pattern matched the spoken number word in 63% of the cases for the 3-year olds. With 94% for the 4-year and 98% for the 5-year olds the percentage of concordant number word and finger pattern was much higher (see Table 1, right). The children with whom the finger pattern and number word did not match were distributed quite evenly over the categories 1 to 3 for the initial question.

%	first reaction to the question “How old are you?” [ <i>number tasks mean scores</i> ]				accordance of number word and finger pattern	
age	number word (1)	finger pattern (2)	number word and finger p. simult. (3)	not able to tell/ show age (4)	accordance	no accordance or not able to tell/ show age
3	28 [10.4]	50 [9.9]	17 [10.4]	5 [4.0]	63	37
4	56 [19.3]	22 [14.5]	22 [17.9]	0	94	6
5	60 [24.8]	12 [18.4]	28 [20.8]	0	98	2

**Table 1: Relative frequencies for children’s reactions to the question “How old are you?”; mean scores for number tasks (in brackets); accordance of number word and finger pattern**

In looking at the way children produced their finger pattern (see Table 2, left) it is striking to see that (nearly) 100% of the 4- and 5-year olds raised their fingers simultaneously (static finger pattern) and not as an end-product of a counting process. Most of the 3-year olds (67%) did the same, still over a fifth (22%) raised their fingers one by one. A similar pattern can be found for the type of finger patterns (see Table 2, right). Nearly 100% of all 4- and 5-year olds showed canonical finger patterns. Over half of the 3-year olds showed canonical, but one third showed non-canonical finger patterns.

%	production of finger pattern			finger pattern		
age	static	dynamic	shows no fingers at all	canonical	non-canonical	shows no fingers at all
3	67	22	11	56	33	11
4	98	2	0	98	2	0
5	100	0	0	100	0	0

**Table 2: Relative frequencies for way of production and type of children’s finger patterns**

## Discussion

This study examined young children’s use of finger patterns in a very common, everyday situation, and, furthermore, related children’s number development to it. Results show that 3- to 5-year olds spontaneously communicated their age by either showing a finger pattern, saying a number word, or simultaneously doing both. The frequencies in which they did so, however, changed over the years with the younger children signing, the older children using number words most frequently. The increase in verbal answers might be due to the general language development during early childhood. Children might also adapt their reactions to the adults’ way of verbally talking numbers.

Comparison of children’s number development with regard to their initial reaction showed no significant differences for the 3-year olds but for the 4-year olds. The direction, though not significant due to low power, was the same for the 5-year olds, suggesting that older children who told their age by saying the number word have developed a deeper understanding of number concepts than their

peers who showed a finger pattern. This does not mean that early mathematical educators should aim to quickly and early detach children from using finger patterns. In my opinion it rather shows the relevance and potential of finger patterns as an aid in the acquisition of number concepts from concrete to abstract number representation. A finger pattern, therefore, may be one of the concrete foundations that is needed at the beginning and is left behind when a mental concept of the particular number is developed. These findings contribute to Gunderson and colleagues (2015) results that children who had not yet mastered the cardinal principle performed significantly more accurate in labeling set sizes when responding by finger pattern than by number word. Together they strengthen the evidence for taking age and specific number knowledge into account as factors for finger patterns' relevance in early numerical development. For further studies it seems reasonable to differentiate between very young (2 to 3 years) and young children (4 years and older) and specifically look at the number concepts these children already have or have not acquired.

This study adds to previous research because it explicitly looks at the way young children produced their finger patterns. All finger patterns for *four* and *five* were presented canonically. This is not surprising as the finger pattern for *five* equals simply holding up one hand. The only alternative would have been to produce different hand shapes with each hand, a difficult task at this age. As I considered *four* with the folded thumb as well as with the folded pinkie finger as canonical, all produced finger patterns for *four* and *five* were canonical for the children's countries of origin. Together with the fact that nearly all patterns for *four* and *five* were produced statically, I conclude that the 4- and 5-year olds have the respective finger pattern memorized like a familiar pattern. They use it as a symbol, similar to the verbal number word. As there are more possibilities to produce a non-canonical finger pattern for *three*, it is not surprising that a third produced a non-canonical and just above half of the 3-year olds a canonical finger pattern. This fact can only partly be explained by the children's migration background. Over half of the non-canonical showers were German children. The younger children also differed from the two older groups in the way they produced the finger pattern. With over a fifth unfolding three fingers one by one (dynamically) until three fingers were reached and still a tenth not being able to produce a finger pattern for *three* at all, it might be suggested that the utilization of fingers in order to represent age develops in early childhood (possibly starting between the age of two and three). Further research, therefore, should look at 2-year olds' ways of communicating their age and in general their knowledge and utilization of finger patterns. In summary, the presented study results show that finger patterns are an important preverbal way of experiencing and communicating numbers for many young children.

*Taking inspiration from recent literature about algebraic thinking at early grades, we wonder if and how we can prompt and recognize relational thinking at the kindergarten level. Adopting a design-based research approach, we analyze students' answers to a task, both with the aim of developing its potential in prompting relational thinking and the aim of getting clues about how to recognize relational thinking at the kindergarten level. Analyzing students' behavior while facing our task, we find evidence of relational thinking in students aged 5, even if at different stages. The task proves to be effective in stimulating children relational thinking and in making distinguishable their answers.*

### Introduction

The distinction between instrumental and relational understanding of mathematics has been originally defined as, respectively, knowing just how mathematical procedures work and knowing both the how and the why (Skemp, 1976). Such definition found application in the field of arithmetic: several researchers paid attention on prompting students in understanding operations' properties standing behind calculation algorithms. A commonly proposed task consists in finding the missing number in an equality between two arithmetical operations like  $39 + 52 = \text{''} + 55$ . Usually, it is assumed that relational thinking is shown if students do not resort to calculation of the results on the two sides of the equality, but they find a solution by compensation or other strategies based on operations' properties and numbers decomposition (Carpenter, Franke, & Levi, 2003; Stephens & Wang, 2008).

According to Mason (2018), "recognizing that  $87 + 54 = 84 + 57$  without doing any calculation contributes to and is part of algebraic thinking" (p. 343) and it is never too early to let children thinking in this way. He claims that "the use of natural powers which, when expressed in words and symbols is recognizable as algebra, is called upon from birth if not before" (Mason, 2018, p. 347). Such claim is a starting point for us in wondering if and how we can prompt and recognize relational thinking at the kindergarten level. Adopting a design-based research approach, we analyze students' answers to a task, both with the aim of developing its potential in prompting relational thinking and the aim of getting clues about how to recognize relational thinking at the kindergarten level.

Number sentences written with arithmetical symbols could be inaccessible to students aged 5. This same issue was dealt by Steinweg and colleagues (2018) and Lenz (in press). They developed a suitable task to let kindergarten students approach unknowns. In their task, there are two fictitious characters playing with marbles. They both have the same amount of marbles, but some of them are visible and others are inside colored boxes. Boxes of the same color contain the same amount of marbles. The student is asked to understand how many marbles are in the boxes. Figure 1 schematizes a possible instance of the task by Steinweg et al. They administered the task to students aged from 5 to 10.

**Figure 1: Schematization of the task by Steinweg and colleagues (2018)**

Steinweg et al. (2018) observe that many fourth graders show relational thinking while facing this task. However, according to their data, it seems that younger students have difficulties in dealing with it relationally: “While the majority of kindergarten children indicate numerical values, some children in grades 2 and 4 are already able to describe relationships or dependencies” (Lenz, in press). Kindergarten students “neither describe a relation nor display the dependency between the amounts of marbles in the boxes” (Steinweg et al., 2018, p. 19). We modified the task: In our modified version, students know that there are two characters having the same number of marbles. The first character’s marbles are completely visible, while part of the marbles of the second character are in a box. Children have to figure out how many marbles are in the box. Differently than the original task, the amount of marbles in the box is fixed. An example of our task is obtainable taking away the red boxes from Figure 1. We analyzed students’ behavior in solving this task assuming the perspective described in the following section.

## Theoretical framework

When analyzing their data, Steinweg et al. (2018) consider as evidence of relational thinking those cases in which a student can express verbally a relation between the quantities of marbles in the boxes: according to them, sentence like “In the green box is always one marble more, than in the orange box” (p. 19) can be considered as relational, because there is an explicit connection between the amounts of marbles in the boxes. Those cases in which students just tell the number of marbles that are in a box were interpreted by them as evidence of the fact that children see the amounts as fixed. We are convinced that some of these cases could be applications of relational thinking. We believe that this can be unveiled by analyzing the process that is enacted by the student to find such results.

Carpenter et al. (2003) describe four different benchmarks in the interpretation of number sentences containing the equal sign.

- First benchmark: a very first step in interpreting the equal sign is the student’s ability to express his/her own interpretation of the equal sign.
- Second benchmark is achieved when students accept equivalences that are not in the standard form  $a+b=c$ , for instance  $c=a+b$  or  $a+b=c+d$ .
- Students at third benchmark compare the two sides of the equal signs carrying out the calculations on each side of the equal sign.
- Fourth benchmark is achieved when students can compare the sides of the equality without performing calculations. According to the definitions above, this is relational thinking.

We must stress that, in this paper, we are analyzing a task that is not the same that was used by Carpenter and colleagues to describe these benchmarks. Numbers, operations and equality are not expressed symbolically, but by means of boxes, marbles and verbally. Furthermore, our version of the task does not require calculation on both sides of the equality: the number of marbles on the left side is visible. The algebraic structure of our task is  $a=x+b$  with known  $a$  and  $b$  (number of visible marbles) and unknown  $x$  (number of marbles in the box).

We reinterpret benchmarks by Carpenter et al. (2003) in the context of our task. According to our interpretation the first benchmark is reached when children can explain that the number of marbles on the two sides must be the same. Literature shows that understanding the property of ‘being the same in quantity’ is not granted at kindergarten level (Sfard & Lavie, 2005).

Second benchmark is achieved if students recognize the structure of the equivalence  $a=x+b$ . This is not the case if the student gives  $a$  as value for  $x$ , interpreting the first part of the equivalence as  $a=x$ . This is not reached even if the student counts all the marbles, interpreting the equivalence as  $a+b=x$ . Evidence of the reaching this benchmark could be guessing a value for  $x$  that is smaller than  $a$ . When the third benchmark is reached, students use counting to determine the value of  $x$ . They can count-on starting from  $b$  until they reach  $a$ , or they count backward from  $a$  to  $b$ . We can say that a student reaches the second benchmark, but not the third, when s/he tries to guess a number for  $x$  but s/he cannot use counting as a checking strategy. Students at the fourth benchmark can find the number of marbles in the box without a counting procedure, but decomposing numbers, hence showing relational thinking. For instance, they can split  $a$  marbles in a group of  $b$  marbles and consider that the remaining marbles are as much as those in the box.

We analyzed students answers to the task coding them according to the reached benchmark. The aim is that of answering the following research question: Administering the task, which benchmarks can we observe, distinguish and describe at the kindergarten level?

## Methods

Kindergarten children may not be aware of what an adult means while saying that two quantities are “the same” (Sfard & Lavie, 2005). For this reason, we organized a first session in which the task was implemented with concrete objects. A group of 21 Italian kindergarten students (aged 5) was divided in small groups of four or five. They seated in front of two paper-characters, one of them holding a box (Figure 2a). Plastic balls were used as marbles. A certain quantity of balls was put in front of the character without box (Marco). The interviewer said that the character with the box (Penelope) had the same quantity of marbles. Some of them were onto the box and some of them were inside. Children were asked to say how many marbles were inside the box. After they said a number, they could actually check by opening the box. We will refer to this first session as training session.

In a second session, the students were again divided in groups of four or five. The task was administered showing images on an interactive whiteboard (Figure 2b), so this time they did not have the chance to open the box to check the number of marbles inside it. The interviewer asked them to say how many marbles are in the box. She also interacted with them asking how they figured it out. In this paper, we analyze video-data from this second session, that we call testing session. Both the training and testing sessions were completely video-reordered and fully transcribed. While

transcribing, texts were enriched with screenshots from the video when gestures were performed. Students interventions have been coded with the benchmarks described in the previous section. Both authors discussed together to decide on such coding.

**Figure 2: Settings during training session (left side) and testing session (right side)**

## Data analysis

Due to the limit of space, we are not able to show here the complete data analysis. We selected some examples of the different benchmarks that we were able to detect and interpret in our data.

The first benchmark is not reached by all children: When asked to explain the situation, few of them are not able to express in words that the two characters must have the same number of marbles. Apparently, they do not understand what is asked to them and they remain in silence or they change the topic. The following is an example in which we consider that the first benchmark is reached:

Interviewer: Do you remember what we did the last time?

Sofia: Because they always took the balls in the same number, so if he... if Marco took seven, Penelope could take seven because they became friends at the end of the story.

Here the interviewer prompts the child to recall the training session. The student uses the expression ‘the same number’ to refer to the fact that the two characters have the same amount of balls. According to Sofia, the two sets of balls must have the same property of being seven. Similar explanations are found in other children. They never talk about a correspondence between the two sets of marbles; in other words, they never refer to the fact that for each marble of Marco there is one of Penelope. Statements like that by Sofia, with different numbers as example, are common.

Concerning the second benchmark, we have several examples of children who did not achieve it. For instance, the following excerpt reports the discussion of a group while facing the task in the case in which Marco has six marbles and Penelope has just two marbles outside her box.

Interviewer: What is going on there?

Martina: Penelope has just two balls.

Interviewer: Just two balls? [...]

Martina: No, because the others are inside the box.

Interviewer: And where are those two? [...] I heard ‘outside’. Is it right?

Emma: The two balls are outside, but the others are inside.

Interviewer: How many are inside?

Asia: Eight!

Asia answers to the interviewers' question naming the number eight, that is the total amount of marbles that are shown in the image (two belonging to Penelope and six belonging to Marco). Even if the question is specifically referring to the marbles inside the box, the student is interpreting the equivalence differently than expected. She is not considering the situation in the form  $6=x+2$  but as if it were  $6+2=x$ . According to our interpretation, the second benchmark is not yet reached. This happens again in the same little group of students when they face the situation of Marco having five balls and Penelope with four balls outside the box. The students suddenly state that they have the same number, so the interviewer invites them to check by counting; they react counting all the marbles that are shown in the figure. We can notice that reaching the first benchmark is necessary to achieve the second one, but it is not enough. This is shown clearly in the following excerpt.

Luca: They must have the same number.

Interviewer: They must have the same number; Marco has seven and Penelope has three, how many has she got in the box?

Luca: She must have...

Emma: Seven balls?

Luca: Seven.

Luca can state that the two character must have the same number of marbles, however he interprets this sentence relating the number of Marco's marbles with those in Penelope's box. Emma and Luca seem to interpret the equivalence  $7=x+3$  as if it were  $7=x$ , ignoring the role of the '+3', and so they give the number seven as answer. This is like some cases documented by Carpenter et al. (2003), who found children justifying the presence of an additional number after the equal sign with statements like "it is there just to trick you".

In our data, we do not have cases of students who reached the second benchmark but not the third. Indeed, all those who interpreted correctly the equivalence, then used some counting strategy.

Leonardo: If Penelope has two outside...

Ginevra: The other four are inside the box.

Leonardo: Because two plus four...

Ginevra: Here she has two [she points the two marbles that are drawn outside the box] so here she has four [she points the box].

Leonardo: Two [he raises two fingers of his right hand] plus four [he raises four fingers of his left hand], how much is it? Count! [he faces Ginevra, Figure 3a]

Ginevra: One, two, three, four, five, six.

Giulia: Indeed, they are six.

In this last excerpt, we can see that Leonardo do not determine the sum  $4+2$  by himself, but he involves his peers in calculating it to check if the result of such operation is the number of marbles owned by Marco. It is not clear how Ginevra determined that the number of marbles in the box is four. One possibility is that she guessed. Indeed, we have evidence of tentative numbers that are put aside after checking that they are not correct.

**Figure 3: Leonardo's and Ginevra's gestures**

- Interviewer: Who wants to tell me what he sees?
- Rebecca: Penelope now has two balls while Marco has many.
- Interviewer: How many?
- Rebecca: Six.
- Interviewer: So, Marco has six balls. And what about Penelope? Does she have just two balls?
- Sofia: Penelope has got two outside. Like the last time. Marco has got six, so if she has two outside, it could be that she has... that she has two inside. [...]
- Emma: If there are two balls outside and other two inside it makes four and Marco has six, so it is not the same number.

Apparently, Sofia is trying to guess the number of marbles in the box, she tries with the number two. Emma follows Sofia's reasoning and she confutes it by summing the supposed amount of marbles with the number of visible marbles owned by Penelope. She realizes that the total amount is different than the number of Marco's marbles and so she rejects Sofia's hypothesis. This kind of guessing and testing strategy could appear not sophisticated but, as Mason notices, "*Guess & Test* is not only good mathematics, but it can develop over time into more sophisticated versions: *Try & Improve*, in which the guess is modified according to some principle rather than being essentially random" (Mason, 2008, p. 85). It cannot be considered as relational thinking, but it constitutes a preliminary step for it.

Counting as strategy to determine a sum is frequently used to check the correctness of suggested amounts for marbles in the box. Determining the right number of marbles in the box with different processes appears less frequently. The following excerpt shows one of the few examples. The children are facing the task in the case of Marco having seven marbles and Penelope with three marbles outside the box. They are discussing about the number of marbles that are inside Penelope's box.

- Leonardo: They aren't four.
- Emma: Yes, four! Because there are seven there.

Ginevra: Look! Here she has three [she moves her finger along the three marbles that are outside the box, Figure 3b]. Look: here he has three [she moves her finger along three of Marco's marbles] and he has four [she points with both hands to the remaining four Marco's marbles, as she were grasping them, Figure 3c]. So here she has three [she repeats the gesture in Figure 3b pointing to marbles that are outside the box] and here [she repeats the 'grasping gesture' on Penelope's box] she has four.

Interpreting Ginevra's gestures, we can notice that she creates a correspondence between Marco's marbles and Penelope's one. She selects three marbles among Marco's one and she isolates them from the remaining four. Then she notices that Penelope's marbles can be divided again in a group of three (that is shown) and a group of four that is inside the box. The correspondence is made evident by the use of the same gesture (moving the finger along the balls) to point to the groups of three, and a different gesture (grasping the balls with both hands) to point the groups of four. Ginevra is decomposing the number 7 has the sum  $4+3$  and so she finds the amount of marbles in the box making use of such decomposition. We consider this as an evidence of reaching the fourth benchmark.

## Discussion and conclusion

Developing suitable task to let kindergarten students think relationally appears as an important objective if we believe that it is never too early to start thinking algebraically (Mason, 2018). In this paper, we try to develop such kind of task basing our work on that made by others before. We have modified the task proposed by Steinweg, Akinwunmi and Lenz (2018) because we were not convinced by the fact that they could not observe evidence of relational thinking in children at kindergarten level. Mutuating benchmarks by the work by Carpenter et al. (2003), in our data we can observe different levels of interpretation of a number sentence containing an equivalence. In particular, most of students reach the first benchmark, being able to state what they mean while saying that two amounts are the same in number. We noticed that there are children that are not achieving the second benchmark: they interpret the equivalence  $a=x+b$  as if it were  $a+b=x$  or  $a=x$ . Apparently, they reinterpret the equivalence according to schemes that are more familiar to them.

We do not have evidence of students reaching the second benchmark without reaching also the third one. Using counting to add numbers is used to check the correctness of the amount of marbles in the box. It is not clear if they are using a *guess and test* method (Mason, 2008), or if there are other mental processes leading students to suppose a number for the unknown marbles in the box. Evidence of the fourth benchmark are rare, but there are some. Eventually, we can answer to our research question stating that we find distinguishable evidence of all the four benchmarks.

This result appears in contrast with that by Steinweg et al. (2018), however we must notice that it is not easy to directly compare their work with ours. Indeed, even if we are both speaking about relational thinking, it is not sure that we are speaking about the same thing. We used the benchmarks by Carpenter et al. (2003) who consider relational thinking equivalent to the fourth benchmark. We interpreted students' utterances, but also their gestures, as evidence of the process enacted to solve the task. Steinweg and colleagues (2018) use just the words as data and so it is possible that they interpreted differently some cases that we would interpret as relational thinking.

We are aware that there are limitations in this study. Our theoretical framework is modified for this situation, adapting it from the original one that was thought for primary school level. This was necessary because we do not have frameworks for relational thinking at kindergarten level. The framework works well here in describing differences between the behaviors, however it should be tested in other contexts.

We are convinced that the task proved to be effective in terms of eliciting students' processes in determining an unknown quantity in a simple number sentence. Taking the perspective of the designers, we can notice that the task is effective both in stimulating children and in making distinguishable their answers. However, there is still a problem in evidencing those cases in which the second benchmark is reached while the third one is not. Modifications to the task could solve this problem. We can also notice that in our data we have interesting examples of kindergarten students' arguments; it seems that the task could be suitable also to solicit argumentation.

*In the paper we examine possible factors that enhance young students' mathematical reasoning. Particularly, we present the characteristics of seven mathematical tasks, which were chosen based on an a priori analysis, in order to elicit reasoning among a pair of young students. Additionally, we examine the reasoning processes that were manifested during the students' interactions while solving the tasks. Our results show how particular task characteristics affect reasoning processes.*

*Keywords: Task design, mathematical reasoning, task characteristics.*

## Introduction

Algebra constitutes one of the most significant elements of mathematics, and children, even at a small age, have access to mathematical ideas such as mathematisation, connections, argumentation, number sense and mental computation, algebraic reasoning, spatial and geometric thinking, data and probability sense (Perry & Dockett, 2002). This has led to the “Early Algebra” movement, which has been the background of a number of studies (see, e.g., Kieran, Pang, Schifter & Ng, 2016). The main process involved in algebraic thinking – and in all mathematical activities – is undoubtedly generalisation (Mason, 2005), which therefore has been the focus of the majority of studies in early algebra. However, other significant processes are also involved in algebraic thinking: Blanton et al. (2011) (as cited in Kieran et al., 2016, p. 12, our emphasis) refer to “the processes of generalizing, representing, justifying, and *reasoning with mathematical structure and relationships*”. One of the questions that may then arise is whether it is possible to design and propose mathematical tasks that enhance reasoning among young students. Having this question in mind we designed a case study aiming to examine how particular task characteristics relate to the reasoning processes of two eight-year-old students. Thus, our main research question is what are the characteristics of the tasks which promote mathematical reasoning. Particularly, we aim to examine how specific factors of the tasks are related to reasoning processes.

## Algebraic reasoning and task design

Algebraic thinking is defined as “a process in which students generalize mathematical ideas from a set of particular instances, establish those generalizations through the discourse of argumentation, and express them in increasingly formal and age-appropriate ways” (Kaput & Blanton, 2005, p. 99). This is in line with “Early Algebra”, which can be characterised by the following shift:

... from a traditional content-centered characterization of algebra to that of the mathematical reasoning processes and representations that would seem appropriate for young children, as well as to the nature of the early algebra activities that might promote the development of these processes and representations (Kieran et al., 2016, p. 5).

The above statement leads us to the importance of engaging young students in activities that promote reasoning. But how should such activities look like? This question might prove misleading, since there are various factors that contribute to a learning situation: besides the task itself, we may refer to the teacher and the students participating and interacting. This list is not exhaustive; one could also consider the wider social and classroom context, the available resources and artefacts, the histories of the students and their interactions, etc.

In our research paper, we focus on the teacher (as a task designer), as well as on the students (their reasoning activities as they manifest during their interactions). The importance of task design in enhancing students' engagement and promoting mathematical reasoning has been stressed in research focused on reasoning (Francisco & Maher, 2005) as well as assessment (van den Heuvel-Panhuizen, 2005). These studies have provided comprehensive suggestions on task characteristics, including the expected teacher and students' roles. They can be summarised as follows:

- “the problems must be accessible, inviting and worthwhile to solve” and “the students must have the opportunity to give their own answers in their own words” (van den Heuvel-Panhuizen, 2005, p. 3); moreover, pictures play an important role as context-bearers and they serve multiple functions (van den Heuvel-Panhuizen, 2005);
- “the development of a sense of ownership of the mathematical activity enhances the building of personally meaningful mathematical understanding and students' confidence in their abilities” and working collaboratively and discussing “helps the students become flexible in problem comprehension and adaptive rather [than] routine experts at solving problems” (Francisco & Maher, 2005, p. 371).

## **Context of the study and methodology**

Based on the type of our research questions we have adopted an exploratory case study approach (Yin, 2014). The participants were two eight-year-old female students studying together in the 2nd grade of a public primary school in an urban area in Poland. They both had good marks in mathematics and volunteered to participate in the research. The session took place in one of the students' house, lasted for two hours and was videotaped, after the parents' consent was obtained. Both authors of the paper were present in the session and both were familiar to the students, who worked together for solving the tasks. The role of the first author of the paper consisted of the following: challenge pupils, support pupils, evaluate their progress, think mathematically in order to pose challenging and interesting mathematical questions, supply and recall information and promote pupils' reflection (da Ponte, 2001).

### **A priori analysis of the tasks**

Task design was based on the assumptions mentioned in the previous section. Seven tasks were chosen from two sources (Lankiewicz, Sawicka & Swoboda, 2012; Treffers, 2008), based on: their potential to stimulate students' interest, be solvable, or at least approachable, in more than one way and without the use of tricks, illustrate important mathematical ideas, serve as first steps towards mathematical explorations and be extensible and generalisable (Schoenfeld, 1994). Table 1 below presents all tasks, except Tasks 3 and 5, which will be presented and analysed later.

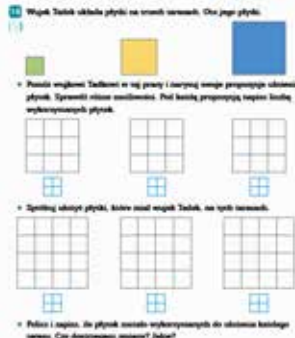

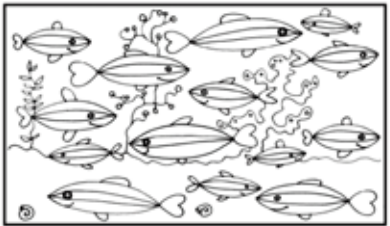

<p><b>Task 1: Chairs</b></p> <p>Jak możesz rozmieścić krzesła dla dwóch zbiorów po cztery?</p>  <p>How you can divide the chairs into 2 sets of 4 chairs in each?</p>	<p><b>Task 4: Tiles</b></p> <p>Uncle Ted tiles three terraces. Here are the tiles he uses.</p>  <ul style="list-style-type: none"> <li>Help uncle Ted in his work and draw your propositions for the tiling. Check different possibilities. Write under every proposition the number of used tiles.</li> <li>Try to tile the following terraces by using the tiles of uncle Ted.</li> <li>Count and write how many tiles you used for every terrace. Do you notice any changes? Which ones?</li> </ul>
<p><b>Task 2: Fish</b></p> <p>Je rybek można pokolorować trzema kolorami tak, aby każde było inne?</p> <p>Mam trzy kolory: zielony, pomarańczowy, niebieski.</p>  <p>How many fish can you colour by three colours so that every fish is different? You have three colours: green, orange and blue.</p>	<p><b>Task 7: Caterpillar</b></p> <p>You choose two numbers less than 100. Each successive number is the sum of the previous two. For example:</p>  <p>Try to make a 5-part caterpillar with 100 as the last number.</p> 
<p><b>Task 6: The parrot Waku-Waku</b></p>  <p>This is a talking parrot; his name is Waku-Waku. Unfortunately, he can say only one word: five. You want to show your friends how clever parrot you have. Ask him some questions, for which the answer is “five”.</p>	

Table 1: Five of the given tasks

Our a priori analysis of the tasks initiated by identifying the mathematical concepts and processes involved in the tasks' solutions as anticipated by us and, wherever applicable, by the original task designers. The mathematical fields contained in the tasks correspond to those included in the Polish curriculum for the particular age group. All tasks contained a written description, but in our a priori analysis we also analysed the role of the accompanying images, according to van den Heuvel-Panhuizen's (2005) pictures' functions: motivator (M: making the task more attractive), situation describer (S: describing the context of the task), information provider (I: providing necessary information), action indicator (A: an action is elicited that has the potential of a strategy that leads to a solution), model supplier (MS: the picture structuring possibilities that can be used to solve the problem), and solution and solution-strategy communicator (SC: the picture contains the solution and aspects of the applied strategies). The analysis of the tasks' contexts was based on de Lange's (1999) assessment framework: zero-order (0): fake context, not considered for the solution (to this category we also inserted mathematical contexts, e.g. Task 5, which will be analysed later); first-order (1): relevant context, needed for the solution; second-order (2): relevant context, mathematisation needed for the solution; third-order (3): the context serves for constructing or reinventing mathematical

concepts. Finally, each task was categorised as open or closed. As shown in Table 2, all tasks but one were open.

Task	Field	Concepts	Image	Context	Type
1	set theory	categorisation	I	1	open
2	combinatorics	combinations	I	0	closed
3	geometry & arithmetic	dimensions, shapes, areas, multiplication & properties	S & MS	2	open
4	geometry & combinatorics	areas, tiling, combinations	I & A	2	open
5	arithmetic	addition & properties	I	0	open
6	arithmetic & algebra	numbers, operations, equations	M	0	open
7	arithmetic	addition, subtraction & properties	I	0	open

**Table 2: Task characteristics**

### A posteriori analysis of the tasks

In our a posteriori analysis, we focused on the interactions that took place among the students and the researcher, during the research session. For this analysis we have adopted Lannin, Ellis and Elliot's (2011) manifestations of essential understandings related to mathematical reasoning: developing conjectures, generalizing to identify commonalities, generalizing by application, conjecturing and generalizing using terms, symbols, and representations, investigating why, justifying based on already-understood ideas, refuting a statement as false, justifying and refuting the validity of arguments and validating justifications. To these we added: reformulating conjectures or justifications, monitoring each other (a form of collaborative reasoning), concluding and explaining (a form of informal justification). After identifying the above understandings, we made a cross-analysis of all tasks, in order to identify commonalities and differences among them.

### Results

As we see in Table 3, the reasoning processes which persevered were: developing conjectures and reformulating conjectures or justifications.

	Reasoning processes / Tasks	1	2	3	4	5	6	7
R1	developing conjectures		Ü		Ü	Ü		Ü
R2	identifying commonalities	Ü					Ü	
R3	generalizing by application					Ü		
R4	investigating why		Ü					Ü
R5	justifying based on already-understood ideas		Ü	Ü	Ü			
R6	refuting a statement as false				Ü	Ü		Ü
R7	justifying and refuting the validity of arguments					Ü		
R8	validating justifications					Ü		
R9	reformulating conjectures or justifications		Ü	Ü		Ü		Ü
R10	monitoring each other				Ü	Ü		Ü
R11	concluding							Ü
R12	explaining	Ü				Ü	Ü	

**Table 3: Tasks and reasoning processes**

Next, we present the analyses of Tasks 3 and 5; these tasks are chosen because they demonstrate the range of reasoning processes that we have encountered.

**Figure 1: Task 3 and Task 5, containing students' work**

### Task 3: Christmas baubles

In Figure 1, on the left, we read: “Design different boxes in which you can put 12 Christmas baubles in such a way that every bauble is in one compartment.” The mathematical concepts come from geometry (shapes, dimensions, area) as well as arithmetic (numbers and multiplication); we anticipated that students will shift from the geometrical representation of the problem to an arithmetic one. The image of the grid can be categorised as a situation describer and a model supplier. The students – signified by A and M, while R stands for the researcher (the first author of the paper) – started by drawing a  $4 \times 6$  rectangle on the grid and placing their drawn baubles in every second compartment. Initially, it was hard for them to imagine how the baubles can be arranged. Later, they discovered that the box they designed can contain more baubles than they thought, and they justified it. However, they were not able to use this knowledge for the design of boxes of different sizes; they were more focused on the shape, the colours and the sizes of the baubles. In the following excerpts our notes are in brackets and (...) signifies an omitted part of the discussion. The number(s) of the reasoning processes (as they appear in Table 3) are put in brackets at the end of the respective lines.

R: Could we put more baubles to this box? [the box on the right edge of the grid]. For example, could we put one more bauble?

A: I guess not.

R: If I had one more bauble and I would tell you: girls, put that bauble to your box...

M: I would pack it in such a square. (...)

R: (...) then how many could we pack here?

A [immediately]: More, 24.

R: How do you know that 24? You didn't count.

A: Because there are 12 baubles and 12 empty places. [R5]

R: And how do you know that there are 12 empty places?

A: Because here in the 4 squares there are 4 places and in 2 of them there are baubles and those 2 are left. And in the same way you can count to the bottom so it will be 24. [R9]

M: Or  $4 \times 6$  [showing the dimensions of the rectangle]. (...) [R9]

R: Are those boxes different? [showing the four boxes drawn on the grid]

A: Uhm.

R: By what? [A and M thinking]

A: Here are bigger baubles [the second and third box] and here smaller [the first box].

M: And these are medium ones [the fourth box].

During the whole interaction only two aspects of mathematical reasoning were manifested: justification and reformulating the justification. The students eventually discovered different arrangements of the baubles (in different boxes) but they could not find any relations between them, neither geometric nor arithmetic.

### Task 5: Magic squares

In Figure 1, on the right, we read: “Complete the empty fields so that the sum of the numbers in rows and columns is 20”; and then: “Try to create a similar table for your friend or somebody from your family”. The main mathematical concept is addition and its properties: identity, commutative and associative. The images of the task are information providers. An extensive analysis of the students’ interactions (Maj-Tatsis & Tatsis, 2015) has led to the following understandings related to mathematical reasoning: developing conjectures, generalizing by application, refuting a statement as false, justifying and refuting the validity of arguments, validating justifications, reformulating conjectures, monitoring each other and explaining. Thus, this task has proved fruitful for mathematical reasoning among our students. In the following excerpt the students have completed working on the first magic square and are discussing on the second. It is interesting that student M started filling the square by number 9 (which means that then one has to put 0 in the third square) which was the extreme case in the first square, and it took them some time to accept it.

M: Here for example 8 [in the centre] and put 1 here [above 8] [R1]

R: Aha (...) What if here we put 7 [in the centre], then what will be here? [above]

M: 2

R: And what if 6?

A & M: [loudly] 3!

R: How do you know it’s 3?

A: Because when it was 7 then it was 2. And if we decrease it more then it will be 3. [R1, R12]

R: What if we put 5?

M: Then 4 (...)

R: What’s the biggest number we can put in the centre? (...)

M: For me 9, because  $10+11$  would be already 21. [R1, R7]

The differences between this task and the Christmas baubles task lie not only in the extent of reasoning processes, but also in their depth. Although in this task the students were able to articulate, justify and validate mathematical conjectures in order to support their mathematical reasoning, in the baubles task they did not manage to cross the boundaries between arithmetic and geometry; this has resulted in limited opportunities for extensive mathematical reasoning.

### **Cross-analysis of the tasks**

We have seen the greatest extent of reasoning processes in Tasks 5 and 7 (followed by Tasks 2 and 4), while Tasks 1, 3 and 6 proved the poorest concerning the manifested reasoning processes by the students. The common characteristic of Tasks 1 and 6 is that they both required the identification of commonalities and explanations; furthermore, the students' interactions have shown that there was no explicit need for justification or generalisation. Tasks 5 and 7 were similar concerning the mathematical concepts involved (addition and its properties); additionally, they were both open, but with a finite number of solutions (unlike Task 6). At the same time, the only task with a single solution (Task 2) allowed for a considerable extent of mathematical reasoning; this was probably due to the many ways of solution. Task 3 was the one that demonstrated the influence of context: the students were engaged in a non-mathematical investigation concerning the size and the type of baubles, which in turn minimised the reasoning processes and hindered a thorough investigation of the task. It might be also the influence of the geometrical nature of the task that had created obstacles in its generalisation.

### **Discussion**

The fact that reasoning processes were manifested in all tasks goes in line with relevant studies of the "Early Algebra" movement and strengthens the claim that students at a young age are able to reason mathematically. The variety of our tasks has proved that young students, even with a minimum help, can develop, justify, validate and refute mathematical conjectures.

Our main research question was what are the characteristics of the tasks which promote mathematical reasoning. Firstly, we have not seen any influence of the images that accompanied the tasks; however, we have seen that context might move students away from reasoning (Task 3). Some tasks have proven more fruitful than others concerning the reasoning processes they evoked. It seems that open tasks do not pose any difficulties to the students, when they have a finite number of solutions (Tasks 5, 7). The same is the case with closed tasks that can be solved in many different ways (Task 2). On the contrary, our students experienced difficulties when faced with a task that required a shift from geometrical structures to numerical ones (Task 3). At the same time, they manifested a variety of reasoning processes during another geometrical task (Task 4), which did not require an explicit shift to numerical properties. Based on all the above, although our exploratory study has not led to conclusive results, we believe that it may assist the design of mathematical tasks aiming to promote reasoning among young students.

# Exploring how primary teacher education prepares pre-service teachers to teach early years Mathematics

Justina Longwe Mandala

University of Malawi, Chancellor College, Malawi; [jlongwe@cc.ac.mw](mailto:jlongwe@cc.ac.mw)

*Keywords: Teacher education, Malawi, early years mathematics, pre-service teachers.*

## Introduction

Learner underachievement in mathematics still remains an issue of concern in primary schools in Malawi. Analysis of Early Grade Mathematics Assessment (EGMA) indicates that learners in the early grades continue to perform poorly and experience mathematics as memorization of facts and procedures to determine the correct answer to questions, instead of experiencing it as a meaningful, sense-making, problem-solving activity (MTPDS, 2010). This may mean that the teaching of mathematics in early years is not being effective. Teachers tend to approach mathematics as facts that need to be learned through practice and speed drill (Boaler, 2016). This approach to teaching mathematics to beginning learners raises questions on how teachers are trained to teach mathematics in early years, bearing in mind that pre-service teacher education is the principal source of teacher knowledge (Shulman, 1986). Ball & Forzani (2011) recognize that there are different factors that affect educational outcomes, such as curriculum, assessment, parents; however, they argue that learner success basically depends on skilful teaching which is largely a result of well trained teachers. They claim that if teachers fail to help learners learn, it is possibly because, among other reasons, they do not receive enough preparation during training. Scherrf & Singer (2012) argue that pre-service teachers enter training programs with their own perspectives of mathematics teaching from their learning experiences. Thus, their pre-service training should help them refine their perspectives. If they receive insufficient preparation, they may likely be compelled to teach according to their own experiences of learning.

In Malawi, to the best of my knowledge, research is silent on preparation of pre-service teachers to handle mathematics in early years. It is against this gap in knowledge that this study seeks to gain an understanding of how primary teacher education prepares pre-service teachers to teach mathematics in early years, which include standards (grades) 1 to 4. The study seeks to answer the following question: How does primary teacher education prepare pre-service teachers to teach early years mathematics? And the following are the specific questions: What examples, tasks and explanations do mathematics teacher educators use when teaching the concept of number and operations to student teachers? How do mathematics teacher educators involve student teachers in their lessons on early years mathematics? How do student teachers use knowledge obtained from teacher training to teach mathematics in early years during teaching practice?

## Theoretical framework

The study is guided by Adler & Ronda's (2015) Mathematical Discourse in Instruction (MDI) framework. MDI is theoretically grounded in the sociocultural theories and empirically grounded in mathematics teaching practices. The framework was chosen because it specifically targets mathematics teaching practices and constitutes interrelated elements that are encouraged in

mathematics teacher education, which include object of learning, exemplification, explanatory talk and learner participation. The study focuses on how mathematics teacher educators encourage the use of these elements as they teach pre-service teachers.

## Research Methodology

This is a qualitative case study in which 4 mathematics teacher educators from one public teacher training college will be observed teaching and then interviewed. Pre-service teachers practicing their teaching in any 4 teaching practice schools belonging to the participating college will be involved in focus group discussions. Document analysis on mathematics schemes of work, lesson notes, lecturers' and students' handbooks will be done to supplement information on where teacher educators get examples and tasks. Participants were purposively sampled based on mathematics teaching experience at college level for teacher educators and accessibility for teaching practice schools. FGD participants are all student teachers teaching mathematics in lower classes in the sample schools. Data will be analyzed thematically. Transcribed data will be read carefully, coded, and then sorted into potential themes.

## Piloting

Piloting was done on one mathematics teacher educator. Preliminary pilot results show that in terms of exemplification, mostly, one or two examples were used in the lessons. In all the lessons, there was more emphasis on what resources to use when teaching a concept. In student participation, student teachers were invited to participate by mostly answering yes/no questions, finishing teacher's sentences, group discussions, and demonstrating how an activity is done.

## Acknowledgement

# Preschool children's understanding of length and area measurement in Japan

Nanae Matsuo<sup>1</sup> and Nagisa Nakawa<sup>2</sup>

<sup>1</sup>Chiba University, Faculty of Education, Chiba, Japan; [matsuo@faculty.chiba-u.jp](mailto:matsuo@faculty.chiba-u.jp)

<sup>2</sup>Kanto-gakuin University, Japan; [nagisa@kanto-gakuin.ac.jp](mailto:nagisa@kanto-gakuin.ac.jp)

*This study assesses preschool children's understanding of length and area measurement through the activities of a mathematics program in Japan. Japanese preschool children do not formally learn mathematics; thus, we designed mathematical measurement activities for young, less-experienced preschool teachers to implement for nine five- to six-year-old children. We conducted structured clinical interviews with the children individually, both before and after the measurement activities, and qualitatively analyzed the results by comparing their answers and connecting them to the activity contents. Results indicate that children learn to understand direct comparison through activities; however, it is more difficult to establish understanding of measurement by non-universal units.*

*Keywords: Preschool children, mathematical activity, length measurement, area measurement*

## Research on measurement in preschool

Much of the current research focuses on elementary mathematics education for preschool children and younger elementary school students (e.g., Brandt, 2013); however, measurement has not been sufficiently included in these studies (Sarama, Clements, Barrett, Van Dine, & McDonel, 2011; Smith, van den Heuvel-Panhuizen, & Teppo, 2011), even though it is an important real-world area of mathematics used in everyday life. In addition, Hachey (2013) states that mathematical conceptual change in young children is as effective as a substantial change in early childhood mathematical teaching practice, as a large body of developmental research advocates that young children are born mathematicians, and therefore, early childhood mathematics education is vital.

It is known that the development of children's understanding is related to foundational or key ideas of measurement such as comparison, unit iteration, number assignment, and proportionality (Lehrer, Jaslow, & Curtis, 2003; Wilson & Osborne, 1992), and several kinds of teaching methods for measurement have been developed (Battista, 2006; Kamii, 2006). Although Piaget (1968) assumed that children up to seven years old are unable to consider more than one stimulus dimension in their judgments, subsequent research has demonstrated that preschoolers can consider two dimensions; for example, they can consider the width and length of rectangles to estimate their area (Wilkening, 1979). Further, Ebersbach (2009) addressed the question of whether children can also take three stimulus dimensions into account and showed that preschoolers have the cognitive competencies required for multidimensional reasoning. There have also been numerous other important studies on preschool children's understanding of measurement. Sarama et al. (2011) proposed a learning trajectory for length and area in the early years and evaluated it. Zöllner and Benz (2013) concluded that four- to six-year-old children could compare directly and indirectly, but cannot measure using a non-standardized unit. Tzekaki (2017) indicated that a seven-month intervention helped preschoolers improve their abilities to reflect on their own activities and express their ideas regarding measurement. Skoumpourdi (2015) verified that preschoolers do have some strategies for length

measurement, but confuse the concept of length with perimeter and area. Finally, Kotsopoulos (2015) showed that a free exploration approach in the context of a play-based learning environment is more effective in teaching length measurement than guided instruction and center-based learning.

This article examines whether preschool children can improve their understanding of length and area measurement, especially direct and indirect measurement, as well as measurement by non-universal units. It does so with an elementary mathematics play-based program, which can even be implemented by young, less-experienced teachers who have not been trained in mathematics instruction, thereby fostering children's understanding of measurement. These play-based activities are intended as a further contribution to the existing research. The article also seeks to explain the specific reasons the program is effective. First, we compare pre- and post-interview results for five- to six-year-old children. Next, we intentionally choose two children with different degrees of change between their pre- and post-interview results. Finally, we discuss the reason the change occurred, scrutinizing each child's actions and attitude during the activities, as well as his/her post-interview.

## **The early childhood mathematics program in Japan**

Elsewhere, we have proposed a framework for constructing an early childhood mathematical curriculum (Matsuo, 2016). The theoretical and methodological underpinnings of our program are social constructivism (Ernest, 1994), mathematical guided-play (Weisberg et al., 2013), and the Structure of the Observed Learning Outcome (SOLO) taxonomy (Biggs, 1982). This program presents a scope for the content of preschoolers' activities, while the learning process of those activities are explained from the viewpoint of sequence, based on the relationship between age and modes of representation and focusing on activities for five- to six-year-old children to create a program tailored to these concerns. Based on this framework, we have proposed a mathematical education program to enable a smooth transition from preschool to elementary school mathematical education (Matsuo, 2017). Less-experienced preschool teachers should be able to use these activities to better incorporate mathematical content into children's play and recognize activities that will make children think and act mathematically. This practical program was designed for preschools and elementary schools.

## **Methodology**

### **Research participants**

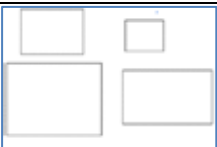

The preschool kindergarten in an urban area of Kanagawa Prefecture of Japan participated in our pilot study. This article focuses on nine five- to six-year-old children in the oldest classes. The children are all Japanese, coming from middle- and upper-middle-class families in Japan. There were six boys and three girls. The school's focus was on physical activities, as well as entrance to candidate schools for the International Baccalaureate (IB). Children started to learn Japanese letters and English to prepare themselves for primary education in September 2017.

The oldest classes of the preschool had two teachers: Teacher A, a male teacher with three years of experience teaching preschool, and Teacher B, a female teacher with two years of experience teaching preschool. Teacher A taught the first three sessions of measurement activities in the first cycle of the program and Teacher B taught the latter three sessions in the second cycle. For the analysis, we intentionally chose two children, T1 and T7, based on the results of pre- and post- interviews, to

intensively examine their outcomes and learning processes, as well as to determine the relations between the interview results, their actions, and the detailed observations of the teachers during the activities. T1 was actively engaged in the activities, but provided incorrect answers in the post-interview. T7 was not actively engaged in the activities, but made correct observations and provided correct answers in the post-interview. To compare the two children's understanding, we discuss the level of understanding of direct and indirect measurement, as well as measurement with non-universal units, in connection with the young teachers' instruction.

### Data collection and analysis

In the project, we developed six play-based activities related to numbers, measurement, and shapes. Among these activities, we carefully chose those that were better tailored to relate to numbers, shapes, and measurements, things that are necessary for our curriculum to focus on and develop. To evaluate the improvement of children's mathematical skills after these activities, we developed pre- and post-interview questions. Pre-interviews were conducted in June 2017 and all six activities were implemented twice; therefore, twelve activities were implemented after the pre-interview. After all activities had been completed, a post-interview was conducted with each child in February 2018. Sixteen questions were developed for the pre-/post-interviews, corresponding with the planned activities and previous research by the author (Matsuo, 2016), as well as the SOLO taxonomy. Four of the sixteen questions were in the area of measurement, as shown in Table 1.

Q12	Prepare four different pencils, each of a different length, as shown in the diagram, and ask, "Which do you think is the longest pencil of the four? And tell me the order of the length, from longest to shortest."	
Q13	Show four different pencils, each of slightly different length as shown in the diagram, and ask, "Which do you think is the longest pencil of the four? And tell me the order of the length, from longest to shortest."	
Q14	Prepare four different rectangles as shown in the diagram, and ask, "What do you think is the biggest rectangle of the four? And tell me the order of the area, from biggest to smallest."	
Q15	Prepare four different rectangles as shown in the diagram, and ask, "What do you think is the biggest rectangle of the four? And tell me the order of the area, from biggest to smallest."	

**Table 1: Description of the interview questions and the problem contexts**

Methodologically, the authors conducted structured clinical interviews (Goldin, 1998). To alleviate children's anxiety, the teachers conducted the interview themselves, while one of the authors sat next to the child to record. The assigned teachers rehearsed the interviews to be consistent with mathematical words and expressions. During the implementation, each child came to the room randomly and the teacher sat in front of the child. The pre-interviews took fifteen to twenty-five

minutes, and the post-interviews took ten to fifteen minutes. During the interview, the children could use a ruler, transparent paper, grid paper, and clips to answer questions 12 to 15. The results were qualitatively analyzed.

### Description of measurement activities in the intervention

Teacher A taught the children the first course in how to measure the length of something carefully using clips as non-universal units. They measured assorted items by connecting clips (e.g., measuring the edge of the desk, the mat, the height of the teacher). Teacher B taught the second course, in which the children tried to connect eight clips in order to use them to measure shorter objects than the ones measured in the first course. After the children used the connected clips to measure a building block or a box, the teacher asked the children to find objects with lengths equivalent to eight clips. Next, they looked for objects with lengths equivalent to sixteen clips. They lined up sixteen red magnets and set out to measure them using the clips.

In the area measurement activity, the children employed indirect comparison and measured using non-universal units, such as length measurement. The activity was implemented like a code-breaking game, and when the code was solved, figures whose areas were objects for measurement were supposed to be arranged in descending order. A teacher directed the children to count the square grids covered in rectangular paper to measure the total area. First, the children copied the target onto plain paper, put this paper on grid paper, and counted the number of squares as non-universal units. The sizes of the three kinds of rectangles (thirty-two, forty, and forty-eight squares) were relatively large, and the children had been actively counting quite carefully. Finally, the paper with a number written on it was matched with a corresponding letter, which enabled them to solve the code. Letters with meaning were arranged in order so that the numbers became larger.

### Results and Discussion

Table 2 shows that there is not a significant difference of the correctness toward questions between length and area measurement.

Child No.	Gender	Birthday	Q12		Q13		Q14		Q15	
			Pre	Post	Pre	Post	Pre	Post	Pre	Post
T1	F	MAY	1	1	0	0	1	1	1	0
T2	M	JULY	1	1	1	1	1	1	1	1
T3	M	NOVEMBER	1	1	0	1	1	1	0	1
T4	F	NOVEMBER	1	1	0	1	1	1	0	1
T5	F	AUGUST	1	1	1	0	1	1	1	0
T6	M	JUNE	1	1	0	1	1	1	1	0
T7	M	DECEMBER	0	1	0	1	0	1	0	1
T9	M	JULY	1	1	1	1	1	1	0	1

**Table 2: Pre- and post-interview results for measurement of length and area**

\* 1 means correct, 0 means incorrect

Looking at the transition of the results from the pre- to post-interview, problems whose answers are incorrect in both pre- and post-interview cannot be seen except for T1. In the case of Q12 and Q14,

children got the correct answers in the pre- and post-interview, excluding T7. Since the edges of some part of the figures in these problems are aligned, it is possible to judge the difference in size from the difference in other parts by visual observation. Children were thought to be mature, developable, and able to maintain natural demeanor. Regarding Q13 and Q15, about half of the children answered correctly in the pre-interview, but they had incorrect answers in the post-interview. T2 had correct answers for everything both pre- and post-interviews. T9 also had correct answers, except for Q15, in the pre-interview. T8, who was absent from the length and area measurement activity of the second course, was excluded from analysis.

### **Comprehensive analysis of eight children's understanding of measurement**

Table 2 indicates that every child understood direct measurement in Q12 and Q14 in the post-interview, though in Q13 and Q15, a few children did not understand indirect measurement nor measurement by non-universal units. An erroneous view prevails that the area measurement is harder to understand than length measurement, as the number of dimensions is higher. As Ebersbach (2009) stated, not only length and area but also volume can be estimated by a young child, and the rate of correct answers does not change much between children and adults. It is possible for preschoolers to tackle activities that are not limited to length, area, and volume measurement, as we inferred from the results of our survey; however, even though children were working well on the measurement activities, most of them gave incorrect answers for area measurement.

T3, T4, and T7 answered incorrectly in the pre-interview but correctly in the post-interview for Q13 and Q15. Although they answered visually for Q13 and Q15, they were correct. We infer the program implemented had a positive effect, especially because the measurement using non-universal units is not commonly done at home or in preschools. While there were scenes in which they could not be regarded as proactively working on the program activities, in many cases, it is mentioned that they were working on collaborative and individual work well and could observe other subjects' behavior.

Conversely, T1, T5, and T6 had incorrect answers in the post-interview even if they were correct in the pre-interview, revealing that the influence exerted by the activities of the mathematics program are strongly related to this fact. Let us consider why they did not have correct answers for Q15, even if they were trying to answer based on measurements in non-universal units using tools and enjoyed it in the post-interview. It is probably because children could not distinguish between the measurement of length and area and did not associate the numerical value measured in non-universal units with the results of the comparison of length and area, or because they could not understand the meaning of the work and retain this understanding even if they acquired skills related to measurement. This can be judged from the state of the post-interview.

### **Qualitative analysis for two children who had different results and processes of playing**

We will now compare and examine the results of two children, T7 and T1, their post-interview responses, and the teacher's findings regarding them in Table 3.

T1 was engaged in acting as a group leader in length measurement. After the clip-connecting activity, she was looking for various items to measure, like building blocks, etc. She was highly interested in the length-measurement activity. Further, in the area-measurement activity, she actively worked on counting. She did the measurement work again, but her answer was not correct. She did not seem to have an opportunity to objectively review the meaning of the work after she had concentrated on it.

It can be surmised that because the meaning of the work was unclear, she confused length and area. The result of this study is consistent with previous studies (e.g., Skoumpourdi, 2015). The length and the area are different in dimension, and in daily life, for a child, the length comparison is familiar and more understandable than the area comparison.

T1	Q12	She replied visually, pointing with her finger.
	Q13	She took the fine-grid tracing paper, and after a little measuring, she answered, "Oh, I understood it."
	Q14	She replied visually.
	Q15	She laughed and took the clips first, and asked, "Can I measure them sideways?" She joined the clips, measured the length of the rectangle sideways, adjusting the length of the joined clips. Next, using the tracing sheet (with a grid), she aligned the edges and measured the length of the rectangle.
	Post-test state	She said, "I was looking forward to it today," and "It's fun to find different lengths in measuring activities."
	Teachers' findings	She is not good at detailed work. She is good at drawing. She loves playing football and moving her body. She would rather move her body than sit and work. She is interested in the alphabet.
T7	Q12	He pointed in a sequential order visually.
	Q13	He pointed in the descending order visually and quickly without using tools.
	Q14	He pointed in the descending order visually and quickly.
	Q15	He pointed in the descending order visually and quickly.
	Post-test state	He worked silently. He did not use any tools at all in the measurement, and answered quickly and visually. He enjoyed the math activities and especially enjoyed using the clips to measure the room. He did not seem to be an noteworthy type.
	Teachers' findings	He is good at fine work and studying. Currently, he is learning division and fractions progressively. He is shy and not good at speaking in front of people.

**Table 3: Results of T1 and T7 for Q12-15, post-interview results and teachers' findings**

Conversely, T7 did not do much work and wandered around. He did not work as actively as the other children, though he observed the other children's activities well. During area measurement, everyone was absorbed in drawing figures and counting the squares, while he also worked and looked around. It is highly likely that his reply was affected by this behavior. As a result, T7 who did not actively work, gave the correct answer by visual observation. It can be inferred that this is due to the child's rich sense of length and area, fostered during the activities (Schoenfeld, 2016). Through these activities, it seems that the sense of long/short, wide/narrow is more sharpened. Preschool children may not have this vocabulary, but instead use "big" or "small" to express differences in quantity. Since children who observed better than doing their own work seemed to grasp the size correctly by visual observation in the post-interview, rather than just doing work, by sharing the work process of early mathematical activities, it can be said that the sense of quantity has been enhanced.

Further, even when it seems that a child is not actively working on a problem, or appears not to be thinking too much, we must accept the fact that the child considers silently and may still answer correctly. According to Shinohara (1942), since observation is an educationally effective activity, like experiments, it is important for children to observe others' behavior and imitate it. In the case of

young children, it is often difficult for them to express in words; therefore, it is important for the teacher to observe the situation and guess from the usual activities or the activities with other children. From the countereffect by the program, it appears that by depending on teachers' questioning, summary, etc., children concentrate on the work without thinking about its meaning.

## Conclusion

Children in this study showed different outcomes of learning in measurement. The children continued to understand direct comparison in all activities; however, it was difficult to establish understanding of measurement by non-universal units. The intervention activities seemed to affect their learning outcomes, although we only focused on how two children's actions related to their interview results. Play-based activities offered by the young teachers influenced children's understanding in both positive and negative ways. This suggests that play-based activities are effective, but should be meaningful and substantial mathematical activities, not superficial. This study only analyzed a small number of children's understanding of measurement, and therefore cannot be generalized further. Future research should analyze a larger number of children.

# The use of structure as a matter of language

Lara Müller<sup>1</sup> and Kerstin Tiedemann<sup>1</sup>

<sup>1</sup> Bielefeld University, Bielefeld, Faculty of Mathematics, Germany; [lara.mueller@uni-bielefeld.de](mailto:lara.mueller@uni-bielefeld.de);

*Keywords: Subitizing, use of structure, language.*

## Introduction

Recent research shows that structure plays an important role for the arithmetical development and the development of number sense (Lüken, 2012; van Nes, 2009). In this context, using structure for identifying the cardinality of a set of objects is a main achievement of children's competence in the early years (Clements, 1999; Schöner & Benz, 2018). The ongoing study presented in this poster focuses on language to foster children's structure abilities. The aim is to explore which language children (can) use to talk about structures when determining the cardinality of sets.

## Theoretical Background

The use of structure to determine the cardinality of a set of objects is defined as *conceptual subitizing* (Clements, 1999; Sarama & Clements, 2009). Structuring a set of concrete objects into subsets which can be determined easily and used to determine the cardinality of the whole set of objects is an important mathematical ability and should be learned and fostered during the early years (Clements, 1999). In a recent study Schöner and Benz outline that many children aged between 5 and 6, who are able to perceive and use structure to determine the cardinality of a set, "often lack the words to describe their constructions and approaches" (2018, p. 141). The most common way to describe their approaches is counting (Schöner & Benz, 2018). It seems like children are missing language to describe structure and their use of it. In order to be able to foster conceptual subitizing in the everyday interaction in kindergarten, we want to explore which language children (can) use to talk about structures in sets of objects and their use of this structures when determining the cardinality of sets. This is an important issue, because language and communication play an important role in the learning process of children. Communicating about mathematical concepts can foster the insight into the abstract mathematical notion (Maier & Schweiger, 1999). Furthermore communication can facilitate a deeper reflection on the mathematical structures and structures that may still be implicit can become explicit (Maier & Schweiger, 1999). Thus, talking about structures in sets of objects possibly helps children to interpret numbers as wholes which can be composed to larger wholes.

In order to analyze the specific language requirements for describing the process of conceptual subitizing, we refer to Sfard's (2008) approach of reification. With a view to mathematical discourses, she distinguishes between two types of discursive entities: mathematical processes and mathematical objects. According to Sfard (2008, p. 47), mathematical objects can be understood as reified processes: In a discursive transformation mathematical processes can be reified into mathematical objects. We can use this approach for analyzing how children describe structures in sets of objects and their use of this structures. Thus, one example of the distinction between processes and objects is that of natural number. We can talk about numbers by talking about the process of counting (e.g. "one, two, three,...") or we can talk about numbers as static objects which can be manipulated as

wholes in new processes (e.g. “four times three”) (Sfard, 1991, 2008). In terms of determining a set of concrete objects the *talk about numbers as objects* is prerequisite for describing conceptual subitizing. Children who subdivide the whole set in structured subsets which can be recognized and manipulated as wholes (e.g. *three* and *four*) and composed to a larger whole (e.g. *seven*) need a specific kind of language: In order to describe conceptual subitizing in discourse, they need *language for talking about numbers (subsets) as objects* and *language for the new process “linking”*. Thus, they talk about numbers as objects which can be used and manipulated in a new process.

## Method

This theoretical analysis of the language requirements leads to two distinct questions:

*How do children talk about objects and processes while they determine the cardinality of a set of objects? How do children adopt ways of describing from the discourse with an adult?*

To answer this questions, preschoolers, aged 5 to 6, will be interviewed individually. The interview will be divided in to two parts: At the beginning of the interview, the child will constantly be encouraged to describe his or her process of determining the cardinality of a set of concrete objects. Depending on the child’s talk about the objects and processes, the interviewer will make adaptive offers of language.

# Children's use of mathematical language

Beate Nergård

Queen Maud University College of Early Childhood Education, Trondheim, Norway;

[bne@dmmh.no](mailto:bne@dmmh.no)

*Sixteen assemblies in a Norwegian kindergarten have been studied to identify characteristics pointing to when and how 5-year-old children use mathematical language when expressing their thoughts. When participating in an assembly the children are in a situated social context where communication is an important part of the context. The analysis shows that children use mathematical language when they compare, explain and argue. This paper links the way children use mathematical language in interaction with others through verbal language, body language and body movements.*

*Keywords: Kindergarten, Mathematical language, Comparing, Explaining.*

## Introduction

In all mathematical activities and play, language and the use of concepts are an important part of learning (Riccomini, Smith, Hughes, & Fries, 2015). According to Clements (2001), we may look at mathematics as a language based on structure and logic, where rich interaction with mathematical concepts is important for the development of children's mathematical knowledge (Purpura, Napoli, Wehrspann, & Gold, 2016). Even though research shows connections between children's linguistic understanding and their mathematical achievements, the causal relationship between mathematical language and mathematical knowledge has not been fully investigated (Purpura et al., 2016). By examining patterns in dialogues and interactions between adults and children it may be possible to gain a better understanding of which linguistic elements are important for the child's mathematical thinking and understanding (Trawick-Smith, Swaminathan, & Liu, 2016).

Children's development of mathematical vocabulary cannot be ignored as it is of great importance for their further learning of mathematics in school (Monroe & Orme, 2002). The article will focus on the use of mathematical language in a kindergarten. The study, exploring the use of mathematical language, is relevant both in relation to the increasing interest in the learning aspect and the increasing focus on language and mathematics in Nordic kindergartens (Hammer, 2012).

To contribute to the discussion about mathematics and the place of mathematical language in Norwegian kindergarten this article has the following research question: How do some five-year-olds use mathematical language when they express their thoughts about natural phenomena?

The research methods involved studying 16 assemblies in a Norwegian kindergarten. The Nordic kindergarten tradition is placed in what the OECD (2006) calls a "social pedagogical tradition", with a broad and open view of learning where children are seen to learn by playing and through their everyday activities. An activity which is often a regular feature in the kindergarten is the assembly. Assemblies in a Norwegian kindergarten involve typically 12 – 32 children. One characteristic of the assembly tradition is that it is organised and planned in advance by the adults and is probably the most structured and adult-led activity in the kindergarten. Children and adults come together to take

part in various activities focusing on a topic for the assembly. Assembly may be considered a social situated practice where learning can take place. This then is a particular, pedagogic and social context where the child uses language as a tool in interaction with others to explain and find words for his or her thoughts.

## **Mathematics in the kindergarten**

Bishop (1989) divides children's experience with mathematics into six fundamental mathematical activities: 1) explanation, 2) locating, 3) measuring, 4) counting, 5) design and 6) playing. He states that these mathematical activities are independent of culture and are reflected in children's everyday lives. Bishop (1989) claims that the number of activities is not important. What is important is how these six mathematical activities might help us gain a broader and more nuanced perception of what mathematics is and can be for children in kindergarten (Bishop, 1989).

Counting and measuring are both related to numbers, but in different ways. Counting relates to the perception of numbers and ways of determining numbers, while measuring refers to describing a magnitude by means of a system of numbers. In kindergarten, children gain experiences of counting using numerals, they count and experience that the numerals describe different amounts, where language becomes a tool for explaining how much of something they have. When measuring, children use numbers to compare and when put things in order to indicate how much there is of something or how big something is. When children measure, the need arises to sort things so that they can compare the objects they measure to find similarities and differences in their magnitudes rather than in their attributes.

According to Bishop (1989), locating and design are two important ways of developing mathematical thoughts based on the need to order space. Locating refers to the ability to describe where objects are placed in space, while design is about describing the form of a shape or how it is created. Bishop states that locating is a description of how several objects are placed in relation to each other and refers to how the children use language to say something about direction and placement, to orient themselves and to find their way in the three-dimensional space they are in. Design basically refers to the language children use to describe the characteristics of an object independent of location.

Explanation is used by children to express their experiences through language and action, while playing are the methods or activities through which children may experience mathematics. Bishop maintains that while counting, measuring, locating and design are related to our physical environment, play and explanation are also connected to our social environment. Through explanation and argumentation the child is challenged to give grounds and explain, find words for thoughts and tell about his or her reasoning. The child's power of explanation depends on his or her linguistic ability to express logical conclusions (Bishop, 1989).

## **Mathematics and language**

Children who do not master the mathematical language or understand the mathematical concepts may experience that they do not understand the mathematics required of them when they enter school. Mathematical language is used to describe structures, and language plays an important part when children develop their understanding of mathematical concepts. In mathematics, a mathematical

language is a verbal and written linguistic expression, body language, such as looks, gestures and movements, and also characters, words and number symbols (Clements, Baroody, & Sarama, 2014). Understanding a concept is nevertheless much more than merely recognising the word designating the concept. The children need to hear the word used in different contexts and with different meanings, and to understand not only the concept but also the changed meaning of the particular word. Understanding mathematical vocabulary allows children to understand the meaning of mathematical discussions with others as well within instructional learning activities (Purpura et al., 2016).

There are two specific aspects of mathematical language which turn out to have an important role in early learning of mathematics: quantitative language and spatial language. Quantitative language, referring to amounts includes concepts such as fewer, less than, more than and many. Understanding quantitative concepts helps children to make and describe comparisons between numbers and amounts. The magnitude of amounts (cardinality) and order of numbers (ordinality) comprises a language which may be particularly difficult for many, as teaching often uses explanations which rely on one's understanding of verbal language, for example concepts such as big, little, more, few, before, after or next (Barner, Chow, & Yang, 2009).

Spatial language includes concepts such as above, before, near and over. Some spatial words, such as after and before, indicate magnitude as well, as they are often connected to the number sequence and indicate decrease and increase in quantity (Purpura et al., 2016). Understanding of the spatial language is related to children's spatial thinking, where the concepts help the children to talk about relations between objects and numbers, and not least help children to develop spatial skills that are important for mathematical development. Also, children with rich spatial language may be able to decrease the cognitive load involved in mentally transforming and describing a shape (Pruden, Levine, & Huttenlocher, 2011). Mental rotation and spatial visualization are related to geometric problem-solving, and in order to describe spatial relationship and create mental images of geometric shapes the children need to use spatial concepts such as top and bottom (Ferrara, Hirsh-Pasek, Newcombe, Golinkoff, & Lam, 2011).

The process goals in the Framework Plan for Kindergartens in Norway (Ministry of Education, 2017) states that pre-school teachers must support the mathematical development of children through everyday activities in the kindergarten. Pre-school teachers must encourage children to undertake systematic reflection and thinking and make mathematical relationships visible for them. Moreover, pre-school teachers must actively use mathematical language in a reflective manner so that the children develop understanding of basic mathematical concepts and are inspired to undertake mathematical thinking. By enriching the play the pre-school teachers will help children to experience the joy of mathematics. In such an educational practice it is important that learning in kindergarten is based on play (Björklund, 2014). The Nordic kindergarten didactics is child-centred and based on the pedagogical idea that children are playing and learning individuals in a socio-cultural society (Doverborg, Pramling, Pramling Samuelsson, & Haukeland, 2015). From a socio-cultural perspective, communication and the use of language are very important and are the link between the child and his or her environment. Socio-cultural theory is based on the thoughts and ideas of Vygotsky (1978). Language has a key role in Vygotsky's theory, where all thinking is based on language. To

understand this view the concept of language must be expanded to include other ways of expression, such as drawings, body language and gestures. Ehrlich, Levine and Goldin-Meadow (2006) suggest that using gesture to instruct children may have a profound and positive impact on the development of early spatial skills. Gesture provides children with a second, complementary problem-solving strategy that can be integrated with spoken language and lead to better understanding of the principles of mathematical equivalence (Wakefield, Novack, Congdon, Franconeri, & Goldin-Meadow, 2018).

## **Methodology**

### **Design, data and participants**

The data used in this article is a part of a larger data set collected for my PhD. Video observations of everyday activities in a Norwegian kindergarten were collected over a period of seven weeks spread over one year in a privately-operated kindergarten, in a city in southern Norway. This kindergarten is special in the way it focuses on natural science activities. The participants are adults and 25 five-year-old children in this kindergarten.

This paper reports from the study of 16 assemblies. The examples in this paper are from two of the 16 assemblies. In these two assemblies mathematical language was most utilized. The structure and topics of the 16 assemblies differed. However, the adults used a particular method when they were working on experimentations with natural phenomena. The adults explained and demonstrated a natural phenomenon, and asked questions like; “What does this look like?”, “Why do you think this happens?” and “Why would this one sink?” The children participated by answering, describing, asking questions and experimented in different ways with the natural phenomena.

### **Analytical approach**

The analytical approach used was the constant comparison method (Corbin & Strauss, 2008), where comparisons are made in a socially situated context and regularities or patterns in when and how adults and children used mathematical language are identified. Coding the videos directly allowed for both verbal and visual cues to be considered, such as gesturing, movements and the use of artefacts. Six salient categories emerged from the data 1) children compare, 2) children explain and argue, 3) children respond to questions, 4) adults describe, 5) adults ask question and 6) adults respond.

This paper focuses on two of the six categories: 1) children compare and 2) children explain and argue. Bishop’s (1989) six fundamental mathematical activities are used to illuminate the findings and to describe which mathematical activity the children are relating to when they use mathematical language.

## **Findings**

### **Comparison**

During the assemblies the children were asked to observe and compare objects. When the children observed, they would often respond that “it looks like” or “it is similar to”. They observed and explained the similarities and dissimilarities of the objects, familiar objects and activities presented to them. Features used by the children to describe the similarities and dissimilarities were aspects of color, shape, size and function.

One assembly presented the planets and the adults showed a model of each planet in the solar system. During this assembly, the children used many verbal comparison expressions. They compared the shape using expressions such as “it looks like a ball” and “they’re all round”. Measurements were used when comparing the size of the planets, with such terms as “it’s the smallest”, “it’s bigger than Earth” and “Jupiter is the biggest”. One child also used comparison in the description of how hot the sun is. He stated, “It’s just as hot as the asphalt is in summer”. This child uses measurement and describes a quality using his experiences of the concept “hot”.

When the children describe qualities of objects and phenomena this can be seen in conjunction with their nascent learning of mathematics, where it is important to distinguish between similarities and dissimilarities to be able to sort and classify. Sorting and classification are about creating order, structure and having an overview. Ordering the object by size helps the children to use quantitative language, which is important in early mathematics (Barner et al., 2009).

The children often used gestures in the comparison given of what things look like and what they resemble, and when they explained themselves. In the assembly where they were to describe the planets and what characterized them, size and shape were expressed by gestures. The children would draw a circle in the air while saying “the planet is round”. Here the concept of circle is supported by a physical gesture. When comparing the size differences of the planets they demonstrated it by drawing circles in the air, either smaller or bigger than the last circle. One child supported the non-verbal language by saying “it’s sooo big”, drawing a big circle in the air. Body movements can be seen as a physical comparison of the size of a circle. When using the body in making comparisons between the planets, the non-verbal language helps the children to visualize what they are thinking and comparing. Children would often measure verbally while demonstrating with their body, testing out language in their comparison. I observed this in several cases where the children described height by lifting their hands up, width by stretching out their hands to the side, and little by holding two fingers close together. Such gestures complemented the children’s verbal expression to visualize their understanding of different sizes (Wakefield et al., 2018).

### **Explanation and argumentation**

During the assemblies the children got opportunity to explain and argue what they thought. By explaining verbally, the children expressed what they were thinking; they gave reasons for their thoughts and explained relationships.

An example of this is from an assembly exploring if objects float or sink. Each child was given an object to feel its mass in their hand before describing its property and state whether they believed it would float or sink. For each object to be explored, the child was allowed to describe the object to the others and give reasons why he or she believed it would float or sink. In children’s explanations about whether objects would float or sink they argue according to previous observations or what has taken place earlier in the assembly. Different explanations, such as “this is as heavy as a rock so I know it will sink”, “it’ll sink because it’s bigger than the other one we put in”, “this will float because it has the same material as a sponge” and “it’ll float because it’s only plastic” show that the children base their argumentation on different experiences. The children emphasized different

arguments for what was going to happen based on the size, weight, mass and characteristics of earlier known objects.

Explanation and argumentation by the children in this assembly were often supported by using their sensory impressions. The children used their tactile sense by holding two objects, each in one hand. They begin discussing the weight of the two objects by lowering the hand where they felt the most heavy object, this to determine whether the object would float or sink. In doing so, these children were able to compare whether the object had more or less mass. No measuring instruments were used and so no specific quantification was mentioned. Instead, the comparisons were described using terms about heavy and light (Helenius, Meaney, Lange, Wernberg, & Johansson, 2016).

Some children were still unable to explain verbally why they meant an object would float or sink and would use the objects in their explanation. One boy experienced that a small object sank and a big one floated, despite that he had predicted otherwise. To explain why he had predicted that the small object would float and the big one would sink, he took the two objects out of the water and held them close together, while saying “this is why I think this one would sink, because it’s bigger than this one”. Then he held up the smallest object and said “this one have the same size as another who floated”.

The children’s explanations in this assembly helped them to use mathematical language related to their understanding of the aspect of measurement, and they described what they meant by heavy and light, by both using spoken language, body language and the artefacts. The children gained experience with measuring and explaining mass in different ways.

## Discussion

The analysis shows that when children compare what they see, hear or touch, they deal with mathematical language, which in particular can be seen in relation to Bishop’s measuring, design and counting mathematical activities. By identifying similarities and differences in objects relating to measuring and design, the children use mathematical language, which become tools for classifying and ordering objects according to size and quantity, and they used a quantitative language to compare (Barner et al., 2009). When children were asked to explain their thoughts about an object or phenomena, the analyses show that the children used mathematical language in relation to Bishop’s locating, design and measuring.

The mathematical topics shape and size were mostly explained by using both words and gestures. By supporting their verbal language with physical movements, the children demonstrated visually with their bodies how they believed the shape appeared. In the situations where the children used non-verbal language in their comparisons, the analyses show that design was also present in their communication.

If the children did not have the language to give a verbal comparison or explanation they would show what they meant by using body language. Non-verbal responses – such as pointing, shaking their head and moving objects – were frequently prominent. The children showed their solution strategies by using their body language or the artefact as a support for the spatial language (Pruden et al., 2011). When the children explained and argued by using the artefact they supported their body-language

with mathematical words related to locating and size, they expressed their spatial movement while they moved their body or the artefacts.

In the social interaction and ongoing dialogues in the assemblies, the children encounter mathematics, which is related to locating, measuring, counting and design. The analysis shows that the children used mathematical language to make sense of the situation and their experience, to clarify their thinking and to communicate their understanding to others. The mathematical language in the informal talk around a natural phenomenon might help the children to gain a better understanding of the situation, and rich interaction with mathematical concepts in the communication might contribute to the children's mathematical development.

The analyses of the children's comparing, explanations and argumentation show that they classify and sort what they see, hear or touch during the assemblies. Despite the fact that the topic in the assemblies was on natural science phenomena, my analysis shows that the children were, in a large extent, using mathematical language to express their thoughts about natural phenomena. By acting and thinking freely they were given the opportunity to discover mathematical relationships. Descriptions of what the children do, see and think help them to use mathematical language they need if they are to talk about their actions. Mathematics then becomes a way of thinking and a language used to solve problems (Björklund, 2014). An identification of when children use a mathematical language shows a multifaceted opportunity for speaking about mathematics in kindergarten.

*Keywords: Early years mathematics, pattern competencies, physical activity.*

## Introduction

Studies on early pattern competencies in the primary grades show a close relationship between children's competencies in this domain and their general mathematical competencies. Furthermore, several studies suggest that children's pattern competencies can be fostered by implementing patterning activities in intervention programs or in regular mathematics lessons (Lüken & Kampmann, 2018). Those interventions usually involve concrete objects or iconic representations. In contrast, the exploratory study presented in this poster focuses on physical activity to foster children's patterning abilities. This pilot study aims to develop, implement and evaluate movement games dealing with a variety of activities concerning repeating patterns.

## Theoretical Background

In accordance with Lüken and Kampmann (2018) a mathematical pattern can be defined as any predictable regularity. One of the types of patterns relevant for the primary grades are *repeating patterns* with a cyclic structure, consisting of a sequence of elements (the *unit of repeat*) that is repeated indefinitely (e.g., ABAB...). A longitudinal study reported by Lüken et al. (2014) reveal a significant effect of children's repeating patterning abilities one year prior to school on their mathematical competencies at the end of grade 1. Furthermore, elaborated repeating patterning abilities are also relevant for further mathematical developments, e.g. in algebraic thinking (Warren & Cooper, 2006). Tasks and interventions are frequently based on a variety of activities, such as conceiving, reproducing, and extending repeating patterns (Warren & Cooper, 2006), often involving concrete materials. While dealing with materials solely involve fine motor activities, a higher level of motoric engagement is realised by whole-body movements. In this domain, two approaches can be distinguished: either the movement accompanies the learning process only in time, or it is directly related to the content (Bayer & Rottmann, 2018). While there is evidence of positive effects of physical activity for the learning process in general, research investigating the added value of connecting the movement to the specific content is largely missing. One of the few exceptions is the exploratory study by Bayer and Rottmann (2018), which shows an improvement of first and second graders understanding of multiplication in an intervention based on movement games.

## Methodology

The exploratory study (09-10/2017) reported in this poster aimed to answer the following research question: To what extent can children's repeating pattern competencies be fostered by physical activity? Therefore, a diagnostic tool and three movement games directly related to repeating patterns have been developed and trialed in a German primary school with 19 first graders. The trial included

seven teaching units. The diagnostic tool was conducted as a paper-pencil-test in the first and the last unit in a pre- and post-test-design. It contained tasks to reproduce and extend repeating patterns with various units of repeat as well as tasks demanding to identify the unit of repeat, extrapolate a pattern and create a new one. Typical movement games from physical education (e.g. “Reversal Relay Race”) were implemented in the remaining five lessons. Each movement game focused on different activities relating to the learning content. For example, to extend a repeating pattern by physical activity in the Reversal Relay Race, children had to rerun a unit of repeat consisting of single whole-body movements like *jumping with one’s legs apart – jumping with one’s legs tightly* to move on in the gym. A reflection phase to direct children’s attention to the unit of repeat in the pattern was integrated into each game. Apart from playing the games in physical education lessons once a week, further teaching of repeating patterns did not take place.

## Results and Outlook

The results of the pre- and post-test indicate a positive development of children’s repeating pattern competencies. In the pre-test, an average of 9.2 tasks (from 16 tasks in total; 58% of tasks) is answered correctly, whereas the number of successfully solved tasks increases to an average of 12.7 tasks (79% of tasks) in the post-test. It is conspicuous that there are considerable differences within the sample regarding students’ mathematical competence level. Compared to the pre-test, the group of four students with difficulties in learning mathematics demonstrated an increase of 5.25 tasks solved correctly in the post-test. Progress was related with identifying the unit of repeat, continuing and completing repeating patterns. These first results indicate a positive influence of physical activity on children’s repeating pattern competencies. However, it is still an open question to what extent this positive effect was caused by the physical activity itself, or by the respective (linguistic) reflection of the activity induced in the reflection phases following each movement game. A subsequent research project is in preparation to further investigate this question.

*The focus of this paper is on possibilities for children to discern elements of structure and to develop structural awareness through play. In Sweden, preschool is part of the education system why teaching is to be conducted. At the same time, play is to be promoted and consciously used. In this paper, we explore possibilities for the youngest preschool children (2-3-yearolds) to discern structural elements in a rule-based play. In the example, discerning structural elements becomes of importance for being able to participate proficiently in the play. As such, the example shows that a conscious use of play may promote toddlers' development of structural awareness which in turn is of importance for further mathematical learning and for their participating in the play.*

*Keywords: mathematizing, play, structural awareness, toddlers*

## Introduction

Studies show that early mathematics has positive effects on later school performance (Duncan et al. 2007; Ginsburg, 2009) but there is no consensus when it comes to *how* early mathematics is to be conducted (Palmér & Björklund, 2016). A long-time debated question is if teaching is to be integrated with or separated from children's play (Bennet, 2005) and similar to other countries there is a discussion in Sweden regarding the relation between play and teaching. In this discussion, play-oriented activities withholding mathematical content sometimes are set as a counter-pole to systematic teaching of a content. At the same time as there are researchers emphasizing a consolidation of play and teaching (Pramling & Pramling Samuelsson, 2011) there are traditions that uphold children's right to play, undisturbed by adults, for the sake of play itself (Sundsøl & Øksnes, 2015).

In this paper we will not immerse in this debate but instead focus on an example where children need to mathematize the idea of structure, to be able to participate proficiently in an ongoing play. Structural awareness has been researched by Mulligan and Mitchelmore (2013a,b) and been shown to be both salient and critical to children's mathematical learning. Mulligan and Mitchelmore (2013b) have made interventions to promote children's structural awareness. These interventions showed that teachers can plan and direct children's attention towards patterns and structures in a developmentally suitable way. In this paper we analyze an example where young children (2–3-yearolds), to be able to participate in an ongoing play, need to discern the elements of the structure of the play. Thus, the children in this example are younger than the children in the studies by Mulligan and Mitchelmore (2013b) and the setting is very different. The aim of this paper is to explore *if* the research on structural awareness by Mulligan and Mitchelmore (2013b) is applicable in this context and *how* these young children with support of their preschool teacher may discern structural elements in the ongoing play. This is of interest since such a discernment would be of value both for their possibility to participate proficiently in the ongoing play and for their further mathematical learning, as suggested by Mulligan and Mitchelmore (2013a,b).

## Teaching and play

In Sweden, preschool is a non-mandatory pedagogical practice available to all children aged one to six years. Preschool is part of the education system why teaching is to be conducted (Education Act 2010:800). At the same time, play is to be promoted and consciously used in relation to children's learning (National Agency for Education, 2010). In the national curriculum it is however not expressed or exemplified *how* play is to be incorporated with children's learning.

According to van Oers (1996), the relation between teaching, mathematics and play can be seen as either "mathematics made playful" or "mathematizing elements of play" (p.74). Games in which counting, sorting and different mathematical operations are prominent are examples of mathematics made playful while mathematizing elements of play implies that the primary act is play but a teacher introduces mathematical concepts or operations into the play. The teacher's way of acting towards children's play thus have implications for how mathematics is introduced and thereby made meaningful to the children. Walsh, McGuinness and Sproule (2017) have found three different approaches towards children's play that are considered to be based on the teacher's views on play, learning and teaching. Some teachers do not participate in children's play as they think children learn and develop naturally through play why the participation of preschool teachers would primarily destroy a natural process. An opposite to this is teachers that continually interrupt children's play by asking questions, questions that seldom are meaningful in relation to the play but rather connect to different curriculum content. The third approach includes a balanced commitment to participation in children's play: not entirely child-centered or teacher-led but a balanced mix of reciprocity and listening to children's initiatives and need for support. This third approach was shown to be most successful for children's learning in the study of Walsh et al. A similar approach based on empirical studies is found in so called Developmental Education (van Oers, 2012) which has been further developed and theorized as play-responsive teaching in a recent study by Pramling et al. (in press). Both these theoretical stances emphasize a starting point in children's meaning making and a collaborative structuring (between children and teacher) of activities (for example play) that are enriched with cultural meanings (for example mathematics) in interactive processes.

Teachers who actively take part in children's play with pedagogical intentions may however do this in distinctly different ways which has been observed by Björklund, Magnusson and Palmér (2018). Some *confirm children's direction of interest*, which implies that the teacher responds to and confirms the children's initiatives and ideas. A teacher may also contribute by *providing strategies*, which is a more goal-oriented act of directing the child towards skills or tools that will help him/her master a challenge. Thus, providing strategies can be understood as the teacher providing the child with new strategies to facilitate the activity the child is involved in. If a teacher is *situating known concepts*, this implies that the teacher is applying a mathematical concept known from another situation into the play, enabling generalization of the concept. Finally, when *challenging concept meaning*, the teacher highlights or introduces a mathematical problem or concept within the play context where the child/ren need to work together in an intellectual way to solve the problem or to clarify the concept. All of these different ways to actively take part in children's play can be considered as a balanced commitment of participation (c.f. Walsh, McGuinness & Sproule, 2017) that may extend the child/ren's knowledge and may also add new value to their play.

## Pattern and Structure

It is well known that preschool children can both note and construct different kind of patterns. However, it is only more recently that research has shown that children's exploration and construction of patterns may have positive influence on their general learning of mathematics (Cross, Woods & Schweingruber 2009; Mulligan, Mitchelmore, Kemp, Marston & Highfield, 2008). For example, exploration and construction of patterns offer children opportunities to discover and understand repeating structures, which in turn is fundamental for later understanding of variables, functions and algebra (Moss & Beatty, 2006).

According to Mulligan and Mitchelmore (2013a) awareness of mathematical pattern and structure is both salient and critical to mathematical learning, since effective mathematical reasoning involves the ability to note patterns and structure. They define *pattern* as involving a predictable regularity and *structure* as the way in which various elements (for example in a pattern) are organized and related. Based on studies on children aged 4-8 Mulligan and Mitchelmore (a.a) divide children's development of structural awareness into four levels. *Prestructural awareness* implies children taking notice of properties or features that appeal to them but often the properties or features are not relevant to the underlying mathematical concept. *Emergent structural awareness* implies that children start to distinguish some regularities and/or structures but they are unable to organize them appropriately. *Partial structural awareness* implies that children distinguish several patterns and/or structures but they still struggle with organizing and representing them as a whole. The forth level is *structural awareness*, which implies that the children correctly organize and represent a given structure. In the studies by Mulligan and Mitchelmore (a.a) the children's structural awareness were consistent across tasks and the level of structural awareness correlated with the children's mathematical performance. In later studies, Mulligan and Mitchelmore (a.a) added a fifth level, *advanced structural awareness*, implying children being able to generalize underlying features between contexts.

Based on the above, Mulligan and Mitchelmore (2013b) have made interventions to promote children's structural awareness. These interventions show that teachers can plan and direct children's attention towards patterns and structures in a developmentally suitable way. When children in their interventions had developed structural awareness they learned basic properties of number, space and measurement more easily and they also made more connections between numerical, measurement and spatial mathematical ideas. There are few studies on structural awareness among preschool children below three years but there are examples of an emerging senses of structure and internal relations expressed when children are allowed to explore materials and activities in play-based manners or with guidance (Björklund, 2016), relationships that however may not always be based on logic but on the child's own experiences and intuitions (Björklund, 2014).

## The Study

The empirical material in this paper stems from a larger research project [1] aiming to investigate the teaching-play relation in Swedish preschool practice. Data for analysis consists of teachers' self-collected video-documentations where the teachers together with their preschool children are engaged in different kinds of play. Only children with written consent from their legal guardians (in accordance with ethical guidelines from the Swedish Research Council, 2017) participate in the video-documented activities. For this particular study, one video-documentation is chosen as it

contains a teacher initiated rule-based play where certain acts and roles are necessary to comprise. To participate proficiently in the play it becomes important to discern certain structural elements. Because the play contains repeated parts of actions, it is possible to gain a comprehensive understanding of the complexity of the play and the necessary skills that are needed to conduct the play. Thus, the example is information-orientated aiming to maximize the utility of information from small selection (Flyvbjerg, 2006). In the analysis we explore how the youngest preschool children (2-3-year-olds) discern structural elements in the play. We also explore if Mulligan and Mitchelmore's (2013a) four levels of structural awareness is possible to apply on a situation quite different from the situations in their studies. In their studies, the analysis is based on children's written documentations and the level of structural awareness is set in relation to different mathematical concepts. In this paper the analysis will be based on children's actions in the play and the level of structural awareness is set in relation to children's discernment of the structural elements in the play.

In the following section the example will first be presented divided into 7 episodes. Each episode constitutes a part of the play where the teacher and the children initiate an act and follow it through. These episodes are then analysed through thematic analysis (Braun & Clarke, 2006) to identify themes or patterns in the observed activity that are interpreted in accordance with a theoretical framework; in this case the levels of structural awareness (Mulligan and Mitchelmore, 2013a).

### Discerning elements of structure – an example

Three boys and one girl, aged 2 and 3, are to play *hide the key* with their preschool teacher. Instead of a key they have a green toy dragon that is to be hidden. It is a new play for the children and to be able to participate proficiently in the play the children need to discern the elements of structure in the play. The video-documentation is ten minutes long and will be presented and discussed through 7 episodes where the children are called boy 1, boy 2, boy 3 and girl 1.

**Figure 1: Picture of the room where the play is conducted. The door is in the upper corner.**

**Episode 1:** The children are standing outside the room while the teacher hides the dragon behind a basket standing under a shelf. She opens the door, sits down and says that she has hidden the toy dragon *far down, not high up*. She emphasizes *down* and *high* by movements with her hand. The children are then encouraged to start looking for the toy dragon. Boy 1 finds the toy dragon before the others have even started their search.

**Episode 2:** The teacher says that now the child who found the toy dragon is to hide it, that he can hide it *far down* or *high up* but he should wait until the others are outside the room. Boy 1 who is to hide the toy dragon is left alone in the room. He is standing in the middle of the room holding the toy dragon in his hand up towards the ceiling. He says “high up”. After a little while the teacher opens the door to ask if he is finished.

Teacher: Can I help you?

Boy 1: I hide it up. (stretches his hand with the dragon towards the ceiling) I hide it head.  
 Teacher: In the ceiling?

The teacher takes the toy dragon and hides it high up (not visible where in the video). The boy opens the door and the other three children instantly run to the previous hiding place. The teacher says to the boy who has hidden the toy dragon not to tell where it is hidden but to tell if it is hidden far down or high up. Boy 1 then looks up and points towards the hiding place.

**Episode 3:** Boy 2 is in turn to hide the toy dragon and he shows with his hands that he wants to hide it far down. The teacher helps him to find a hiding place behind some big pillows under a table (to the right in Figure 1). After he has opened the door to let the other children in he himself directly walks to the hiding place and points towards the toy dragon. The girl follows him and takes the toy dragon but then boy 2 gets angry. Boy 3 does not take notice of them but instead searches at the first hiding place. While the teacher explains to boy 2 that it is now the girls turn to hide the toy dragon the girl walks out and closes the door. The teacher goes after her telling that she should stay inside because it is now her turn to hide the toy dragon. Then the girl takes the toy dragon and before the other children has had time to leave the room she puts it on same shelf as the first hiding place. Boy 1 and 2 leave the room by themselves and the teacher walks boy 3 out of the room.

**Episode 4** When all three boys are outside the room, the girl again hides the toy dragon on the same shelf as the first hiding place. Then she walks to the door. It seems like she is going to go out and close the door but the teacher stops her and asks her to let the other children in and tell them that the toy dragon is hidden *quite far down*.

**Episode 5:** Boy 3 is to hide the toy dragon and he chooses the same hiding place as in episode 1 and 4. He himself also “finds” the toy dragon immediately afterwards, before letting the other children into the room. The teacher explains that he instead should let the other children into the room. When he does, they go directly to the hiding place.

**Episode 6:** Boy 1 says that it is now his turn to hide the toy dragon. The girl immediately goes out of the room and the other two boys follow her. The teacher tells boy 1 that he is to hide the toy dragon in a new place and she emphasizes *far down* and *high up*. She also tells him not to tell the others where it is hidden. He hides the toy dragon at a new place under a box standing on the floor. When he lets the other three children into the room they directly run to the previous hiding place. When the toy dragon is not there they seem to get a little confused. They start to look at other places but find the toy dragon first after some guidance from the teacher.

**Episode 7:** Boy 2 is about to hide the toy dragon and he chooses the same hiding place as in episode 1, 4 and 5. The teacher tells him not to tell the others where it is hidden but to tell them if they should look *far down* or *high up*. When the children are let into the room the boy himself runs to the hiding place and “finds” the toy dragon. As the teacher tries to explain for him that it was the others who were to search for the toy dragon the girl walks outside the door.

### **Analysis - structural awareness in the play**

According to Mulligan and Mitchelmore (2013a) *structure* is the way in which various elements are organized and related. To make use of a structure the child needs to recognize the internal relationship

between the elements. In the “hide the toy dragon play” there are various elements that form the structure of the play that the child has to discern and relate to other necessary elements:

- choose between two options of hiding positions: far down or high up
- all but one should leave the room and close the door when the toy dragon is to be hidden
- only the one who is to hide the toy dragon can stay in the room
- the hiding place should be different from the previous turn
- after hiding the toy dragon the door is to be opened and all children gather inside the room
- when being let into the room you are to search for the toy dragon
- if you have hidden the toy dragon you are not to tell where it is hidden but indicate with spatial instructions “high up” or “down low”
- the one who finds the toy dragon is in turn to hide it the next time
- all children are to hide the toy dragon once which is not an element of the play but connected to fairness

During the play the children successively distinguish some of the elements above but they are unable to organize them appropriately which is labeled as *emergent structural awareness* by Mulligan and Mitchelmore (2013a). For example, all children know that they should search for the toy dragon when they enter the room (observed in all episodes). However, mostly they start to search at the same hiding place as the previous turn (episode 2, 3, 5, 6) and boy 3 “finds” the dragon when he is “the hider” (episode 5). Often they also hide the toy dragon at almost the exact same place as the teacher did in episode 1 (episode 3, 4, 5). The element of leaving the room after the toy dragon has been found is not discerned by boy 3. Instead, the teacher takes his hand and walks him to the door each time (for example episode 3). This element is however immediately discerned by the girl who very quickly leaves the room each time the dragon has been found. On the other hand, she does not recognize the specific circumstances of being the “hider” to which this element does not apply, which is shown as she leaves the room when she is the one who found the dragon and thus in turn to enact the hiding element (episode 3). The girl has discerned that one is to leave the room after the toy dragon has been found but has not yet discerned the internal relationship of being a hider and a searcher, a role that in turn is determined by who found the dragon. Thus, one issue that increases the difficulty in discerning the elements of the structure in the play is that the structure’s internal relationships change when you are the one who finds the toy dragon. Another expression of this complex relationship is shown when the boys in episode 3 and 7 “finds” the toy dragon they themselves have hidden.

## Discussion

Mulligan’s and Mitchelmore’s (2013b) interventions showed that teachers can plan and direct children’s attention towards patterns and structures. The children in our study are younger and the setting is very different why we in the analysis explored possibilities for the youngest preschool children (2-3-yearolds) to discern structural elements based on an ongoing play. We also explored if the four levels of structural awareness is possible to use when analysing a play situation. Even though the teacher’s mathematical focus initially seems to be on *far down* and *high up* she *provides strategies* (c.f. Björklund et al., 2018) for the children to discern elements of structure. The example illustrates that elements of structure is possible for children to discern within play if a teacher provides strategies for this. The example also indicates that *emergent structural awareness* starts to develop among children younger than those in the studies by Mulligan and Mitchelmore. The notion of *mathematizing*

implies a process where mathematics becomes of importance when children explore different phenomena (Freudenthal, 1968). The example in this paper can be seen as mathematizing structural elements of play (van Oers, 1996), not in the sense that the teacher tries to introduce mathematical concepts or operations into the play but instead in the sense the teacher tries to make visible mathematical elements of the play. By repeating the play several times children's discernment of important features becomes visible. It also becomes visible how the teacher has an important role in this discernment process. The teacher shows a balanced commitment in the play (Walsh, McGuinness & Sproule, 2017), with a mix of reciprocity and listening to children's initiatives and need for support. Considering the emphasis in the Swedish curriculum on play as a way to teach and learn in preschool, this study broadens our knowledge of how discerning structural elements becomes of importance for children to be able to participate proficiently in rule-based play. While Mulligan's and Mitchelmore (2013a,b) have shown that structural awareness is both salient and critical to children's mathematical learning the analysis in this paper indicates that structural awareness may start to develop among children even younger than previously thought and in situations not obviously labelled as mathematical.

# What can five-, six- and seven-year-olds tell us about the transition from mathematics in kindergarten to that in school in Norway?

Geir Olaf Pettersen and Monica Volden

UiT The Arctic University of Norway, Norway; [geir.olaf.pettersen@uit.no](mailto:geir.olaf.pettersen@uit.no), [monica.volden@uit.no](mailto:monica.volden@uit.no)

*As we grow from small children to adults, we experience several transitions. This paper focuses on children's voices on the transition from mathematics in kindergarten to that in school. What are their thoughts on going from one institution to another with a different curriculum, culture and values regarding mathematical learning? This paper reports answers from focus group interviews with children, ages five, six and seven, about mathematical learning. The study was situated within a research and development project SUM at UiT The Arctic University of Norway. The findings show that even though the transition is clear for teachers, both in kindergarten and school, we need to discuss how to present mathematical activities to children such that these activities help to ease the transition from one level of education to another.*

*Keywords: Mathematics, kindergarten, transitions, school.*

## Introduction

The transition to school is one of many transitions that children experience during childhood, youth and adolescence. First, they undergo the transition from home to kindergarten. In Norway, we use the term kindergarten for institutions providing early childhood education and care for children from ages one to five years. Next, they experience the transition from kindergarten to school and therefore go from one institution to another, which have different curricula. Finally, the transition to higher education and/or work occurs.

This study was situated within a research and development project called SUM (Blomhøj, 2016) – the acronym for the Norwegian title of the project, *Sammenheng gjennom Undersøkende Matematikkundervisning*. SUM focus on five transitions in the educational system. These are Kindergarten => Primary school => Middle school => Lower secondary => Upper secondary => University. At all five transitions students typically experience a discontinuity in their mathematics teaching. For each transition, a group of teachers and researchers will design, test and evaluate inquiry based mathematical activities. One assumption in SUM is that inquiry based mathematics education (IBME) can help students to explore the transitions as more continuous and transparent. IBME can be seen as a way to motivate students to learn mathematics through investigation in and with mathematics (Artigue & Blomhøj, 2013). Consequently, it is necessary to listen to the students voices on both mathematical activities and how they explore the transitions.

This paper presents children's descriptions of mathematics and mathematical activities in kindergarten versus school, and their thoughts about the differences going from kindergarten to school. Do we as professional teachers take some aspect of the transition for granted? Accordingly, our research question was as follows: *What can children, ages five, six and seven, tell us about mathematics in kindergarten and in school and the transition between these institutions?*

## Theoretical background

Transitions have been recognised as a challenge for children. Einarsdóttir (2007) reports that children characterise preschool and first grade in similar ways. They expect a change from more free play in preschool to more academic work in primary school. According to Hogsnes and Moser (2014), kindergarten teachers and schoolteachers agree on the importance of children experiencing a connection in the transition to school and it being well-defined. However, Hogsnes and Moser also stress that the transition will have to represent some changes. The children also expect this distinction, as Einarsdóttir (2007) finds. Further, Hogsnes and Moser (2014) argue that one way of making the connection is to allow children to present in school something in which they were involved in kindergarten. Almost 70% of the kindergarten teachers in their study see this presentation as important, whereas 60% of the schoolteachers find it somewhat important or unimportant.

The Framework Plan for Kindergartens (Kunnskapsdepartementet, 2017) defines the content and tasks for kindergarten in Norway. The core values of kindergarten shall be “promulgated, practised and manifest in every aspect of a kindergartens pedagogical practices” (p. 7). This means that play and the children’s initiative are important parts of the curriculum. The framework is structured on the basis of learning areas instead of traditional subjects. For mathematics, the learning area is called *quantities, spaces and shapes* and is based on Bishop’s six mathematical activities. Regarding the transition, the Framework Plan states that “working in partnership with the parents, the kindergarten shall ensure that the child has a safe and good transition from kindergarten to school” (p. 33).

Bishop (1988) defines six universal mathematical activities – namely, *counting, locating, measuring, designing, playing* and *explaining*. For these six activities to provide a useful structure to help children experience a successful transition into formal mathematics, he argues that it is necessary to embed them in the value-laden frameworks of the classroom (Bishop, 2016). Bishop presents six value clusters, grouped into three sets of complementary pairs. The first pair is *ideology: rationalism and objectism*. Argument, reasoning, logical analysis and explanation are all aspects of *rationalism*. Encouraging students to search for different ways to symbolise and represent ideas falls under the value of *objectism*, as does appreciating and creating mathematical objects. The second pair is *sentiment: control and progress*. *Control* involves rules and prediction. Valuing control means emphasising not just the correct answer but also the checking of answers and explaining why other answers are not correct. *Progress* concerns how mathematical ideas grow and finding alternative and non-routine solutions. This value also contains individual liberty and creativity. The third and last pair is *sociology: openness and mystery*. Valuing *openness* means appreciating sharing and defending answers in class. A good practice is asking students to explain their ideas to the whole class. Valuing *mystery* means promoting thinking about the origin and nature of knowledge. This can be done by telling stories about old mathematical puzzles and searches for negative numbers and zero. Bishop (2016) concludes that values in preschool and school are not the same and we must be conscious of the differences.

In the curriculum for the common core school subject of mathematics (Kunnskapsdepartementet, 2013), the focus in years 1–4 is on numbers, geometry, measurements and statistics. After years 2 and 4, competency goals are formulated. Regarding the curricula for school and the Framework Plan

for Kindergartens, there are some important differences to note. The most obvious difference is between the competency goals in school and more process-oriented goals in kindergarten. This also means that there are cultural and value differences between these Norwegian institutions. However, both plans emphasise the importance of explorative, playful, creative and problem-solving activities, which is also the aim for the SUM project.

Developing the IBME theoretical framework in order to address challenges in transitions is the focus in the SUM project (Blomhøj, 2016). The teachers and researchers jointly designed two inquiry based mathematical activities. Both activities followed the phases from inquiry-based mathematics education (Artigue & Blomhøj, 2013). However, since this was the first year of the SUM project, the emphasis was on phases one, *setting the scene*, and two, *students' investigative work*. The teachers in school and kindergarten tested the activities. The aim of the activities in SUM is to investigate if and how they can contribute to a transparent transition.

The first activity involved a tangram. The given introduction was the story about how Tan wanted to impress the emperor. Then the children had to conduct the investigative work of determining ways of putting the tangram into different figures. The progress differences from kindergarten to school were visible through the focus on visualisation in kindergarten and on properties and counting edges in school. The second activity involved word problems and early arithmetic. Here, the introduction was aimed at creating a story that could make room for word problems. The jointly developed story was about a bus, and the focus was passengers who got either on or off the bus at bus stops or stories from inside the bus. An example is as follows: “There are seven seats in the bus. Three are taken. How many are free?” One group of kindergarteners created a story about a human-like creature from Sami folklore, Stallo, who likes to eat people.

### **Data collection and analysis methods**

Data were collected using focus group interviews with eight groups from kindergarten and elementary school (Cohen, Morrison, & Manion, 2007). There were four groups from two different kindergartens (age 5), two groups from year 1 of school (age 6) and two groups from year 2 of school (age 7). In total, 13 children from kindergarten and 12 schoolchildren participated. We used convenient sampling for selecting the participating children. All interviewed children are participants in the SUM project. The argument for including also second graders (age 7) was that they in general have more developed language. The interviews were semi-structured and the questions were based on different aspects of mathematics from the SUM project. Each interview began with the same question: “What is mathematics (about)?” Subsequent questions concerned what they do when they do mathematics; whether we need mathematics (and for what); whether they find mathematics interesting; and how to be good at mathematics. Some questions differed for children in kindergarten and those in school. The kindergarteners were asked what they thought mathematics would be like in school. Conversely, the schoolchildren were asked what mathematics they had done in kindergarten. In addition, we brought tangrams to the kindergarten interviews to help the children remember the activities from SUM. The schoolchildren were asked to show examples of mathematics on paper.

The interviews were video-recorded and transcribed to the written Norwegian standard bokmål, and then translated into English. NVivo 12 was used to analyse the data. For each question in the

interview, we coded the answers and created categories. E.g. for the first question “What are mathematics about?” the categories were counting, calculating, numbers, shapes, measurement and others, like homework. The presented excerpts are to be seen as anchor examples of the categories.

Interviewing children can be challenging also due to which term to use. The term mathematics was challenging because the children did not seem to use the term themselves or have a full understanding of it. However, we clarified the term together with the children. We therefor used the term in the rest of the interview.

## Results

This section will present and discuss our findings from the interviews. The section is structured according to the interview questions.

### What is mathematics about?

When asked what mathematics is about, most of the kindergarteners were silent or said that they did not know. After some consideration, two children answered that mathematics is about counting and adding things together. Some children also answered making movies, reading and homework.

To move the interview along, the interviewer proposed that mathematics could be about doing arithmetic. In the curriculum in Norway the term calculate is used as a synonym for doing arithmetic. The children then said that they knew about calculation. John said, “Calculation is about doing homework”. However, what he meant by “calculation” was unclear, because he later said he added letters. Olivia said that she had heard about mathematics because her older sister was doing mathematics; however, she did not clarify what she meant by “doing mathematics”.

The picture gleaned from the schoolchildren’s interviews is more diverse. Some of the six-year-olds were not familiar with the term mathematics, but the most common answers were counting and calculating numbers, followed by shapes and measurements.

In terms of children’s understanding of mathematics, some differences between the children in kindergarten and the schoolchildren are evident. The children in kindergarten gave in addition examples of activities like making movies, reading and colouring. These are not typically mathematical activities but can include and give children experience with mathematics.

### Do we need mathematics?

When asked if we need mathematics, most kindergarteners and schoolchildren answered yes, but their answers differed somewhat. One group of kindergarteners said that there was no need for mathematics in kindergarten because they were so young. The following example is from an interview in a kindergarten:

John	Because we then know what to do in school.
Interviewer	Do we need mathematics outside of school?
John	Maybe
Olivia	Yes

Interviewer When do we need mathematics?

John Because we try to learn all the things we are going to do at school.

Interviewer What do you think, Olivia? When we are not at school, you said we need mathematics. When do we need it?

Olivia I do not know. I am not thinking about it. I am just thinking about butterflies.

John said, “Because we then know what to do in school”. Then the interviewer asked if we need mathematics outside of school. John did not really answer this question; instead, he returned to his original statement about knowing what to do at school. When Olivia was directly asked about mathematics outside of school, she replied, “I am just thinking about butterflies”. This may indicate a lack of interest in mathematics, at least in the interview situation.

The schoolchildren agreed with the kindergarteners that mathematics is not necessarily required in kindergarten. However, they gave more examples of situations where we need mathematics – namely, shopping, readiness for work and to carry out mathematical tasks. The following excerpt is from an interview with seven-year-olds.

Interviewer Why is it wise?

Lucy Because it is easier to go shopping

Kate and, if someone gives you a math task

Lucy It is wise to know.

Lucy argued that we need to know mathematics because it is wise to know in order to go shopping. According to the schoolchildren, this is the most common situation where we need mathematics. Kate’s statement, “and, if someone gives you a math task”, may indicate that mathematics is something you only need in school.

### **How to be good at mathematics**

In general, the kindergarteners and schoolchildren said that practising and working with mathematics can make you good at mathematics. They also considered homework as a significant factor.

Interviewer How can you be good at mathematics?

Lucy We have to practise and make mistakes

Kate Yes

Sarah You can learn from your mistakes

...

Interviewer In what way can you learn from others?

Lucy If you have an older brother or sister, you can learn mathematics.

Interviewer Can you learn from students in your class?

Lucy Yes

Lucy (age 7) started by stating that you need to practise, but also that you can learn from your mistakes. Sarah and Kate agreed with that statement. Learning from mistakes places the focus on finding one right answer, but also that a wrong answer can lead to an opportunity to learn. Instead of focusing on correct answers, the children in kindergarten were more focused on doing mathematics.

### **What do you do in kindergarten and how do you expect it will be in school?**

The kindergarteners said that the mathematics they were doing was mostly about counting, arithmetic and shapes. They also mentioned making movies and baking as mathematical activities.

In the interviews, we asked the children directly about the activities in SUM.

Interviewer Do you remember what you have been doing? Have you done *Formjakt* (an activity that entails looking for different shapes)?

Audrey No, we did the bus

Interviewer What was that about?

Audrey It was about counting.

“We did the bus” is a reference to the word problem activity in SUM. The children remembered the activity and clarified that it was about counting.

Audrey and we have put shapes together

Audrey and we remember the man who made a nice gift and...

Leah ... then he fell on the steps. And then...

Audrey ... we had to build it up again.

Audrey But it was just a story.

Audrey and Leah showed that they remembered the story about Tan. Even though their initial response was that they did not remember, without help from the interviewer they recalled important actions from the story. They also remembered that they had to put it all together. We can identify both the setting of the scene and investigative work components of the activity from SUM. In the last statement, Audrey clarified that overall, it was just a story.

In the kindergarten where the setting of the scene was about the Sami creature Stallo, we wanted to see if the children remembered the activity. They confirmed with “mm”, meaning yes.

Interviewer Maybe I could create a word problem

Sophie I can make one. Once upon a time there were three bears sliding down a hill. And at the bottom of the hill, there was Stallo.

This is a clear reference to the activity. Sophie could recall the situation and was able to create the beginning of a word problem. The reason why she referred to bears instead of children is most likely that we had introduced counting bears in the interview. It is quite challenging to create a word problem on the fly and in an interview like this. We recognised this as a sign that they had remembered the activity and had gained experience from the first two phases. Regarding the children’s expectations

of what mathematics would entail in school, they emphasised learning about numbers and doing arithmetic.

### **What do you do in school and how is it compared to kindergarten?**

Concerning this question about mathematics in school, it became apparent that the schoolchildren could name more mathematical activities, including discussions and playing games. However, they still mostly brought up activities like calculating numbers, working with shapes and using textbooks or worksheets.

They did not remember much about their experience of mathematics during kindergarten. As Lucy said, “No, I think maybe in the last year. Sometimes, maybe once. We gathered to do worksheets – math worksheets – very easy tasks”. Several children mentioned easy tasks in kindergarten as things they remembered. For example, Ryan (7 years old) said the following:

Interviewer    Do you find the mathematics in kindergarten simple?

Ryan            Yes

Interviewer    Do you find the mathematics in school hard?

Ryan            It was not so easy in kindergarten either, because we were much younger. Then it was the same as we have it now, in kindergarten.

First, he claimed that mathematics in kindergarten is easy. After the interviewer followed up this statement, he did not directly answer the question, but gave a reflection on learning.

### **Discussion and implications**

First, we wish to discuss the content of, and the need for, mathematics as children see it. Our data show that children in kindergarten, in general, are not familiar with the term mathematics. Sæbbe and Samuelsson (2017) offer a possible explanation: most kindergarten teachers avoid using the term mathematics when they engage children in mathematical activities. According to the kindergarten teachers, they are afraid that the activities could be regarded as boring and “schoolish”.

In the curricula for both kindergarten and school, mathematics is about helping children understand the world. Although the aim is to prepare the children for developing a broader understanding of mathematics, our data show that the kindergarteners and schoolchildren had a narrow understanding of mathematics, viewing it mostly as being about doing something with numbers, shapes and counting. The schoolchildren, however, also talked about subjects in mathematics.

Significantly, according to Bishop (2016), the values in school and kindergarten are different. Lucy said that you can learn from your mistakes. This could indicate a focus on checking answers and knowing why an answer is not right, similar to Bishop’s *control* value. At the same time, children in kindergarten have a strong focus on doing – hence, *progress*. This could be an indication of the distinction between the process aim in the kindergarten curriculum and the competence aim in the school curriculum.

When we asked about doing mathematical activities, the kindergarteners and schoolchildren gave more detailed examples. It is clear from our data that the children remembered activities from SUM,

but did not necessarily see them as mathematical. This raises some new questions regarding the transition to school. Is mathematics a Trojan horse, as Fosse et al. (2018) claims? Does the term mathematics scaffold the transition or is it an obstacle? One way to investigate this further would be through projects like SUM. In SUM, the goal is to develop enquiry-based activities that follow the curricula and cultures of both kindergarten and school. Our data suggest that activities may be the missing link in order to make the transition more transparent. Our findings also imply a need for a discussion on how to present activities so that children have the opportunity to discover the mathematical ideas regardless of whether the term mathematics is used.

# Inquiry-based implementation of a mathematical activity in a kindergarten classroom

Chrysanthi Skoumpourdi

University of the Aegean, Rhodes, Greece; [kara@aegean.gr](mailto:kara@aegean.gr)

*Although inquiry-based education is an approach that supports student-centered ways of teaching involving students in the development of their own learning, it seems that inquiry-based instruction has not been employed broadly in the subject area of mathematics and the few studies that have been conducted are not focused on very young children. In this paper an inquiry-based implementation of a mathematical activity in a kindergarten classroom is presented investigating the way it was applied by the teacher and the way students participated into it. The activity was related with plane geometrical shapes as a mathematical construct that cause difficulties to young students. From the results it emerged that even though the inquiry-based implementation is a demanding approach it had many benefits for both teacher and students.*

*Keywords: Inquiry-based education, early childhood education, mathematical activity, plane geometrical shapes.*

## Introduction

A mathematical construct that cause difficulties to young students is the plane geometrical shapes. It is a concept that needs to be communicated multimodally (Clements & Sarama, 2007), because their iconic representations need ‘observation’, ‘reading’ and parallel ‘description of this reading’ in order to be understood (Skoumpourdi, 2016). The ‘observation’ factor has to do with shape’s visual perception. The ‘reading’ factor is focused on shape’s figural properties. The ‘description of this reading’ factor requires the description/communication of the above. The above three factors can help students face their difficulties, so as, to develop gradually the shape’s concept, but through the appropriate teaching method, since, geometrical thinking is main influenced by instruction.

Inquiry-based teaching is a theoretical approach that supports more student-centered ways of teaching. It is an approach that actively involves students in the development of their own learning supporting their active participation to the teaching/learning process. But, the effects of inquiry-based teaching remain limited and the inquiry-based education has been slow in mathematics due to several reasons such as the very low attention that has been paid to that approach, the imprecise definition of the approach, as well as, the peculiarities and the demands that are required for its adoption and promotion.

Taking the above into consideration an educational design research study is conducted, aiming to investigate how teachers and students adopt and apply the inquiry-based approach in the mathematics classrooms. In this paper an inquiry-based implementation of a mathematical activity related with plane geometrical shapes in a kindergarten classroom is presented investigating the benefits and the demands of such an implementation in order to design the gradual adoption of the approach in the subsequent educational levels. The research questions were the following: 1. How the teacher implements a mathematical activity related to plane geometrical shapes, in a kindergarten classroom,

grounded on the inquiry-based approach? 2. How the students participate in the inquiry-based implementation of a mathematical activity related to plane geometrical shapes?

### **Geometrical Shapes in the Kindergarten**

Kindergarten children identify and describe shapes through levels. The first one is the pre-recognition level (Clements & Sarama, 2007), in which children may recognize only a subset of a shape's visual characteristics. In this level, children cannot distinguish the basic shapes from their counterexamples. The other levels are the first two of Van Hiele's levels of thought (Yin, 2003). At the first one, 'visualization', children identify shapes according to appearance and cannot form mental images of them. At the second level, 'analysis', children start analyzing and naming properties of geometric figures. They use shapes' properties to recognize and characterize shapes.

Circle, square, triangle and rectangle, when represented in a prototype way can be recognized and named by kindergarten children. Shape's features and whether they can be defined (closeness, straight sides and exact number of sides) or not (orientation, position, sides' length and angles' size) influence the accuracy of children recognitions (Satlow & Newcombe, 1998). Young children identify circles accurately, they are less accurate in identifying triangles and their average accuracy for rectangles is low (Clements & Sarama, 2007).

Children in the age of five-years-old have a difficulty in describing shapes. The language that children use to describe shapes is gradually developed (Clements & Sarama, 2007). Initially they answer the question "what shape?" with the use of just a word, the shape's name. Then they match this word with specific shape examples. After that, they combine the correct shapes' names with the prototypical examples of the shapes. When children are asked to explain their decision, they are induced to describe shapes' features, using, initially, a subset of the shape's visual characteristics, such as the quantity and the size of sides (Yin, 2003). Although children's primary descriptions may include various terms and attributes they usually base these descriptions in the comparison with the specific shape's representation. Later, children become more capable of distinguishing attributes and adding to their descriptions other visual-spatial elements like right angles.

Children's written schematisation for a circle is something closed and 'rounded', for a square something closed with almost equal sides and nearly right angles, for triangle something closed and 'pointy' and for a rectangle something closed with 'long' like-parallel sides (Clements & Sarama, 2007).

Instruction influences the development of geometric thinking more than age does (Van Hiele, 1986). But in traditional geometry programs, during formal and informal instruction, little emphasis is given on understanding plane shapes, incorrect statements and terminology are used, no new content is added (Clements & Sarama, 2007) and inappropriate examples of geometric shapes are used. On the other hand, in contexts such as team games, that teacher's guidance is limited, it seemed that kindergartners recognized shapes in different types, sizes and orientations and could describe some of the shapes' basic attributes such as sides and angles (Skoumpourdi, 2016). But children did not use more sophisticated descriptions related to shapes' specific characteristics like the equality of shapes' sides, and the schematisations they used in the game, to describe an atypical shape, were not accurate. Thus, it was hypothesized that inquiry-based approach could be an effective method of

teaching plane geometrical shapes in the kindergarten.

### **Inquiry-Based Mathematics Education**

Inquiry-based mathematics education, is one of the main aspirations of innovation in the field of mathematics education focusing more on cooperative problem solving, on understanding, on learning processes and strategies, on posing and answering questions and on cultivating exploratory practices, than learning mathematical skills only (Calder, 2015). Students in that approach are in the center of the learning process. They are actively involved in explorations and discussions, in posing questions, in making assumptions, in expressing, explaining and communicating their opinions, presenting their solutions to a problem, justifying them in a way that is understood both by the other students and the teacher (Eckhoff, 2017). Teachers create opportunities to students and work cooperatively with them to facilitate and support their mathematical constructions. They transfer the problem-solving responsibility to the students by posing questions linked with the inquiry-based activity, giving meaning to student's actions and developing their understanding without, at least initially, intervening and suggesting ways of thinking.

Research results highlight the benefits and demands of inquiry-based method on teaching practices. When analyzing a teacher's practice following an inquiry-based program, it emerged that although the teacher at the beginning of the program had very limited knowledge of the subject, after the program he was able to apply inquiry-based practices (Towers, 2010). Also, in a research program, it came out that although the process brought uncertainties and tensions within the teachers' practice and between the practices of teachers and didacticians, the value of the approach for the learning emerged by the knowledge gained by participants (Goodchild, Fuglestad, & Jaworski, 2013). In a study on how prospective teachers adopt inquiry-based approach in their professional development it seemed that they: 1. resisted to the adoption of the inquiry approach, 2. partially adopted the inquiry approach, or 3. fully adopted the inquiry approach. At the end of the course all students stated that they built a theoretical understanding of the inquiry teaching and they felt a bit more able to design and implement inquiry-based activities (Σκουμπουρδή, 2017). Teachers' difficulties to adopt inquiry-based pedagogies, to develop and manage collaborative cultures within the classroom and plan lessons that adapt to the emerging needs of learners (Swan, Pead, Doorman, & Mooldijk, 2013) are mentioned in research. Other obstacles and difficulties that the teachers face in adopting the inquiry-based method for teaching are the lack of experience and of complete understanding of the method, the lack of enough allocated teaching hours, as well as the lack of believe that students can be prepared for succeeding in tests with that method (Chin & Lin, 2013). The lack of teachers' familiarity with the method and the need of advanced professional development, which will equip them with multiple teaching strategies to create an adaptive and enriched learning environment is also indicated in research (Wu & Lin, 2016). In sum, active teachers lack knowledge of the inquiry-based approach, they have difficulty in adopting and applying this approach in practice, as well as they have difficulty in designing inquiry-based activities. These obstacles might cause the lack of inquiry-based instruction being employed broadly in the subject area of mathematics and the lack of studies being conducted with a focus on very young children.

Taking into consideration the above results an 'inquiry-based implementation' of an activity related

to plane geometrical shapes, was conducted in a kindergarten, investigating the way it was realized by the teacher as well as the way that kindergartners participated in such an intervention.

## Method

For the main research study, which aims to investigate how teachers and students adopt and apply the inquiry-based approach in the mathematics classrooms, the design-based research is used, as the methodology to develop learning theories and tools designed to support learning (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). Through this method, which is intrusive in nature, changes and revisions are taken place, in every stage of the main research which enables the simultaneous development and testing of the inquiry-based approach as an innovative learning environment, giving an insight into whether, how and under which circumstances this approach can work. In this paper the benefits and the demands of the approach in a kindergarten classroom is presented.

### The kindergarten classroom and the mathematical activity

The kindergarten classroom, where the intervention took place, had 25 students divided by the teacher in four teams and was chosen because the teacher uses student-centered methods, cultivating the conditions for math discussion. She is also positive to innovations.

The author explained to the teacher the basic characteristics of the inquiry-based approach and encouraged her to use it through the Framework for Inquiry-Based implementation of Activities (FIBA) (Skoumpourdi, 2017). The FIBA consists of seven stages: 1. Task: A problem-based task is invented and presented. 2. Exploration: Children use their own problem-solving strategies to explore the problem. 3. Presentation: Children share their explorations with the whole class by presenting their solutions. 4. Connection: Teacher, in cooperation with students, connect the presented solutions with each other, with the task that was explored and with the mathematical aims. 5. Generalization: Teacher is generalizing students' solutions. 6. Translation: Students translate their solutions through different modes—verbalizing, gesturally and schematizing. 7. Expansion: Expanded problems are posed. For the implementation of the mathematical activity by the teacher the FIBA was used.

The mathematical activity, designed by the author, was developed in such a way as to problematize and incite children, engaging them in a problem solving and posing process. The problem to be solved was a non-standard, unfamiliar, a bit complex and novel situation in order not to be solved just by applying existing knowledge and already-known strategies, but through exploration and discussion.

**Figure 1: The ‘Enchanted butterfly’**

**Figure 2: Students shapes’ schematizations**

The scenario of the task was the following: "Once upon a time, a strange magician, who envied the happiness of the Shape-Town, captured with his spells its inhabitants (shapes) on the wings of butterflies flying around his enchanted forest. This strange magician would be good enough to solve the spells only if the children would help the inhabitants-shapes to liberate. The spells would be solved only if the children managed to recognize the shapes hidden in the butterflies' wings". The butterfly had in its wings the four-basic plane geometrical shapes (circle, square, rectangle and triangle) in various types and orientations, as well as counterexamples of them (Figure, 1).

## Results

In the beginning, the problem-based task was presented by the teacher through the context of the 'Enchanted Butterfly' (FIBA's 1<sup>st</sup> stage: Task). The teacher in this stage asked each team of children to mark one kind of shape. The 1<sup>st</sup> team had to mark the shapes they thought to be circles, the 2<sup>nd</sup> team the squares, the 3<sup>rd</sup> team the rectangles and the 4<sup>th</sup> team the triangles.

Each team independently explored the shapes on the Butterfly, posing questions to each other and to the teacher in order to identify and mark the correct shapes giving a right answer to the problem (FIBA's 2<sup>nd</sup> stage: Exploration). Although, in general, each child thought about the problem on their own and marked a shape, each in turn, there were instances in which wrong shapes were marked and thus interesting discussions between children of each team and with the teacher took place regarding the identity of the shapes. Debates of whether a shape is a triangle or not, is a square or not, is a rectangle or not, is a circle or not, took place. An example is described in the following dialogue [The letter T refers to the teacher and S1, S2 etc. refer to the young students. The symbol ( ) is used when many children speak simultaneously and our notes are in brackets]:

- S1: Is this a circle?
- T: You will discuss with your team and you will find out.
- ( ): It is circle, it is not, it is circle, it is not, it is circle but is a small circle [a girl tried to mark it but the other girl pushes her hand away] ...., it is not a circle, is an oval.
- S3: These are the ovals: one, two [a boy counted by showing the oval shapes].
- S2: Mrs, is that correct [shows the marked circle that created a debate in the first stage]?
- T: What shape is it?
- S2: It is circle.
- T: Yes, it is.
- S2: I was telling you ... [said to her classmate that she insisted that the shape was oval]

Similar debates were also carried out for the other shapes and especially for the non-prototypical examples and the counterexamples. The identity of the triangles, the squares and the rectangles were justified, by the children, by counting shapes' angles. But this strategy was not always effective. For example, when a girl showed a counterexample as a triangle, another child told her: "No, this is a 'square' because it has four angles" and the other team members disagreed by saying "No, it is not, it is a shuttle". The orientation of the shapes did not seem to confuse the children. This might have

occurred due to the way the team members sat around the table, allowing them to have different perspectives of the shapes. Once they explored the shapes and discussed about them each team marked ‘their shapes’.

After that, each team shared their explorations with the whole class by presenting/describing their shapes (FIBA’s 3<sup>rd</sup> stage: Presentation). The teacher, in that stage, observed and organized each team’s presentation, posing questions to help children describe, explain and open out their explorations, as well as to ensure effective and understandable presentations. For example, during the ‘circle team’ presentation the following discussion took place:

- T: How did you understand that all these shapes are circles?
- S2: Because it is round, and this is round, and this is round ...
- T: I think that this is also round [showed an oval, placed horizontally].
- S3: No, this is like an egg.
- T: So, is not a circle?
- () : No.
- T: Is that shape circle [showed an oval placed vertically]?
- () : No, this is not a circle.
- T: But in my opinion is round, why it is not a circle?
- S2: Because it is oblong [showed with her hands] and the circle is not oblong.
- T: Why are these shapes circles?
- S3: Because they do not have angles.
- S2: And because circles are thicker than ovals

For the other shapes, children’s answers in the question ‘why these shapes are triangles (squares/rectangles)?’ were focused on the amount of their angles as well as the amount of their sides, with the usual answer being that: “It is triangle because it has 3 angles and 3 lines/sides”.

The teacher posed advanced questions to the members of each team. For instance, when a boy presented his teams’ shapes and said that “this shape is rectangle because it has four sides”, the teacher continued, by showing a square near it, asking “So I can assume that this shape is also a rectangle because of its four sides?” and vice versa. Or, she was addressing to the children supposing that “this shape (showing counterexamples) is e.g. triangle (rectangle)” calling them to reflect on that statement. Children, in general, had answers to those questions, justifying them by relying on the specific iconic representation. Their answers were as follows: “It is not a rectangle because it has different height”, “It is not a square because it is thin”, “It is not a triangle because this shape has seven lines”. When children had difficulty in their justifications they used gestures in order to present their solution: “It is not a rectangle because it is like that ... (trying to show the curvature sides by gestures)”.

After the presentations, teacher, in cooperation with all the students, orchestrated a mathematical discussion trying to connect presentations with each other, with the ‘Enchanted Butterfly’ task, as

well as with plane geometrical shapes concept so that a shared meaning to emerge (FIBA's 4th stage: Connection). She also tried to generalize plane geometrical shapes concept connecting it with students' previous knowledge (FIBA's 5th stage: Generalization). She posed combining questions to the students, bringing back, for negotiation, issues that were discussed such as: "Does the circle looks like the triangle?" or "Does the square looks like the rectangle?". In the first question, children's one-word answers, through the re-questions of the teacher, were transformed into 'documentations', such as "Circle does not look like triangle because circle does not have angles", "the triangle is pointed ... the circle is not". Teacher's second question seemed to confuse children and their answers differed, claiming that they look like, but the rectangle is bigger or that they do not resemble because they are different shapes with different sizes. These issues, such as the similarities and differences of shapes (circle and oval, square and rectangle), expanded the activity and could be the context of new activity in order to be discussed more thoroughly (FIBA's 7th stage: Expansion). At the end of the activity, students were asked to make a painting in order to explain to their parents what they had done in that activity (FIBA's 6th stage: Translation). Children's schematizations looked like the visual prototypes except the rectangle which was placed vertically (Figure 2).

## Conclusions-Discussion

An inquiry-based implementation of a mathematical activity is a complex situation, that requires from the teacher time, effort and deep knowledge of both the approach and the subject matter and from the students to develop various skills, abilities and capabilities to be actively involved in their own learning, constructing mathematics concepts and ideas. From the results of the implementation it seemed that the FIBA, as a readymade framework, helped the teacher to adopt and realize an inquiry-based teaching process encouraging exploration, presentation, connection, generalization, translation and expansion, cultivating cooperation, communication and justification, through a child-centered approach. In all the FIBA's stages, teacher activated students' questions, ideas, actions and comments and tried to turn them into learning opportunities. She also successfully scaffolded the mathematical discussion between the students and herself, guided team work and the whole classroom as a community of learning. Inquiry-based approach helped students to develop their cooperation, communication and justification capabilities. It also helped them to construct the idea of plane geometrical shapes.

The research results about young children's abilities for plane geometrical shapes were confirmed in this paper. But it also became obvious that although there were children in the pre-recognition level, recognizing only some of shape's visual characteristics, they moved on the visualization and the analysis level using shapes' properties to recognize and to characterize typical and atypical shapes through the cooperative exploration, discussion and justification process. Children, initially, described or compared the shapes using specific shapes' representation features. All shape's features either defined or undefined were recognized by children because of the way the activity presented and implemented. Students had identified and named plane geometrical shapes in various forms and orientations, recognized them among counterexamples, communicating their descriptions, discussing about their characteristics and particularities. They had also translated their solutions and constructions to schematic representations that looked like the visual prototype but there were also variations.

# Perceiving and using structures in sets – the contribution of eye-tracking in a three-level evaluation process

Priska Sprenger<sup>1</sup> and Christiane Benz<sup>2</sup>

<sup>1</sup>University of Education Karlsruhe, Germany; [priska.sprenger@ph-karlsruhe.de](mailto:priska.sprenger@ph-karlsruhe.de)

<sup>2</sup>University of Education Karlsruhe, Germany; [benz@ph-karlsruhe.de](mailto:benz@ph-karlsruhe.de)

*The investigation of children's perception of structure gains in importance in research of mathematics education. In this article we discuss a three-level evaluation process to generate hypotheses about the way preschool children perceive structures and how they use them to determine the cardinality of sets. Eye-tracking data can help to get some deeper insights into these processes of perception and determination. In sum it is shown that the interaction of three different types of data (observation aspects, explanation and eye-tracking data) are important to generate some final hypotheses about the two processes.*

*Keywords: Perceiving structures, structural use, eye-tracking, preschool education, early mathematics education.*

## Introduction

Structures play an important role both in the daily life of children and also in mathematics and therefore in mathematics in early childhood education (Schöner & Benz, 2018). Looking on children's mathematical development, structures are obviously essential e.g. for geometrical and arithmetical patterns, for learning the number sequence from twelve onwards but also for identifying quantities. Mulligan & Mitchelmore (2013, p. 31) point out that structure “has been also a growing theme in the past two decades of research on students' development of numerical concepts.”

## Theoretical background

Hunting (2003) describes very clearly the importance of perceiving structures for numerical development by emphasizing the ability to change the focus of counting every single item to perceiving and identifying structures of parts in sets. If children are able to identify structures in sets they have the chance to develop a mental image of a number which does not only exist of many single items but also of parts. A mental image of a set consisting of parts is equivalent to the part whole understanding of numbers. Studies confirm the connection between the ability to perceive structures and part-whole understanding (e.g. Young Loveridge, 2002) and also general arithmetical abilities (Lüken, 2012, Mulligan et al., 2004; Obersteiner, 2012).

Because perceiving is an individual and invisible act it is not easy to investigate how and if children perceive structures. Eye-tracking can help to get some insights. Eye tracking data “draws on the so-called “eye-mind” hypothesis (Just & Carpenter, 1976) meaning that what a person looks at is in the focus of the person's cognitive processes and that a person's eye-movements are tightly related to their cognitive processes (Jang et al., 2014)” (Schindler & Lilienthal, 2017, p. 47). Still, using eye-tracking with young children is quite new in the field of mathematics education and data has to be interpreted carefully (Schöner & Benz, 2018). Especially concerning young children's perception of structures in sets there is no comparable eye-tracking data available. Therefore, the aim of the study

reported in this paper is to investigate if and how children perceive structures in sets and if and how they use it for identifying the cardinality of sets. When children determine the cardinality of a set, observations such as audible counting can indicate how a child has determined the number. Subsequently, the child can also be questioned how the number was determined. But, in order to get insights into the perception process, in this paper it is examined how the research tool eye-tracking can help to give insights into this invisible act of perception. In order to analyze the data a theoretic model is used, in which it is distinguished between the process of perceiving a set and determining cardinality. These processes can be subsequent or coincide e.g. as it is the case by (structural) subitizing (Schöner & Benz, 2018).

## Research question

In this paper we aim to answer the research question regarding the way of investigation visual structuring abilities of preschool children:

What can the eye-tracking data contribute to the analysis approach of children's perceiving and determination processes concerning the use of structures?

## Design

The presented study has a pre-, post-, follow-up-design. 95 children were interviewed individually at three times. The children were between five and six years old and they attended the last year of kindergarten. They were divided in a treatment group ( $n=55$ ) and a control group ( $n=40$ ). The first interview took place at the beginning of the kindergarten year, the second after an implementation phase for four months and the third at the end of the kindergarten year. The treatment group got a box with different materials and games which offer the opportunity to discover and facilitate perceiving structures in sets and using the structures to determine the cardinality. The control group didn't get these materials and games. All the three interviews with the children described above consist of different parts. In this paper we focus only on the part with photos of egg cartons of ten eggs. This is the usual package for eggs children usually know from daily life. Different numbers of eggs were presented on a monitor. With the help of an eye-tracking camera the eye-movements of the children were recorded. In the presented evaluation, the six items with the cardinality of five, seven and nine were used (cf. Figure 1).

**Figure 1: Items that have been evaluated**

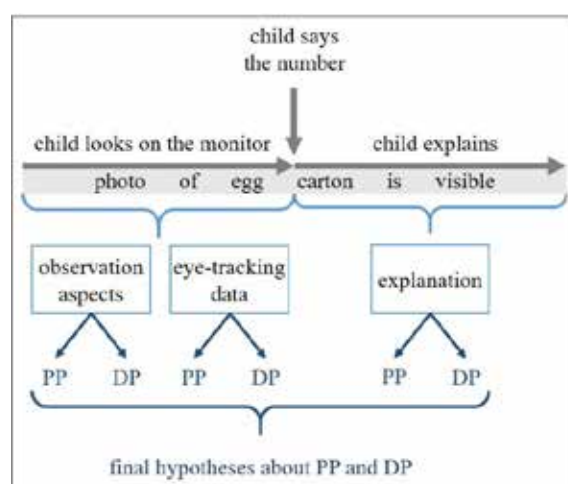

Before the interview started, the children had been told that the interviewer always wants to know "how many eggs" there are and that they should say the number as soon as they know it. The children were given no time restrictions. As soon as the child said a number, the interviewer asked for example: "How do you know that there are  $n$  eggs?" In addition to the eye-tracking camera, there were two more cameras. Activities such as finger pointing or lip movements could be observed through an external camera positioned diagonally behind the child and through a webcam. These gestures are considered when evaluating the processes of perception and determination.

## Task

Each child was shown photos of egg cartons on a monitor. On the photos different numbers of eggs were presented at the same position on the monitor. Each item started with the presentation of a closed egg carton. Then an open egg carton with eggs appeared. The child said a number, the interviewer asked how it came to the result, the child explained and then a closed carton was presented again.

## Aspects of analyzing

The basis of the analysis consists of qualitative categorization processes. Based on a theoretical model (cf. Schöner & Benz, 2018) the analysis of the data is divided in two processes: the process of perception (PP) and the process of determination (DP) (cf. Figure 2). Hypotheses about these processes are generated on three different types of data. There are *observation aspects* generated during the time the child sees the egg carton until it says the number of eggs such as gestures, sounds or promptness of the answers. Additional information by *eye tracking data* is gained recording the eye tracking movements until the child says the number of eggs. The eye-tracking data provides insights into the children's process of perception. After the child said the number there is also data of children's *explanation* (cf. Figure 2).

**Figure 2: Scheme of evaluation process**

Based on these three kinds of data, hypotheses about perceiving structures in sets and structure-using strategies to determine the cardinality can be formed. These three kind of data lead to a final hypothesis about the perception process (PP) and the determination process (DP). Because of the limitation of the number of pages the way coming to these final hypotheses cannot be presented in detail here (see Schöner & Benz, 2018). So the evaluations are based on a hypothesis-generating process. In the following, the frequencies are given for perceiving structure or perceiving no structure during the PP and using structure or using no structure for the DP. Only hypotheses which could be assigned to these categories are included, all other categories are here not taken into account.

## Results and first interpretations

In the following tables the arithmetic average of strategies solving the five described items is given. In this paper, the focus is not on significant differences between points of investigation or groups, the percentages are rather used to show how the three types of data can help to give insights into the

analysis process. The percentage frequencies given in Table 1 are based on the observation aspects. They are divided in the two processes the PP and the DP. The range for structure perception and structural use for determination is between 2% and 9% for both groups. Perception is very difficult to observe because it is actually an invisible act (cf. Schöner & Benz, 2018). This fact could be one possible interpretation for these low percentages. An observation aspect which could be assigned to the category structure for example is, when a child uses his hands to show a structure or verbally names a structure. As shown in Table 1 observation aspects which indicate that a child does not perceive a structure (cf. Table 1) could not be found. On the other hand, for the non-structural use in the determination process for both groups, the range of the percentage frequencies is between 30% and 58%. Nodding, pointing with the finger or audibly counting are aspects which can be observed easily. Therefore counting every single item, which means using no structure to determine the cardinality is more obvious to observe. Here, both groups show a different decrease: 16% for the control group and approximately 28% for the treatment group. An assumption for the decreasing frequencies of counting every single item from t1 to t3 is that perhaps the children start to use more and more structures to determine the cardinality.

	Perception Process (PP)						Determination Process (DP)					
	structure			no structure			structure			no structure		
	t1	t2	t3	t1	t2	t3	t1	t2	t3	t1	t2	t3
<b>treatment</b>	8.5	5.2	4.5	0.0	0.0	0.0	4.2	2.4	3.9	57.6	37.3	29.7
<b>control</b>	5.4	7.5	5.4	0.0	0.0	0.0	3.3	5.4	4.2	47.8	40.4	32.1

**Table 1: Arithmetic mean of percentage frequencies based on observation aspects**

Table 2 shows the percentages of structural and non-structural perceiving as well as the use for determination based on the child's explanation after saying the number (cf. Figure 2). Such an explanation could be, for example, the naming of subsets or the statement "I have counted". Based on the explaining, more structural perceiving and structural use could be observed than based on the observation (cf. Table 1). The variation in (not) perceiving structures and (not) using structures are very similar in both groups and for both processes. Both in terms of perceiving structures and using structures to determine the cardinality, an increase of approximately 36% from t1 to t3 can be observed. In addition, the non-structural use to determine the cardinality decreases from t1 to t3 in both groups.

	Perception Process (PP)						Determination Process (DP)					
	structure			no structure			structure			no structure		
	t1	t2	t3	t1	t2	t3	t1	t2	t3	t1	t2	t3
<b>treatment</b>	31.2	49.4	66.7	0.3	0.3	0.0	27.0	45.2	63.6	13.0	9.1	2.4
<b>control</b>	29.2	42.9	67.1	4.6	7.9	0.0	32.9	48.8	66.3	18.3	7.9	2.1

**Table 2: Arithmetic mean of percentage frequencies based on explanation**

In Table 3 the arithmetic mean of percentage frequencies of structural and non-structural perceiving and using based on the eye-tracking data is shown. The eye-tracking data shows in which order and how long the child has fixed the (individual) eggs. An illustration of Table 3 is presented in the diagram in Figure 3.

	Perception Process (PP)						Determination Process (DP)					
	structure			no structure			structure			no structure		
	t1	t2	t3	t1	t2	t3	t1	t2	t3	t1	t2	t3
<b>treatment</b>	<b>31.2</b>	<b>47.6</b>	<b>60.6</b>	<b>30.9</b>	<b>21.2</b>	<b>17.9</b>	<b>26.1</b>	<b>40.0</b>	<b>54.5</b>	<b>30.6</b>	<b>26.4</b>	<b>23.0</b>
<b>control</b>	<b>50.4</b>	<b>48.8</b>	<b>54.6</b>	<b>18.3</b>	<b>22.9</b>	<b>19.6</b>	<b>37.1</b>	<b>40.0</b>	<b>48.3</b>	<b>24.6</b>	<b>29.6</b>	<b>24.6</b>

**Table 3: Arithmetic mean of percentage frequencies based on eye-tracking data**

For all categories the range based on eye tracking data is between 18% and 61% for both groups. The range for the structural perceiving and using is between 26% and 61%, the range for the non-structural perceiving and using is between 18% and 31%. In the determination process an increase for the use of structures could be observed for both groups. In sum, a lot of hypotheses could be built. Looking on the PP there are differences between the groups. An increase of approximately 30% is observed in perceiving structures of the treatment group (from 31% (t1) to 61% (t3)). The control group starts at t1 at a higher frequency, and increases in total from t1 to t3 only by about 4% (from 50% (t1) to 55% (t3)). Also a decrease from t2 to t3 is observable (cf. Table 3). The frequencies of perceiving structures in the treatment group at t3 are higher than those of the control group. In the DP, a similar tendency can be seen. An increase of approximately 30% is observed in the structural use of the treatment group (from 26% (t1) to 55% (t3)). The control group starts at t1 again with higher percentages, but increases in total from t1 to t3 by about 10% (from 37% (t1) to 48% (t3)) (cf. Table 3 and Figure 3).

**Figure 3: Arithmetic mean of percentage frequencies based on eye-tracking data**

The percentage frequencies given in Table 4 are based on all three types of data: observation, explanation and eye-tracking data. These frequencies correspond to the final hypotheses briefly mentioned above.

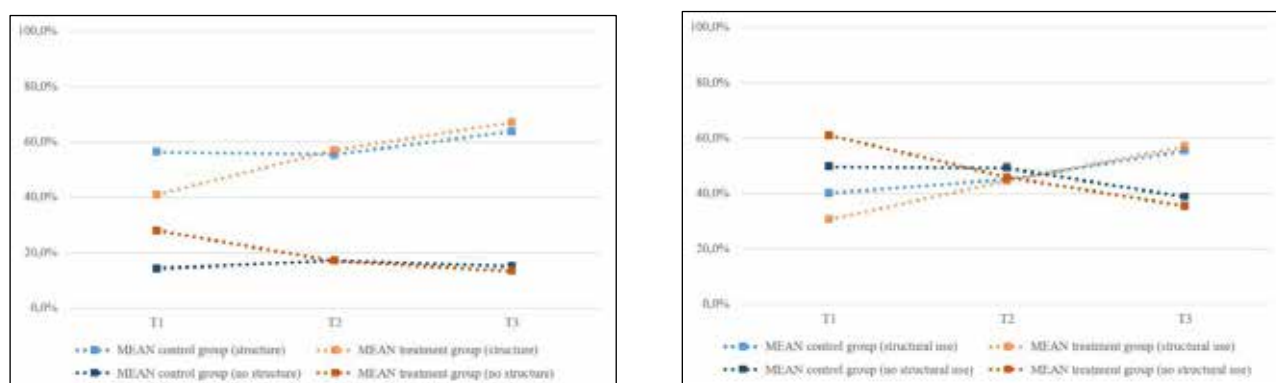

Perception Process (PP)		Determination Process (DP)	
structure	no structure	structure	no structure

	t1	t2	t3	t1	t2	t3	t1	t2	t3	t1	t2	t3
<b>treatment</b>	<b>40.9</b>	<b>57.0</b>	<b>67.0</b>	<b>27.9</b>	<b>17.0</b>	<b>13.3</b>	<b>30.6</b>	<b>44.5</b>	<b>57.0</b>	<b>60.9</b>	<b>45.8</b>	<b>35.5</b>
<b>control</b>	<b>56.3</b>	<b>55.4</b>	<b>63.8</b>	<b>14.2</b>	<b>17.1</b>	<b>15.0</b>	<b>40.0</b>	<b>45.0</b>	<b>55.4</b>	<b>49.6</b>	<b>49.2</b>	<b>38.8</b>

**Table 4: Arithmetic mean of percentage frequencies based on observation aspects, explanation and eye-tracking data**

An illustration of the frequencies of Table 4 can be seen in Figure 4. Here similar tendencies can be seen as in the data based only on the eye-tracker (cf. Figure 3).

The frequencies of the structural perceiving and using both for the PP and DP of the control group are also higher at t1 than of the treatment group. Nevertheless, the percentages of the treatment group increased both for the PP and DP, so that the percentages of structural perceiving and use at t3 are higher than those of the control group. In the determination process an increase for the structural use could also be observed for both groups. For the frequencies of non-structural perceiving and use an opposite tendency can be noticed for the treatment group. The more structures are in the PP and DT, the less non-structural can be seen or vice versa (cf. Figure 4). In the control group a similar tendency can be observed. It's remarkable that in the PP there is a decrease from t2 to t3 and overall, a smaller increase can be seen compared to the treatment group (cf. Table 4).

**Figure 4: Arithmetic mean of percentage frequencies based on observation aspects, explanation and eye-tracking data**

## Summary of the results

*Observation aspects* only provide few data (range: 0-9%) for perceiving and using structures. For the development of perceiving and using structures to determine the cardinality only few hypotheses can be derived. The sole exception is found in the DP concerning non-structural use. In the DP, a decrease is observed in non-structural use in both groups (control group: 16% from t1 to t3, treatment group: about 28% from t1 to t3). A possible interpretation would be that non-structural use decreases but perceiving structures increases. The latter case could not be seen in the observation aspects but nevertheless the conclusion about an increase in perceiving structures becomes possible.

Data based on *explanation* provide more information about structural use in DP and PP (range: 27%-67%). There are very similar tendencies: In each group, an increase of approximately 36% in perceiving structures and structural use is observable. Similar to data based on observation aspects

no information can be gained for non-structural use in the PP. In the DP there is less information available than for data collected with observation aspects.

Data based on *eye-tracking* (cf. Table 3) provide more information than data based on observation aspects and explanation. The data show an increase in perceiving and using structures to determine the cardinality (Treatment group: PP: 30% from t1 to t3, DP: 30% from t1 to t3 / Control group: PP: 4% from t1 to t3, DP: 10% from t1 to t3). In both cases (PP and DP) the control group starts at t1 at a higher frequency and the frequencies of perceiving structures in the treatment group at t3 are higher than those of the control group. In sum, a lot of hypotheses could be generated.

Hypotheses based on all *three kinds of data* (observation aspects, explanation, eye-tracking) show similar tendencies as the eye-tracking data. The frequencies show nearly the same increase of perceiving and using structures to determine the cardinality in the treatment group (PP: 26% from t1 to t3, DP: 26% from t1 to t3). In comparison to this a very small increase is also observable in the control group (PP: 8% from t1 to t3, DP: 15%) (cf. Figure 3 and Figure 4). Also the frequencies for no structural perceiving and using are similar. In sum, the changes in perceiving and using structures for determining the cardinality are almost identical to the changes shown by the eye-tracking data (cf. Table 3 and 4).

## Discussion and Conclusion

The following tendencies about perceiving and using structures to determine the cardinality are generated only from the observation aspects and the explanation (without eye-tracking data): The data from the observation aspects show a decrease of the non-structural use which leads to the interpretation that there is a simultaneous increase of using structures to determine the cardinality. In the data of explanation an increase of perceiving and using structures can be observed and also a decrease in non-structural use. This leads to the conclusions that there is a consensus in the increase for using structures to determine the cardinality and also for perceiving structures. Both groups nearly have the same frequencies and ranges.

Coming back to the research question: What can the eye-tracking data contribute to the analysis approach of children's perception and determination processes concerning the use of structures? One advantage of the eye-tracking is to get some deeper insights in the invisible perceiving process when making it visible. This could for example be interesting if children have a lack of words to describe how they perceived a structure. These linguistic difficulties may be due to the linguistic development (because of the age of the children) or to another native language. The eye-tracking data leads to additional information especially for the PP. The data also show that in the treatment group a clearer development in perceiving structures and using structures to determine the cardinality has taken place than in the control group. In a next step, the significance for these frequencies are checked.

However, eye-tracking data has to be interpreted. So far, there are no comparative data from children in this age from other studies that could help or give some directions. In order to come to an interpretation of the recorded eye-movements, the explanations and the observation aspects of the children are often important. So an inductive approach to generate hypotheses from the eye-tracking data is necessary about how children perceive structures in sets.

In the first step of analysing data most of the eye tracking data only could be interpreted because of the additional information from the observation aspects and the explanation. Due to this data, categories could be generated in order to analyse the eye-tracking data. In a second step of analysing the data it could be referred to these categories of eye-tracking data, especially in cases where no additional data exists. For this reason, all three types of data are important not only for the interpretation of the eye-tracking data but also for generating the final hypotheses. Thus, in this study the three-level evaluation turned out to be viable, because the observation aspects, the explanation and the eye-tracking data complement each other and interdepend.

# Construction of scientific basis for pre-school teacher education

Christina Svensson

Malmö University, Sweden; [christina.svensson@mau.se](mailto:christina.svensson@mau.se)

*Keywords: Teacher education, mathematics education, variation theory, preschool*

In university education, students are prepared for a future that is both known and unknown (Marton, 2014). Educators try to prepare the students in the unknown by raising the known. The best and most powerful way is to try to develop and contribute tools that can support students for new situations in future professions as a teacher (Marton, 2014). Investments in teacher education indirectly affect what opportunities for education future students have. In Sweden, several studies have made it clear that students' skills are not enough internationally. This has increased focus on preschool opportunities to contribute to higher goal achievement later on in school. Furthermore, discussions about higher goal achievement can be discussed in relation to how pre-school teacher education contributes to the opportunities for students in future enable success in the subject of mathematics. Niss (2001) argues that the term mathematics constitutes five different "faces", each face representing mathematics in a certain context. A mathematical content can thus be interpreted differently depending on the face or context from which it is considered. For example, teacher education can be taken into account as both a very important element as very different in the fourth face. Furthermore, Alrø and Johnsen-Høines (2010) argue how communication between educator and child affects the quality of mathematics learning. They consider that teachers in the early ages rather use an evaluation strategy of mathematic knowledge than investigative methods in their mathematic teaching. This teaching strategy could impede a more exploratory approach to mathematics education (Alrø & Johnsen-Høines, 2010). A strategy that can be related to Marton's (2014) argument for the development of deep understanding. It can be put in context in the sense of deepening their own mathematical understanding in order to identify others' understanding of the subject. In order to highlight the complexity it means to visualise understanding of a subject and thus the understanding of others, by using more theoretical frameworks (a.a). Several arguments arise in relation to the teacher's importance in creating a structure for the learning in mathematics in preschool. Research in mathematics teacher education is therefore of great importance because the quality of education affects the quality of future teacher training, which in turn affects the quality of student performance. In this study teacher students are challenged during an intervention study based on theoretical knowledge input consisting of Bishop's six mathematical activities (1988) and variation theory (Marton, 2014). This leads to the following question: In what way does theoretical knowledge input contribute pre-school teacher students to identify children's mathematical understanding in different learning activities in preschool?

## Theory

Within the variation theory, the purpose of learning is the ability to do something with something (Marton, 2014). In order to understand learning, especially what is crucial for learning, it is necessary to take into account what is actually learned in different learning activities (Marton, 2014). Further in variation theory, the differences in which aspects are perceived at the same time are significant for learning. In order to experience or understand something in a certain way, certain aspects must be perceived. It is the perception of these aspects that are crucial to learning (Marton, 2014). From an

educational point of view, aspects that are considered important on the basis of the learning of a chosen learning object. Marton (2014) describes how a difference in how the same phenomenon is experienced has to do with differences in discernment. Discernment based on variation theory which focuses on learning activity (Marton, 2014). Furthermore, learning is also a question of being able to distinguish and differentiate which aspects are considered critical to a specific group in a specific situation based on a chosen learning object. It is thus through increased understanding of what is critical to distinguish that increases knowledge and conditions for learning in relation to the goals.

## Method

A pre and post -test has been constructed consisting of eleven learning activities in preschool based on Bishop's (1988) activities. The empirical data consists of data from the respondents' written reflections of the pre-and post -test. Data collection has taken place three times before, between and after they have participated in teaching with different designs. The two different designs within the course consist in offering two groups (73 students) of six more opportunities for teacher supervision by teacher educators, who are involved in both theories, based on their completed documented field studies that integrate theory and practice. All six groups have been taught in the two theoretical elements but individually. Analysis of the collected empirical data consists based on variation theory, focusing on identifying differences in how students in the different groups distinguish the object of learning for the children and the opportunity for the children's understanding on the same.

## Results and Conclusion

Preliminary results indicate that the teacher students who are offered more support into the two theoretical elements at the same time, identify more mathematical learning objects in the constructed pre- and post-test. Which leads to discussion of what in the theoretical input contribute and support meta-reflection in relation to deeper understanding of other mathematical understanding. A contribution to the development of the student's profound understanding through theoretical input at the same time as a mathematical content and structure of teaching in pre-school, focusing on the actual learning of learning ability. The latter as an important element in preparing the teacher student to identify others' mathematical understanding of the learning ability. The poster will visualize and discuss the students' understanding of the intentional learning object for the children in the designed pre and post-test, based on the different teaching design the teacher students were included in the intervention.

*As teacher educators, we recognize the importance of considering teachers' self-efficacy for teaching mathematics. In this study, we investigate preschool teachers' self-efficacy for teaching repeating patterns, both before and after participating in a professional development program. Findings from questionnaires indicated that self-efficacy related to subject-matter knowledge changed little, while self-efficacy related to pedagogical-content knowledge, increased. Interviews with teachers shed light on these findings.*

*Keywords: Repeating patterns, self-efficacy, preschool teachers, professional development*

## Introduction

Recently, several countries have introduced specific guidelines for introducing mathematical concepts during the early years. Along with new guidelines comes a need for enhancing preschool teachers' knowledge for teaching mathematics. Knowledge, however, may not be sufficient. Teacher self-efficacy is another factor which may impact on teachers' classrooms interactions and student achievement (e.g., Guo, Piasta, Justice, & Kaderavek, 2010). Teacher self-efficacy may be conceptualized as "a teacher's individual beliefs in their capabilities to perform specific teaching tasks at a specified level of quality in a specified situation" (Dellinger et al. 2008, p. 752). With regard to mathematics, Hackett and Betz (1989) defined mathematics self-efficacy as, "a situational or problem-specific assessment of an individual's confidence in her or his ability to successfully perform or accomplish a particular [mathematics] task or problem" (p.262).

This paper focuses on preschool teachers' self-efficacy for engaging young children with repeating pattern activities. Repeating patterns are patterns with a cyclical repetition of an identifiable 'unit of repeat' (Zazkis & Liljedahl, 2002). For example, the pattern ABBABBABB... has a minimal unit of repeat of length three. According to the Israel National Mathematics Preschool Curriculum (INMPC) (2008), "patterning activities provide the basis for high-order thinking, requiring the child to generalize, to proceed from a given unit, to a pattern in which the unit is repeated in a precise way" (p. 23). In this paper we take a close look at a group of preschool teachers who attended the Repeating Patterns professional development Program (RPP) aimed at enhancing their knowledge and self-efficacy for teaching repeating patterns. We examine their self-efficacy before and after the program, and through interviews, we attempt to untangle variations in their self-efficacy beliefs.

## Background

For the past several years, we have been employing the Cognitive Affective Mathematics Teacher Education (CAMTE) framework for investigating preschool teachers' knowledge and self-efficacy

for teaching mathematics, as well as planning for professional development with preschool teachers (Tirosh, Tsamir, Barkai, & Levenson, 2017). The framework is based on Shulman's (1986) recognition of teachers' subject-matter knowledge (SMK) and pedagogical-content knowledge (PCK), as well as Ball, Thames, and Phelps's (2008) refinement of these elements.

Subject-matter		Pedagogical-content		
Solving	Evaluating	Students	Tasks	
Knowledge	Cell 1: Defining, drawing, extending repeating patterns	Cell 2: Identifying examples of repeating patterns	Cell 3: Knowledge of students' ways for drawing, extending, and comparing repeating patterns	Cell 4: Designing and choosing tasks for promoting and evaluating children's knowledge of repeating patterns
	Cell 5: Mathematics self-efficacy related to Defining, drawing, extending repeating patterns	Cell 6: Mathematics self-efficacy related to evaluating solutions	Cell 7: Pedagogical-mathematics self-efficacy related to children's conceptions	Cell 8: Pedagogical-mathematics self-efficacy related to designing and evaluating tasks

**Table 1: The CAMTE framework illustrated within the context of repeating patterns**

Regarding teachers' knowledge of patterning, several studies pointed out the need to promote teachers' knowledge of the language of patterns. For example, Waters (2004), described how one preschool teacher showed the children dress materials with, what she called, patterns. Some of the materials contained a mixture of shapes, colors, hearts, and stars, and demonstrated random designs without any regularities. The teacher did mention the need for repetitions, but did not focus on what exactly is repeated. Similarly, in our study of preschool teachers' patterning knowledge (Tirosh, Tsamir, Levenson, Barkai, & Tabach, 2018), we found that teachers have difficulties verbalizing what exactly is repeated, although most referred in some way to the unit of repeat and to the notion of repetition. We also found that when asked to draw or continue repeating patterns, teachers mostly drew repeating patterns that have three cycles of the unit of repeat and a unit length of three. In addition, teachers' continuations of given patterns indicated a strong tendency to end patterns with a complete unit of repeat.

For each knowledge cell in the framework, there is a related self-efficacy cell, emphasizing teachers' mathematics self-efficacy as well as their pedagogical-mathematics self-efficacy, i.e. their self-efficacy related to the pedagogy of teaching mathematics (see Table 1). This differentiation was also pointed out by Bates et al. (2011), who investigated the relationship between early childhood (pre-K to third grade) preservice teachers' mathematics self-efficacy and their mathematics teaching self-efficacy. Results of that study showed that teachers who reported higher mathematics self-efficacy were more confident in their ability to teach mathematics than teachers with a lower mathematics

self-efficacy. However, participants with a high mathematics teaching self-efficacy did not necessarily perform well on the mathematics skills test. Some teachers who scored low on the skills test still felt confident to teach mathematics. We also note that self-efficacy beliefs are not only domain-specific (e.g. mathematics, history, science) and content-specific (e.g., within the domain of mathematics there is numeracy, patterns, geometry, etc.), but also task-specific (e.g., extending patterns, duplicating patterns, etc.) (Zimmerman 2000).

The aim of this paper is to report on preschool teachers' mathematics self-efficacy as well as their pedagogical-mathematics self-efficacy, before and after the Repeating Patterns Program (RPP). The teachers in this study met seven times (21 hours in total) over a period of about four months. All lessons were planned by the four authors of this paper. The fourth author did the actual teaching. The program revolved around patterning tasks that we designed, which teachers could implement with children, but could also be used to engage teachers with the mathematics involved in patterning, and promote their knowledge of patterning tasks and children's ways of solving those tasks. Towards the end of the program, teachers implemented patterning tasks with children in their classes, video-taped their implementations, and then brought those recordings to the program for discussion. (See Tirosh et al. (2017) for additional information regarding this program.) Specifically, we ask: (1) Was there a change in teachers' self-efficacy from before to after the program, and if so, what was the nature of this change? (2) When reflecting on self-efficacy, how do teachers explain their self-efficacy beliefs?

## Methodology

Participants in this study were 18 preschool teachers enrolled in the RPP. All had a first degree in education, between 1 and 38 years of teaching experience in preschools, and were currently teaching children ages 4-6 years in municipal kindergartens. All sessions were videotaped and transcribed.

Before the program began, and again during the last session, teachers were asked to fill out a questionnaire which began with the following self-efficacy statements: I am able to say what a repeating pattern is; if shown a repeating pattern along with several suggestions for continuing the pattern, I am able to choose appropriate continuations; I am able to point out repeating patterns that most preschool children are able to continue appropriately; I am able to choose tasks for investigating children's patterning knowledge. A four-point Likert scale was used to rate participants' agreements with self-efficacy statements: 1 – I do not agree that I am capable; 2 – I somewhat agree that I am capable; 3 – I agree that I am capable; 4 – I strongly agree that I am capable.

Approximately one month after the program was over, seven teachers, chosen to reflect a variety of responses (e.g., no change in self-efficacy, increased self-efficacy, decreased self-efficacy) were interviewed individually. The aim of the interview was to further investigate teachers' self-efficacy beliefs for teaching patterning by evoking their reflections on these beliefs, and focusing on changes that may have occurred with regard to self-efficacy. In general, the interview questions were of the form: "Before the program began, you wrote that you strongly agree (somewhat agree/agree/do not agree) that you are capable of \_\_\_\_\_. At the end of the program you wrote \_\_\_\_\_. Can you tell me more about this?" The blanks were filled in with the different tasks taken from the questionnaire and teachers' self-efficacy assessments in the pre- and posttests. In addition, teachers were encouraged to freely reflect on their self-efficacy beliefs. Interviews were recorded and transcribed.

## Findings

### Results from the questionnaires

Table 2 shows the mean values for teachers' self-efficacy scores before and after the program (on a scale from 1-4). As can be seen, teachers had a rather high regard, both before and after the program, in their ability to define a pattern and to choose appropriate continuations for a given pattern, with their self-efficacy rising slightly after the program. Teachers also had a high self-efficacy for identifying patterns that children could continue, with seemingly no change between before and after the program. The greatest change was noted in the last question. Before the program, teachers were not so confident in their ability to choose appropriate pattern tasks for investigating children's pattern knowledge, whereas after the program, their self-efficacy was noticeably higher.

	Self-efficacy statement	Pre		Post	
		Mean	SD	Mean	SD
SMK	I can say what a pattern is.	3.3	.59	3.8	.44
	I can choose appropriate continuations for a repeating pattern.	3.6	.62	3.8	.38
PCK	I can point out patterns that most preschool children can continue.	3.2	.56	3.3	.69
	I can choose appropriate tasks for investigating children's patterning knowledge.	2.2	.79	3.4	.72

**Table 2: Means and SD per self-efficacy statement before and after the program (N=18)**

Taking a closer look at the distribution of self-efficacy scores, Table 3 presents the frequencies of teachers whose self-efficacy scores increased, stayed the same, or decreased.

	Self-efficacy Statement	Increased	No change	Decreased
SMK	I can say what a pattern is.	6	12	-
	I can choose appropriate continuations for a repeating pattern.	5	13	-
PCK	I can point out patterns that most preschool children can continue.*	4	9	4
	I can choose appropriate tasks for investigating children's patterning knowledge.**	12	4	-

\*One teacher did not respond. \*\*Two teachers did not respond.

**Table 3: Changes in self-efficacy beliefs between pre and posttests (N=18)**

In general, approximately two-thirds of the teachers did not feel a change in their self-efficacy related to SMK, while the rest of the teachers' self-efficacy increased. However, when it came to PCK-related

self-efficacy beliefs, findings were more complex. With regard to knowledge of students, approximately half of the teachers did not feel any change, but 25% of the teachers felt a rise in their self-efficacy and 25% reported a decrease. With regard to knowledge of tasks, approximately 75% of the teachers' self-efficacy scores increased, with the rest showing no change.

### **Interviews: Reflecting on self-efficacy**

As seen in the previous section, most teachers' SMK-related self-efficacy beliefs were high and did not seem to change. When asked to comment on her SMK-related self-efficacy, Michelle (this and all other names are pseudonyms), who rated her self-efficacy both before and after the course at level 4, said, "Before the course, I don't think I knew how to define a pattern. I'm trying to remember when I learned this topic. But after we studied this in depth during the program...I know a lot more now." While Michelle does not explain why in the beginning of the course she had such a high self-efficacy, thinking back, she realizes that her SMK regarding defining a pattern actually increased.

With regard to being able to choose appropriate continuations to a pattern, Anne explains why she rated her self-efficacy as very high before the course, "Before the course, I knew that a pattern could be continued in several ways." However, she adds, "But now, I understand the reasoning behind these options, and I can explain it better to the children." In other words, although her self-efficacy rating has not changed, she feels that her knowledge has increased. Rina, who also had rated her self-efficacy as 4 both before and after the course, had a different reason for why no change was reported:

In the beginning of the course, when they asked me these questions, I think I didn't really know what they [repeating patterns] meant. At the end of the course, now, I understand what is meant by a repeating pattern, that it can end in the middle [with a partial unit of repeat]. Now, the question is clear. I don't remember what I wrote in the beginning.

In other words, Rina reflects back on before the course, and can now say that before the program, she did not really know what was meant by a repeating pattern, and was not aware that patterns do not have to end with a complete unit of repeat. This is similar to Michelle. Both teachers seem to acknowledge that their self-efficacy ratings in the beginning of the course were incorrectly high. In fact, when Rina was asked what score she should have given herself in the beginning of the course, she answered, "Now, I'm a 3-4. Then, maybe a 2, because I did know a little."

When it came to reflecting on their PCK self-efficacy beliefs related to knowing children's patterning abilities, teachers again had varied responses. Prior to the program, Anne had evaluated her self-efficacy at level 3, and at the end she reported level 4. She told the interviewer that her self-efficacy increased and explained, "Today, I can define it [a repeating pattern] better. I know that there is a minimal unit of repeat, and that it is made up of elements. This definition organizes my thoughts and adds to my self-efficacy." Although Anne was asked to relate to her ability to point out patterns that most preschool children can continue, her response focused on her ability to define a repeating pattern. It could be that for Anne, her knowledge of the centrality of the minimal unit of repeat, affected her belief in her ability to assess children's knowledge.

Rina, who consistently rated her self-efficacy to assess children's knowledge at 4, said, "If, in the beginning of the course, I didn't really understand about repeating patterns, then of course, I couldn't

really know about the children.” Rina is acknowledging her over-confidence in the beginning of the course. Moreover, she connects her SMK with her PCK, by connecting her knowledge of patterns to her knowledge of students. Sharon, who consistently rated her self-efficacy at level 3 said, “I’m not so sure of myself here. I think I need more experience working with children to feel more sure of myself in this area.” This explains why currently, her self-efficacy is a 3 and not a 4. When asked to reflect back, she adds, “Before (the course), I would give myself a 2. I didn’t engage with patterns as much as I do now, and so I’m more self-confident now that I can do things better.” She now acknowledges that her self-efficacy in the beginning of the course was too high.

Lottie’s self-efficacy for assessing children’s patterning knowledge decreased from a 4 to a 3. During her interview, she stated the following:

For me, before the course, I would have children make patterns by giving them a red sticker, and then a yellow sticker, and so on. This course was a wake-up call. Patterns can be made with different materials... I was stuck on one type. There is also the pattern ABB. Before, I engaged the children with patterns, but without reflecting on what I did.

Lottie states that before the program, she engaged children with patterning tasks. This could be the reason that in the beginning, she felt very strongly that she could say which patterns children would be able to complete. After the course, Lottie acknowledges that her previous patterning knowledge was limited. Perhaps, this causes her now to be unsure regarding her knowledge of children.

Finally, we review teachers’ reflections regarding their self-efficacy for choosing appropriate tasks. Recall that most teachers’ self-efficacy for choosing tasks increased. Rina, who increased her self-efficacy from a 3 to a 4, commented, “I did work with repeating patterns with children, but they were not so varied, they did not end in the middle (with a partial unit of repeat).” Sharon, who went from level 2 to 4, said, “The program gave me lots of tools, and also self-confidence.” However, she qualifies her response by adding, “I think I still need more experience.” Similarly, Anne, who also went from a self-efficacy of 2 to 4, said, “The patterns that Ruthi (the program instructor) gave us in the course, really helped me to organize my thoughts and implement them in the kindergarten. I know that another teacher also uses them, and even when in the yard she uses sound patterns, because it’s very nice, and we really liked it.”

## Summary and discussion

This study examined preschool teachers’ mathematics self-efficacy as well as their pedagogical-mathematics self-efficacy, related to teaching repeating patterns, as well as teachers’ reflections on these beliefs. Regarding teachers’ SMK-related self-efficacy beliefs, results indicated that no significant change was felt. That teachers reported high SMK-related self-efficacy beliefs at the end of the program, was satisfying. However, we are left with two questions: How is it that teachers had such a high self-efficacy before the program began? In addition, even though the reported self-efficacy beliefs did not change, did teachers feel some change?

Regarding the first question, it could simply be that teachers indeed knew how to complete these tasks in the beginning, although to a lesser extent than they did in the end. In a previous study (Tirosh et al., 2018), we found that most preschool teachers did recognize that a repeating pattern must have

unit of repeat, but missed stating that the unit must be structured. On the other hand, they could all construct and extend given repeating patterns. Regarding the task of choosing an appropriate continuation for a given repeating pattern, in general, teachers were able to choose appropriate continuations, although they had greater success in choosing appropriate continuations for the patterns which ended with a complete unit, than for the pattern which ended in a partial unit.

Teachers' interviews shed additional light on the issue of their self-efficacy. During the interviews, some teachers acknowledged that their first self-efficacy reports were higher than they should have been. They explained these initial high self-efficacy reports by saying that the topic of repeating patterns was not new to them. Thus, it might be that teachers did feel a change in their knowledge, but that this change was not reflected in the questionnaires. This finding raises the complexity of investigating self-efficacy beliefs. First, it could be that a scale of 1-4 was not sensitive enough to capture changes. In addition, this study, like most self-efficacy studies (e.g., Bates et al., 2011), relied on Likert-scales. It was the addition of interviews that revealed teachers' changes in their beliefs. Thus, we encourage the use of interviews when investigating self-efficacy.

Regarding teachers' PCK-related self-efficacy beliefs, from the questionnaires, it seemed that teachers did not feel a change in their self-efficacy related to knowing children's patterning abilities. Taking a closer look, we found that some teachers' self-efficacy increased, some stayed the same, and some teachers' self-efficacy decreased. As one aim of the course was to support teachers' self-efficacy beliefs, this result is surprising. One explanation is that after the program, teachers realized how much more there is to learn. They also mentioned feeling the need for more experience engaging children with patterning activities. Thus, this may actually be positive outcome of the program.

Regarding teachers' self-efficacy for choosing patterning tasks that can investigate children's knowledge, we ask, why is it that before the course this particular self-efficacy belief was relatively low? One possibility is that we asked teachers if they could choose tasks for the purpose of investigating children's pattern knowledge. It could be that if they were asked to choose tasks that had the potential to promote, rather than assess knowledge, their self-efficacy might have been greater. In a previous study of preschool teachers' knowledge and self-efficacy for teaching three-dimensional figures (Tsamir, Tirosh, Levenson, Tabach, & Barkai, 2015), we found that teachers' self-efficacy related to designing tasks for promoting knowledge was greater than their self-efficacy related to designing evaluation tasks.

Finally, this study highlighted the connection between teachers' SMK-related self-efficacy and their PCK-related self-efficacy. When asked about her self-efficacy for knowing children's pattern abilities, Anne referred to her improved ability to define a repeating pattern. Rina and Lottie also connected their knowledge of repeating patterns, including that a repeating pattern does not have to end a complete unit of repeat, to their knowledge of children and patterns. While previous educators (e.g., Ball, Thames, & Phelps, 2008; Shulman, 1986) connected teachers' SMK to PCK, this finding connects teachers' SMK-related self-efficacy to their PCK-related self-efficacy, and suggests that if we wish to promote positive self-efficacy for teaching mathematics, we should also consider teachers' self-efficacy for solving mathematical tasks.

## Generalization in early arithmetic

Marianna Tzekaki<sup>1</sup> and Evaggelia Papadopoulou<sup>1</sup>

<sup>1</sup> Aristotle University of Thessaloniki, [tzekaki@auth.gr](mailto:tzekaki@auth.gr)

*Research in the field of early arithmetic and relevant international educational programs present a variety of approaches (activities, tasks and material) that aim at teaching children from early age to count verbally or count quantities or to recognize and compare without counting, etc. However, a deeper insight into underlying arithmetic thinking, reasoning and early generalization always remains required. In our study, 23 preschoolers (of 5 to 6 years) participated in a program focusing on generalizing in early arithmetic. Task-based interviews before and after this program were conducted to examine children's improvement in conceptual development and generalization related to numbers. Findings indicate that appropriated teaching approaches with relevant tasks and discussion supported children to extract more general ideas about numbers, their properties and interrelations.*

*Keywords: arithmetic learning, number sense, generalization*

### INTRODUCTION

Arithmetic learning is one of the most well-known and recognized mathematical field of teaching and learning in early years, thereby, there is an extensive related literature with different approaches and views. Programs around the world suggest a wide variety of projects, tasks and materials aimed at effective numerical learning. Thus, children from early age learn to recognize and compare quantities without counting, recite the arithmetic sequence, count objects, etc. What is though genuine arithmetic learning and how can we ensure it? Researchers have long ago pointed out that daily numerical activities or involvement with arithmetical elements with numbers and operations could not assure the development of numerical meaning. First references regarding this issue started with Brownell (1947) who attempted to distinguish 'meaning of' from 'meaning for' that essentially differentiates the use of numbers in real life from generalizations that lead to mathematical conceptualization.

Long ago also, researchers highlighted the gap between everyday use of numbers and development of mathematical number concepts in education (Carraher et al., 1985). The value of spontaneous or informal use of mathematics by students or practitioners is generally recognized and studied, but this use does not automatically link mathematical elements to relevant mathematical concepts. It could be supported that counting quantities or realizing other numerical tasks in everyday situations keep a 'concrete' aspect that is not simply transferred out of its context. Thus, the development of number sense towards the correspondent mathematical meaning demands a shift from the specific situation and content in which it functions to a broaden level through systematic generalization processes. As it was recently underlined by many researchers related to the learning and teaching of arithmetic in early years "...our knowledge of how children develop accurate and general understanding of basic arithmetic principles and make use of them as strategies for arithmetic problem solving remains incomplete..." (Björklund et al., 2018, p. 126)".

In this paper, we will attempt to highlight different levels of generalization that pre-schoolers can achieve in arithmetic learning when they are systematically encouraged by relevant teaching approaches.

## Arithmetic Learning

Research in the field of early arithmetic and consequent educational programs presents a variety of supplementary or complementary approaches, activities, tasks and material, emphasizing their importance for later mathematical proficiency. However, while all these advances support the need of meaningful arithmetic knowledge and the development of number sense, cognitive expectations and educational outcomes remain to be clarified by teachers and educators. Moving away from the (initial) Piagetian logical operations related to arithmetic learning and from other relevant psychological research, newer approaches such as subitizing and counting-based arithmetic appear to focus more on quantity and number sense (e.g. Clements & Sarama, 2014). Current suggestions orient also their interest to number structure and connections (Venkat & Askew, 2017).

Researchers who emphasized the importance of counting as a base upon which number concepts could be developed, supported that counting connects knowledge coming from outside with in-school understanding (Fuson, 1988). However, when children count quantities by reciting a sequence of number names and pointing out one by one different objects (even respecting the relevant principles: ordered names, one-to-one and cardinal principle, Carpenter et al., 2016) follow a rather procedural than conceptual understanding (LeFevre et al, 2005). Studies have revealed that while young students, knowing in general object counting, attempted to complete a simple task of change (e.g. 4 to 8 or 8 to 5) stayed more depended on counting or perceptual information (use of fingers or blocks) than on numerical facts. Subsequently later, research in early arithmetic learning (e.g. Baroody, 2004; Clements, 1999, etc.) studied the representational flexibility of subitizing that reinforced children to interconnect and generalize numerical concepts, maintaining however the importance of counting and recognition of number interrelations for arithmetic learning.

In this brief presentation, we attempted to justify why, despite the volume of research related to early arithmetic, a deeper insight into underlying arithmetic thinking, reasoning and early generalization remains always required.

## Generalizing in early arithmetic

Generalization is an important prerequisite for arithmetic learning, similarly to every other mathematical learning. As presented in an earlier paper, generalization (Tzekaki & Papadopoulou, 2017, p. 1926) “...could be firstly identified as the level at which students, starting from specific situations, proceed to more general ideas and conclusions, identifying patterns, structures, relationships etc.” (see, e.g. Döfler, 1991; Kaput, 1999), with fundamental elements the “*reflection over actions*” and the “*expression of more generalized ideas or rules*”. Despite its importance in the mathematical development, research in early childhood generalization is mainly limited to patterns.

On the other hand, research and proposals in early arithmetic place its focal points on counting, subitizing, ordering and connecting quantities and numbers. Relevant proposals underline the need of pupil’s shift from ‘*quantity sense*’ to ‘*number sense*’, by first perceiving the magnitude of numbers,

then understanding their multiple interrelations and finally operating on them (Wagner & Davis, 2010), thus, moving beyond perceptual or procedural practices, both in counting and subitizing or in operating with other means such as fingers or relevant material (Dehaene, 1997).

Combining views on generalization with proposals for early arithmetic we attempted to examine whether young children were able to overcome perceptual subitizing or verbally object counting in a concrete content and apprehend numbers in a more generalized level. Thus, in our study we examined whether preschoolers managed to approach and verbally express more global ideas about quantities, numbers and their interrelations, beyond perceptual or procedural practices in the four strands of early arithmetic (1) verbal counting up to 10, (2) subitizing, (3) analyzing and combining quantities and numbers, (4) relating and ordering quantities and numbers (Clements & Sarama, 2014). Moreover, we investigated whether these ideas could be evolved when working in teaching approaches that systematically encouraged generalizations.

## Methodology

23 preschoolers aged 5 to 6 years (selected by classroom teachers on the basis of their common age and attendance in the same school and school area) participated in an 8-month teaching program focusing on generalization related to all fields of early mathematics education (shapes, patterns, measurement and numbers, Tzekaki & Papadopoulou, 2017), with the number module to be the last, from late April to late May. Task-based interviews were conducted to examine pre-schoolers' arithmetic achievement and levels of generalization before and after the teaching program (following a design study). The content of the task-based interviews followed the strands mentioned earlier: counting quantities up to 10 (4 cases), subitizing quantities up to 10 (3 cards), combining numbers (1 task with quantities in dot cards) and transforming numbers (2 tasks of change, see tasks in Table 1). The interviews' questions aimed at examining statements related to children's conceptualization of numbers concerning their way of acting (e.g. *what did you do to ...*, *how did you do it...*), children's thinking (e.g. *what did you think to ...*, *what did you notice to...*), children's justification (e.g. *why did you do it...*) and finally children's more general ideas (e.g. *Is it always the same or it may be different...*, *how can we find that...*) (Dougherty et al., 2015). The interviews were conducted individually, recorded and transcribed.

To approach children's ideas about numbers, we analyzed their utterances in the transcribed interviews and categorized them in a three-stage generalization model, following current literature. Preschoolers' explanations at a *first stage* do not present any characteristics or properties or relationships related to quantities or numbers, as children remain verbally reciting the number sequence (see, e.g. Baroody, 2004). Children's explanations at a *second stage* show a perceptual or procedural approach of characteristics, properties or relationships related to quantities, as children order or combine quantities mainly by counting or by subitizing small quantities and recognize only a part of interrelations (see, e.g. Clements, 1999). Children's expressions at a *third stage* start presenting a certain awareness of characteristics, properties or interrelations of numbers, as children conceptually subitize and stabilize number facts (see, e.g. Clements & Sarama, 2014; due to space restrictions examples of each stage will be presented along with the results). After their initial examination and categorization, these 23 pre-schoolers, individually or in teams, dealt in their

classroom with rather usual arithmetic tasks, materials and games for four weeks (e.g. games for verbal counting quantities forward and backward, games for subitizing dot cards with different configurations, tasks for comparing, ordering or analyzing quantities, recognizing numbers in numbers cards, etc., see Clements & Sarama, 2014). During this program, they were systematically encouraged by their teacher to discuss about their actions, strategies, methods, decisions, reasoning and to proceed to verbal formulations regarding more general ideas related to their outcomes of their activity. Thus, they were reinforced to move from a *local level* with conclusions made out of a specific task or activity (e.g. way of doing it) to a *broader level* with assumptions about mathematical ideas (e.g. number 4) and finally *formulation of rules or propositions* (e.g. numbers' relations) (Dougherty, et al., 2015) and they were reexamined in similar tasks. After working for several months on other mathematical fields, these children improved, in general, their flexibility to find common elements in different contents, to reflect on their actions and produce more general conclusions deriving from specific situations.

## Results

The table below (Table 1) shows differences between the initial and final examination of the children as they appear in the transcripts of their interviews. These results provide an overview about preschoolers' achievement and progress in relevant tasks after a rather short teaching period.

Items	Quantities or Numbers	Initial	Final
Verbal counting	Up to 10, one by one or by twos, forward and backward	6	18
Subitizing	Dot-cards with 5, 7, 8 dots	3	15
Combining	Quantities with dot-cards to form 6	8	17
Transforming	7 to 4 and 2 to 6 (in numbers)	3	15

**Table 1. Number of correct answers before and after teaching period in numbers.**

Correct answers in this table concern: for *verbal counting*, correctly counting in all four cases (one by one or by twos, forward and backward), for *subitizing*, correctly recognizing all dot cards with 5, 7 and 8 dots without counting, for *combining*, putting together dot cards in all possible combinations (5+1, 3+3, 4+2 and 2+2+1) and for *transforming* from 7 to 4 and 2 to 6, correctly completing both changes.

Seeking for a deeper insight into preschoolers' number conceptualization and, thus, their underlying more *generalized ideas about numbers and interrelations*, we analyzed their explanations in the interviews according to the three-stage generalization model, presented earlier (in brief: reciting the number sequence, perceptually subitizing or procedurally approaching relationships, conceptually subitizing and stabilizing number facts). In general, there were no children at the first stage.

- In the initial examination of verbal counting (Baroody, 2004), all 23 children were able to recite the arithmetic sequence one by one forward, but did not show the same stability in all counting tasks (by twos or backward, by ones or twos). Seven children who were identified as being at the *second stage (mostly procedural)* were able to count one by one, but could not do it backward, hesitating especially

for numbers after 7, missing one or two numbers in the sequence or starting counting with their fingers. They had greater difficulties in counting forward or backward by twos, not being, thus, able to realize that number sequence was stable (e.g. 5,7... so backwards 7, 5...) or to perceive relationships between numbers. For example, a child said, “*It may be something else...*” and another one “*10, 8, 6, 2, 0, ... there must be some numbers missing*”. Eleven children, who were considered as being *at the third stage* (more advanced procedural), recited the arithmetic sequence fluently, but did not have the same fluency in counting backward or counting by twos, while the rest (5) with the same procedural approach were able to count by using the one by one correspondence and to explain based on it, e.g. “*0, 2, 4 (plus 1), 5, (plus 1), 6, ...*”, showing, thus, an awareness of stability and simple relationships between numbers (see Table 2).

In *the final examination of verbal counting*, 22 children verbally counted correctly in all cases and, furthermore, declared that the order of number sequence was stable, being identified thus *at the third stage*. However, their explanations regarding this order might be indicative of different levels of generalization, as 6 of them who recognized certain relationships (e.g. 8 and 1 is 9 or 3 and 2 is 5) could not generalize them throughout the whole number succession, or other 5 children who had stabilized knowledge of succession one by one, were not in the same state when counting by twos. Finally, with more or less complete understanding, 11 children seemed to be aware of numbers’ interrelations that generate the number sequence, appearing to be at a more advanced level (see Table 2).

- In *subitizing dot cards* (Clements, 1999), *initially* most of the children (15) could not recognize quantities or explain how to do it by perceiving subgroups of quantities and interrelations between them, being thus *at the second stage*. Very few children (3) could recognize quantities with more than 3 dots and, except one, they said that they counted silently. Some other also (5) used the combinations they knew, e.g. “*I saw 3+3 that is 6 and then 7...*” (partly recognizing and partly counting). These 8 children were identified as being *at the third stage*. In *the final examination*, after working with relevant tasks and discussing on number characteristics and relationships, 15 children declared that they recognized subgroups and did not use counting, e.g. a child said “*No, I didn’t count, I did 3+3 and plus 2...*”. Some children (6) made use of patterns of previous cards and said “*this was 7, then this is 8*”. Some other still (2) combined subitizing small quantities and counting. These different approaches (some procedural and some conceptually subitizing) show also different kinds of generalization *at the third stage* (see Table 2).

- While *combining dot cards to form the number 6* (Clements & Sarama, 2014), 15 children *initially* presented only the combination 5+1 of one 5-dot card and one 1-dot card. The children (8 in total) who provided all the right combinations were divided into two groups: in the first group 3 pre-schoolers mainly used a ‘trial and error’ method and counted the dots one by one, without knowing if always 4 plus 2 was equal to 6. For example, a child started with a 5-dot card and put it together with a 2-dot card and counted all the dots, as the result was 7 s/he changed with a smaller card. In the second group, 5 children put cards together using the relationships they already knew, but they checked the result by counting. This group of children remained mainly at a procedural and, thus, *second stage*.

In the final examination, 15 children were able to present all the combinations for 6 (third stage) while 8 remained in 1 or 2 -3 of them (second stage). Eleven of the 15 pupils did not use the method of “trial and error” or of counting, but, in general, they were able to put together groups of quantities, showing, thus, an awareness of relationships of quantities and numbers. They could be considered being in a course of a conceptual understanding, as they were competent to explain with numbers e.g. “*I said 3+2 makes 5, plus 1, 6...*” and “*...then 3+3 makes 6*”. For the other four pupils of this stage, the interrelations between quantities and numbers were generally less developed, as they verified every suggestion by counting, showing that they remained at a procedural stage.

- Finally, in the task of transforming 7 to 4 or 2 to 6, initially all the children were at the second stage. Twelve of them counted in different ways, e.g. a child said “*I counted with my fingers and (showing) if I put out 3 remains 4 fingers*”, or, more generally, they did it with number sequence, “*I put out 1, 6 and then 5, so we get 4*”, while 11 children were not able to find a way of doing it (see Table 2).

But in the final examination, 12 children were identified as being at the third stage, but in different levels of conceptualization. Thereby, a group of 5 children explained the changes with numbers in a more general way e.g. “*3 and 3 and 1 equals 7, if you keep 4 you have 3...*” showing a conceptual understanding, while 7 others did the same without being sure about the results (between conceptual and procedural). E.g. for 7 to 4, a child said “*I can see a group with 3 and a group with 4... so (hesitates)... then 3...*” or they put groups together and counted (in a procedural stage). The rest 11 children were still not able to do it correctly. This analysis is summarized in the Table 2 in which the initial three-stage model was analyzed in more details, as there was no child in stage 1 but, as it was previously presented, differences were revealed in other stages.

Pre-schoolers’ explanations of stage 2 are divided in three sub-stages: 2a, in which their utterances revealed a procedural recognition of quantities and basic relationships, with no specific awareness; 2b, in which they presented a wider procedural recognition of quantities and relationships and 2c, in which they showed children mainly able to manage procedurally quantities and numbers. For example, in the task of combining dot cards to form a quantity of 6 dots, children of 2a put together cards with 5 and 1 (basic) dots, without being able to present other combinations, while children of 2b started putting together more cards by counting them and children in 2c were able to find cards and in case of errors (e.g. 4-dot card and 3- dot card) to directly change with other dot cards but also count for checking.

Pre-schoolers’ explanations of stage 3 were also divided in three sub stages: 3a, in which their utterances revealed recognition of a part of groups/subgroups of quantities and numbers or their interrelations, 3b, in which they presented a wider recognition of interrelations of quantities or numbers but without consolidation and (a final) 3c, in which children recognized numbers, their order and their interrelations. For example, in the task of subitizing, children of 3a started by recognizing small quantities and continuing by counting, while children of 3b recognized some of the proposed cards and explained e.g. for a 5- dot card “*I saw these 4 and this 1*”, but still misjudged a 7-dot card, finally 3c children recognized all cards and explained e.g. “*2 plus 2 and 1 equals 5*” or “*3 plus 3 plus 2 equals 8*” showing the relevant groups in the cards.

		Stage 2: perceptual and procedural approach			Stage 3: procedural and conceptual approach		
		Stage 2a	Stage 2b	Stage 2c	Stage 3a	Stage 3b	Stage 3c
Reciting	Initial	4	3	0	11	5	0
	Final	0	0	1	6	5	11
Subitizing	Initial	8	5	2	5	2	1
	Final	0	0	0	2	6	15
Combining	Initial	15	3	5	0	0	0
	Final	4	4	0	3	1	11
Transforming	Initial	11	9	3	0	0	0
	Final	4	4	3	7	3	2

**Table 2. Number of children in different generalization stages in the initial and final examination**

This table provides an overview of these children's improvement in approaching and verbally expressing more global ideas about quantities, numbers and interrelations indicating, thus, a more substantial conceptual understanding.

## Discussion

The results presented indicate in brief that the participating children were initially able to count verbally up to 10, but they did not recognize more generalized interrelations between quantities or numbers, remaining mainly in this procedural counting. Conversely, after working in the teaching program that systematically encouraged them to reflect over this counting and express more generalized ideas related to quantities and numbers, most of these children (almost 19 out of 23) started developing flexibility in combining quantities and numbers, in realizing numbers' relationships and consolidating several numbers' facts. Despite the small sample that does not allow wider conclusions, these outcomes suggest that guiding young children to focus on dynamic and relational aspects of numbers and express more general ideas related to their numerical tasks could support decisive numerical understanding and more generalized arithmetic knowledge.

Arithmetical learning has many approaches, but the dominance of counting tasks does not often make apparent whether children develop number sense, structural numerical elements or relationships, as this study attempted to show. Many deficiencies in the first arithmetic learning prove to cause difficulties to students to conceptualize the multiplicative, relational and repetitive structure of numerical system. Teaching approaches that encourage children to generalize seem to be required for numbers as they are for any other mathematical concept, since learning mathematics is not only to practice in situations with material, but also to reflect and draw more general ideas out of this practice

<sup>3</sup>Fundació Escoles Garbí, Spain; [arubio@escolesgarbi.cat](mailto:arubio@escolesgarbi.cat)

*The goal of this study is to identify the learning trajectories that students aged 6 to 8 years old follow during the construction of the notion of length measurement. An instrument based on the construct of a hypothetical learning trajectory was designed to ascertain the different levels of understanding of this notion among the children. The implementation of the said instrument and the subsequent analysis are described. The results obtained from the study were used to situate the children on their predominant learning trajectory level. At the same time, the results reveal what mathematical topics teachers should focus on to ensure that children can move on to the next level of their trajectory and thus consolidate their learning.*

*Keywords: Learning trajectories, length measurement, early years.*

## Introduction

From the standpoint of the pre- and primary school education mathematics curriculums, measurement is a fundamental area of content and strongly related to the mathematics used in everyday life (Battista, 2006; Clements & Sarama, 2009; Chamorro, 2003; Smith, van der Heuvel-Panhuizen, & Teppo, 2011; Antonopoulos, Zacharos & Ravanis, 2009). Nonetheless, sometimes not enough effort is invested in teaching length measurement formally because it is considered social knowledge that will be acquired by students outside school (Chamorro, 2003).

Length measurement has the potential to connect different mathematical domains such as numeracy and geometry (Clements & Sarama, 2009; Smith, van der Heuvel-Panhuizen, & Teppo, 2011). It is also a tool without which many descriptions of a spatial type would be vague and imprecise (Battista, 2006) and it provides a practical skill that is important in everyday life (Buys & De Moor, 2005).

On the other hand, like Sarama, Clements, Barret, Van Dine and McDonel (2011) we believe that an understanding of the learning trajectory involved in length measurement gives us, as teachers, resources to improve teaching and learning strategies that support children's acquisition of this competence. The goal of this study is to identify the learning trajectories followed by pupils aged six to eight years old in order to construct the notion of length measurement.

## Learning length measurement

Research on measurement learning at an early age shows that educators place the focus on arithmetic (counting, comparing quantities) and geometry (constructions, shapes and patterns) rather than on measurement (Benz, 2012), despite the huge presence of measurement in children's day-to-day lives. Copley (2006) expresses himself in similar terms when noting that measurement is an often-neglected

mathematics topic in the education of young children; and also, Barret et al. (2012), for whom measurement learning is little connected to its mathematical foundations, often meaning that educators miss opportunities to strengthen measurement concepts such as the idea of the unit. And as pointed out by Clements and Sarama (2009) mechanical learning of the notion of measurement should be avoided.

Piaget, Inhelder and Szeminska (1960) define the notion of length measurement as the synthesis of subdivision and change of position, which includes extracting a part of the total and iterating this unit throughout the entire object. Measurement for Clements & Sarama (2009) “can be defined as the process of assigning a number to a magnitude of some attribute of an object, such as its length, relative to a unit” (p.163). These attributes are measured in continuous quantities so that they can always be divided into smaller quantities (Clements & Sarama, 2009). For these authors “length is a characteristic of an object found by quantifying how far it is between the end points of the object” (p. 164). Thus, to determine the length it is necessary to first subdivide the object into equal units of measurement and iterate them along the object (Clements & Sarama, 2009).

According to Clements and Sarama (2007; 2009), learning of measurement, and in particular of length measurement, involves the comprehension of eight concepts: (i) understanding of the attribute (of length); (ii) conservation (of length); (iii) transitivity; (iv) equal partitioning of the object to be measured; (v) units and unit iteration; (vi) accumulation of distance and additivity (the number of iterations indicates the space covered by the units up to a specific point); (vii) origin; and, (viii) relation between number and measurement.

## **Hypothetical Learning Trajectories**

The construct of the Hypothetical Learning Trajectory (here in after HLT) was developed by Simon (1995) as part of his teaching cycle model. According to this author, an HLT is built around three components: a) the learning goal, b) the mathematical tasks that will be used to promote learning, and c) the hypotheses about the learning process. The aim is to make a prediction of how students can learn a certain mathematical content based on their previous knowledge and experience.

Clements & Sarama (2009) state that children follow natural processes of development when learning mathematics. These developmental paths form the basis of learning trajectories. Thus, in a similar way to what was proposed by Simon (1995), these authors consider that learning trajectories involve three essential components: a) a mathematical goal; b) a developmental path; and c) a set of instructive activities or tasks typical of the levels of thinking of the path. They also suggest that the use of learning trajectories can help answer key questions concerning teaching and learning processes: the goals to be set; where to start; how to decide the direction of the next step; and how to achieve that next step.

Specifically, in the case of length measurement, Clements & Sarama (2009) propose an HLT organized at different levels of development, with some associated instructional tasks. It is assumed that these levels indicate the path taken by children while constructing meanings for length measurement. Some learning goals defined by key aspects of the curriculums of each pre and primary school class level are considered in order to specify these levels. Importance is given to the fact that children initially have to identify the attributes of measurement and compare objects using these attributes. Later they must be able to order objects according to their length. As the children advance

in their understanding of numbers, their learning should be geared towards the recognition of connections between the metric and numeral systems, making measurements that imply the use of units and counting those units. Finally, children must be able to recognize the need to have units of equal length, through the use of standard units, and be able to identify and use measurement tools.

The levels proposed by Clements and Sarama (2009) for the learning trajectory involved in length measurement are as follows: Pre-Length Quantity Recognizer (PR); Length Quantity Recognizer (R); Length Direct Comparer (DC); Indirect Length Comparer (IC); Serial Orderer to 6+; End-to-End Length Measurer (EE); Length Unit Relater and Repeater (RR).

To improve children's understanding of length measurement, it is necessary to identify how they act in the various situations that involve this notion. We see the HLTs as a construct that serves to verify this understanding and thereby provide key elements for the definition of specific actions related to the teaching and learning processes.

In this study, we use the HTL construct in order to design our instrument and also as an analytical framework. Particularly we compare the current performance of each child with the hypothetical learning trajectory about length measurement.

## Methodology

Our research uses qualitative methodology. An ad-hoc data collection instrument featuring open and manipulative activities was designed to respond to the research goal. The instrument was used in interview format with 20 students aged six to eight years old. The data was recorded audio-visually. The following factors were considered when defining the sample: a) *Gender*, there were eight boys and twelve girls. b) *The time of the year when they were born*, with six participants born in the first four months of the year, six in the second four months and eight born during the last four, the children were distributed by age, which resulted in a more homogeneous sample. c) *Diversity in mathematical performance*, we find children who are able to solve different mathematical activities and others who usually have some difficulty in carrying them out.

The data collection instrument considered the components of the HLT. It consisted of seven activities related to the key concepts underlying measurement: *recognition*, *comparison*, *ordering* and *iteration*. By way of an example, Table 1 presents instrument activities 1 and 3, consisting of the goal, the task, the description and a series of questions that guide the dialogue during its implementation.

	Goal	Activity	Description	Image	Dialogue
Recognition	Find out whether the child recognizes the attribute of length in objects. Assess whether the child is on the <b>PR</b> or <b>R</b> level.	Discussion about the length of pieces of string	Four pieces of strings are handed out, with different attributes: thickness, colour, and length. The idea is children talk about the attributes of the pieces of string during the activity and that they clearly refer to the notion of length.		What differences do you observe between these pieces of string? Are the four the same? How are they different? Can you see any other features that are different? How do you say it when they are different in their "bigness"?

<b>Comparison</b>	Find out whether the child can make indirect comparisons between objects in order to discover which is longer. Assess whether the child is at IC level.	Comparing pencils with a piece of string.	An object is placed on the table (notebook or box) that prevents the child from seeing both pencils at the same time. A pencil is placed on one side of the notebook and the child is asked to place his/her pencil on the other side. The child can look at and touch the pencils without moving them from their place. They can use any object they have available.		Can you use the piece of string to discover which pencil is longer? Can you use another object to measure them?

**Table 1: Data collection instrument activities 1 and 3**

The data collected came from 20 videos, one per student, lasting between 9' 21'' and 26' 28''. Each student was tagged with a number in chronological order. The analysis focused on the actions and processes performed by the children in order to situate their level (L) on the trajectory for each activity (Act.) carried out. Using the levels proposed by Clements and Sarama (2009), some indicators associated with each of the activities are described (Table 2).

Act.	L	Indicators
1	R	The student is capable of identifying the attribute of length
2	DC	The student is capable of making a direct comparison
3	IC	The student is either capable of making an indirect comparison or does not do so properly, but he/she certainly understands the notion that two objects can be measured using a third one in order to know which is longer
4	O	The student is capable of ordering the five strips using length as a criterion.
5	EE	The student takes into account the origin and purpose of the objects when measuring them but does not show any signs of understanding that the accumulation of units of measurement serves to measure the total length. He/she overlaps the units of measurement, leaves gaps between them, or does not show an understanding of the possible subdivision of units of measurement
6	EE/RR	The student takes into account the origin and purpose of the objects when measuring them and shows some signs of understanding that the accumulation of units of measurement serves to measure the total length. He/she does not perform the procedures needed to carry out the measurement in the right way (i.e. by avoiding overlaps, gaps and unequal positioning of units of measurement)
7	RR	The student takes into account the origin and purpose of the objects when measuring them, and shows that he/she understands that the accumulation of units of measurement serves to measure a total length

**Table 2: Correspondence between activities and levels**

Once the videos were transcribed, the dialogues generated by each activity were established as units of analysis. The information about each student was then organized according to the following

factors: the activity, the unit of analysis, the graphic evidence and the researchers' observations. At this point the level evidenced by the children in each unit of analysis was identified (Table 3).

Act.	Unit of analysis	Evidence	Observations	L
2: Direct comparison of two pencils	<p>Student: This one.</p> <p>Tutor: This one? How do you know?</p> <p>Student: Because this is the small one and this is the big one. Because this one is longer.</p> <p>Tutor: Ok, but how do you know? What did you do with the pencils to find out?</p> <p>Student: Measure them, and I saw (pointing to where the pencils are different) that this one was longer than that one.</p>		Lining up the ends	DC
5: Measuring pencils with paperclips	<p>Tutor: Why do you put them like that, on the other side too? Can you tell me what you're doing now?</p> <p>Student: That's it.</p> <p>Tutor: That's it? How many paperclips long is it?</p> <p>Student: (counts) 6.</p> <p>Tutor: 6? Ok</p> <p>Student: 1,2,3,4,5,6.</p> <p>Tutor: And why do you do it like that? Can you tell me?</p> <p>Student: Because I put them in 3s. 1,2,3, 1,2,3 and that's how I know.</p> <p>Tutor: Ok. And why have you put them on both sides. Wasn't one side enough?</p> <p>Student: No...</p> <p>Tutor: Did you have to put them like that?</p> <p>Student: Yes, I had to put them like that.</p> <p>Tutor: (...)</p> <p>Student: I think it's 6 metres.</p> <p>Tutor: 6 metres? Or 6 paperclips?</p> <p>Student: Well, 6 metres I think</p>		<p>The student places them at an equal distance but on both sides. She always uses paperclips of the same size.</p> <p>She leaves gaps between the paperclips. The student does not take into account the beginning and the end of the pencil.</p> <p>She does not understand the accumulation of units of measurement because if she did she wouldn't measure the pencil on both sides.</p>	DC /IC /O
7: Measuring pencils with a ruler	<p>Student: It measures a 1 and a 7.</p> <p>Tutor: A 1 and a 7. Do you know what number that is? A 1 and a 7?</p> <p>Student: Twenty.... seven? Isn't it?</p> <p>Tutor: I don't know, I'm asking you....</p> <p>Student: 17.</p> <p>Tutor: 17 what?</p> <p>Student: 17 metres.</p>		<p>The student puts the pencil under the ruler. She lines up the beginning with the ruler.</p> <p>This is the only moment when we see EE.</p>	EE

**Table 3: Example from analysis instrument corresponding to student A10**

## Results

The results of this research visualise the individual trajectory of each student and these trajectories provide a characterization that encompasses the whole sample. Thus, it can be seen in Table 3 that student A10 is capable of recognizing the attribute of length, of making direct and indirect comparisons, and ordering. To contrast the hypothetical learning trajectory with the real trajectory of each student, we drew up a two-dimensional adhoc graph that relates the activities to the levels.

**Figure 1: Real learning trajectory of student A10 in relation to the HLT**

According to Figure 1, student A10 performs the first activities (Act 1 - Act4) in consonance with the HLT. However, in the activities geared towards measurement levels (Act 5 - Act 7) there is no consonance. As shown by the data collected in Table 3 and Figure 1, we can position student A10 on the IC level. At this level children are able to use rulers but often show a lack of understanding or ability. We only find student A10 performing actions on the objects on the EE level during the last activity.

It is important to clarify that the purpose of the graph contrasting the HLT with the real trajectory (Figure 1) is to provide a visual overview that shows where each child is situated during the performance of each activity. For this reason, although the transition from one level to another is not always the same, when drawing up the graph the levels have been positioned equidistantly. This makes the HLT appears to rise on a steady gradient, which is not really the case.

In Figure 2, the results obtained by the sample are presented visually, indicating in what levels the students are for the set of activities. Each point on the graph represents one student's level in each of the respective tasks of the instrument.

**Figure 2: Learning trajectories in the sample**

Once the individual trajectories of the children had been established, it was observed that 70% of the group were either moving between the EE and RR levels or on the RR level. Only 20% showed no signs of the RR level, with 15% located at the EE level and 5% at the CI level. On the other hand, we can see that in activities 5, 6 and 7 related to the levels of measurement, the students were moving between the EE, EE/RR and RR levels but they did not necessarily stay at the same level during the performance of the three activities. In activities 1 and 4 all students were situated at the corresponding HLT levels. In Activity 2, all students except one were on the DC level.

## Discussion

This study provides an overview of the group on the basis of the children's levels and trajectories. All the children, except one, were situated on levels EE and RR or were moving between them. According to Clements & Sarama (2009) and Barrett et al. (2012) children reach the EE level of measurement when around six years old and the RR level when around seven. This affirmation concurs with the data generated by this study. The transition between these two levels is very subtle and for this reason we decided to divide it into two sub-levels so that we could see more clearly where the children were situated.

During the analysis of the data, it was observed that children, although they are shown to be working mostly on one of the HLT levels, apply concepts and perform actions on the objects that correspond to levels considered higher. And, of course, they also apply strategies and perform actions on objects that belong to lower HLT levels (Sarama et al., 2011).

Once the data was analysed, we noted that despite the fact that all the children except one were above the EE level, not all of them were able to cope with the challenge of transitive inference. Although we are aware that the study is limited by the performance of only one activity linked to the IC during data collection, and the fact of working with only 20 children, in our case we suggest the following explanation: the EE level is either usually reached a little before the possibility of transitive inference, or work on specific mathematical experiences related to this inference is needed prior to its development. In this respect Sarama et al., (2011) conclude in their study: "(...) children achieved the Indirect Length Comparer level of thinking just prior to the End to End measurer level" (p. 678).

In this study we found students who, despite being mostly on the RR level, were not able to make explicit transitive inferences. This finding also supports the idea that children do not need to acquire conservation, nor the concept of transitivity, in order to acquire certain notions about measurement (Hiebert, 1981; Clements, 1999, cited by Sarama et al., 2011).

It is noteworthy that in this type of study is relevant to consider the influence of the interaction between the child and the tutor, as it could make a difference in the evaluation of actions in the various activities. In some cases, this could be considered a limitation of the study. In our case, the tutor who participated is a teacher who knew the children and was involved in the research.

A knowledge of the Hypothetic Learning Trajectory and its levels can enhance the teaching of length measurement (Barrett et al., 2012). This study showed us where the six-to-eight-year-olds in our sample were situated and which mathematics topics demand greater attention to enable them to move on to the next level of the trajectory and thereby consolidate their learning.

## Chances and obstacles of ‘indirect’ learning processes in situations with preschool teachers

Anna-Marietha Vogler

Goethe University Frankfurt, Germany; [vogler@math.uni-frankfurt.de](mailto:vogler@math.uni-frankfurt.de)

*From a co-constructive perspective, interactions are key variables for learning processes. In the context of learning preschool mathematics, these interactions are often characterized by ‘indirect’ negotiations of mathematical meaning: while, on the surface, everyday problems are discussed, ‘mathematically rich contents’ are nevertheless involved and negotiated latently in these interactions. The following paper focuses on such interactions that emerge in situations with preschool teachers and children in self-designed learning situations in German “Kindergärten”. I will point out how different forms of interactive support entail different opportunities for the children to participate in the interaction and especially in the ‘mathematically rich contents’ of the ‘indirect’ learning situations.*

*Keywords: preschool teacher, interaction, indirect learning processes.*

### Introduction

For children, entering primary school is not the first time when they learn mathematics. It is rather the preschool or the family context in which children collect first experiences with mathematics. Compared to a time when toddlers and infants were seen as mostly incapable of learning mathematics, today, the appraisal changed to the concept that mathematics is - besides the early learning of the mother tongue - an important topic to learn and that the early years are a sensitive period for learning it. In addition to the early learning at home, learning mathematics in preschool has been a field of increasing attention over the last decades. While learning at home with parents and siblings is surely a formative learning context, learning in kindergarten is also an important factor for children’s learning biographies: it is the first time of institutional learning for young children and also builds a crucial basis for future schooling (Claesens & Engel, 2013). Hence, the question arises regarding how mathematics learning can be integrated and supported in preschool to make use of this ‘potential’.

From an educational point of view, preschool teachers play an important role in supporting young children’s learning. Preschool teachers are major attachment figures as well as “more competent others” (Vygotsky, 1979) who support children in their interactive learning processes. For this reason, the following paper focuses on these interactions between preschool teachers and children. The analyzed interactions take part in the self-designed learning situations of the preschool teachers. But, while some researchers observe, analyze and evaluate teaching and the quality of preschool teachers acting and content knowledge, below, the interplay and the negotiation of meaning between the preschool teachers and the children is centered. There is a particular situation on which this paper focuses in which so-called ‘indirect’ learning processes take place and mathematical meanings are not explicitly negotiated, but rather implicitly involved within the interaction. This focus is chosen because indirect learning can be considered as characteristic for co-constructive learning processes since it conforms with ‘discovery learning’. But, missing explicitness within the process of

negotiation of meaning cannot only be seen as characteristic; from some perspectives, it can also be perceived as an obstacle for learning. On the one hand, it can be obstructive if learners are not able to interpret the ‘hidden’ meaning and, as a result, cannot participate in the learning process. On the other hand, it is also hindering if the “more competent other” is not able to recognize what the learner associates with the interaction. Hence, it seems fruitful to examine to which extent mathematical interactions between preschool teachers and children are characterized by missing explicitness and whether this form of indirect interactive learning is really an obstacle for learning. An important consideration is the kind of supportive guidance from preschool teachers that helps children to discover also ‘hidden’ meanings.

## **Preschool learning and curricula in Germany**

In response to the low performance of German learners in international comparative studies such as PISA and the already existing curricula for preschool learning in other countries, Germany has also, since the early 2000s, established different ‘curricula’ for “Kindergärten” (meaning: preschool) and “Kindertagesstätten” (meaning: day care centers) for children 0 to 10 years in each of its states. Concerning mathematics, there is more or less concrete advice regarding how to ‘teach’ different mathematical contents. Co-constructive learning is picked out as a central theme for all contents in all these curricula. Thus, even mathematics should be learned within situations where children are actively helping to shape the interactional process. Furthermore, several studies could prove that children develop a sustainable understanding of elementary mathematics by being integrated in such co-constructive learning processes.

## **Theoretical Framework**

### **Co-constructive learning processes within the preschool context**

Under the co-constructive approach, interactions are ‘key variables’ for learning (mathematics). Within these interactions, children actively construct meaning by themselves in interplay with others. From this perspective, learning is conceptualized as the increasing autonomy of participation within interactional practice (Sfard, 2008). Therefore, the more or less active participation in processes of negotiation about mathematical meaning gives learners the opportunity to also recognize mathematical contents as the interactive rules for presentation and interpretation. Concerning the learning of mathematics, the children should participate in interactions that can be characterized as ‘mathematically rich’ to develop mathematical meaning that is full of relations and outlives the situational context. Especially in preschool interactions, these mathematical meanings are not necessarily negotiated directly; rather mathematics “is, as knowledge of abstract relations, not directly accessible” (Steinbring, 2015, p. 281), and mathematical meaning is developed in a process of the increasing ‘mathematization’ of situated contexts. For primary school classrooms, Maier and Voigt (1989), were able to show that, in most situations, the teacher keeps the interaction going on rather than explicitly negotiating mathematical (complex) meaning. Even in preschool situations, teachers and children seem to negotiate mainly every day meanings like how to tidy up or how to play with different materials. While, on the surface, every day meanings are discussed, mathematically rich meaning is sometimes nevertheless (latently) involved. For mathematics, this conclusion seems to be obvious because, in some cases in mathematics, the concrete and every day meaning already contains

the general and abstract mathematical meaning. Hence, the concrete meaning superimposes the abstract. The result is a ‘double layer structure’ where learners can participate on both levels of the interaction – the concrete situational and the abstract mathematical meaning. However, successful mathematical learning can be characterized as an increasing participation on the (latent) *abstract* level of meaning – only, of course, when there is mathematical content contained on this level. But, which level of meaning is accessible for the learner depends on her or his subjective interpretations.

### **Indirect learning mathematics in the early years**

Krummheuer (1997, p. 9) calls learning processes, which are characterized by this ‘double layer structure’ of the process of negotiation of meaning, “*indirect* learning processes” (Krummheuer, 1997, p. 9). In his approach of “the narrative character of learning”, he stresses that the indirect learning processes are characteristic of early learning in primary school. Krummheuer (1997) revealed that indirect learning processes are sometimes obstructive for learning because learners and teachers must have high interpretation competences to cope with this kind of learning (Krummheuer, 1997, p. 95). For mathematics learning in secondary school, other researchers also found evidence for cumbersomeness in indirect learning processes (e.g. Strähler-Pohl, Fernández, Gellert & Figueiras, 2014). Oevermann, Allert, Kunau and Krambeck (1979, p. 384) more generally describe that children in their early ages often do not interpret meanings which are socially constructed and latently involved in interactions; rather, they perceive the meaning of interaction as naturally undistorted, and, so to speak, affectively truthful. In this synopsis on several studies on indirect learning processes, the following questions emerge:

- (1) whether early mathematical learning in *preschool* is also characterized by mainly indirect processes of negotiation of meaning, and
- (2) whether this kind of learning is a necessary obstacle for learning because it consequently drops children out from early learning mathematics.

From the findings above, the demand also evolves to analyze how preschool teachers can support children in indirect learning processes.

### **Methodology**

To analyze the different direct and indirect processes of negotiation of meaning, a two-step analysis is implemented. In order to analyze the explicit processes of negotiation of meaning and the included opportunities of the children to participate, (1) the interactional analysis is used (e.g. Krummheuer, 1997). For the not explicitly negotiated but latently involved meanings, an extension of this analysis is needed, because interactional analyses mainly take *situational* processes into account that generate “taken as shared meanings” (Krummheuer, 1997). Thus, mathematical concepts or processes that are not negotiated explicitly within the situation cannot be analyzed in a sophisticated manner. Therefore, (2) the interactional approach is enlarged by elements from the objective hermeneutical approach as developed by Oevermann et al. (1979). This approach focuses on the “latent rules of the interactional system” that are characteristic of the indirect learning processes on which this paper focuses. Hence, the enlargement also provides the opportunity to even reconstruct meanings that originate from individual ‘fields of experiences’ (Bauersfeld, 1983). By this means, it is possible to also reconstruct the ‘hidden’ meaning of the interaction that originates from one of the participants of the interaction.

For this purpose, (linguistic) “markers” within the interaction are taken into account. These markers are words or phrases that are used by the recipients to interpret the meaning of a communication (Heller, 2015). The final ‘product’ of that analytical process is a reconstruction of different levels of interpretational perspectives that emerge in the interactions, which are summed up in the following matrix (e.g. Figure 1). With the help of this matrix, it is possible to determine (1) meanings that are latent, which means they are not explicitly negotiated and interpreted in the interaction and only reconstructed by the so-called markers, (2) explicitly negotiated meanings, called manifest, that are interpreted by the participants in the situation, as well as (3) manifest meanings that are negotiated and that have trans-situational origins, and (4) latent meanings that can be only understood with the help of knowledge outlying the situational process and stems from a wider knowledge background.

	situational	trans-situational
latent meanings	<i>situational, latent fields of experience</i>	<i>trans-situational, latent fields of experience</i>
manifest meanings	<i>situational manifest fields of experience</i>	<i>trans-situational manifest fields of experience</i>

**Figure 1: Representation of the different levels of interpretational perspectives**

The situational and also trans-situational latent levels of interpretational perspective are both levels of the interaction that are more or less implicit. In the following sections, I will summarize how these levels of interpretational perspectives can be found in a situation with preschool teachers and how indirect learning processes take place in these situations.

## **Empirical Results - Obstacles and chances of indirect learning processes**

The presented empirical data is part of the erStMaL study (*early Steps in Mathematics Learning*) at the IDeA center (*Individual Development and Adaptive Education of Children at Risk*)<sup>1</sup>. Within the study, the research team encouraged 25 preschool teachers from different “Kindergärten” to develop and implement mathematical situations with groups of two or four children by themselves each year (from 2009 to 2012). Therefore, the teachers were asked to create the situations in reference to one of the five mathematical domains. The situations are videotaped and transcribed. One of these situations is presented below. The situation can be seen as a paradigmatic example of ‘successful’ learning situations in preschool – even if that is not directly obvious.

### **“Which are belonging together? ... Compare!” – Increasing autonomy through constancy of the level of latent meaning**

The analyzed situation takes place with four children from a kindergarten in Germany: Hannah (3.3 years), Michael (3.7 years), Bettina (4.7 years) and Martha (5.3 years); and their preschool teacher Nicola. The materials which are used include two green paper circles with different diameters (0.5m and 1.0m) and a burlap sack which is filled with ten different yet pairwise similar objects - in each case in two different sizes. In the following described scene, two nails (3cm and 5cm) and two building blocks (15x7x4cm and approx. 5x3x2cm) are mentioned. The blocks, as well as the nails are lying together with the other, yet pairwise similar objects on the two paper circles (e.g. Figure 2).

During the time of the situation, the children are sitting on a carpet together in front of the paper circles with the teacher.

**Figure 2: Arrangement of the objects on the paper circles**

At the beginning of the scene, the kindergarten teacher Nicola asks the children to find two things that belong together. She asks: “And which are belonging together?”. After a girl, Bettina, pointed at two building blocks, Nicola continues with her instructions.

### *Scene 1*

- 456 Nicola: Take a look Bettina. (.) Put two things together. Here we make a line.<sup>2</sup>  
 457 *pointing with her finger in a line right beside the paper circles parallel to the edge of the carpet ...*  
 459 Start right here.  
 460 *pointing at one point near the edge of the carpet*

In line #456, Nicola instructs Bettina to locate (the) objects on the edge of the carpet where they are separated from the paper circles. She says that they have to be located in a line. She marks with a gesture the starting point of the array and the accompanying expression: “start right here” #459.

- 469 Bettina: *placing the bigger pin to the place that is marked second and the smaller pin to the place that is marked first by the nursery teacher*  
 470 Nicola: Exactly! This way.  
 471 *adjusts the pins on the carpet the way that they are lying parallel to the edge of the carpet and the heads of the pins are abreast*  
 472 Who wants to search for two things that belong together now?

When Bettina lays down the nails #469 on the positions marked by Nicola in #460, the teacher corrects the arrangement by putting the nails side by side until the nails are parallel to each other and the carpet’s edge. She additionally confirms the successful ending of the task through her expression “Exactly! This way!” in #471 and asks the kids who would like to find the next objects that belong together in #472. In the next scenes, the kids position pairs of objects on the carpet in a line with the first two nails. Later on, the children compare the objects in the different lines and the teacher Nicola accompanies these interactions linguistically using phrases like ‘which is the biggest’ and other superlatives that underline the process of comparing.

### *Scene 2*

- 583 Nicola: What **else** can we do with it? Does anybody have an idea?  
 584 Martha: Compare.  
 585 Nicola: Compare! How would you do that, Martha? (...)  
 586 Martha: There you can see it. It is beautiful like that.  
 587 Nicola: mh?

- 588                    *turning to Martha*  
 589 Martha:        It is beautiful like that.        ...  
 592 Nicola:        The way it is lying here or different? (..)  
 593 Martha:        The way it-  
 594                    *she squirms*  
 595 Bettina:        is lying there.  
 596 Nicola:        The way it is lying here?  
 597 Martha:        mh!  
 598 Nicola:        okay! mhhh (5 sec) now (.) which is the absolutely biggest of the things?

In that scene, Nicola asks the children about the use of the two ‘lines’ of objects lying on the carpet. Martha specifies the use as ‘comparing’ #584. But, after Nicola asks for the way to compare, the girl astonishingly replies that one can see it because it is beautiful #586. And the girl maintains her opinion, although Nicola asked again – probably to change Martha’s mind. Bettina even agrees with Martha #595. At the end of the episode, Nicola modified her question and explicitly asked for the biggest ‘size’ #598.

### ***Reconstruction of the different levels of meaning***

Nicola’s last turn, in line #598, particularly provides evidence that there is also a latent meaning involved in the interaction in Scene 2, as well as in Scene 1. On the surface, it could be interpreted that Scene 1 deals with putting nails on a carpet, but, on the latent level of the interaction, especially in Scene 2, it is understood that the preschool teacher Nicola introduces an early concept of ‘size’ by directly comparing objects of equal shapes and different sizes. The latent meanings are also revealed *within* Scene 1. This can be mainly interpreted from the marker in line #472. Based on this marker and the interpretations from the other scene (amongst others, #583-598), different levels of the negotiated meaning can be reconstructed. They are presented in the following matrix.

	situational	trans-situational
latent meanings	One big and one small pin from the paper pad should be placed on the carpet at a time	Two objects of similar shape and different size are building a pair and should be placed to visualize the exact geometrical difference in size in order to enable a direct mathematical comparison
manifest meanings	The pins are placed on the carpet  <b>Marker:</b> <i>Nicola adjusts the pins on the carpet so that they are lying parallel to the edge of the carpet and the heads of the pins are abreast #471</i>	

**Figure 3: Representation of the different levels of negotiation of meaning in Scenes #456 - 472**

Three of the latent and manifest levels in Scene 1, from #456 to #472, can be reconstructed: on the manifest and situational level of interpretation, Nicola and the kids ostensibly put some objects in order, but, on the latent level, it is obvious that, within the interaction, the preschool teacher also tagged on mathematical issues concerning size. Thereby, an interpretation of these mathematical themes is possible on the situational level. Here, it is perceptible that two similar objects are belonging together because they are equal in shape and different in size. Together with the interpretations of the

second scene, from #583 to #598, the mathematical theme is additionally enlarged. The preschool teacher Nicola also addresses direct comparisons and size. This interpretation is only possible with the knowledge about the mathematical concepts.

### ***Participation and Support***

When looking at the participation of the children, it becomes apparent that the girl, Bettina, first participates on the level of manifest meaning where the (right) placement of pins is negotiated - although she could interpret the latent meaning as well. In Scene 2, it is Martha who describes the use of the lines and manifests the meaning, which is also latently involved in Scene 1. Additionally, Martha characterizes the arrangement of the objects in two lines (side by side) as beautiful. Thereby, she introduces a further aspect to the interaction that can be interpreted as profound from a mathematics perspective: one could say she described a kind of mathematical well-ordering with words of the aesthetic kind (e.g. Sinclair, 2006) when she says the lines can be compared because they are beautiful #586. As the second scene shows, the girl Martha, and maybe also Bettina, participate as a result of the 'rich' mathematical contents of the interaction and rather manifest them over time. In addition, they contribute some own mathematical ideas in the form of the aesthetic of the lines which are to be compared. It can be assumed that the increasing autonomy of the children emanates from the coherence of latent meaning throughout the situation, which is maintained by Nicola. She supports the children by consequently focusing on the size of the objects and the direct comparison. Unfortunately, she does not recognize Martha's idea #586. Further, it can be supposed that the 'double layer structure' of the indirect process of negotiation of meaning, which can be analyzed in Scene 1 in Figure 2, is supportive because it helps the children to participate over time. As does Bettina, for example, the children get the opportunity to be active on the manifest level of the interaction on which every day meanings are negotiated, while they can also interpret the latent meanings which are more abstract and maybe 'hard' to understand. In the course of the ongoing situation, a bunch of markers open several opportunities for the child to participate on more than just the every day level.

### **Discussion**

The aim of this paper was to examine whether learning processes in preschool situations with teachers and children can be characterized as 'indirect' and whether that has to be seen as an obstacle for the participation of children. While the indirect processes of learning in the context of school are seen as repressive for learning (e.g. Strähler-Pohl et al., 2014), the analysis of the situation provides evidence that indirect learning in preschool situations can be seen as a chance for children to participate and 'learn over time'. Crucial for the success of this learning over time is a 'double layer structure' of every day meanings and abstract mathematical meaning. Thereby, especially the latent and abstract mathematical meaning has to be coherently introduced throughout the whole situation. Thus, the learners can discover the mathematics and mathematize their everyday experiences over time. By means of such a 'supportive' structure, maybe even 'struggling' learners could have the opportunity to participate (somehow) within the interaction and recognize further latent meanings later on. Of course, that structure also involves risks for the learning processes of young learners, because they can be unable to perceive the meaning of the markers that lead them to the further implicated

meanings, as many studies observe. Further analysis should show, how other interactional aspects could also support the interpretation process of young learners.

## Introduction

Numerical magnitude understanding by young children, ways of stimulating this f.e. with intervention programs and their impact on future mathematics achievement, started in cognitive neuropsychology, is now a virulent field of research in the didactics of mathematics. Some others like pattern and structure assessment (Mulligan et al., 2015) or the role of executive functions in mathematics achievement (Van Dooren & Inglis, 2015) are getting more attention recently, linking mathematics education and neuropsychology again. Neuropsychological evidence suggests that abilities of processing spatial information play a significant role in grasping magnitudes and emphasize the potential benefit of promoting their development early on (Verdine et al., 2014). However, studies have still to attest a beneficial value of trainings for spatial abilities. The current study focuses on the development and evaluation of such a training program for preschoolers. The training was developed on the bases of two trainings designed for children with constructional apraxia (Schroeder, 2015; Muth et al. 2001). Constructional apraxia is a visuomotor disorder with deficits in perceiving the extrapersonal space and building/drawing objects (Hanser, 2000). Tasks within these trainings focus on the perception of shapes, angles, lengths and spatial axes, cognitive processes like mental changes in perspective, spatial orientation and navigation as well as the construction of 2- and 3-D objects. Materials and tasks were partially derived, adjusted in difficulty and modified to fit in a coherent 10-days training with 27 consecutive tasks. Afterwards, the training was reviewed by preschool teachers, revised and implemented for evaluative purposes.

## Methods

Six daycare centers with 60 preschoolers (31 males; ages from 5.5 to 7.2 years;  $M_{age} = 6.2$ ) participated. Thirty-seven children received the training (EG; experimental group), while 23 children resumed their normal day routine (CG; control group). Before and after the training, performance tests (sustained attention: DL-KG, numbers and magnitudes: ZAREKI-K, motor skills: M-ABC-2, intelligence: CFT) were applied to measure training effects. In addition, preschool teachers were asked to evaluate the improvements of each child during this period on targeted skills (spatial perception, spatial imagination, math skills, fine and gross motor skills, social skills) and not targeted skills (artistic skills, verbal skills) on stepless scales between “degraded” and “improved”. For further improvement of the training, teachers rated each task on stepless scales between “adverse” and “beneficial” for target skills. All stepless scales deliver values between -5.0 and +5.0. They also assessed difficulty, excitement and entertainment value of each task as indirect moderators of general learning success (e.g. via motivation and attention) on 5-point Likert scales.

## Results

MANOVAs were applied to reveal training effects (EG > CG) on improvement ratings. A significant effect of the training was found for target skills,  $V = .88$ ,  $F(6,5) = 6.62$ ,  $p = .03$ . The univariate  $F$  tests showed a significant difference between EG and CG for spatial perception,  $F(1,10) = 9.93$ ,  $p = .01$ ,  $\eta^2 = 0.49$  and spatial imagination,  $F(1,10) = 6.11$ ,  $p = .03$ ,  $\eta^2 = 0.38$ . Due to unevenly distributed missing values, pre-post improvements were contrasted between EG and CG with  $t$ -Tests, revealing benefits for intelligence (CFT;  $t(42) = 1.81$ ,  $p = .04$ ) and a tendency for higher improvements of sustained attention (DL-KG;  $t(52) = 1.47$ ,  $p = .07$ ) in the EG.

On average, the training was rated as beneficial (+2.8) by preschool teachers. Each task was considered beneficial ( $> +2.5$ ) for at least one target skill. The difficulties of 9 tasks need to be increased. Ratings of excitement were mainly mediocre. The entertainment value of 19 tasks was rated positive.

## Discussion

Overall, beneficial effects of the training were reported by subjective teacher ratings for spatial perception and imagination. Furthermore, intelligence increased more strongly in children with the training. Considering the relation between intelligence, working memory and mathematical abilities (Alloway & Alloway, 2010) this training-related increase might also be moderated by an increase in math skills. Developing a specific diagnostic tool for spatial abilities as well as applying follow-up tests might be promising to reveal objectively measured benefits for targeted skills. As one main goal of the current survey, feedback revealed several approaches for improving the effectivity of the training and thereby paving the way to the next phase of the evaluation.

### Introduction

The TWG14, *University Mathematics Education* (UME), was launched in CERME7 (Nardi, González-Martín, Gueudet, Iannone, & Winsløw, 2011) showcasing the fast growth of research in UME and also the specificity of the research context. In particular, the abstract, formal nature of a significant portion of the mathematical content; the absence of national curriculum guidelines, and therefore the great variations in organization and practices across institutions; the general lack of professional development or of systematic preparation for teaching; and, the volume of content to learn in a short period of time, and the degree of autonomy expected from the students and faculty. The consolidation of this research area, both outside and inside CERME, was recognized by the ERME community in inviting the first, three-time leader of this TWG to present a summary of UME research as a CERME10 plenary lecture (Nardi, 2017). Moreover, an ERME Topic Conference, *International Network for Didactic Research in University Mathematics* (INDRUM) was launched in 2015 with two successful conferences ([INDRUM2016](#) and [INDRUM2018](#)) since then, with the first one leading to a [special issue](#) in the *International Journal of Research in Undergraduate Mathematics Education*, the new journal in the UME field. Future developments include a forthcoming book on *Research and development in University Mathematics Education* (Durand-Guerrier, Hochmuth, Nardi, & Winsløw, in preparation).

The number of papers submitted to TWG14 has been increasing since its inception. This year, we received 52 paper and 13 poster submissions, with 35 papers and 15 posters presented at the

conference and published in the proceedings. Having received the largest number of papers in CERME10 and the second largest in CERME11, the number of papers led to the decision to split TWG14 into two isomorphic groups, TWG14A (18 accepted papers) and TWG14B (17 accepted papers) that ran in parallel; we held some common sessions during the conference. Each of the groups covered the same range of areas of research pertaining to UME, therefore the isomorphic label. The decision was prompted because splitting thematically would have resulted in losing perspective on the complexity of the issues that participants wanted to address. Furthermore, because the call for papers was open to a range of themes it would be unfair to assign contributions to a new group that might not align with the authors' original aim. This introductory paper summarizes the works presented in both groups organized according to the discussed themes, as well as the common discussions.

Some themes continue work from CERME10. For instance, we received a large number of papers focusing on students' learning of specific topics (10 papers), such as calculus, reasoning, and proof. We accepted seven papers proposing interventions, whereas in CERME10 we received five papers; however, relative to CERME10, the number of papers about teachers and their practices and about mathematics for non-specialists decreased from ten to four and from seven to two, respectively. We had two new themes: one on curriculum and resources and one on transition. In the next section, we briefly present the seven themes used to organize the work this year, with examples from paper contributions. It is important to note that many papers could fit in more than just one theme; this classification helped us to structure the presentations and the discussions during the sessions.

## **Themes and paper contributions**

### **Students' learning of specific topics**

Ten papers were classified under this theme: Aaten, Roorda, Deprez, & Goedhard; Gabel & Dreyfus; Herrera Alva, Figueroa, & Aguirre de la Luz; Kondratieva; Kontorovich; Lankeit & Biehler; Malaspina & Torres; Bašić & Milin Šipuš; Mkhathshwa; and, Pinto & Cooper.

Calculus was prominent in several papers (Aaten et al.; Herrera Alva et al.; Lankeit & Biehler; Malaspina & Torres; Mkhathshwa), with an increasing interest in two-variable calculus (Malaspina & Torres; Mkhathshwa) and analysis (Kondratieva). Under-researched topics were also present: differential geometry and its connections with two-variable calculus (Bašić & Milin Šipuš) and the use of conventions (Kontorovich). We also received papers addressing reasoning and proof (Gabel & Dreyfus; Pinto & Cooper).

Some of the papers discussed in this theme also concerned questions related with teachers and teaching. For instance, an intervention to improve in-service teachers' comprehension of discontinuity in one or two variables was also presented (Malaspina & Torres), as well as studies about the challenges in providing feedback that is actionable by students when revising a proof (Pinto & Cooper) or when teaching proofs (Gabel & Dreyfus). These last two studies raised questions in relation to the teaching of, and communication about, proof relevant to other themes we discuss below.

## Resources and curriculum

Five papers were discussed in this theme: Bosch, Hausberger, Hochmuth, & Winsløw; Howard, Meehan, & Parnell; Pepin & Kock; Sabra; and, Viirman & Jacobsson.

From a student perspective, but also in relation to lecturers' intentions, Pepin and Kock explored what type of resources first year engineering students use and how they use/orchestrate these resources for their study of mathematics. They found that students' type and use of resources varied in relation to the type of course and the lecturer's expressed expectations. In relation to assessment, Howard et al. discussed student engagement with resources and continuous assessment in a mathematics course for business students.

Some of the papers studied the relation of university mathematics instructors with resources. For instance, Viirman and Jacobsson put forward the role of the mathematical content in the didactical choices made by university mathematics lecturers in course design; they highlighted how differences in the epistemological character of the topics to be taught may have affected the course design. Similarly, Sabra showed how different teachers with different training may focus on different aspects of the content to teach using some resources.

Finally, Bosch et al. presented a study about the didactic transposition processes that lead to the creation of undergraduate mathematics programmes, which fills a gap on the rationale behind the creation of such programmes. Overall, the papers discussed in this theme show how the use of resources is related to learning and teaching practices, a question that was discussed in the other themes as well.

## Transition

Four papers were discussed in this theme: Bampili, Zachariades, & Sakonidis; Bergsten & Jablonka; Doukhan & Gueudet; and, Pinkernell.

Different aspects of transition were present in these papers. For instance, Doukhan and Gueudet studied praxeologies in pre-university and university courses regarding the notion of random variable; they showed that the content learned in secondary school may not prepare students for tertiary courses. Regarding institutional support, Bampili et al. showed how institutional support (or the lack of it) at university can influence the trajectories of novice students. Furthermore, Pinkernell reported on a frame (WiGORA), founded on five characteristics of understanding mathematics, for supporting students' transition towards university mathematics.

Transition towards and within university courses has been investigated in the last years through several lenses. Bergsten and Jablonka presented a review of literature concerning the secondary-tertiary transition, referring to five theories. Their review evidenced that, while there is a move towards socio-cultural theorizing, some dimensions pertaining to social issues still appear under-researched.

Literature on transition addresses, in many cases, students' challenges. This calls for intervention, and some specific examples were discussed in the following theme.

## Interventions

Seven papers were discussed in this theme: Feudel & Dietz; Florensa, Barquero, Bosch, & Gascón; Ghedamsi & Lecorre; Hochmuth, Schaub, Seifert, Bruder, & Biehler; Kuklinski et al.; Thomas, Jaworski, Hewitt, Vlaseros, & Anastasakis; and, Uysal & Clark.

A relatively recent approach to constructing interventions—framed by the Anthropological Theory of the Didactic (ATD)—is the study and research paths (SRPs); SRP is a specific form of inquiry-based intervention. Florensa et al. discussed ten years of SRPs implemented at university level, showing their utility as a methodological tool for the systematic design of interventions. Other interventions included the implementation of a coaching program to support conceptual learning in a first-year mathematics course (Feudel & Dietz) or innovative lectures that foster more social interactions and student engagement than traditional ones (Kuklinski et al.). These studies investigated the impact of the interventions on student engagement. Finally, Uysal and Clark reported on the use of history in learning mathematics and its potential to support mathematical and emotional aspects of students' transition from high school to university.

On a more theoretical level, Ghedamsi and Lecorre compared and contrasted the Theory of Didactical Situations (TSD) and ATD with the aim of combining them in the design of a teaching intervention on real numbers and sequences. Many papers presented in this theme were related to other themes. Hochmuth et al. presented the structure of a diagnostic and evaluative test that helps students decide about what bridging courses are more appropriate for them; this paper has connections to the transition theme as well. Thomas et al. presented a project involving a bridging module, and showed that student-partners in task design furthered their own understanding of the topics (complex numbers) and developed didactical insights when designing mathematical tasks for others; this paper has connections to the transversal issue of collaborations in UME.

## Students' identity and experience

Three papers were discussed in this theme: Thoma & Nardi; Toor, Mgombelo, & Buteau; and, Voigt, Rasmussen, & Martínez.

Students' experiences were seen by Thoma and Nardi in relation to their participation in the mathematical discourse. They used the theory of commognition to study students' substantiation of claims in exam scripts, in a first-year course called "Sets, Numbers and Theory." They demonstrated that students' participation in mathematical discourse, at least in the exam, was mostly ritualized. On the other hand, Toor et al. studied the experiences of post-secondary mathematics students learning to use programming as a computational thinking instrument for mathematics. They argued that identity is essential to the development of productive dispositions in learning to program for mathematics investigation and modeling. The notion of identity was central in the work of Voigt et al. as well. Adopting a sociocultural perspective and the notion of *figured world*, they showed how three different variations in a calculus course can have an impact on a student's trajectory and relationship with mathematics.

## Teachers and teaching

Four papers were discussed in this theme: Costa Neto, Giraldo, & Nardi; Mali, Cawley, Duranczyk, Mesa, Ström, & Watkins; Mesa, Duranczyk, Watkins, & AI@CC Research group; and, Stewart, Epstein, Troup, & McKnight.

The involvement of and the tension between different communities in relation to the teaching of mathematics was addressed by Costa Neto et al. Using a re-storying methodology, their study examined disputes between mathematicians and mathematics educators in Brazil over the curriculum of a pre-service teacher education program. Teaching at the post-secondary level is the focus of Mesa et al. who describe the development of an instrument for the evaluation of community college algebra instruction, Evaluating the Quality of Instruction in Postsecondary Mathematics (EQIPM), through the analysis of video recorded data that include codes for student-content, instructor-content and instructor-student interactions. Specifically, Mali et al presented two of the twelve characteristics of instruction included in EQIPM: *Instructors Making Sense of Procedures*, and *Student Mathematical Reasoning and Sense Making*. Although these characteristics can contribute to the quality of instruction, the authors showed that exemplary instances of instruction with these characteristics were relatively rare. Finally, Stewart et al. addressed the work of a mathematician preparing his course on eigenvalues and eigenvectors, showing how the use of some didactic constructs may be useful for the mathematician to organize content and to reflect on his practice.

## Use of mathematics by non-mathematicians

Two papers were discussed in this theme: González-Martín & Hernandez-Gomes and Tetaj & Viirman.

Artigue, Batanero, and Kent (2007) stated ten years ago that the study of issues related to mathematics as a service course would certainly need the use of sociocultural approaches. This is the case of the two papers discussed in this theme. For instance, González-Martín and Hernandez-Gomes studied the teaching of mathematics to future engineers with an institutional perspective based on ATD. Using textbook analysis, they compared how the integral is taught in a calculus course and in a mechanics of solids course for engineers. The authors identified a rupture in the study of a similar task (the sketching of the graph of an antiderivative), likely to prevent students from using their calculus knowledge in professional courses. Tetaj and Viirman used the commognitive approach to analyze the mathematical discourse of undergraduate biology students. Their results showed students' tendency to develop a ritualized approach, as well as their difficulties to mathematize a biological phenomenon; their lack of familiarity with relevant construction routines may prevent them from developing abilities to deal with certain problems.

## Transversal issues addressed in plenary discussions

### Resources in university mathematics education

Research on resources and their use in UME is growing, with works investigating the use of textbooks (e.g., González-Martín, Nardi, & Biza, 2018; Mesa & Griffiths, 2012) and technology (e.g., Lavicza, 2010). Some authors consider a general concept of resource, as anything likely to re-

source the activity of a teacher (e.g., Gueudet, 2017) or a student (e.g., Gueudet & Pepin, 2018). Since CERME10, TWG22 has been dedicated to studies related to the use of resources in mathematics education, but, in TWG14, some papers explicitly or implicitly addressed resource use and analysis of resources. For instance, the design of interventions is linked to the design of specific resources and the teaching of mathematics for non-specialists uses particular resources. The discussions on this topic in TWG14 raised several questions. Choosing an appropriate definition of resource is a first complex step. Should this definition encompass mathematical knowledge, professional knowledge (in the case of teachers), or affect? Different definitions may be needed depending on the question studied. The question of the use of resources for the research activities of the lecturers, as well as lecturers' interactions (or absence of interactions) with resources for teaching also requires further study.

### **University mathematics: teachers and teaching**

Relative to school settings, research on teachers and teaching is less common in UME (e.g., Speer, Smith III, & Horvath, 2010). In contrast, CERME has three groups dedicated to teachers and teaching (TWG18, TWG19, and TWG20), four if one counts assessment (TWG21). The growing interest of UME in this area is evidenced in our TWG14, which discussed some of the challenges of working at the intersection of university mathematics teaching and research in mathematics education (RME). To begin with, the conception of what it means to know mathematics at university may be quite different from conceptions that are common in pre-tertiary RME. As a result, the models of university-level teaching may not be consonant with theoretical models and frameworks that typically guide RME. This state of affairs can be particularly challenging for researchers who set out to investigate their own mathematics lecturing. Another type of challenge has to do with relationships between the two communities involved: university lecturers do not always value RME as a scientific field, while educational researchers are often critical of lecturers' approach to teaching. Thus, to support research-based professional development for university lecturers there is a need for teacher educators with expertise in both content and teaching, credentials that may be scarce. These challenges and others were addressed in TWG14 contributions, as summarized in the *Teachers and Teaching* section. Finally, many research works involving the study of practices (e.g., teaching, resource use, planning, and assessment) of mathematics lecturers and also mathematicians call for the development of fruitful collaborations.

### **Collaboration with mathematics lecturers, mathematicians, and other professionals in research and development in UME**

Collaboration and relationships between mathematics lecturers<sup>1</sup> (ML) and mathematics education researchers have been addressed in UME research studies (e.g., Nardi, 2008). This collaboration can be seen from (at least) two different perspectives: (1) through the roles of each group in such collaboration (e.g., UME researchers researching the practice of ML; ML researching their own

---

<sup>1</sup> We use “mathematics lecturer” or “mathematics teacher” to refer to a person who teaches mathematics at university. This person may be active in research in mathematics or not.

practice in collaboration with UME researchers; or UME researchers and ML collaborating in UME research and development); and (2) through the contribution of research in UME to developmental projects in industry and practice (e.g., what is the ‘utility’ of research to practice?) and to mathematics teaching and curriculum development (e.g., how a research finding is transformed in order to be used as a curricular ‘product’?). Collaborations and tensions in such collaborations were addressed in contributions to this conference as we have exemplified in the themes above. The discussion on this topic had two directions: (a) theoretical and methodological tools that will help to study such collaborations and make them fruitful; and (b) the role and impact of theory in such collaborations, from the perspective of both UME researchers and ML. Indicative points raised in the discussion concerned the observation that collaborations engage communities with different practices, as a result we should work on the: need of theoretical tools to study collaborations; need for tools to study boundary crossing, even though the boundaries between the communities are not clear (e.g., ML may also be UME researchers); need of ways to identify the goals and expectations of different professionals (e.g., mathematicians, chemists, biologists, engineers, etc.) who are involved in such collaborations; and, a need for better understanding of institutional factors (e.g., institutions may or may not facilitate such collaborations).

## Reflection and ways forward

We initiated the discussion in the concluding session of our work at the conference summarizing some of the main points of the chapter *Research on university mathematics education* (Winsløw, Gueudet, Hochmuth, & Nardi, 2018), published in the book celebrating twenty years of CERME. Winsløw et al. (2018) synthesize the main contributions of CERME to research in UME in terms of: (a) *what is it?*, namely research into current practices of UME (with no direct intervention), such as: mathematical content; methods and resources; transition phenomena; student experiences; and, teaching non-mathematics specialists; and (b) *what could it be?*, namely developmental or experimental research, that includes an intervention design as part of the research project (e.g., research on, and for innovation in UME; i.e., interventions in specific courses or programmes) and professionalization of UME practice (preparation of ML).

In our discussion in the concluding session we reflected on these areas as well as on the studies we discussed at the sessions and we suggested the following ways forward: 1) because many areas and topics of UME require the establishment of varied collaborations (with ML, mathematicians, engineers, school mathematics researchers) we need to develop theoretical tools to study these collaborations; 2) some papers presented an articulation or networking of different perspectives which could be a way to study complex phenomena (there were papers using “external” theories, e.g., sociology); 3) large-scale studies are needed to consolidate some results; 4) innovative methodologies are also being developed, such as those to study the use of digital textbooks; 5) most of the current studies in UME are local, and therefore, we need to develop studies and tools that help to transfer findings to other educational contexts; and 6) new topics appeared in this conference: the use of history of mathematics, curriculum design and its origin, the role of course coordinators. We predict more new topics will appear in the years to come. We anticipate that the coming CERME conferences will allow us to pursue research on the areas and questions discussed this year and to bring research on some of these areas forward.

*Undergraduates' mathematical reasoning often lacks mathematical foundations and metacognition. This is worrying since it may negatively influence mathematics learning. Little is known however about whether and how undergraduates' reasoning foundations and use of metacognition evolve over time. In preparation of an educational intervention to enhance undergraduates' mathematical reasoning, we investigate the evolution of students' mathematical reasoning on calculus tasks during bachelor studies in mathematics, using a framework on mathematical reasoning we developed in an earlier stage. In this article, we discuss the case of Lisa to shed light on mathematical reasoning evolution, and on the role of mathematically founded reasoning and metacognition in this evolution.*

*Keywords: Mathematical reasoning, undergraduate students, calculus, metacognition.*

### Introduction

Since Lithner (2003, 2008) introduced his theoretical framework on mathematical reasoning, many studies have used his distinction between creative mathematically founded reasoning and imitative reasoning. Lithner (2003) showed how undergraduates' reasoning is often not mathematically founded, but instead relies on imitation of exemplary or recalled solution strategies. Jonsson, Norqvist, Liljekvist, and Lithner (2014) have investigated learning effects of tasks requiring creative mathematically founded reasoning and found that it enables students to solve the same task at a later point in time. For moderately non-routine tasks however, undergraduate mathematics students have difficulties to think of suitable strategies (Selden, Selden, Hauk, & Mason, 2000). To gain more insight into undergraduates' mathematical reasoning, also on moderately non-routine tasks, we investigated its development at undergraduate level at two research universities and used Lithner's ideas concerning creative mathematically founded reasoning as a starting point.

### Framework to analyze mathematical reasoning

For our research, we used Lithner's (2008) concepts in a different manner than in the original framework, because of its limitations for characterizing any reasoning observed in students' task solving (Aaten, Deprez, Roorda, & Goedhart, 2017; Mac an Bhaird, Nolan, O'Shea, & Pfeiffer, 2017). From the single category of creative mathematically founded reasoning, we disentangled two dimensions: reasoning foundation and novelty. Furthermore, we added a third dimension: metacognition level. Building upon Lithner (2008), we define *mathematically founded reasoning* as reasoning in which decisions are based on mathematical properties that are relevant to the decision. *Superficially founded reasoning* is reasoning that is not mathematically founded. Lithner (2008, p. 266) defined *novel reasoning* in situations when "a new (to the reasoner) reasoning sequence is created, or a forgotten one is re-created". Since we encountered difficulties in discerning whether a

reasoning sequence is new or not, we choose to see novel reasoning as the opposite of recall, where *recall* means that a strategy is selected because the strategy was used before to solve similar tasks.

### Metacognition levels

Since metacognition plays a central role in learning mathematics (Desoete & Veenman, 2006; Schneider & Artelt, 2010) it is important to include this aspect into our analysis. Several studies indicate that undergraduates' use of metacognition is limited (De Backer, Van Keer, & Valcke, 2012; Radmehr & Drake, 2017). However, not much research has been done on the evolution of metacognition during undergraduate mathematics courses. Since Flavell (1979) introduced the notion of metacognition, various conceptions have been developed. In this study we build upon research that distinguishes levels of metacognition explicitly, or implicitly by discerning types of metacognition or metacognitive behavior. Wilson and Clarke (2004) consider three aspects of metacognition: awareness, evaluation, and regulation, where *awareness* concerns the connection between the task at hand and past experience, *evaluation* is about the task solving actions just undertaken, and *regulation* anticipates specific task solving actions. In analyzing students' solutions, they discern regulation that builds upon awareness (e.g. retrieval of procedures) from regulation that builds upon evaluation of awareness, for instance, regulation as a "consequence of the need for a decision [...] as to how best to proceed" (Wilson & Clarke, 2004, p. 38). This distinction is similar to Koichu's (2010) distinction between circular heuristic behavior and spiral heuristic behavior. The former concerns employing strategies without building upon the intermediary outcomes, while the latter does build upon intermediary outcomes. Nunokawa (2005) similarly distinguishes initial problem analysis and knowledge application from problem solving by building upon obtained information, e.g. transforming the problem or finding new perspectives.

Based upon these models, we define two metacognition levels. *High-level* metacognition builds upon evaluation of components of the task solving situation. By task-solving components we mean the task itself, strategies that are used or considered, intermediary outcomes of strategies, and sub-goals formulated during task-solving. *Low-level* metacognition lacks such evaluation, for instance, if a student takes the decision to use a different strategy without reflecting upon what could be learned from the steps taken so far.

### Research question

In the light of the above, we aim to answer the question: in what way do undergraduates' reasoning characteristics evolve over the course of bachelor studies in mathematics and what is the role of mathematical foundations and metacognition? In our larger study on undergraduates' mathematical reasoning when solving calculus tasks, we noticed how some students' reasoning barely evolved over the years, while the reasoning of other students did develop, even though the courses taken by the students, and the way the courses were taught (lectures and tutorials, a little project work), were similar. To answer the research question of this study, we focus on a student whose reasoning did evolve over the years: Lisa<sup>1</sup>, who started off unsuccessfully but improved over the years is a bachelor

---

<sup>1</sup> Pseudonym

student in mathematics but has taken courses in econometrics before. In the first year of her mathematics studies, Lisa's average exam scores were low but sufficient to pass most exams.

## Method

To investigate students' reasoning, the first author administered task-based think-aloud interviews in three different years. In each interview, Lisa solved three tasks, see Table 1. In post-interviews after each task, she explained her solutions and answered questions such as: 'How did you come to think of using this strategy?', 'How certain were you that this strategy would help you solve the task, and why?', 'Have you seen this type of task before?'. The interviews were video and audio recorded and transcribed.

	Y 1	Y2	Y3
A: $\int \frac{1}{1+e^x} dx$	X		X
B: $\int \frac{1+x^{1/2}}{1+x^{1/3}} dx$		X	
C: $\int \sqrt{9-x^2} dx$	X	X	X
D: $\int \sqrt{x^2-9} dx$	X	X	X

**Table 1: Overview of tasks given to Lisa.**

The tasks used are indefinite integrals that can be solved with methods from the first year course on integral calculus. We chose these tasks, because students had learned a large number of integration strategies they could choose from, and because we expected that these specific tasks would be difficult to many students. This would give rise to longer and more elaborate

CODE:	CODE ASSIGNED IF:
<b>Mathematically founded reasoning</b>	student explicitly gives relevant mathematical reasons for why the strategy selected will help to solve the task
<b>Superficially founded reasoning</b>	reasoning does not comply with the criterion for mathematically founded reasoning
<b>Recall</b>	student selects strategies because they have been used before to solve similar tasks
<b>Novel reasoning</b>	reasoning does not comply with the criterion for recall
<b>High-level metacognition</b>	student evaluates components of the task solving situation when selecting a strategy
<b>Low-level metacognition</b>	little to no evaluation takes place for selecting strategies

**Table 2: Coding scheme**

solutions compared to solutions of routine tasks, therewith giving more insight into students' reasoning. To be able to compare reasoning over the years, some tasks have been used each year. In order to be able to correct for a possible test-retest effect, we alternately used task A and B. Although Lisa was given task A both in year 1 and in year 3, Lisa did not seem to recognize the task.

## Analysis

To analyze the interview transcripts, we used the coding scheme in Table 2. For each dimension, one code is given per task solution as a whole, based upon Lisa's on-task utterances, and upon explanations and answers during the post-interview. We made use of Lisa's own analysis of her reasoning (e.g., that she recalled a strategy) and of our impression of her reasoning inferred from Lisa's statements and actions. These various angles served to complement each other and where possible to triangulate our findings. This analysis led to nine codes for each dimension, which together give the global picture of Lisa's reasoning evolution, or more specifically, the evolution of each of the dimensions.

To determine one code per dimension per task, we chose to focus on the phase of strategy selection, since that phase is especially essential in solving difficult tasks (Selden et al. 2000). This implied in general that the initial orientation phase is left out of the analysis, just like the execution phase. While one solution often contains various strategy selection phases, we focus on the phases in which the

solution progressed, or was close to making progress. Considering these progressing task selection phases, we determined what type of reasoning was prominent.

When coding the reasoning characteristics, we deliberately ignored mathematical correctness of calculations and arguments, but we did evaluate the *success* of the solution as a separate category. This code is given somewhat indulgently: if a (lengthy) task was solved correctly almost completely, and only a minor error or lack of time appears to have been the cause of not finding the correct answer, the solution is coded as successful.

## Results

We first describe how Lisa's reasoning on task A evolved over time. Due to space limitations, Lisa's reasoning on the other tasks is not discussed in detail, but the codes are included in the overview.

**Lisa's reasoning on task A:**  $\int \frac{1}{1+e^x} dx$

We briefly describe and illustrate Lisa's solutions. In year 1, Lisa used only one strategy to solve this task: she calculated the derivative of the integrand, then considered what adjustments should be made to the integrand to obtain the anti-derivative. We call this strategy derive-and-correct.

Lisa: Eh, what sometimes helps is taking the derivative of that part. I am not sure whether that will help this time. Sometimes I see a pattern that I can apply to the integral. I will try that now.  $\left[\frac{1}{1+e^x}\right]' [\dots] = \frac{1+e^x-e^x}{1+e^x} = \left(\frac{1}{1+e^x}\right)^2$

She made an error here, in applying the quotient rule, but did not notice.

Lisa: Well, the only similarity I see is that both have a fraction  $\frac{1}{1+e^x}$ , but this is twice that fraction.  $\frac{1}{1+e^x} \cdot \frac{1}{1+e^x}$ . Ehm, to find the anti-derivative, I would, in one way or another  $(1+e^x)^{1/2}$ , the fraction, I think. [...] Let's see if I get the same. I'm afraid I won't, but I can always try. (Then she calculated the derivative of  $\left(\frac{1}{1+e^x}\right)^{\frac{1}{2}}$ )

Here, Lisa again made an error, interchanging taking-power and taking-derivative, which are not commutative. She continued for some time, observing intermediary outcomes, considering what to infer to adjust the presupposed anti-derivative, et cetera. She did not find the correct answer.

There was no progress in solution, so we considered all strategy selection phases. Lisa did not explicate relevant mathematically founded reasons for her strategic decisions: her reasons are non-mathematical ("I can always try") or merely superficially related to the task ("this is twice that fraction")

Lisa	Year 1

to decide to take the square root). This latter quote illustrates how Lisa, although superficially and incorrectly, did evaluate intermediary outcomes for how to proceed, which is coded as high-level metacognition. Lisa used only one strategy, which she also used when solving the other tasks in the interview. She chose it because it ‘sometimes helps’, which we coded as recall. See figure 2.

In year 3, Lisa employed various strategies to solve task A:  $\int \frac{1}{1+e^x} dx$

Lisa: Eh, I try to solve this integral by substitution. Let’s see whether that works. I take  $u = e^x \rightarrow du = e^x$ , so this is equal to  $\int (1+u)^{-1}$ . Ah wait, this is getting complicated. [...] Ehm, if I take  $u = e^x$ , then  $\frac{du}{dx} = e^x \Rightarrow du = e^x dx$ . Ehm. This is not correct.

Then Lisa attempted substituting  $u = 1 + e^x$  but stopped. She then decided to derive the integrand.

Lisa: I don’t see it. Eh. I’ll check what the derivative becomes. Perhaps that will help.  $\left(\frac{1}{1+e^x}\right)' = [\dots] = \frac{e^x}{(1+e^x)^2}$ . (silence) [...] If I take the derivative of this,  $[1 + e^x]'$ , then I have  $= e^x$ , so that is not possible either. Hmm.

Next, Lisa modified the integrand.

Lisa: And...  $\int \frac{1}{1+e^x} dx = \int \frac{e^x}{e^x(1+e^x)} dx$ . If I take this  $u$ , take  $u = e^x$ ,  $du = e^x dx$ . Ehm. Then it becomes  $= \int \frac{1}{u(1+u)} du$ . Does this help?

After some more thinking, Lisa thought of partial fractions, and solved the task correctly.

The episode in which the integrand is modified after which substitution is implemented, is the progressing phase in the solution. Here, the task is manipulated in such a way that the task is simplified. In the post-interview, Lisa explained how she came to think of this:

Lisa: I took the derivative to see whether there is a pattern [...] to see what step you can use to find the antiderivative [...] Sometimes you obtain an  $e^x$ , you see what to do to find the anti-derivative. So in the end it did help for this step. So I thought, wait, if I multiply with  $\frac{e^x}{e^x}$ , that is simply times 1. Then I used again  $u = e^x$  for substitution. [...] And I thought, what if I put an  $e^x$  here, multiply the anti-derivative<sup>2</sup> with  $\frac{e^x}{e^x}$ . [...] Because I still had this substitution ( $u = e^x$ ) in mind, and then, if you have an extra  $e^x$ , then you have  $e^x dx$  and that can be replaced by  $du$ .

In this last phase, Lisa evaluated how she could use the intermediary outcome obtained by deriving the integrand and combined it with the requirements of the previously attempted substitution  $u = e^x$ , which indicates high-level metacognition. She did give relevant mathematical foundations for these strategic choices: “if you have an extra  $e^x$ , then you

<sup>2</sup> Probably Lisa meant: integrand

have  $e^x dx$  and that can be replaced by  $du$ ". Lisa did not make any statements that indicate she recalled the strategy to use for this type of task, but instead she considered various substitutions and task modifications, which indicates novel reasoning. The coding is visualized in Figure 3.

### Lisa's reasoning evolution

We analyzed Lisa's reasoning on nine tasks over three years. The codes for each dimension for each task in each year are put together in Figure 4 and summed in Figure 5. We summarize the coding below and frame them based upon observations in the data. Since Lisa was given task B only once, her reasoning on task B is excluded from the analysis of reasoning evolution. However, since task A and B require the same integration strategies, we did consider them sufficiently comparable for the global analysis of Lisa's reasoning evolution.

On task A, we see a change from superficially founded reasoning to mathematically founded reasoning, and from recall to novel. Level of metacognition is high in both years. A factor that was apparent from the data but not visible in these codes is that in year 3 Lisa used a much larger variation of strategies.

On task C, we see a change from low-level metacognition to high-level, from superficially founded reasoning to mathematically founded reasoning, and from novel to recall. In addition to these codes we remark that Lisa's solution in year 1 was extremely brief, without any real solving attempt. After the interview in year 2, Lisa had looked up the solution to this task, which she recalled in year 3.

On task D, Lisa's reasoning was consistently superficially founded, changed from recall to novel reasoning, and with varied level of metacognition. We add that in year 2 she used various strategies, and made several correct manipulations. In year 3, Lisa built upon her successful solution strategy used on the related task C. She modified that strategy to fit task D, which appeared somewhat mathematically founded, but her explanations were not explicit enough to code her reasoning as mathematically founded.

For each year, the number of tasks characterized by the codes of mathematically founded reasoning, novel reasoning, high-level metacognition, and success are included in Figure 5. These numbers give an overview of how Lisa's reasoning evolved over time. The overall impression is in line with the examples described and the coding per task: at the beginning of her bachelor in mathematics, Lisa used high-level metacognition, no mathematical

foundations, little novel reasoning and was not successful in solving the tasks. Over time, Lisa consistently used high-level metacognition, used more mathematically founded, some novel reasoning, and was more successful in solving the tasks.

## Conclusion and discussion

The analysis of Lisa's reasoning using the framework shows how her reasoning evolved during three years of bachelor studies in mathematics, which is especially interesting given the many worrying characteristics in the first year: Lisa's reasoning was superficially founded (like often observed in undergraduate students), the solutions were full of errors and not successful. In this first year, Lisa appeared to have limited access to strategies and to be unaware of what mathematical properties are relevant in selecting a strategy. Given these rather weak characteristics, coding Lisa's reasoning as using high-level metacognition even seemed somewhat out-of-place. However, in comparison to other students who reasoned superficially founded, Lisa's metacognition level was clearly higher. The finding that Lisa's reasoning evolved towards mathematically founded (while other students' reasoning remained superficially founded) suggests that high-level metacognition may play a supportive role in developing mathematically founded reasoning.

The variety of strategies used by Lisa increased, which is captured by the 'novel' code. Thinking of suitable strategies to solve moderately non-routine tasks is difficult (Selden et al., 2000) and requires insight into what mathematical characteristics are relevant for choosing strategies (Mason, 2013), which is needed to make mathematically founded strategic decisions. In Lisa's reasoning, we see that her use of high level metacognition preceded mathematically founded strategy choices. This observation can be used as a starting point to stress the use of high-level metacognition in mathematics teaching.

## Limitations

Our choice to use integration tasks has influenced the reasoning observed in this study, so we should be careful about extrapolating the findings to other contexts. However, the tasks have proven to arouse extensive reasoning of various kinds and, by using the same/similar tasks over the years, to bring to light an evolution in the way Lisa reasoned about challenging integration tasks.

## Acknowledgment

We would like to thank Anke Haaksma for her help in transcribing the interviews.

# Students' conceptions of the definite integral in the first year of studying science at university

Inen Akrouti

Virtual University of Tunis, ISEFC, Tunisia; [akroutiinen@yahoo.fr](mailto:akroutiinen@yahoo.fr)

*Keywords: Definite integral, antiderivative, area, limit of approximation, student conceptions.*

## Theoretical considerations and method

To explore students' interpretation of the definite integral and to deepen their understanding of its application, I draw on the works of Tall and Vinner (1981) and Sfard (1991). Tall and Vinner (1981) consider an individual's concept image for a given concept is "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p.152). They used the expression "evoked concept image" to indicate the elements of the concept image that were uncovered by their responses. According to Sfard (1991) a mathematical concept possesses two aspects: a process aspect and an object aspect. The first one identifies the operational nature when students focus their thinking on the procedure, action and algorithms contained in the concept. The second one identifies the structural nature when students conceive the mathematical concept as if it is an abstract object. Sfard notes that an individual is said to have a pseudo-structural conception when the object conception manifested by that individual does not refer to the objects of lower levels and to the processes that led to it. For the definite integral concept, the image of the area and antiderivative conceptions are usually due to insufficient abstraction of the integral image. However, the limit of approximation is due to the reification of the summation process into the symbol  $\int_a^b f(x)dx$ . So I consider that students of this category possess both the process and the object aspects of the evoked concept image. It is important to emphasize that students concerned by this study may possess elements that are never uncovered by their responses. Therefore, I am exploring their involved conceptions in response to given questions. Students participating in this study attended a first-semester calculus course at Bizerte University of Science. The year before this study, they had all succeeded at the baccalaureate examination with mathematics as an option. They were 18/19 years old. Eighteen students were interviewed in January 2017 and fifteen others in January 2018. The test consisted of five questions that focused on students' conception of the definite integral. The students written responses were analyzed according to Jones' categories. In this paper, I focus on the first question of the test:

**Q1:** Suppose  $\int_a^b f(x)dx = k$ ,  $k$  is a real number. Explain what  $k$  means and how it was obtained.

This question was designed to explore how students interpret definite integral when asked to describe its meaning.

## Preliminary results

Based on Jones' categorization (2015), my preliminary analysis of students' responses found three categories. The first category describes the definite integral in terms of anti-derivative. This category focuses on symbolic representation of integrand function.  $K$  is evaluated by manipulating the FTC: one takes an anti-derivative  $F$  of  $f$ , and substitutes  $b$  for  $x$  and  $a$  for  $x$  and finally evaluate  $\int_a^b f(x)dx$  by subtracting the values of  $F$  at the endpoints of the interval  $[a, b]$ . The second category describes the

definite integral  $\int_a^b f(x)dx$  as an area under the curve, where  $f$  is a positive function and that  $a < b$ , the boundary being the  $x$ -axis and the vertical lines  $x = a$  and  $x = b$  as illustrated in Figure 1. Finally, the third category describes integral as an approximation process. They write this type of response “ $\int_a^b f(x)dx = k$  is the area of the region that lies under the graph of the function  $f$  which represents the limit of the sum of the areas of approximating rectangles as shown in the Figure 2 below”.

**Figure 1: area conception**

**Figure 2: limit of approximation conception**

## Discussion

Preliminary results from the analysis show that most of the students (42%) interpret the definite integral as an area underneath the graph of the function and roughly, half of the remaining students (27%) describe it in terms of an antiderivative. The area conception involves the idea that an integral represents an area even though  $f$  is a negative function on  $[a, b]$ . It is based on generalization of a special case ( $f \geq 0$ ). This consideration is not always evident, it produces unsatisfactory results in some situations where  $f < 0$ . Students of this category confuses between definite integral and area. They should be reminded that integral could be negative, zero or positive value. It is interesting that, although area conception leads to the procedural aspect of definite integral, this conception is it is necessary to develop a conceptual learning. The second category bases its reasoning on FTC. However, the response of students in this study is quite unsatisfactory since it conflicts with the formal definition of the definite integral. One of the students of this group thinks about a symbolic expression of the FTC. Even though it is a satisfactory response, it is not sufficient for structural understanding. It joins definite integral to antiderivative and limits it to algebraic representation. It is noteworthy that 15% students describe  $\int_a^b f(x)dx$  as an approximation process. This conception enables the students to understand the meaning of definite integral, not only as a process but also as an object. Moreover, it brings out the epistemological aspects of integration. All students show that the definite integral represents an infinite process, however they focus only on positive functions. These preliminary results show that the large number of the students in this study evoked conceptualizations of integration that fail to emphasize the underlying structure of the definite integral. It seems to be a pseudo-structural thinking as described by Sfard (1991).

# The transition from high school to university mathematics: the effect of institutional issues on students' initiation into a new practice of studying mathematics

Amalia-Christina Bampili<sup>1</sup>, Theodossios Zachariades<sup>1</sup> and Charalampos Sakonidis<sup>2</sup>

<sup>1</sup> National and Kapodistrian University of Athens, Greece; [amabab@gmail.com](mailto:amabab@gmail.com), [tzaharia@math.uoa.gr](mailto:tzaharia@math.uoa.gr) <sup>2</sup> Democritus University of Thrace, Greece; [xsakonid@eled.duth.gr](mailto:xsakonid@eled.duth.gr)

*The present paper reports on a study of the challenges faced by two first year mathematics undergraduate students during their transition from secondary to tertiary education, focusing on the institutional issues that shape the initiation into their studying university mathematics practice, through the lenses offered by the Communities of Practice framework. We consider transition as developing a new identity of studying mathematics, that is, of studying university mathematics, aiming to examine the trajectories of this development. Data were gathered over students' first two semesters of attendance predominately through interviews. The results of our analysis reveal that the students' introduction into an unknown, strongly institutionalized community of practice has a powerful effect on their initiation into the new practice of studying university mathematics.*

**Keywords:** Transition, studying university mathematics practice, identity, institutional issues.

## Introduction

The transition from high school to university mathematics is itself an exciting and often confusing experience for students. After tough examinations, the successful students have yet to adjust to new learning environments, new modes of study, and above all, higher expectations of the self. The transition from high school to university mathematics can be seen as the result of many interacting transitions: social, institutional, mathematical content transitions as well as others (Alcock & Simpson, 2002). The aim of this paper is to study how two first-year students in a Mathematics Department of a Greek University dealt with transition issues, focusing on the ways that institutional conditions, in fact the institutional support provided, affect students' studying university mathematics. For this purpose we draw on data gathered over the students' first year of attendance predominately through interviews. To situate our study within this institutional perspective on studying, we identified certain crucial elements of the Mathematics Department under consideration as an institution and of participating in this institution as a student.

## Literature review

Students in transition undergo changes requiring an adjustment of learning strategies, time management skills and a shift to more independent studying. Mathematical practices at university level are distinguished from those at secondary level for reasons related to the mathematical content as well as to the participants in each of the two practices (i.e., teachers and students) (Biza, Jaworski, & Hemmi, 2014). Considering a mathematics department as a community of practice, teachers and students, as members of this community, distinguish themselves as well as they develop shared ways of doing things, forming a unique identity in the community (Hemmi, 2006).

The new environment demands a different type of critical thinking; students witness an increased emphasis on the precision and rigor of the mathematical language something for which students are

not necessarily prepared (Biza et al., 2014; Clark & Lovric, 2009). Hence, learning new mathematics via independent studying might involve developing some new skills (Alcock, 2013). Liebendörfer and Hochmuth (2015) state that students' autonomy depends on both the person (including competence) and the environment and that learning strategies and institutional norms are critical. Hernandez-Martinez et al. (2011, p.119) see the transition "as a question of identity in which persons see themselves developing due to the distinct social and academic demands that the new institution poses".

University as an institution and university mathematics are encountered as new worlds, where new communication and participation rules are required to live in, which might make the novice student feel like a foreigner (Gueudet, 2008). Winsløw, Barquero, De Vleeschouwer and Hardy (2014) claim that two viewpoints, the internal viewpoint and the viewpoint of external observers, are needed to treat in depth questions, such as: "What can be done to help my students pass the exams?" The external viewpoint focuses on the conditions and constraints for university mathematics education practices, which refer, among others, to more general constraints derived from the way our societies organize the study of mathematics.

The above suggests that students studying mathematics at university level enter a new community where the practice of being a student differs from that of the school community. Hence, the need for shifting to new ways of 'being' and 'belonging' signifies the need for developing a new identity of practicing mathematics.

## **Theoretical framework**

We employed the Communities of Practice (CP) framework based on the work of Lave and Wenger (1991) and Wenger (1998) to explore the ways in which the subjects of the study dealt with identity issues through analysing the changing forms of their participation to the studying university mathematics practice during the transitional phase: from entrance as a newcomer, to becoming an old-timer.

Within this perspective, the person is defined by as well as defines relations, which are in part systems of relations among persons (Lave & Wenger, 1991). Activities and understandings are part of broader systems of relations in which they have meaning. In this sense, identity in practice arises out of an interaction of participation and reification. Lave and Wenger consider learning as increasing participation in CP, which concerns the whole person acting in the world:

...a community of practice is a living context that can give newcomers access to competence and also can invite a personal experience of engagement by which to incorporate that competence into an identity of participation (Wenger, 1998, p. 214)

The transition from newcomer to old-timer involves differing trajectories of identity. According to Wenger (1998), a trajectory can be seen as a continuous motion through time that connects the past, the present and the future. The characteristics of the mathematical identity of high school students 'good in mathematics' might be: ability to solve exercises following specific methodologies predetermined by the teacher, to identify if an exercise corresponds to some worked examples, to probably leave the teacher to take responsibility for deciding how much practice is needed. In other words, as Solomon (2007, p.90) states: "... students experience mathematics as something 'done to them' rather than 'done by them'". On the other hand, studying university mathematics requires a

‘shift’ to independent learning, thinking in productive ways, deepening in definitions and theorems, proving and focusing on conceptual understanding (Breen, O’Shea, & Pfeiffer, 2013). These features, some of which are incompatible to those of the way students were used to at school, require/signal a qualitatively different way of studying mathematics. Wenger (1998, p.154) states: “As we go through a succession of forms of participation, our identities form trajectories, both within and across communities of practice”, including peripheral (never leading to full participation) and inbound (from the periphery to the centre) trajectories. Furthermore, an individual’s identity is shaped by combination of participation and non-participation in the community of practice. With respect to the interaction of participation and non-participation, he distinguishes two cases: peripherality (some degree of non-participation enables a less full participation) and marginality (non-participation prevents full participation).

As far as the institutional perspective on studying is concerned, we draw on Sierpiska, Bobos and Knipping (2008) concept of institution. An institution constrains the individual behaviour of the “participants”, through formal as well as informal rules and norms. Members of an institution, which participate in several communities within it, share certain values and goals and give common meaning to the actions (regularised collective actions, as well as enforced actions) of the institution. Participants’ actions are adjusted to rules, norms and strategies of achieving the objectives.

## **The study**

Greek students go through hard preparation to pass the university entry exams. During their final high school year, most of the students undergo a strictly structured life program, including many hours of daily study almost always under the guidance of school teachers and private teachers in paid courses after school. Hence, the social (family, friends-classmates) and the institutional (school and private lessons) communities are aligned: all support them with the aim of passing university entrance exams, an achievement highly valued in Greek society. On the other hand, as soon as they succeed, they are not aware of automatically entering, as students, in a centrifugal process, without strong supports. Some of them continue to flirt with the margin: not to let the centrifugal force to throw them out, because the social (friends-fellow students) and the institutional communities might not be aligned. Flirting with the margin, according to Solomon (2007), might mean alignment with the rules of the community of undergraduates emphasizing summative assessment and surface learning. In what follows, we present those features of the new institutional community which might create centrifugation with a high degree of containment difficulty for students, preventing them from completing their studies on scheduled time (8 semester’s time).

The Mathematics Department under consideration has a highly demanding curriculum: a student has to pass at least 36 courses to get his/her degree, 14 of them are basic courses (mandatory). There is an indicative curriculum, but no prerequisite courses: one can take any courses he/she wants, in any of the 8 semesters required to graduate. What is there is a maximum number of courses that can be chosen in one semester, depending on the semester. The indicative curriculum suggests, for example, the following courses for the first semester: Calculus I (Axiomatic foundation of the real number system. Axiom of completeness and consequences, convergence of sequences, functions, algebraic functions, preliminary definition of the trigonometric functions, exponential function, limits and continuity, etc.), Linear Algebra I, Computer Science I (all three are mandatory courses), and to choose three at most from the elective courses Foundations of Mathematics, Combinatorics I

and Theories of Learning and Teaching. In Calculus I and Linear Algebra I, students are introduced to formal definitions, proofs of various theorems and theoretical exercises using mathematical rigor. There are three exam periods each academic year. A student can try as many times as required to pass the exams. On average, students need 13 semesters to get their degree. Students are required to deal daily and consistently with the subject. First-year students have to attend 27 hours of lectures per week, in overcrowded auditoriums. They do not often know how to make lectures work for them (i.e. how to learn in lectures, how to study after lectures), how to manage time, etc. On the other hand, no institutional support is provided for their effort to effectively attend lectures, for example, pre-university bridging courses, mathematics support centers, bridging lectures in the first semester, support systems accompanying traditional lectures, such as extra tutorials or student learning advisory. Thus, it could be argued that attending lectures and studying daily and consistently highly demanding courses with almost no institutional support are typical features of the practice of studying university mathematics. The work reported in this paper concerns the ways that the institutional support provided affects students' studying university mathematics. This is because contrary to what they had experienced as high school students, the features of the new community of practice, which first year students are invited to join, are to a large extent conflicting: high institutional expectations with reduced institutional support. Thus, the research question pursued in the study is as follows:

“How does the institutional support shape trajectories of identity related to studying university mathematics practice by first-year students”?

In October 2015 we started surveying incoming first-year students (October 2015-June 2016), collecting information. Twelve students volunteered to be interviewed individually to help us look at the interface between social, institutional and studying mathematics aspects of the transition. Four semi-structured interviews (in the beginning of the first semester, before the semester exams, in the middle of the second semester and before the second semester exams) were carried out, each lasting between 25 and 45 minutes; these were audio-recorded and fully transcribed. The questions concerned three aspects of the transition: i) social (e.g. how did they deal with the changes in their social-personal life; how did they experience relating to classmates and friends) ii) institutional (e.g. did they feel being supported in the new learning environment and to what extent; how did they experience teacher-student relationship) iii) studying mathematics (e.g. how was their experience of school mathematics different from that at the university). The analysis of students' answers to the questions related to each of the above three aspects focused on the identification of the specific ways that students experienced the aspects under consideration. Two of these students, Sonja and Paola (pseudonyms), are the focus of the work presented here: Sonja's responses during the interviews strongly indicated that she was undergoing changes (from a peripheral participant to an almost full participant) regarding studying mathematics. On the other hand Paola, from the beginning to the end of her first university year felt that she could not meet the requirements of her studies.

## Results

Drawing on Sonja's and Paola's answers to questions concerning institutional issues and studying mathematics aspects, we identified that they both highlighted two features respectively: institutional

support and the difficulty of the subject matter knowledge. Some characteristic comments related to these features, as expressed in the four interviews, are presented in Tables 1 and 2 and discussed.

As far as the institutional support is concerned, Sonja had great expectations for academic staff support at the beginning. Her adjustment was getting better with great mental and spiritual effort. Regarding studying mathematics, she lost her self-confidence right at the beginning. She struggled a lot with the difficulty of the subject. As time went by, she confronted studying mathematics as a challenge: to turn her disappointment and stress to something powerful and effective (Table 1).

<b>Sonja</b>	1 <sup>st</sup> interview	2 <sup>nd</sup> interview	3 <sup>rd</sup> interview	4 <sup>th</sup> interview
<b>Institutional support</b>	IS <sub>1</sub> : “I have great expectations for academic staff support, like in high school”.	IS <sub>2</sub> : “I believe that professors take it for granted that students understand mathematics. They have high academic expectations from them. I am afraid to ask the professor, because he may think that I am stupid”.	IS <sub>3</sub> : “I am negatively influenced by the absence of any support. Why don’t we have some tutorials?”	IS <sub>4</sub> : “...Although I have to admit that some professors guided us well enough, my adjustment was getting better after a long time with great mental and spiritual effort”.
<b>Studying mathematics</b>	MS <sub>1</sub> : “In high school, I thought that I was good in mathematics because of my good school grades and because I passed the university entrance exams also achieving good grades. When I started studying university mathematics, I was desperate. I was wondering if I had taken the right decision”.	MS <sub>2</sub> : “If I could say only one thing that I still struggle with, this is the difficulty of the subject. ... I felt I turned my love to mathematics to something sick. I try to change the way of studying. I try very hard on my own to understand”.	MS <sub>3</sub> : “...I realized that to do well on the first semester exams, I had to use my “simple” knowledge inductively to solve a problem, rather than knowing many things”.	MS <sub>4</sub> : “I feel more confident. I passed the exams with good grades”.

**Table 1: Sonja’s comments related to institutional support and studying mathematics aspects**

Paola encountered difficulties of adjustment from the beginning until the end of the first year. She had encountered problems with the effectiveness of her studying even from the university entrance

exams. Studying university mathematics is harder than she expected, and until the end of the first year she could not find a way to study and learn independently (Table 2).

<b>Paola</b>	1 <sup>st</sup> interview	2 <sup>nd</sup> interview	3 <sup>rd</sup> interview	4 <sup>th</sup> interview
<b>Institutional support</b>	IP <sub>1</sub> : “Students have to deal alone with their studies more than I expected”.	IP <sub>2</sub> : “...professors do not make any effort to help students understand their lectures”.	IP <sub>3</sub> : “I am negatively affected by the absence of any help. We do not have either a Student Learning Advisor or a Tutor”.	IP <sub>4</sub> : “I need some help. I struggle alone to find out which courses to take, how to study effectively...”.
<b>Studying mathematics</b>	MP <sub>1</sub> : “Although I have studied hard, I am negatively affected by the fact that for the university entrance exams I could not achieve the grades that I expected”.	MP <sub>2</sub> : “I think it was a good decision to study mathematics, but the subject is more difficult than I expected”.	MP <sub>3</sub> : “I could not pass the 1 <sup>st</sup> semester exams. I think that even if I study hard I will again fail the exams”.	MP <sub>4</sub> : “I am struggling a lot. If I get my degree with a low score, how will I find a job afterwards?”

**Table 2: Paola’s comments related to institutional support and studying mathematics aspects**

The results indicate that the lack of studying support, which is a feature of the new institutional environment, affected Sonja almost until the end of the first year. She struggled a lot to achieve necessary changes something that also affected her self-confidence as a mathematics student (IS<sub>2</sub>, MS<sub>1</sub>, MS<sub>2</sub>). Her great mental and emotional effort as well as the influence of some inspiring professors (MS<sub>4</sub>, IS<sub>4</sub>) helped her to take the next step. After the first semester exams and more clearly near the end of the first year, it looks like she had also managed to find the needed way of studying (MS<sub>3</sub>, MS<sub>4</sub>). Overall it might seem that her identity was forming somehow an inbound trajectory (she was close to finding her place within her new community, which is a feature of an old-timer). With regard to Paola, the analysis of the data show that the lack of studying support also affected her until the end of the first year (IP<sub>2</sub>, IP<sub>3</sub>, IP<sub>4</sub>). Although she had no doubts about her decision to study mathematics (MP<sub>2</sub>), the fact that she could not achieve the grades that she expected for the university entrance exams (MP<sub>1</sub>), affected her self-confidence as a math student (MP<sub>3</sub>). It seems that it was difficult for her to find her place within the new community (forming an identity of non-participation which is close to marginality). She failed the first semester exams and almost felt losing her motivation (MP<sub>4</sub>).

## Discussion and conclusions

We consider transition to university as an opportunity to develop a new identity of studying mathematics. In CP terms, developing an identity as a student of mathematics is about negotiating

what counts as legitimate 'being' within various communities, in university and school, comprising shifting conceptions of what mathematics studying is or should be. The results of our analysis reveal that high institutional expectations, with insufficient institutional support, shape differing trajectories of identity. Sonja was negatively affected because of the overwhelming changes imposed in the new institutional environment that strongly influenced her studies; she even considered quitting. For the benefit of her 'being' within the community, she managed to overcome the institutional lack of support with great mental and spiritual effort, as well as with the guidance of some professors forming what Wenger (1998) defines as a trajectory from the periphery to the center. On the other hand, Paola's responses indicated that she was struggling (at least to be a peripheral participant) regarding studying mathematics. She was also negatively affected by the changes imposed in the new institutional environment, but, unlike Sonja, she could not help herself to find a place into the new community: the difficulty of the subject and the lack of support was a major mismatch for Paola. She could not meet the requirements of her studies and at the end of the first year she almost felt losing her motivation. Thus, it could be argued that she was constantly flirting with the margin: not to let the centrifugal force to throw her out.

Students' position in multiple communities of practices, in university and school, with opposing rules of engagement, implies differential experiences of identity (Solomon, 2007). Some of them, who considered themselves to be 'good' in mathematics at school, develop negative relationships with mathematics which might marginalize them and can turn them against further study. The implication of our analysis might be that, if we want to ensure that studying mathematics as a discipline is not only for those who are 'talented' and/or can show great mental and spiritual effort, it is important to take into account that studying mathematics is experienced by some students as excluding, because the features of the new community of practice, which first year students are invited to join, can be to a large extent conflicting. Sierpinska states that

institutions are difficult to change. They are based not only on conventions and rational rules of economy, but also on values that are considered "natural"... Any attempt at changing or developing an institution in certain desired direction must therefore be based on a thorough understanding of...what are the things that can be changed without jeopardizing its existence. (Sierpinska, 2006, p.127)

An interesting element in the direction of moderating the emerging contradictions might be the following: in the Mathematics Department under consideration, among the freshmen who took Calculus I exams in the first semester, 23% passed and only 2 achieved 10/10 (Sonja was one of them). In the next academic year freshmen who took Calculus I could choose to participate in 10 tests during the semester. Among those who took at least 3 tests, 84% passed the final exams and 19 achieved 10/10. This might be seen to suggest that, if high demanding institutional expectations are somehow aligned with sufficient institutional support, university mathematics students may experience transition as well as the formation of a new identity of studying mathematics as a challenge rather than a 'problem'.

# Students' understanding of the interplay between geometry and algebra in multidimensional analysis: representations of curves and surfaces

Matija Bašić<sup>1</sup> and Željka Milin Šipuš<sup>1</sup>

<sup>1</sup>University of Zagreb, Faculty of Science, Department of Mathematics, Zagreb, Croatia;  
[mbasic@math.hr](mailto:mbasic@math.hr), [mlin@math.hr](mailto:mlin@math.hr)

*The aim of this study is to investigate mathematics students' understanding of geometrical objects such as curves and surfaces in space, when these objects are presented algebraically, that is, by their equations. Flexible use of different representations, in this case geometric and algebraic, as well as the ability to convert between implicit and parametric types of equations, is often assumed as a prerequisite in multivariable calculus. We have performed an in-depth analysis of students' answers to exam questions to identify types of students' difficulties in these conversions. However, our results also point to the impact of the didactic contract on students' productions which possibly prevented students to fully present their understanding.*

*Keywords: Transition across university mathematics, multivariable calculus, curve, representation, didactic contract*

## Introduction

In this paper we investigate learning difficulties that students face in the transition from the first courses in linear algebra and multivariable calculus, to more advanced mathematical courses that involve mathematical analysis of functions of several variables. As described by Kondratieva and Winsløw (2018), requests for efficiency and economy of exposition at university level often lead to narrow and disconnected teaching modules. Our teaching experiences indicate similar disparities in the transition from courses in analytical geometry, linear algebra and calculus on one side, to mathematical analysis of functions of several variables and differential geometry on the other. We noticed misconceptions and knowledge gaps in dealing with basic objects such as curves and surfaces in three-dimensional space, in using their implicit and parametric representations, and in converting from one representation to the other. These notions are essential for calculating curve integrals, applying Green-Stokes theorem, or in introductory lessons in differential geometry, for instance, the introduction of curve and surface curvature.

A curve in three-dimensional space can be presented either by a parametrization, that is, as a trace of a moving particle, or by a system of equations in three variables, that is, as an intersection of surfaces. Transitions from one representation to the other and vice versa are theoretically underpinned in multivariable calculus by implicit and inverse function theorems. However, students' work in basic examples usually happens in the domain of algebra and geometry – solving systems of (not necessarily linear) equations and giving them geometrical meaning. We noticed many students' difficulties in this process, starting from a non-meaningful manipulation of equations in a way that just leads to new equations, understanding what a solution of a system of equations is, especially when a solution is not unique, and, finally, providing a geometrical interpretation of the obtained objects. Students' difficulties in the same field but with linear objects,

in recognition of lines and planes given by their implicit (Cartesian) and parametric equation, and the presentation of these objects as sets (subsets in space satisfying the same conditions or equations) are well evidenced (Artigue, 1999; Alves-Dias, 1998; Nihoul, 2016). However, students' work related to curved objects in space is an under-researched area.

## Motivation

Our study was motivated by the following question posed as one of five questions in the midterm exam for the course Introduction to differential geometry in spring semester 2017:

Question. Prove that the space curve given by  $x^2 + y^2 = z$ ,  $x^2 + y^2 + 2x + 2y = 1$  is planar and determine its osculating plane.

The question could be answered by following the procedure taught during the exercise classes (for a somewhat more complicated curve), which requires a curve to be parametrized. From the parametrization, one calculates its torsion, which should vanish for a planar curve, or determines its binormal field, which should be constant. However, in the above example the tedious calculation of a torsion (which often results in a calculation error) could have been avoided by using the definition of the planar curve emphasized during lectures. By a simple manipulation of the given equations, it is possible to eliminate the square terms to get  $2x + 2y + z = 1$ , which could be recognized as an equation of a plane in which the curve lies. Among 136 students who provided any answer to this question (of 172 who participated in the exam), only 7 % (10 students) solved the task using that approach, and 10 % more solved it using both approaches, that means, they obtained the equation  $2x + 2y + z = 1$ , and then still parametrized the curve and applied the tedious procedure. Some 27 % of students obtained the plane equation without providing an interpretation, and 30 % of students solved the question by immediately parametrizing the curve and applying the procedure only. The remaining 26 % did not obtain the equation nor a correct parametrization. This high number of students who focused only on procedure and failed to apply the definition of a planar curve, encouraged us to implement a more thought-out approach in the next year courses followed by a deeper analysis of students' work.

## Theoretical framework and research questions

Mathematical concepts are identified and represented through various representations, which reflect possibly different features of a concept, but simultaneously complement each other. Treating a concept within a certain representation (representational mode or register) and successfully converting between different registers of representation, is considered as a prerequisite for conceptual understanding. Conversion processes entail recognition of the same mathematical objects through representations from different registers and therefore require coordination of registers. Many students' difficulties can be described and explained by the lack of coordination of different registers of representation (Duval, 1993, 2006). Research provides examples (Artigue, 1999; Alves-Dias, 1998; Nihoul, 2016) of students' difficulties in using the algebraic representation of lines and planes in space, and vice-versa, in recognizing straight lines and planes in space from their equations, and in converting between parametric and implicit viewpoints.

In this study we tried to answer the following research question: What are students' learning difficulties in relation to different representations of curves and surfaces in 3-dimensional space?

As observed in the motivational example, it seems that students tend to use lengthy procedures as opposed to conceptual definitions. This indicates that the work of some students does not show their complete mathematical understanding and difficulties, but rather that their answers are governed by reasons of didactical nature. We use the notion of didactic contract from the Theory of Didactic Situations (TDS) by Brousseau (1997), a framework useful to study phenomena at university level (González-Martín, Bloch, Durand-Guerrier, & Maschietto, 2014):

A core TDS conceptual tool is Brousseau's notion of the *didactic contract*, the implicit set of expectations that teacher and students have of each other regarding mathematical knowledge and regarding the distribution of responsibilities during the teaching and learning processes. ... The *didactic contract* is linked to an institution and, in particular at university level, the terms of the *didactic contract* can be quite strong. (pp. 119, 131)

Although our ultimate goal is to study the cognitive and epistemological dimensions for the concept of a curve in space, we first had to analyze the didactical constraints that govern students' answers. Hence, motivated by our students' work we wanted to trace the impact of the didactic contract on students' exam productions and investigate if students' understanding could be improved through some changes in this contract.

## Methodology and mathematical context

The participants of our study in 2018 were in total 173 students at a department of mathematics in Croatia, while participating in elective course Introduction to differential geometry (students of undergraduate program in mathematics and in mathematics education). The course has 2 hours of lecture and 2 hours of exercise class per week for 13 weeks. It is naturally divided into two parts, with the first part that focuses on the use of differential calculus to study geometrical properties of curves in 2D and 3D (curvature and torsion). The second part focuses on the study of surfaces and special curves on surfaces. The emphasis of the course is on low dimensions to encourage students to use the geometrical register in interpreting and understanding the results. The second author is the lecturer, while the first author is one of three teaching assistants for the course.

In 2018, during the exercise classes, the teaching assistants led the discussion about the exam question from the year before. The aim of this discussion was to re-negotiate the didactic contract built during previous courses in which teachers assign tasks and students answer in the way they were taught. In this case, it means that students apply the lengthy procedure, not the definition of a planar curve in space, which is intuitive and, although presented during the course, not exclusively a part of differential geometry content. As learning can be accomplished, in many cases, through the ruptures of the didactic contract (Brousseau, 1997), the assistants showed both strategies and emphasized that the aim of the course is to encourage students to use the geometrical interpretation. In other words, it is the conceptual and not the lengthy approach that was expected and aimed for. It was important for the students to hear that all correct answers are acknowledged at the exam, not just those that follow procedures from the exercise classes, since their comment during the discussion on the "non-standard" approach was that "they did not know this was allowed". In

addition, the teaching assistants addressed other students' difficulties observed by the preliminary insight into students' work in 2017, like false generalizations and analogies from plane to space geometry (2D to 3D) in interpretation of equations and non-adequate conversions between implicit and parametric viewpoints of a curve.

The source of data for the in-depth analysis were midterm exam solutions. Questions were formulated in the geometric register, where curves are given as intersections of surfaces. The properties of the intersection curve can be recognized algebraically (from its equation) or geometrically (by some geometrical properties, such as its curvature). In this paper we analyze the questions presented in Figure 1.

Question 1. Determine the set of points in space given by the equations  $x^2 + y^2 + z^2 = 4$ ,  $x - y = 0$ . Find its parametrization and determine its curvature. Which object does it represent geometrically?

Question 2. The curve  $c$  is given by the equations  $x^2 + y^2 + z^2 = \frac{17}{2}$ ,  $y = x + 1$ . (a) Explain why  $c$  is planar. (b) Determine the curvature of  $c$  and decide what curve it is. (c) What curve is obtained by projecting  $c$  onto the  $xz$ -plane?

**Figure 1: Exam questions analyzed in the study**

In Question 1, the set of points satisfying both equations, the equation of a hyperboloid of one sheet and a special plane, is to be identified either from a system of transformed implicit equations, or from its obtained parametrization which enables determining the curvature. Simple calculation in the algebraic register gives the system of transformed implicit equations as  $x = y$ ,  $z = \pm 2$ , therefore the intersection set consists of two parallel lines that are given as intersections of two pairs of non-parallel planes.

In Question 2, the expected solution is to state that  $y = x + 1$  is an equation of a plane, so the curve is planar by definition. For the second part it is expected that the equation of the sphere is recognized, and that the curve is a circle since it is the intersection of the sphere and the plane. The radius  $R$  of the circle may be determined geometrically, so the curvature can be expressed as  $1/R$ .

The projection onto  $xz$ -plane is given by the equation  $2(x + \frac{1}{2})^2 + z^2 = 8$ , which is the equation of an ellipse. Another correct approach is to parametrize the obtained curve, and then to calculate its curvature by using the formulas from the lecture. Conclusion that the curve is a circle should follow from the fact that the curvature is a non-zero constant, and the projection curve could be recognized from the parametrization with  $y = 0$ .

Students' answers were processed in an iterative way. First, based on our mathematical analysis of the question, we formulated codes regarding the register in which the task was solved: algebraic (following the algebraic procedure given in the exercise class) or geometric (geometrically interpreting equations), as well as the success of the students (if the calculation was completed or the conclusion reached). Second, the codes were refined to track students' different strategies and

unexpected answers pointing to some difficulties. Next, the observed categories and special cases were discussed between the authors and an agreement was reached to cluster the codes with low frequency pointing to the same type of difficulties. As an example, in Table 1 we present the data for Question 2 (a).

Question 2 (a)			
No answer		57	33%
Recognizing the equation of the plane		46	27%
Using torsion = 0 as criterion	Showing that torsion equals 0	8	5%
	Only stating the criterion	23	13%
Wrong arguments	$y = x + 1$ is a line, and lines lie in planes	15	9%
	$x^2 + y^2 + z^2 = 17/2$ is a plane	7	4%
	Substituting and stating that the curve is an ellipse in $yz$ -plane	17	10%

**Table 1: Codes and frequencies for Question 2(a)**

## Results

In Question 1, approximately half of the students (51 %) noted correctly that the intersection of a doubly-curved surface (an hyperboloid of one sheet) and a plane is a pair of parallel straight lines. Most of the students (76 %) who reasoned correctly relied on parametrizing the obtained set as  $c(t) = (t, t, \pm 2)$  and calculating its curvature, which turned out to be 0 in all of its points, and some (29 %) relied on recognizing the lines from the system of transformed equations, whereas 5 % of students used both approaches.

Among students who did not provide a complete solution, approximately half gave no answer at all, further 30 % successfully obtained transformed equations or calculated the curvature, but did not interpret the result geometrically and approximately 20 % misinterpreted the obtained result. Most of the errors in the last group occurred when trying to interpret a transformed implicit equation, which was seen as the requested intersection curve, and not as a new surface on which the intersection curve lies (the intersection set described as a plane, a cone, or a hyperbolic paraboloid); many errors also come from the misinterpretation of a transformed implicit equation without  $z$ -coordinate as a curve (a hyperbola instead of a hyperbolic cylinder).

In Question 2, 46 out of 173 students (27 %) noted that the given equation is an equation of a plane and successfully concluded that the curve is planar without further calculation, and a smaller number (18 %) of them went still for calculation of the torsion. More students than in 2017 successfully concluded that a curve is planar by the first approach, but still more than 70 % did not use this approach. Among the students that did not provide a solution, 9 % stated that  $y = x + 1$  is an equation of a straight line in space, which is a well-evidenced false generalization in transition from 2D to 3D in linear algebra (Nihoul, 2016). Further students' false argumentation runs as follows "since this is a line, and lines belong to a certain plane, therefore the curve is planar". Furthermore, careless approach to ambient space in which a curve is given seems to generate another case of false transition from 2D to 3D, since 38 students chose the formula for curvature that is the formula for curves in  $\mathbb{R}^2$ , not in  $\mathbb{R}^3$ .

Among 122 students who tried to parametrize the curve, 80 students (65 %) used the local parametrization  $c(t) = (t, t+1, \sqrt{17/2 - t^2 - (t+1)^2})$  of the intersection curve, which is not adequate to conclude that the (whole) curve is planar, contrary to the linear case, where the standard procedure provides a global parametrization. To determine the curvature of the curve, students predominantly (70 %) used parametrization for further calculation over geometric approach. Only 15 (9 %) of them used a geometric approach by stating that the plane intersection of a sphere is a circle, with only 4 of them even moving forward to determine geometrically the radius of a circle.

## Discussion

In general, we may state that students' difficulties in *converting algebraic equations into geometrical objects* are persisting, even after the first courses in linear algebra and calculus. In the case of a planar curve identification, students predominantly focus on the known procedure, although it is burdened with calculation, over using the conceptual definition of a planar curve which involves recognizing a plane by its implicit equation. We may also say that we observed the influence of the didactic contract, as the students tried to ensure that their answers included newly learned procedures during the exercise classes. However, students' difficulties in recognizing a plane by its equation can be seen as a particular case of a more general lack of coordination between algebraic equations and spatial geometrical objects. When manipulating equations defining a spatial curve, students interpret the new implicit equation as that intersection curve, not as a new surface on which the curve lies.

The above general observations point out to several further remarks. The first remark concerns evidence on students' false generalizations and analogies in their *passage from 2D to 3D*. As already stated, this was particularly the case when they identified the equation of a special plane with a line, a circular cylinder with a circle, or a hyperbolic cylinder with a hyperbola. Similar difficulties are observed in linear algebra, e.g. in the case of a plane in space given by an equation  $ax + by = c$  (Alves-Dias, 1998; Nihoul, 2016). It is a clear example of the fact that a piece of existing knowledge (a single equation represents a curve) may undergo a hasty generalization, and therefore standing in the way of full comprehension. It is not irrelevant to notice that the missing insight of different ambient (2D and 3D) is also identified in students' inappropriate use of formulas for the curvature of curves.

Our second remark concerns students' use of and conversion between *the implicit and the parametric representation (viewpoints)* of curves. Again, students' difficulties in this process in linear algebra are well evidenced (Artigue, 1999; Alves-Dias, 1998; Nihoul, 2016). In our study with curved objects, we observed that students did not invoke the need for conversion to a parametric representation, nor is the conversion found as flexible as it is assumed, already discussed in the case of linear algebra (Artigue, 1999, p. 1384):

Flexibility seems to be considered as automatically internalized once one has “understood” the notion, as if it were a simple question of homework that one can leave to the private work of the student.

Another remark is related to students' difficulty coming from *the character of non-linear problems*. Conversion from implicit equations to parametrization and vice-versa, that relies on a procedure of

“eliminating a parameter” or “substituting a variable by a parameter” from linear algebra has a local character in the non-linear case and cannot produce an instant answer as in the linear case. This conversion brings many different transformation approaches, usually non-routine ones (especially when trigonometric and hyperbolic functions are involved). For example, in Question 2, a local parametrization is not adequate to conclude that the curve is planar. A relevant explanation can be provided with the implicit and inverse function theorems, which although do not provide a recipe to change representation, should be discussed during the class to emphasize the subtleties in the non-linear case. Students’ focus on procedures suggests that their knowledge is an “amalgamation of practical blocks” (Brandes & Hardy, 2018, p. 506). Moreover, the observed absence of theoretical insight in students’ knowledge might be seen as a missing brick in Transition of type 1 (Winsløw, Barquero, De Vleeschouwer, & Hardy, 2014).

## Conclusion

Different representations of curves and surfaces and their flexible conversions are essential for various mathematical courses that involve the analysis of functions of several variables. We also repeat that our study tries to see some of the students’ bad performances as a result of the impact of the didactic contract. However, students’ productions firstly point out to the existence of difficulties which were also observed in linear algebra in representations of lines and planes (Artigue, 1999; Alves-Dias; Nihoul, 2016). False generalizations from 2D to 3D appear (a line in space is represented by a single implicit linear equation, and vice-versa, single implicit linear equation with, for instance, no  $z$ -coordinate is an equation of a line in space; the same student’s reasoning appears for e.g. a circle and a circular cylinder). This observation may also point to the presence of some learning obstacles in the sense introduced by Brousseau (1997), which needs to be further explored. According to Brousseau, obstacles of various origins can stand in the way of an efficient learning of mathematics. Brousseau distinguishes between cognitive (due to the state of mental development), didactical (due to a certain way of teaching) and epistemological obstacles (due to the very nature of mathematical concepts). Clear distinction among them, due to the complex nature of human’s knowledge acquisition, is not always possible. Obstacles become evident in students’ errors which are not related to chance but persist, or in difficulties and problems that students encounter that slow down the learning process. When this becomes evident, it does not point out to the lack of knowledge, but often to the piece of knowledge that was adequate in a previous situation, but now leads to incorrect reasoning. Brousseau suggests that to overcome an obstacle, a sufficient flow of new situations challenging old knowledge is needed. Whether careful task design with different potentials for student learning would be beneficial as well (Gravesen, Grønbæk, & Winsløw, 2017), is another question to be explored in the future.

## Acknowledgment

We dedicate this paper to the memory of our dear colleague doc.dr.sc. Stipe Vidak (1980-2018) and to our many fruitful joint discussions.

# Understanding the secondary-tertiary transition in mathematics education: contribution of theories to interpreting empirical data

Christer Bergsten<sup>1</sup> and Eva Jablonka<sup>2</sup>

<sup>1</sup>Linköping University, Mathematics Department, Sweden; [christer.bergsten@liu.se](mailto:christer.bergsten@liu.se)

<sup>2</sup>Freie Universität Berlin, Education and Psychology, Germany; [eva.jablonka@fu-berlin.de](mailto:eva.jablonka@fu-berlin.de)

*The paper reports a review of studies on the secondary-tertiary transition in mathematics. With an interest in the contribution of theories, it intends to explore what insights empirical studies using new theoretical lenses have added. While there is a move towards socio-cultural theorizing, some dimensions pertaining to issues of social (re)production still appear under-researched.*

*Keywords: university mathematics, sector transition, theories, socio-cultural studies.*

## Introduction

In mathematics education, the expression ‘transition problem’ commonly refers to difficulties when students enter a new school sector, or begin a new more ‘advanced’ course. While the notion has been used also for passages between other contexts, this contribution focuses on the transition from school to university, which has long been described as particularly problematic (e.g., De Guzman, Hodgson, Robert, & Villani, 1998), *inter alia* alerting to high dropout rates. Nevertheless, a difficult transition may not only be seen as a *problem* for the students, but also “as something potentially positive for their development and future opportunities” (Jablonka, Ashjari, & Bergsten, 2017, p. 76). ‘Smoothing’ the transition may not necessarily be desirable. Conceived as problematic, the transition has attracted much attention in mathematics education over the years, and the analytical lenses employed for its study have been diverse. However, a comparison of the overviews in De Guzman et al. (1998) and Gueudet (2008) shows that new theories might contribute to deepening the understanding of the secondary-tertiary transition. While De Guzman et al. categorized ‘types’ of problems in ‘theoretical’ categories (*epistemological/cognitive; sociological/cultural; didactical*), their discussion also included under-theorized notions (e.g., type of mathematics, contact to teachers, ways of studying). Gueudet (2008) used similar categories (*thinking modes, mathematical language and communication, and didactical transposition and contract*) but in contrast to De Guzman et al. (1998) explicitly contained the discussion within a range of theoretical frameworks with reference to empirical research drawing on these frameworks. In a later “survey of the state of the art” regarding transitions in mathematics education, Gueudet, Bosch, DiSessa, Kwon and Verschaffel (2016) pointed to the diversity of theoretical orientations, but also to the importance of complementarity.

In this paper studies from the last ten years on the secondary-tertiary transition in mathematics education will be reviewed with the aim to trace the development in terms of the theoretical approaches taken and how these have contributed to new insights regarding the transition.

## Method

For an initial literature search, articles published during the last ten years in major (mathematics) education research journals and conference proceedings as well as articles listed in the MathEduc database that explicitly addressed the secondary-tertiary transition were identified. From these, only

articles reporting empirical studies with an explicit theoretical approach were included in a first step of the analysis. From these around 100 articles, a final sample of around 50 articles drawing on theories *not already discussed* in Gueudet (2008) was selected for a second step; weakly theorized quantitative studies were not included. The main stated results of the studies were used to identify how theoretical approaches contribute to insights regarding the transition. For the notion of theory, the selection was guided by the discussions in Radford (2008) and Jablonka and Bergsten (2010). Certainly, some of the theoretical orientations discussed in Gueudet (2008) continued to be used and developed during the period studied; for example, in the first step of the analysis around ten articles drawing on ATD and/or TDS and five using a cognitive approach were found. These represent an important part of the theoretical development of the area but will not be included here due to space limitations. As the literature review was not based on a fully comprehensive search, some recent theoretical developments might have been omitted. The categorization made from the analysis of the sample, however, has a strong base in the articles found.

In the next section, the dominating theoretical approaches identified will be presented. These were found in 37 (of the 50) papers; single studies employing *Horizon content knowledge* (MKT) and *Three worlds* (Tall), *use-and-exchange-value*, *communities of practice*, a framework for textbook comparison, as well as a few studies using theoretically less specified notions such as *competences*, *interest*, *expectations*, *transmissionist pedagogies*, and *perspective*, will not be discussed here.

## Contributions of different theoretical approaches

In the selected articles, five theoretical approaches not discussed in the review by Gueudet (2008) were identified, which unavoidably only adumbrate distinct categories: *Bourdieuian sociology*, *Bernsteinian sociology of education*, *Cultural anthropology*, *Cultural Historical Activity Theory* and *Commognition*. How these contribute to the understanding of the transition will be illustrated by way of examples of specific studies.

### Bourdieuian sociology

A group of studies drew on Bourdieu's notions of *habitus* and *capital* to analyse students' struggles during the transition. Kleanthous and Williams (2013) employed the notion of habitus to develop a framework for measuring parental influence on students' inclination to pursue mathematics studies in higher education. They interpreted their findings to be consistent with a Bourdieusian view in that "family influences might inculcate a mathematical habitus that encourages choosing mathematically-advanced courses at school, which thus enhance mathematical confidence and inclination, and shapes positive dispositions to study mathematically-demanding courses in the future." (p. 64).

That also those students who find the transition hard may hang on to successfully complete the transition was illustrated in Hernandez-Martinez and Williams (2013), where these students were labelled as *resilient*, defined as a socio-cultural term. For the analysis the authors employed Bourdieu's notions of cultural and social capital, adding that "students can *develop* capital through reflection" (p. 49), a capital allowing agency for example during transition to align "their habituses with the conditions of the new field" (p. 49). Based on a narrative analysis of data from two student interviews, the authors identified biographical "narratives of resilience" (p. 50) that showed how reflexivity led to the development of a capital during schooling that eventually became valuable

during the transition, for example when experiencing risks to progression. For education practice the authors therefore suggested that “processes that encourage reflexivity in students should be incorporated in pedagogical practices at all levels” (p. 57).

Bergsten and Jablonka (2013) interviewed students at the beginning, middle and end of their first year of study in a five years engineering programme at two Swedish universities, and interpreted their data in terms of Bourdieu’s notions of *field* as well as *cultural, economic and symbolic capital*. Regarding the choice of programme at university, the outcomes corroborated those of Kleanthous and Williams (2013), showing how “the cultural capital possessed by the families influence the choice to enrol at a university” (Bergsten & Jablonka, 2013, p. 2293). Students also appeared to have acquired a cultural capital in their science- and technology programmes at secondary school that has developed into a disposition towards academic studies (many talking about “a natural continuation”). While expectations about future professions differentiated between students from different study programmes in terms of the importance of cultural and economic capital as well as the symbolic capital that multiplies their impact, the views of the role of mathematics in this context were more coherent, with a focus “less on particular mathematical skills as a form of cultural capital”, but more on “a general habituation to solve problems in a rational way” (p. 2294).

### **Bernsteinian sociology of education**

To identify issues and operationalize notions seen as critical for the transition, some studies employed key concepts from Bernstein’s theory of pedagogic discourse, in some instances combined with other theoretical constructs. Kouvela, Hernandez-Martinez and Croft (2018) focused on the discourses that frame the changes in teaching and learning practices during the transition from school to university, and how these discourses transmit *messages* to the students that affect how they experience and handle the transition. Drawing on Bernstein the authors distinguished *strongly classified* and *strongly framed* messages. The empirical study involved first-year mathematics students and two lecturers, and included lecture observations, student questionnaires and interviews; a grounded theory approach amounted to categories of messages (what students should do during and after lectures, assessment, general study habits). These messages, transmitted by the lecturers to their students, were analysed in terms of classification and framing helping to decompose each message and “identify, through the underlying structures of power and control, in what ways the message can be influential on students’ transition” (p. 173). The general conclusion was that messages common between school and university ease the transition, while differences can “prompt action to be taken by students and can change their thinking” (p. 181).

Jablonka, Ashjari and Bergsten (2017) investigated how first year students interpreted the type of mathematics they encountered at university. To explicate the expression ‘type of mathematics’ and create a language of description for the reading of the empirical data, an analytical framework drawing on Bernstein’s notions *knowledge classification* and *recognition rules*, elements of *social semiotics* by Halliday and Hasan, Eco’s conception of a *model reader*, and Sierpinska’s idea of mathematical and didactical discourses as *mathematical* and *didactical layers* in textbooks was developed. In individual interviews, textbook excerpts were shown to 60 first year engineering students at two Swedish universities, asking them to rank the texts according to which they saw as “more

mathematical”. The framework allowed a description of students’ articulation of their recognition rules, and the authors concluded that “recognition of differences in strength of classification of different mathematical discourses emulated in a range of pedagogic practices relates to success in the examinations” (p. 87). The study thus illustrates how academic success relates to a recognition of the university mathematical discourse.

### **Cultural anthropology**

A couple of studies used theories that can be located in the rather broad field of cultural anthropology. Four research groups referred to the idea of a phased *rite of passage*, coined by Arnold van Gennep at the beginning of the 1900s. Clark and Lovric (2008) first suggested that this is a useful model for the study of the transition to university (mathematics). The transition period is characterised through a *separation* phase (end of school, anticipating university life), *liminal* phase (from finishing school to beginning university), and *incorporation* phase (first year at university). It thus constitutes first of all a formal grid for framing the transition but does not specify what or how to approach the particular issues related to the phases.

One attempt to apply the model is found in a pilot study by Bampili, Zachariades and Sakonidis (2017), which presents data from interviews involving 12 students during their transition to mathematics studies at a Greek university. At the three phases of Clark and Lovric’s model questions were asked regarding the dynamics of the social-personal life, academic life and mathematical content dimensions to investigate how “the academic and social dimensions interact to shape the passage from the liminal to the incorporation phase regarding mathematical content” (p. 1987). In the paper, data from one student were discussed “because her responses during data collection strongly indicated that she was undergoing a rite of passage regarding mathematics” (p. 1987). Based on their findings the authors considered the study as “a good starting point for exploring specific issues considering transition more extensively” (p. 1991).

Wade, Sonnert, Sadler, Hazari and Watson (2016) conducted an online qualitative survey involving secondary and tertiary level mathematics teachers in the USA about what they conceived as good high school preparation for students for the college calculus courses. As a framework for interpreting their data they used the *rite of passage*. In particular, the separation and incorporation phases were investigated through thematic analyses that revealed five categories in which secondary and tertiary teachers “differed significantly in the relative frequency of addressing them” (p. 7). While teachers at university pointed at preparation of specific areas within algebra and precalculus as vital, teachers at secondary level highlighted “classroom environment realities of teaching in the separation phase.” (p. 7). The authors concluded that a better understanding of the “gap between the teachers’ and the professors’ outlooks” is needed and that these two groups need to “realize more clearly that they are part of one and the same rite of passage process” (p. 13).

Corriveau and Bednarz (2017) drew on *cultural theory* (referring to the work of Edward T. Hall), in particular the distinction between *formal*, *informal*, and *technical* modes of culture and on *ethnomethodology*. They sought to understand how differences in secondary and post-secondary teachers’ “ways of doing mathematics” rather than differences in formal or technical aspects of mathematics present difficulties for students. More specifically, the secondary teachers aimed at

“giving form” to symbols that “speaks” to the student, representing particular generalisations, while the post-secondary teachers worked to “give voice” to the pre-existing general symbols. The authors concluded that “the ‘informal’ mode of mathematical culture specific to each teaching level plays a key role in attempts to better grasp transition issues” (Corriveau & Bednarz, 2017, p. 1).

### **Cultural Historical Activity Theory**

Several transition studies used Cultural Historical Activity Theory (CHAT) to frame their research. In a project in the UK on student participation in post-compulsory mathematics education, Black et al. (2010) interviewed 40 students at three occasions during the transition period. In doing so, they used a notion of *identity*, which in their reading of CHAT is “historical in origin and emerges from the subjectivities (how one views oneself) we experience in the process of doing activities” (Black, Williams, Hernandez-Martinez, Davis, & Wake, 2010, p. 58). The authors argued that what they termed *leading identity* (based on Leont’ev’s concept *leading activity*) defines a student’s motive for study and also influences the relation to mathematics. A narrative analysis of interviews with two students with different experiences and showing “contrasting aspirations in their interviews” (Black et al., 2010, p. 59) was conducted. For the analysis an operationalization of the constructs leading activity, leading identity, cultural models (such as ‘math is hard’) and troubles/obstacles used to read the data was developed. The two students were both drawing on “cultural models regarding learning mathematics and studying in general” (p. 68) which framed their leading identities; in one case to become an engineer, in the other to obtain a university degree. The authors suggested that a leading identity implying the use value of mathematics as a motive for its study has a stronger potential to “bring about a commitment to persisting with mathematics, particularly for at-risk students who may face more difficulties or challenges than others” (p. 71).

Within the same project, investigating the transition from school to college mathematics in the UK through student pre- and post-transition interviews, Hernandez-Martinez et al. (2011) categorised the transition ‘problems’ in *social dimension*, *continuity of curriculum/pedagogy*, and *individual-progression/differences*. Rather than only a discourse focusing on problems, the authors also identified “a more positive discourse on challenge, growth and achievement” (p. 119). They focused on the notion of *identity*, relying mainly on CHAT, in particular the ideas of *self in practice* and *consequential transitions*. As a result, the authors suggested it to be viable to “re-think transition as a question of identity in which persons see themselves developing due to the distinct social and academic demands that the new institution poses” (Hernandez-Martinez et al., 2011, p. 119).

### **Commognition**

A number of studies drew on the theory of *commognition* (Sfard, 2008) to analyse the transition to university mathematics education as a *discursive shift* that may involve a *commognitive conflict*, that is “the encounter[s] between interlocutors who use the same mathematical signifiers (words or written symbols) in different ways or perform the same mathematical tasks according to differing rules” (Sfard, 2008, p. 161). This approach provides a language for describing mathematical work as discursive practices, characterized by their shared *word use*, *visual mediators*, *endorsed narratives* and *routines*. In a UK context, Thoma and Nardi (2018) investigated how a group of first year mathematics students solved closed book exam tasks, and also interviewed the two lecturers involved

in the courses. In the students' scripts four manifestations of (unresolved) commognitive conflict were observed, two of which (the numerical domains involved, and visual mediators and rules of school algebra and set theory) seen as “stemming from the use of visual mediators and rules from the school mathematics discourse” (Thoma & Nardi, 2018, p. 165). A challenge for beginning students at university is then to recognise the switch and adapt to different discursive contexts, which was not required in the arithmetic and algebra dominated school mathematics. Some further examples are found in Nardi, Ryve, Stadler and Viirman (2014) who discuss empirical studies highlighting “*commognitive conflicts* that characterise the transition to *literate* mathematics” (p. 194).

## Discussion

The studies reviewed above illustrate how the framing of the secondary-tertiary transition in mathematics education has widened in scope during the last decade. With the exception of *commognition*, the theoretical approaches identified as “new” have been developed outside mathematics education; however, most of them have been imported first into other research areas in mathematics education. Many of the studies recruit a combination of different theoretical resources in order to achieve their research aims. Overall, the transition as a process has come more into focus, which is also reflected in the methodologies (e.g., interviewing students at different points in time). Referring to recent work, Gueudet et al. (2016) made a similar observation in noticing a trend towards approaches that intend to grasp transition as a process in its complexity.

Notably, all approaches discussed might be subsumed under “socio-cultural” theorizing. This is a move away from views that essentialize students' mathematical and cognitive dispositions that may (or may not) make them successful in crossing the boundary between school and university mathematics education. The new approaches illustrated above certainly have enriched the field, as transition is not only pictured as problematic but as necessarily involving discontinuities. By drawing on theoretical tools developed within coherent frameworks in the analyses of mathematics-specific practices, critical experiences of the transition as well as social and cultural (dis)continuities have been identified that otherwise would have remained hidden; some questions would not have been asked without turning to theories developed outside mathematics education. This applies not only to such issues as implicit rules for the use of mathematical symbols or modes of argumentation, but also to the organization of the content of mathematical courses, their modes of study and resources used. This development is also in alignment with the general trend in mathematics education research, including university level (cf. Inglis & Foster, 2018). However, the dominant focus here is on the “cultural” to the detriment of the “social” in “socio-cultural” theorizing. How social orders or hierarchies are (re)produced in the transition remains under-researched, despite numerous statistical reports on underrepresentation or dropout in higher (STEM) education of particular social groups. While, for example, ATD offers a precise language of description for conceptualising differences between mathematical cultures, sociological approaches, in particular if they allow a description of mathematical practices, discourse and knowledge structures in relation to mechanisms of inclusion and exclusion, are important to understand how particular social hierarchies are (re-)produced *within* particular mathematical cultures (see e.g., Bergsten, Jablonka, & Klisinska, 2010; Bergsten & Jablonka, 2013; and the review of sociological theories in mathematics education in Jablonka, Wagner, & Walshaw, 2013).

As to the cultures of doing mathematics, similarly as noted by Gueudet (2008), technology as one area relevant for the transition appears under-researched in our sample of papers. While as long as 30 years ago technology (in particular CAS) was seen as a key resource for ‘reshaping calculus’ in the USA, “the potential of technology in helping students in the ‘rite of passage’ to tertiary education has not yet been researched” (Bardelle & Di Martino, 2012, p. 787). There are however recent attempts in theorizing technology use in the transition (Gueudet & Pepin, 2018). Still, even after suspending traditional ways of doing university mathematics (e.g., through technology), going through a status of liminality will be necessary in the process of enculturation.

*Undergraduate mathematics programmes in Europe are typically delivered in hierarchical structures of modules whose contents are in general assumed to be quite similar across universities. These programmes and the mechanisms through which they are maintained, revised and developed, have so far not been the subject of systematic research, as most research (including intervention-based research) takes the programme for granted. This paper furnishes a theoretical and methodological framework for undertaking didactic research in this area and provides some results from a first study in four universities in Denmark, France, Germany, and Spain.*

*Keywords: undergraduate mathematics, external didactic transposition, curricula.*

## Introduction

As one of the main challenges for future research on university mathematics education (UME), Artigue (2016, p. 22) noted the need to “maintain some connection between the living field of mathematics [...] and undergraduate mathematics education”. She relates this to the fact, already noted by Kahane (cited in Bass, 2005, p. 417), that “in no other discipline is the distance between the taught and the new so large”. It is an illusion that the contents of university mathematics teaching flow directly from the source of research, being continuously updated with the advances of mathematics.

Most research studies consider teaching and learning processes related to a given mathematical piece of knowledge that takes place within one or a few curriculum subjects, domains or modules. These modules seem to function as a context of the study that is not in itself submitted to research—neither at the level of the entire study programmes nor at the level of the modules and their syllabi. In some studies, this context is found to offer constraints or even obstacles to student learning and teaching innovation of the piece of knowledge considered, but the module itself—its structure and place in the curriculum—is rarely put under question. The need for research to go beyond this relationship to curricula was emphasized in the conclusion of the chapter on university mathematics education of the recent volume celebrating the 20<sup>th</sup> anniversary of ERME:

We should mention also the potential, but currently quite limited, impact [*of research on UME*] at the level of innovation of curricula and policy. Some of the more global problems identified by [*research on UME*] [...] clearly call for research and impact at this level (Winsløw, Gueudet, Hochmuth, & Nardi, 2018, p. 71).

Creating a research-based approach to the development of undergraduate mathematics programmes appears as an important challenge. Bosch and Winsløw (to appear) have started to address this

question from the perspective of university didactic transposition, using some research available on the evolution of university mathematics programmes (e.g., Huntington, 2015; Tucker, 2013). In this line of research, this paper presents the first results from a study of the structure and evolution of undergraduate mathematics curricula at selected universities in four European countries. Its main aim is to outline some theoretical and methodological directions for this line of research.

## Theoretical framework and research questions

We problematize the elaboration and evolution of university curricula by using the framework of the didactic transposition (Chevallard, 1991; Chevallard & Bosch, 2014). We use this framework as a tool to investigate the precise organisation and structure of the *knowledge to be taught*. Study processes—at all levels—are defined in terms of learning goals to be reached by a given group of people under certain conditions. In the case of European university degrees, these goals are defined in terms of general competencies, materialised in *study programmes*, which are first concretised in a set of *modules* (or subjects). Modules receive a name that can correspond to a sector or domain of a discipline (Algebra, Analysis, Geometry) or to a specific selection of contents (Perspectives in Mathematics, Mathematical language and reasoning, Mathematical modelling). At a second level of concretion, modules are described through a *syllabus* where the learning goals are more precisely defined in terms of subject-based contents and often also skills, learning outcomes, textbooks, prerequisites, etc. Taking the word “knowledge” in a broad sense—to include formal knowledge but also informal practices, skills and competencies, attitudes, etc.—we can say that study programmes, modules and syllabi are the way used by universities to define the knowledge to be taught.

The notion of didactic transposition points to the fact that teaching and learning processes do not begin when teachers and students meet in a classroom. The starting point is the selection and elaboration of the *knowledge to be taught* from what is called the *scholarly knowledge*, which gives legitimacy to the knowledge to be taught. Three institutions intervene in this process: the scholarly institution of knowledge producers and users (the “experts” or scholars); the school institution where the scholarly knowledge has to be transposed (which in our case corresponds to the university); and the *noosphere* which is defined in the neighbourhood of both and includes all those who make decisions about the teaching processes at play. In the case of UME, these three institutions have a large intersection. However, even if they share many of their subjects, we should differentiate the *positions* occupied and the roles assumed by their subjects. Therefore, a mathematics researcher can act as a subject of the scholarly institution—a scholar—when she produces mathematics and acts as an expert of the discipline. She can also act as a subject of the noosphere when she makes decisions about the study programme of a given degree. And she is also the subject of the school institution—this or that university or faculty— when she teaches a module.

The process of selecting, adapting, organizing and declaring the “knowledge to be taught”—beginning from scholarly knowledge and ending with all the teaching materials that can be proposed in a given course—is called *external didactic transposition* (EDT), while the subsequent step towards the “actually taught knowledge” is called *internal didactic transposition* (Chevallard, 1991, p. 35). One can interpret almost all existing research on UME as primarily concerned with internal didactic transpositions, since (as noticed above) the programmes and syllabi are merely considered a context

of teaching and learning processes. When putting the EDT at the core of the study, we consider the following research questions: What are the main processes and rationales in the EDT processes leading to UME study programmes and modules? What are the institutional forces that influence them (from the scholarly institution, the noosphere, and the school)? What common tendencies can be found in European universities, regarding these questions?

## Methodology

This paper only presents a first attempt to provide some pieces of answer to these research questions throughout an exploratory study mainly based on four one-hour interviews with experienced undergraduate mathematics teachers from Denmark (DK), France (FR), Germany (GE) and Spain (ES). Teachers were selected for their experience with recent curriculum drafting. They are all professors in mathematics departments and researchers in different areas of pure mathematics: topology, number theory, algebra, combinatorics, and functional analysis. The main selection criterion was our facility to approach them and their willingness to participate in the study. The bachelor programmes of mathematics of the four universities were analysed before preparing the interviews and used as the empirical basis of our interaction with the interviewees. They are not necessarily representative of other programmes in the same country.

The interview guide contains four sections. The first section asks a rough description of one of the latest undergraduate modules the interviewee had taught. The second section is about the history of this module, the genesis of its syllabus and possible conditions for changing it. The third section includes questions about the whole study program, compared to past programs and to programs of other universities. Finally, the fourth section refers to processes involved in the elaboration of the program, obstacles for changing it, and factors of influence within and outside the department. To support the discussion, the informants were given a copy of the course structure diagram of their faculty, showing modules with titles, ECTS credits and time organisation. In particular, the informants drew arrows on this diagram to show the dependency between modules and referred to it while commenting on the design of the study plan as a whole. Both the design of the interview guide and the choice of informants reflect our assumption that EDT in this context is closely related to the internal didactic transposition, including the daily teaching experience.

The interviews were audio-recorded and afterwards transcribed, and translated into English if not conducted in this language (one of the four was not). After a first reading of the interviews, we identified four themes, which were also to some extent built into the interview guide. Given our research questions, the themes focus on the product of EDT (themes 1 and 2) and its functioning as a dynamic process (themes 3 and 4). We scanned the interviews for utterances about these themes and then identified emerging, shared viewpoints on the EDT. These are presented in the next sections. When quoting informants, we refer to their country (DK, ES, FR, GE).

## Theme 1: Form and contents of study programmes

We first note some initial observations mainly based on the documentation of the study programmes. We focused on bachelor programmes in (pure) mathematics. All four universities also offer master programmes in this area. Therefore, the bachelor programmes may not qualify students for a job in the “real world” but could mainly provide a basis for master studies, which in all four cases may lead

to a job as a secondary school teacher, among other options. All programmes offer a common core of courses on analysis, linear algebra, algebra, numerical methods, and stochastics. The programmes also include some auxiliary subjects such as programming or informatics (all), physics (France and Spain), or a secondary “minor” subject (Germany), but the interviews show that the core mathematics subjects do not rely on such auxiliary modules. Even the use of digital tools such as CAS for analysis courses is mostly optional. A quite substantial difference among the programmes is that in the Spanish and the French ones, almost all modules in the three years are fixed and mandatory, while the Danish and German programmes reserve at least 40 ECTS for elective courses. The elective courses cover many fields, some of which are mandatory in the other two programmes: geometry, topology, functional analysis, advanced algebra, stochastics or statistics, etc. The size of individual modules is also quite different: In the Spanish case all modules are 6 ECTS, the French programme contains courses from 2.5 up to 7.5 ECTS and the Danish and German programmes mostly have 10 ECTS-modules. All larger modules include lectures, and usually also tutorials, labs or problem sessions.

There seems to be a tendency to keep a core of courses that cover the same mathematical domains, with a strong consensus on these core domains:

This program gives a solid foundation for most of the mathematical directions that you would, we want to cover here. I mean you do a solid background in analysis and in algebra... (DK)

On the other hand, details, and emphases of the study programme also depend on local conditions like staff composition, established research units and so on:

If people from the staff are more, say, predominantly from applied mathematics, they tend to shift pure mathematics from the syllabus. And the reverse is true too. (ES)

In spite of differences between the programmes, the interviewees claim that the structures of modules are hard to change (DK) and that there is not very much to play with (ES).

Another common facet relates to the basic idea underlying the overall structure of the programmes and in particular the sequencing of the modules: they are organized according to the logical dependency of notions, definitions, and theorems (mathematics as a product). In the interviews, there was only the case of a discrete mathematics course where the content seems, at least partly, to be organized around problems:

[We] rather start from a concrete problem, a problem that they know, the Fibonacci numbers, and look how the method is developed in that problem you see, how to do, how to get a functional equation for the generating function and then use partial fractions. (GE)

## **Theme 2: Form and usage of module syllabi**

The first part of the interviews centres on a recent module taught by the informant. This provides further information about one particular syllabus, and the ways it functions to structure and direct the actual teaching. Considering all four interviews, we can identify some common points, as hypotheses about how undergraduate mathematics syllabi are elaborated and used more generally. The first common point is that the syllabus consists of a short list of mathematical concepts or results that form the core of the module, while still leaving some initiative to the teacher:

There is still some flexibility, particularly how far one would go with certain topics. (GE)

Not surprisingly, more choice is left to the lecturer in the case of modules that are more “free-standing”, such as a course on order structure and social choice theory. In courses within a longer sequence, such as the first analysis course, the constraints are stronger:

The curriculum was sort of written beforehand and I basically had to stick to it [...] You do have some influence on the weight you would put on certain topics, and I think I spent more time and focus on continuous functions than was perhaps originally intended. (DK)

When the informants describe one of the undergraduate courses they have taught recently, they almost exclusively refer to their lectures, including the particular choices they make in terms of emphases, what to cover, etc. When asked, some of the informants also mention the exercises, often taught by assistants in different sessions, but without giving them crucial importance in the structure of the course. Tutorials are strongly related to the lectures, as the relevant theory should always be treated before being applied in exercises. The exercises are also related to the final exam in the module:

[Tutorials teachers] teach on the blackboard, have 100 students in front of them and they solve the exercises on the blackboard. [...] the list of exercises is a list that comes from father to son. It's the same list that has been there for the past 10 years. [...] they are trained in the classroom with the same kind of exercises that will be at the exam. [...] the key for 60 or 70% of the students to pass is to do an exam that is not essentially different from previous ones. (ES)

All informants agree that their own activity as researchers does not directly influence their activity and choices as lecturers, because the material of the undergraduate course is very elementary:

It's so basic, all of it. [...] I mean, I think most people would agree these are the kind of things that you would include in a course like that, so I am not sure that my particular line of research has played a significant role. (DK)

The interviewees all agreed that syllabi can be revised in reaction to experiences while taking into account the function of the module as a prerequisite for other ones. However, most changes described in the interviews seem to respond to more global changes of an administrative character, such as the passage from quarters to semesters. In two of the universities, changes were also due to the passage from a structure where some basic courses, including calculus, were shared with other study programmes, to a programme where all courses are tailored exclusively to mathematics students. The contents are mainly justified by such a collegial consensus, the needs in other courses and the preparation for the master level, and sometimes also students' prerequisites. Two informants (GE and DK) also made passing references to the perceived needs of future teachers, but otherwise, the contents are not related to needs or factors outside of the programme. All the informants express, in various ways, that the contents of the core modules must be kept:

Changes on the content are really dangerous because either you omit things which are important for other modules or *[you add something new in relation to previous years, with the result that]* the exam, it's going to be a full disaster. (ES)

### Theme 3: Process of design of study programmes and modules

We seek to identify the main constraints of the EDT as a process conducted inside the mathematics department, seen as an institution within the university. External constraints may originate from other disciplines within the university (interrelations of programmes), the university as a whole (coherence and economy of study programmes), the ministry of education (accreditation), the European Union (the Bachelor-Master-Doctorate (BMD) structure or other aspects of the Bologna process), or the socio-economic sphere (needs for qualified labour force in specific domains).

The collected interview data gave an overall picture of EDT as a rather informal process:

There may be two or three people who go teaching this course, and I think we will (for the new accreditation) just sit together again and see what everyone agrees to. (GE)

The module descriptions are thus done by teachers who volunteer, motivated by their involvement in the teaching. The formal constraints imposed by national authorities seem weak and concern only the formal structure of the study programme:

Before the BMD reform, the size of the modules and their names were given by law. The legislation regulated the number of hours of integration theory, differential calculus, and so on, and checked on the syllabus that the study programme fulfilled the expectations of the degree. With the BMD, universities are totally autonomous. (FR)

The autonomy of institutions is indeed furthered by the Bologna Accord. In some cases, this is used as an opportunity to create more independent and pure mathematics programmes. External constraints due to other fields are limited to the few cases when modules are shared with them:

In this version of the programmes, great autonomy was given to the departments, with little constraints on the potential navigation of students between different study programmes. This choice was made by the ruling committee of the faculty of sciences and the consequence that I can see is that it leads to a disciplinary retreat. (FR)

Constraints due to the socio-economic environment were also mentioned: “Here, you have a lot of insurance companies and banks, so we lose some students in this direction” (GE). However, its impact on the EDT seems weak: “In the curriculum, you don’t see it” (GE). Again, students’ mobility was also pointed out, to justify that mathematics programmes need to be fairly similar.

Because of the overall weakness of perceived external constraints, the interviewees came to identify students as the main constraint that EDT meets as a process:

The real constraints are the students. How to build a study programme that is suitable to open to advanced studies in mathematics but also matches the level of students that we find in front of us? This is very complicated. (FR)

### Theme 4: Evolution of programmes and modules

When asked about major evolutions of the study programmes over the last decades, two main changes were mentioned: the tendency to structure programmes in a higher number of (smaller) modules, and the incorporation of new modules related to computer science, programming and discrete

mathematics. All interviewees agreed that the strong compartmentalization of knowledge leads students to specific study strategies, resulting in a loss of connections among subjects:

So, it's not so much the curriculum, but what matters is how people learn. I take my exam after the end of this course right away and then I can forget about it and come to the next thing. So this was different in the diploma system. You had the oral exams after two years and you had a big exam at the end after four or five years. This makes a big difference. (GE)

Another change that can be observed is the incorporation of what we can call “propaedeutic” courses in the first semester of some universities: “Mathematical language and reasoning” (ES), “Perspectives in Mathematics” (DK). In the French case, a more unified start has been achieved by merging the modules of analysis and algebra in the first semester:

In the first years, you need to give substance to a set of mathematics, to have more possibilities of interaction between the different elements of the subject to facilitate the links. (FR)

As for the modular structure, the fragmentation seems to be reinforced by the repartition of subjects among groups of researchers:

[What introduces changes in the curriculum is] the sociological evolution of the laboratory, that is, the number of colleagues that are in this or that team, their thematic orientations. (FR)

The tendency towards disciplinary “purism” also means that subjects which are not linked to research groups in the department tend to be reduced or even disappear.

There appears to be strong stability in the core-curriculum shared by the four programmes, and we see no signs of substantial disagreement about the overall profile of the programmes.

## Conclusion and outlook

Our exploratory study considers the EDT, its processes and rationales, institutional forces and common tendencies, mainly through the lens of experiences reported by lecturers and their reflections on internal didactic transposition processes—how it is framed, determined by obstacles and goals. Our main results (in fact, hypotheses of general trends) are the following:

- § Although the programme structures of the universities look quite different, they have a common core of courses (analysis, algebra, probability, and statistics, etc.), reflecting a broad consensus among mathematicians at large. The interviewees describe and justify relations between the modules in terms of inner-mathematical (logical or theoretical) dependencies.
- § A module is a lecture-based course and it is described essentially through a short list of topics, especially notions and theorems. This list outlines what the lectures should cover, leaving room for variations, but with very little reference to what the students are asked to do (types of problems, exams, etc.).
- § The process of curriculum design is very informal, with no systematic and explicit organisational principles, thus relying on a set of shared assumptions and on the dependence between faculty and teaching needs. Moreover, the interviewees experience weak external constraints (influence of the socio-economic environment, students' mobility) together with a high autonomy to make changes, which seem to reinforce disciplinary purism.

§ An increased modularisation is seen in the last 20 years with a trend towards early specialisation in mathematics. When changes are operated in a study programme, the core of the programme is preserved but some auxiliary modules may be added or replaced, to support students' learning of generic skills (e.g. mathematical reasoning), to introduce new domains (graphs, modelling, etc.) or provide new tools (computer programming).

At this stage of the research, we are far from being able to propose or support initiatives towards a more systematic and knowledge-based EDT—that is, to produce curricula and syllabi that optimize mathematics programmes in relation to institutional contexts and specific sets of constraints. One major motivation is that, if we want to pursue specific agendas—such as broader and more efficient preparation of secondary school teachers, new paradigms of “inquiry-based” teaching, and so on—, we need to understand the processes of EDT that determine the set of conditions and constraints under which such agendas are pursued.

# Students' difficulties to learn derivatives in the Tunisian context

Rahma Bouguerra

Université virtuelle, ISEFC, Tunis, Tunisia; [rahmabouguerra@gmail.com](mailto:rahmabouguerra@gmail.com)

*Keywords: Concept image, formal definition, language, articulation of knowledge, non-technological environment.*

## Introduction and research problem

In my research, I focus on the concept of derivative at a point; this concept was selected as a means to study students' conceptions and difficulties when learning derivatives. This concept has been chosen because it poses problems to students throughout the teaching / learning process. It is known that this concept is connected to many other concepts and it can be represented in various ways. So there are many ways and different interpretations to understand it. In particular, there are many findings reported in the mathematics education literature related to my topic; these include the study of students' difficulties with tangents (Tall, 1986; Vinner, 1983) of with the understanding of derivatives at a point (Park, 2013).

Since 1957, mathematics education in Tunisia has known five reforms at the secondary level. In the current reform, derivatives are first introduced as an instantaneous speed in the third year of secondary school (17-18 years).

In this research, my goal is to identify the obstacles and constraints that prevent students from understanding the concept definition of a derivative and from having adequate concept images of it. My study is guided by the following questions:

1. Does this introduction guarantee a good conceptualization of the derivative at a point?
2. What are the difficulties that prevent secondary and university students from apprehending and visualizing this concept?

## Theoretical framework

In my research, I draw on the frame of Concept Image and Concept Definition (Tall & Vinner, 1981), which is a powerful theoretical construct that allows for analyzing students' representations of derivatives. The total cognitive structure associated with a derivative in a student's mind can give us many ideas about the reasons for the misconceptions and lack of understanding that students have. In this study, I consider the interpretation of a derivative as an instantaneous rate of change, which plays an essential role to strengthen students' concept image.

## Methodology

The participants in my research are third-year secondary students (17-18 years) in the mathematics section in a Tunisian public school, as well as first-year university students in the Mathematics program in a Tunisian University. I chose these participants to identify some types of difficulties that persist for University students. Sixty secondary students and twenty university students were interviewed in January 2019. They also filled a questionnaire.

## Data analysis and discussion

The results show that participants learned by heart the definition of a derivative at a point and therefore give its symbolic representation without knowing that the derivative at a point is an instantaneous rate of change. We interpret this as a result of the teachers' practices (that focus on procedural understanding), as well as the absence of the term "rate of change" in the formal definition in the third-year secondary textbook. Furthermore, institutional choices do not seem to propose contextualized activities where rates of change are used.

This introduction does not help pupils / students understand the derivative at a point, because in physical sciences they have not learned that instantaneous speed is an instantaneous rate of change and in mathematics they cannot find the term "rate of change" in the formal definition. Then, students' difficulties also lie in the articulation of knowledge from physical sciences and from mathematics.

The slope of a tangent is the main representation in their concept image, and to explain their evoked concept image, they use some words referring to language difficulties because their first language is Arabic.

This traditional teaching (where technology is absent) does not allow students either to visualize the concept definition of a derivative nor to develop adequate concept images. There is much to learn and this traditional teaching (using blackboards and static images) does not allow students to see the dynamic characteristics of derivatives especially when there are interplays between settings. These traditional practices hinder our pupils from seeing the link between the slope of the secant line and the slope of the tangent line.

## Acknowledgment

I would like to thank Dr. Alejandro Gonzalez-Martin who let me know about this conference, and my dear Professor Elena Nardi; without her, I would not have been able to do this poster.

# The integration of digital resources into teaching and learning practices of the derivative concept

Danilo Christo<sup>1</sup> and Sonia Iglori<sup>2</sup>

<sup>1</sup>Pontifícia Universidade Católica de São Paulo – PUC/SP, Programa de Estudos Pós-Graduados em Educação Matemática, São Paulo, Brasil; [danilo.christo@gmail.com](mailto:danilo.christo@gmail.com)

<sup>2</sup>Pontifícia Universidade Católica de São Paulo – PUC/SP, Programa de Estudos Pós-Graduados em Educação Matemática, São Paulo, Brasil; [soniaigliori@gmail.com](mailto:soniaigliori@gmail.com)

*Keywords: Resources, document, instrument, derivative.*

This paper presents elements of a preliminary research on teaching and learning of the concept of derivative in higher education to be conducted in a Brazilian university. In the research we intend to study the interactions between teachers and resources systems according to the documental approach to didactics (Gueudet & Trouche, 2010) in order to answer the following research question: How can we develop a joint researcher / teacher actions in the design of resources and analysis of the documental work of higher education teachers when they approach the concept of derivative?

## Literature review

We conducted a literature review and found that some researches in Brazil on the teaching and learning process of the concept of derivative, for example, Leme (2016), and Almeida (2017), show that students express more satisfaction in situations that involve operative aspects than in situations that involve conceptual aspects of derivative. An analysis of didactic books, used in the teaching of differential and integral calculus, in engineering and mathematics Brazil courses, showed that most of these books privilege the use of the technique, offering a superior amount of exercises that focus the technique than in exercises that conceptual aspects.

## Theoretical Framework: The Documentational Approach to Didactics

The documental approach to didactics (Gueudet & Trouche, 2010) refers to the notions of resources, scheme, documental work, among others that support the development of Documentational Genesis theory, an extension of Instrumental Genesis (Rabardel, 1995) to Didactics of Mathematics. There is still in this theory the proposition of the dialectic resources / documents that renew it and even give more force to the questions of the professional practice of the teachers. In the Documentational Genesis (Gueudet & Trouche, 2009), the teachers' documentation, in the action of preparing and implementing their classes, is at the core of the teachers' professional activities and development, and implies: the research of new resources, selection and creation of mathematical tasks for sequential planning and development, time management, and artefact management. For Rabardel (1995), the use of technology invokes the need for any technological artefact that should become an instrument, that is, when the artefact acquires a meaning for the subject, therefore, according to Gueudet, and Trouche (2009, p. 204), this process occurs when an "*instrument* results from a *process*, named *instrumental genesis*, through which the subject builds a *scheme* of utilization of the *artefact*, for a given class of situations". Today, digital resources have become an important part of teacher and student resources systems, and schemes of use: an integration of these resources into teaching and learning practices in mathematics; their appropriate uses within a myriad of available options,

allowing them to be tailored to the specific learning objectives in question and their orchestration<sup>1</sup> and use by students; student resource systems; monitor teacher preparation before and during challenging tasks; and, the role of digital resources in the evaluation performance. Resources with such schemes of use become a document for teachers.

## Methodology

This research will follow a reflective methodology (Gueudet & Trouche, 2010) of the principles of: long-term follow-up, monitoring the process, extensive collection of the used resources and evidence of documental work and reflective accounts of documental work. The research subjects consist of six teachers who teach differential and integral calculus in the early years of a bachelor's degree in mathematics and in aeronautical engineering, computer engineering, electrical engineering, and production engineering courses. Research on teachers' documental work, both within and outside the classroom, through the reflective methodology described above, has been extensively developed with high school teachers and even with higher education teachers. For example, Gueudet (2017) interviewed, collected resources and analyzed documents and resources systems specific to the university context of six French university teachers.

## Conclusions

In the literature review carried out so far, we found a few studies on higher education with focus on teachers' resources and documents systems. We envisage that the direct observation of teacher work, including testimonials and their interactions with students, will provide important insight into their practices. We consider, as at other educational levels that documental work is essential in the practices of university teachers and has high potential in university mathematics education research.

---

<sup>1</sup> An instrumental orchestration is the systematic and intentional arrangement of the elements (artefacts and human beings) of an environment carried out by an agent (teacher) in order to effect a given situation and, in general, to guide learners in the instrumental geneses and evolution and balance of their instrument systems (Trouche, 2005).

# Restoried narratives on the agency and disputes of mathematicians and mathematics educators in the education of mathematics teachers

Cleber Dias da Costa Neto<sup>1</sup>, Victor Giraldo<sup>2</sup> and Elena Nardi<sup>3</sup>

<sup>1</sup>Universidade Federal do Rio de Janeiro, Brazil; [cleberneto@gmail.com](mailto:cleberneto@gmail.com)

<sup>2</sup>Universidade Federal do Rio de Janeiro, Brazil; [victor.giraldo@gmail.com](mailto:victor.giraldo@gmail.com)

<sup>3</sup>University of East Anglia, United Kingdom; [e.nardi@uea.ac.uk](mailto:e.nardi@uea.ac.uk)

*We address agency and disputes of mathematicians and mathematics educators over a pre-service mathematics teacher education programme. The format of these courses has been debated (and disputed) within Brazilian academic communities over decades. We use a re-storying methodology (Nardi, 2016) to construct a fictional dialogue to present and analyze data from interviews with four retired lecturers affiliated with mathematics education, who played key roles in the development of the curriculum of the teacher education undergraduate programme in a large Brazilian university. We support our discussion through a framework that articulates teacher education and curriculum theory. Our analysis indicates that these disputes and agency take place within a landscape that transcends teacher education and reaches broader and more complex political and epistemological terrains closely related to the binarism of mathematics and mathematics education.*

*Keywords: university mathematics education, curriculum, mathematics teacher education.*

## Introduction: mathematics and mathematics education communities in the preparation of teachers

Nardi (2016) comments that the “relationship between mathematicians and mathematics educators has been the focus of debate since at least the 1990s” (p. 362), and adds that this relationship has been often portrayed “as at best fragile” (ibid.). Theories in the field of *curriculum* may help to unveil possible theoretical or political disputes in the terrain of undergraduate education in general, and undergraduate mathematics teacher education in particular. These disputes (Gabriel, 2013) tend to take place mainly because there are different knowledge areas involved, with differences in agency, acknowledgement by scientific community, and affiliation to scientific domains (mathematics in the Exact and mathematics education in the Social Sciences). The complexity of these disputes is highlighted by authors affiliated to post-critical curriculum theories (e.g. Lopes, 2013) and transcend a binarism that typically permeates this discussion. Our study explores this complexity.

The research we report in this paper is part of a broader study, which is the ongoing doctoral research project of the first author supervised by the second author and aims to investigate the curriculum of the undergraduate programme for pre-service mathematics teacher education in the Mathematics Departments at the Federal University of Rio de Janeiro, Brazil (UFRJ), since the 1980s, from the perspective of the institutional and political terrain in which successive curricular versions were conceived and developed. The study focuses on: (i) the institution, and its official documents; (ii) the lecturers as actors who directly influenced these curricular versions; and, (iii) students (prospective teachers), whose professional preparation took place within this context.

In this paper, we report data and analysis from the broader study which address the disputes between Mathematicians and Mathematics Educators over the conception and development of these successive curricular versions. As previous research indicates (e.g. Nardi, 2008), teaching and management in undergraduate mathematics programmes, in particular curricula design, often involve negotiations and disputes between mathematicians and mathematics educators. This can be the case also when prospective mathematics teacher education is concerned. This is the focus of our paper in which we address the following research question: *How, and to which extent, do negotiations and disputes between Mathematicians and Mathematics Educators take place in the context of an undergraduate programme for mathematics teacher education?* We seek to answer this question through analysing the views of lecturers who are involved with this curricular design. Similarly to Nardi (2008), we characterise a participant as mathematician or mathematics educator according to their academic and professional activities, not necessarily their formal qualifications.

Research on pre-service teachers' education has been accumulating a significant theoretical corpus in the last decades, with strong influences from the field of Education, such as Shulman (1986), and Tardif (2013), and the field of Mathematics Education, such as Ball et al. (2008), and, specifically in Brazil, Moreira (2012), Moreira & Ferreira (2013) and Fiorentini & Oliveira (2013) on debates concerning the design of undergraduate programmes for mathematics teacher education. These debates are situated within broader considerations of research in university mathematics education, which, in recent years, has been consolidating significantly (Winsløw et al, 2018) and has been more attentive to institutional, disciplinary and curricular factors that, within broader political contexts, may influence the what, why and how of teacher preparation in undergraduate programmes.

In Brazil, there are separate undergraduate programmes in pure and applied mathematics (called “Bacharelado” and, in general, intended for future academic careers in Mathematics), and in mathematics teaching (called “Licenciatura”, which legally certifies school teachers). The Brazilian Mathematics Education research community (e.g. Moreira, 2012; Moreira & Ferreira, 2013) has been advocating that undergraduate programmes for mathematics teachers should take more into account a professional-oriented perspective (Tardif, 2013), which should be informed by reflections on school practice, and should integrate more explicitly mathematical knowledge for teaching (Ball et al, 2008). In the Brazilian context, this debate is evidenced in the curricular reforms of undergraduate programmes for prospective teachers, at least since the 1980's.

For instance, Moreira (2012) critiques the influence of the “Bacharelado” over the conception of the “Licenciatura” programmes. This influence is mostly expressed by the “three-plus-one” model – three years on “mathematical content”, followed by one year on “didactics” – which was dominant in “Licenciatura” programmes in Brazil until the early-1990's. In this model, pre-service teacher education consisted of two separate, non-overlapping clusters. According to Moreira, even though this organization has been progressively put aside in most Brazilian universities, its internal logic remains largely unchanged and still underlies current curricular structures, which are variations of the “three-plus-one” model. One such variation is the inclusion of a third cluster of modules, the so-called “integrating disciplines”, which focus on mathematics teaching. However, mathematics teaching is often assumed to consist of practical knowledge (that is, an ensemble of techniques on “how to teach a certain topic”), with little overlap with other curricular components. Commenting on attempts to

integrate these clusters of modules, Moreira (2012) argues that “the institutions do not manage to accomplish this task, because its accomplishment is impossible under the three-plus-one logic” (p. 1141). Fiorentini & Oliveira (2013) refer to this variation as a “quasi trichotomy”, alluding to an analogy with the dichotomic logic of types of knowledge (mathematical, pedagogical) needed for teaching. Moreira & Ferreira (2013) claim that, in teacher education in Brazil, there is an explicit clash between two strands – one that understands teachers’ knowledge to be plural in nature, with specificities emerging from school practice; and another that regards mathematical content knowledge as reference knowledge for teacher education and practice – and that in Brazil and elsewhere, there are disputes for “hegemony” over these two strands (p. 1001).

## The Study

### Context, aims and data production

As part of the broader research project, we conducted semi-structured interviews with four retired lecturers of the Mathematics Institute at UFRJ (IM-UFRJ), who played central roles in the curricular reforms over the last 50 years. Criteria to choose these participants included their degree of engagement with the undergraduate programme, including not only teaching but also academic administration positions during the above-mentioned timespan. The participants formally agreed with the study’s terms of confidentiality: their personal identities will be kept confidential, through the use pseudonyms, but the Institution (IM-UFRJ), which provides the context of this research, is known.

The interviewees are identified by the pseudonyms *Ana*, *Elis*, *Inês* and *Olga*. All have undergraduate and masters degrees in mathematics, and have worked as school mathematics teachers before becoming university lecturers. Ana has a doctorate degree in pure mathematics, Inês and Olga in mathematics education, and Elis does not have a doctorate degree. All have experience of research in pure mathematics, at least as masters students; and all migrated their affiliation to research in mathematics education during doctoral studies (Inês and Olga), or later, as lecturers (Ana and Elis). They are all currently retired, and were lecturers at IM-UFRJ from late 1960’s to early 2000’s (Ana from 1978 to 2017; Elis from 1964 to 1993; Inês from 1979 to 2010; Olga from 1976 to 1996). Their academic careers at UFRJ were marked by administrative positions in different levels, active participation in the design of successive curricular versions of the mathematics teacher education undergraduate programme, participation in the Projeto Fundação (a research and development programme on in-service teacher education, and development of instructional resources for the teaching of mathematics at elementary and secondary school). Furthermore, Ana and Olga participated as lecturers in the Graduate Programme in Mathematics Education since its creation in 2006; Ana until 2011 and Olga until now.

The interviews were conducted individually with each participant by the first and the second authors, and were fully transcribed. Interview questions aimed to better understand issues unclear from the analysis of the official documents of the programme (which was part of a previous phase of the study); and, to explore participants’ views on the relationships between Mathematicians and Mathematics Educators. The desing of the interviews scripts was also intended to shed light on lacunar issues that emerged from the analysis of the official documents.

In this paper, we present parts of the interviews with focus on disputes over the undergraduate programme's curriculum. Thus, we focus on participants' responses to the two questions, stated below. As the interviews were semi-structured, these questions were not necessarily made to the interviewees at the same moment, and depended on the flow of the discussion with each.

*Question 1:* Do you believe that there are disputes between mathematicians and mathematics educators concerning the undergraduate programme for pre-service teacher education at UFRJ? If yes, for which reason(s)? If yes, how do these disputes take place?

*Question 2:* Do you believe that there is room for mathematicians and mathematics educators to work jointly in the design of the undergraduate pre-service teachers education curricula? If so, how?

We present data in a dialogic format (Nardi, 2016) which provides readers with an intimate look at contradictions and convergences in the participants' statements. We wish to allow readers different interpretations of the data, but we put in evidence the complexity inherent to the disputes that characterize the curricular terrain in which these participants have worked. We stress that the first and the second authors cannot be regarded as external or neutral observers. On the contrary, both are former students and are currently lecturers at UFRJ, working in departments (Application School and Mathematics Institute, respectively) with joint responsibility for the Licenciatura programme. They are therefore deeply involved with the institution under study. However, we do not see this as a compromise of the research, but as part of the research itself. That is, the results we report here are shaped by the perspectives, (shared) experiences, alliances and divergences of the interviewees and the researchers. What we report is a *restored narrative* (Nardi, 2016) of the agency and disputes of mathematicians and mathematics educators in the undergraduate mathematics teachers education programme at UFRJ – that is, *a possible version of this story, through the lens of its actors* (participants and researchers) which gives prominence to participants' voices.

### **Data analysis method: From individual interviews to fictional dialogue among four lecturers**

To put in evidence the voices of the participants, and to reveal points of agreement, disagreement, and possible contradictions, we gather the voices of the four participants in a fictional dialogue among the four interviewees, grounded on raw data extracted from the transcripts. Conducting the interviews individually was important to avoid inter-participant influence. By gathering them together, we aim to grasp the gist of their responses to the questions we wish to investigate. Such methodology is consistent with the logic that “narratives constructed from testimonials of actors who collaborated in educational research can provide access to the senses and emotions evoked at the moments of data collection, opening space for several interpretations” (Barbosa, 2015, p. 359).

In order to promote this interweaving of the participants' discourses, we use elements of the “narrative approach of re-storying” (Nardi, 2016, p. 362-3), a process for constructing a story from original data, taking into account features, such as a problem, characters involved with a scenario in which they discuss and act upon the problem and its resolution. Here, we identify a common scenario evidenced in the interviews. This scenario, as presented by the interviewers, concerns the views on the relationships between Mathematicians and Mathematics Educators by the interviewees, who worked in the same institution, in a concomitant timespan, and with academic trajectories presenting similarities and distinctions. Each participant's utterances presented here correspond to their actual

responses in the respective individual interviews. However, these interviews took place separately, and the order of these utterances was reconstructed by the authors in the process of composing the fictional dialogue. The interviewer's utterances are introduced in the re-storied dialogue in order to make sense of connections between interviewees' utterances, put together as a whole conversation. Thus, we offer a *re-reading* of the original data – as we believe to be the case for any kind of data description, including those that present full original transcriptions. The order of the utterances and the connections between them in the composed, fictional dialogue and the fact that the first and the second authors are deeply involved in the institution under study produce a particular interpretation of the story, one possible narrative<sup>1</sup>. As Nardi (2016) points out, the proximity of the authors to the raw data, the transparency of the process that makes it “accountable and replicable” (p.364), and (specifically in this work) the possibility of establishing communication between Mathematicians and Mathematics Educators are important constitutive elements of the re-storying method.

To organize and present data, we firstly separated and classified the interviewees' statements regarding agreement or not about the existence of disputes between Mathematicians and Mathematics Educators. Then, drawing on the arguments posed by the interviewees, we constructed the sequence of responses and interactions between them, to create a fictional dialogue among five characters – the Researcher and participants *Ana*, *Elis*, *Inês* and *Olga* – in which the alternation of ideas and the views of the characters on the disputes at stake are present. Thus, we mean *fictional* in the sense that it is presented as a dialogue between five individuals but it is based on four conversations conducted with each one separately. Our design includes a respondent validation phase in which the participants read and comment on the fictional dialogue (at the time of writing, a preliminary part of this phase had been conducted through scrutiny of samples of the dialogue by critical friends in our research group). Our method resonates with that of Nardi (2008, 2016), where the composition of the fictional dialogue was based on interviews with groups of participants conducted separately and choices were made in the light of the study's theoretical underpinnings, literature influences and research questions. We now present a sample of the fictional dialogue resulting from this process.

### **A fictional dialogue among four mathematics lecturers and a mathematics education researcher**

The *Researcher* asks whether there are disputes between mathematicians and mathematics educators concerning the Licenciatura programme. *Elis* says “No”.

*Inês*: I agree. Mathematicians have no interest in undergraduate teacher education.

*Olga*: As far as the Licenciatura programme is concerned, I don't know if there are disputes. But I believe there are disputes about hiring of new lecturers.

Researcher: What are the reasons for such disputes?

*Ana*: They want pre-service maths teacher education out of the Mathematics Institute.

*Elis*: I think mathematicians do not value teacher education. They think it's just not worth

---

<sup>1</sup> In order to allow readers to judge our composition and, possibly, even produce different interpretations, the raw data is in <https://drive.google.com/file/d/1BUm5gGCUQPvuyyhyuSag09WvNgnNXI16/view>.

it, that it's a lesser thing.

*Inês:* But this happens because it's just not their interest. Their interest has always been the Bacharelado. It's to push good students to finish undergraduate fast, and put them in the pure maths graduate programme. It's not to prepare teachers, they never had that in mind. Their interest is to prepare researchers in pure maths.

The *Researcher* asks Olga why she thinks this dispute has to do with hiring new lecturers.

*Olga:* Those people with doctorates in pure and applied maths want to grab everything for them. They want all the new lecturers to them, everything to their fields, dynamical systems, algebra, differential equations. They think only that is mathematics.

The *Researcher* asks whether mathematicians from the Institute have really no interest in the curriculum of the Licenciatura programme at all.

*Ana:* They won't care about that. At most, they will say: "But why is there no Analysis at  $\mathbb{R}^n$  there?"; "Why is there no Calculus with Complex Variables?"

*Elis:* That's true. But it's funny how though they think Licenciatura has no importance, they yet believe that to be a maths teacher one needs to know a lot of maths.

*Inês:* People tend to keep retrograde positions: "let's not change anything". They stand against changes because they wanted Licenciatura under their own control. They stand against changes because they don't want to get involved with other programmes, only in the ones that they have interest in.

The *Researcher* asks whether there is room for mathematicians and mathematics educators to work collaboratively in the Licenciatura programme.

*Olga:* On the one hand, I think that it'd be very good, but I feel a little afraid of putting these lecturers with no link with mathematics education to teach modules in the first year, for example.

*Elis:* I think that, nowadays, maybe yes. For that, there must be more guidelines for lecturers, to try to get the mathematicians who are more committed more involved.

*Ana:* I think this is not possible. I'm too pessimistic, because I'm way apart from the Institute. But what I see is people with intransigent positions, which have no factual support. There'll be collaborative work in the same way there is in the Engineering: we go there, teach our lectures, some do the job very well, other put a lot of effort for students to learn, other just don't care. This kind of "collaborative" work always existed, and will keep on existing.

*Inês:* I have no doubt joint work between mathematicians and mathematics educators is possible. But it has to be with lecturers who do not want to transform prospective teachers into prospective mathematicians. However, I think there are few people with this kind of mentality. I have managed to have very good partnership with a colleague with a doctorate in pure maths at the Institute. But that's rare.

### Commentary on the dialogue and closing remark

Our interpretation of the participants' responses to *Question 1* suggests that they do not consider that such disputes exist, since there is no interest from the mathematicians with respect to teacher education. One of the participants conjectures that such disputes do take place when hiring new lecturers. The claim is that mathematicians appear to resist changes in the curriculum of the Licenciatura programme, and intend on keeping it close to the Bacharelado. These statements confirm that there are disputes, not with respect to different conceptions of mathematics teacher education, but to keep the political territories intact. As evidence for this, we also include the purposes to prepare new undergraduate or graduate students and to hire new lecturers to their own fields.

On *Question 2*, the divergence of opinions among the participants was remarkable. Thus, concerns towards the participation of mathematicians in the first year of the undergraduate programme, the need to engage mathematicians more interested in teacher education, the polysemy and fragility of the term “collaboration”, and the highlight of the need to differentiate prospective teachers and prospective mathematicians are brought about in a debate that implicitly underlines the acknowledgement of disputes between mathematicians and mathematics educators.

Our interpretation of the debate around the two questions suggests that these participants, clearly affiliated with mathematics education, acknowledge the professionalization and the orientation to school practice as constitutive aspects for the education of mathematics teachers, as per, for example, Tardif (2013) and Nóvoa (2009). In this context, disputes initially seem to be over the consideration of what constitutes mathematical knowledge for teaching (Ball et al, 2008) in pre-service mathematics teacher education, as Brazilian research literature advocates (e.g. Moreira, 2012). However, the debate among the participants indicates that these disputes are situated in more strategic goals: the preservation of political terrains, where students in the mathematics department, here prospective teachers, are background characters who suffer the side effects of someone else's quarrels. As others have noted (Lopes, 2013; Gabriel, 2013), the complexity of the disputes we discuss briefly in this paper is evidenced by a displacement of a more local terrain (undergraduate mathematics teachers programmes) to a broader one (preservation of fields and professional agency). The divergence of responses concerning possible collaborations also reinforce this complexity, since the binarism and tensions between mathematics and mathematics education (Nardi, 2008, p.257-292) was not always prominent in the participants' utterances. Such inferences were only possible because of the particular data analysis design we adopted. These utterances, which appeared initially in each individual interview, were intertwined, revealing convergences and contradictions at the same time as they produce dialogues on ideas that might not be present in a collective interview. These ideas are shaped under the authors' own standpoint, which, as we stressed earlier, is not neutral.

In the broader doctoral project, we are now collecting and analyzing data from discussion groups of former and current students of UFRJ's mathematics teachers education programme. The perspectives put forward in the overall study will therefore be enriched and complemented by our triad of analyses of institution (through analysis of official documents), lecturer and student data.

## Acknowledgment

We thank UFRJ for having allowed periods of partial and full study leaves to the first author, without which the development of this doctoral research project would not have been possible.

# Evaluation of a connecting teaching format in teacher education

Andreas Datzmann<sup>1</sup> and Matthias Brandl<sup>2</sup>

*Keywords: teacher education, geometry, conceptualisation, evaluation, concept image.*

## Motivation and teaching format

More than 100 years ago Felix Klein described the problem of the double discontinuity and its consequences. With his “three worlds of mathematics” model, David Tall (2008) saw the problem in the existence of different worlds in school and university, namely a conceptual-embodied respectively proceptual-symbolic world at school and an axiomatic-formal world in university. We wanted to counteract the problem of the double discontinuity by connecting the different worlds of mathematics. Therefore we designed a teaching format that should illustrate the interdependencies of mathematics taught at school and mathematics taught at university in the field of geometry. That these connections do not emerge automatically was already stated by Bauer and Partheil (2008). To aid the learning process of the students our teaching format was supported by a blended learning course and mathematical maps. Mathematical maps are a didactical tool to show interrelations between topics and development of a subject matter in time (Brandl, 2008; Schwarz et al., 2017).

## Theoretical framework and empirical study

To measure the effect of our teaching format, we used the theoretical framework of concept image by Tall and Vinner (1981). The term concept image describes “the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes” (Tall & Vinner, 1981, p. 2). It is built up over time by engaging with the concept and changing as new mental connections are made or older connections are exposed as imperfect. So for us it is interesting how the concept image of the students changed after attending the teaching format and if more mental connections between aspects of the concept taught in school and aspects taught in university are observable. We focused on the concepts of line, circle, congruence and sum of interior angles for this evaluation because they are broadly discussed in school and university.

## Data collection and analysis

For our exploratory pre-post-survey we used a guided interview because it allowed both students who attended the full teaching format to answer freely on the question what they connect with a certain concept and then we were able to specifically ask questions on aspects that were not addressed. In all interviews the questions were the same to provide comparability. For each of the four concepts the theoretical notion of concept image was operationalized into different subcategories to which the statements of the students were assigned. We then examined the relations between aspects taught in school and aspects taught in university in these subcategories.

## Results and discussion

We want to show changes in the concept image exemplarily. For both students, we call them S1 and S2, the summed up concept image of a line in the first interview was very close to school matters.

Lines were only seen as a linear function,  $y = m \cdot x + t$  (S1) and as a slanting dash upwards (S2). The line equation, the slope of a line, parallelism of lines and the number of points of intersection were correctly explained by both students. In the second interview lines were seen as an infinite set of points (S1 & S2) that satisfies the line equation,  $y = m \cdot x + b$  (S2) and also from an analytical perspective as reference point and direction vector (S1 & S2). S1 even gave the axiomatic definition of a line as a set that contains at least two different points and that there is exactly one line for any two points. Contentwise you see a change in the concept image of a line. The conception of a line changed to include different aspects, a set theoretical approach of a line as an infinite set of points, which is mainly used in university and an algebraic and analytical approach which is used in school.

In the first interview S1 understood congruence as being the same shape and size, which is the graphic description from school. She also made a connection to the criteria for congruence of triangles which are taught in school. In the second interview S1 added the following excerpt.

Student 1: [Congruence means that] you can map it onto each other with a motion. And a motion is achievable with a maximum of three reflections [...].

This shows that S1 was able to connect the previously very school based knowledge with formal mathematics. The answer to the question which functions are congruence functions reinforces this.

Student 1: Well, so reflections and rotations definitely are congruence functions. Translations too, but dilation and contraction are no congruence functions.

Overall these results suggest that our teaching format positively influenced the concept image of different terms of geometry. Aspects from school were not replaced by but extended with aspects from university. Especially with the abstract concepts of congruence and sum of interior angles more mental connections between aspects of the concepts taught in school and aspects taught in university can be observed. This suggests that the students were able to establish interrelations between what they learned – and will be teaching later – at school and what is taught at university.

## Students' difficulties at the secondary-tertiary transition: the case of random variables

Camille Doukhan and Ghislaine Gueudet

CREAD, ESPE de Bretagne, University of Brest, France; [camille.doukhan1@espe-bretagne.fr](mailto:camille.doukhan1@espe-bretagne.fr),  
[ghislaine.gueudet@espe-bretagne.fr](mailto:ghislaine.gueudet@espe-bretagne.fr)

*The work presented here concerns the teaching and learning of random variables at the secondary-tertiary transition. Our study takes place in France, where discrete random variables are studied in grade 11 and in the first post-secondary year. Comparing textbooks, we observe that random variables are introduced as tools for the modelling of random situations at grade 11, while they are presented theoretically at the post-secondary level. The answers of first year students to a test confirm this difference: they are able to use random variables to produce interpretations in a concrete situation, but are not prepared for the learning of theoretical definitions. These results can contribute to design a teaching intervention concerning probabilities for first year students.*

*Keywords: Praxeologies, Probabilities, Random variables, Registers, Secondary-Tertiary transition.*

### Introduction

Difficulties encountered by students at the secondary-tertiary transition have been analyzed in many research studies in mathematics education, with different perspectives (Gueudet & Thomas, in press). Some of these studies focus on particular mathematical topics: calculus or linear algebra for example. The transition issues concerning probabilities have been less studied so far; yet probabilities are present in many tertiary courses, for non-specialists of mathematics in particular, like biologists or economists. Our study, taking place in France, addresses this issue with a focus on the concept of random variable. Our research questions are the following:

- How is the concept of random variable taught at secondary school, at the beginning of tertiary education? Which similarities or differences can be observed?
- What do the students know about random variables after the end of secondary school, and does this prepare them adequately for what is taught in the first year of tertiary level?

We study these questions with an institutional perspective. We present in the next section our theoretical tools, and studies about the teaching and learning of probability which inform our research. Then we expose in Section 3 the context of our study and our methods. In Section 4 we present our results, coming from a textbook study and a test proposed to first year students. We draw conclusions from these results and present them in Section 5.

### Theoretical frame and related works

In our work we consider the secondary-tertiary transition as an institutional transition: the mathematics taught is shaped by the teaching institution, and is thus different at secondary school and university. We use the Anthropological Theory of Didactics (ATD, Chevallard, 2006), which introduces, in particular, the concept of praxeology. A praxeology has four components: a type of tasks,  $T$ ; a technique,  $t$  to accomplish this type of tasks; a technology  $q$  which is a discourse explaining and justifying the technique; and a theory  $Q$ . Comparing the praxeologies at the end of secondary

school and at the beginning of university can illustrate different kinds of changes in the mathematics taught (see e.g., Winsløw, Barquero, De Vleeschouwer & Hardy, 2014). Some changes are very general: for a given type of tasks, a single technique is taught at secondary school, while several techniques can be expected at university; similarly, at university the theoretical block (formed by the technology and the theory  $[q, Q]$ ) is more important than the practical block  $[T, t]$ . Other changes concern a particular type of task, for example in our case: “Determine the probability distribution of a random variable,” studied below.

We also use in our work the concept of semiotic registers (Duval, 2017). Mathematical concepts, in particular random variables, can be described through different semiotic registers: a text, a table, or a graph. Compared with secondary school, the institutional expectations concerning the flexible use of different registers increase at university (Gueudet & Thomas, 2018). Hence observing the registers used, in particular the need to combine several registers in the same technique for a given task, can illustrate discontinuities in the transition process.

Concerning probability, several works acknowledge the specific nature of probabilistic reasoning. Batanero et al. (2016) state for example that “probabilistic reasoning is a mode of reasoning that refers to judgments and decision-making under uncertainty and is relevant to real life” (p. 9). Such link between probability and real-life is emphasized by many authors, and in the curriculum of different countries (Batanero et al., 2016). However, some studies indicate that an important proportion of probability problems proposed to students are not related to real life situations and that the problems involve more algebraic than probabilistic reasoning (20% in entrance tests to university in Andalucía according to Batanero, López-Martín, Arteaga, & Gea, 2018). Student difficulties are observed and connected with the teaching practices; for example Burrill and Biehler (2011) claim that a formal teaching of probabilities focusing on set theory and counting techniques can hinder the understanding of the associated phenomena.

Research in mathematics education concerning random variables is scarce. At the beginning of university, Amrani and Zaki (2015) observed student difficulties, after a very formal teaching about random variables. Given a random experiment, they had difficulties proposing a model with an appropriate random variable and determining the probability distribution for a given random variable. Nevertheless these authors did not observe the impact of a less formal teaching.

## Context and methods

Our research takes place in France, where probability is an important part of the official curriculum at secondary school, starting at Grade 9. We focus here on Grade 11 of the scientific track (called “S section”). Students encounter random variables for the first time at Grade 11, in the context of discrete random variables. The concepts of *probability distribution*, *expected value*, and *variance* are defined; the Bernoulli and binomial distributions are introduced. According to the official curriculum: “*The concept of probability distribution of a random variable permits the modelling of random situations and their study with the tools of probability*”. At Grade 12 students encounter continuous random variables, with the concept of density and the Gaussian distribution.

We chose to focus on “preparatory classes” in the tertiary level, selecting high-achieving students, who want to enter a “*grande école*” after two years of preparation. The classes are organized is

similarly to secondary school, hence we claim that the institutional differences mainly come from the mathematics taught. Moreover, because they are high achieving, the difficulties encountered by these students should not come from an insufficient grasp of secondary school praxeologies. The official curriculum of the first year of preparatory classes (in our case an “Economics and Commercial – Scientific, ECS,” preparatory class) concerning random variables is limited to discrete random variables (continuous random variables appear only in the second year). The curriculum revisits the notions taught at Grade 11: random variable, probability distribution, expected value, and introduces the study of pairs of random variables, and independent random variables. The official curriculum states that “Modelling simple random situations with random variables is a skill expected from students”, meaning that the preparatory classes institution is not responsible for this modelling skill.

In the study presented here, we used two kinds of methods. First, we performed a comparative analysis of a secondary school textbook, and a preparatory class textbook. The secondary school textbook (Barbazo, 2015), is used by a large number of Grade 11 teachers in France. The students in the preparatory classes did have a textbook, but they often bought books to complement the course given by their teacher. The content across books was quite similar, so we chose Gautier and Warusfel (2012). We compared the chapters concerning random variables according to five characteristics: the structure of the chapters in terms of course vs exercises (theoretical vs practical block), the definition of random variable given (considered as an important aspect of the theory), the registers of representations used, the types of tasks and associated praxeologies, and the contexts in which the exercises and examples were situated. For each chapter studied, we listed and counted the types of tasks requested in each exercise or worked example. The theoretical block appeared mainly in the content parts of the chapters (definitions, theorems, demonstrations, proposals) whereas the practical block appeared in the exercise and example parts of these chapters.

Second, we designed a test and submitted it to the students from a first year ECS class before the teaching of random variables (see Appendix). The teacher only allowed us to use 20 minutes to administer the test in class, so we had to limit its length. The test started with three questions: mathematical definition of a random variable, how to explain to a Grade 12 student what a random variable is, and give an example of random variable; then an exercise in an economical context was proposed. This exercise, taken from a website for Grade 11, was typical from what can be found in secondary school textbooks for this level. It corresponded to a random situation in a “real” context. Nevertheless the students’ responsibility for modelling was reduced: the random variable to be studied was given in the first question. The types of task were: “Determine the distribution of a random variable (described by a text)”; “Compute the expected value of this random variable and interpret it”; and “Study the influence of a change in the initial data on the expected value”. Forty-four students took the test at the beginning of a course. We analyzed the students’ answers using the following categories: for Questions 1 and 2: elements of theory and technology used, errors, ideas or elements related to randomness, and type of answer (theoretical, related to randomness, other). For the Question 3 we looked at example correct or not, if not why, in what context it was stated, and which registers were used. For the exercise, the categories were: answer correct or not, the technique used, the technology (justification of the answer), use of registers, and result correctly interpreted.

## Modelling “real” situations and mastering formal definitions

### Comparing secondary school and preparatory classes textbooks

We noted a large difference in the proportions of courses/exercises within the chapters studied, in terms of number of pages dedicated to each: 15% for course in the Grade 11 textbook; more than 80% in the ECS textbook. We consider this as an indicator of the much greater importance of the technological-theoretical block in higher education, compared to secondary education.

Concerning the definition of random variable, in the Grade 11 textbook the students already knew the concept of sample space  $W$ ; a random variable  $X$  was defined as “a function from  $W$  to  $\mathbb{R}$ ”. We claim that this definition was difficult for Grade 11 students, who mostly met functions from  $\mathbb{R}$  to  $\mathbb{R}$ . The definition of the probability distribution; as a function from  $\mathbb{R}$  to  $\mathbb{R}$ , followed immediately and it was more familiar. In the ECS textbook, the definition of random variable was situated at a much more general level. The definition of  $\mathcal{S}$ -algebra was introduced together with the notion of probability space as a triple  $(W, \mathcal{F}, P)$ . In this context a very general definition of a random variable was given: “an application  $X$  from  $W$  to  $\mathbb{R}$  such that  $\forall x \in \mathbb{R}, \{w \in W / X(w) \leq x\}$  belongs to  $\mathcal{F}$ ”.

We categorized the registers of representations present in the parts of courses, in the examples of the courses and in the exercises of the chapters studied. We observed seven different registers: symbolic, natural language, and five kinds of graphical registers: tree diagrams, function graphs, tables for representing the random variable distribution, some charts representing the random situation and various illustrations (e.g., photos). The symbolic register and the register of natural language were omnipresent in both textbooks. The graphical registers were more frequent in Grade 11 (68 examples used these registers) than in ECS (18 examples). There were, in particular, many illustrations in Grade 11, and none in ECS. There were 36 tables representing the random variable distribution in Grade 11 and only six in ECS. Overall, there were very few tree diagrams. In the secondary school textbook, random situations were often represented by charts or diagrams, but relatively few by trees.

Regarding the contexts in which the examples and exercises were posed, we distinguish two categories: exercises and examples in a non-mathematical context and in a mathematical theoretical context (what Batanero, *et al.* 2018 call “problems with no context,” p. 113). This choice is governed by the claim of the secondary school curriculum, about the importance of random variables for “the modelling of random situations” (Ministère de l'Education Nationale, 2010, p. 5).

In the first category, *exercises and examples in a non-mathematical context*, we identified real-life situations such as the lifespan of a robot or the waiting time at a doctor, but also “artificial” situations such as a flea moving on a graduated axis or a drawing of balls from an urn. There were also situations in other scientific fields such as the study of physical uncertainty of measurement. The proportion of examples and exercises in a non-mathematical context is 78% for Grade 11 and 67% for ECS (out of a total of 108 exercises and examples, respectively 66).

In spite of this difference, we observed similarities concerning the types of tasks. For both Grade 11 and ECS, the three most frequent types of tasks were: “determining the probability distribution of a random variable,” “proving that a random variable admits an expected value and/or calculating it,” and “proving that a random variable admits a variance and/or calculating it.”

For example, for the type of task “determining the probability distribution of a random variable,” the following technique was described in the Grade 11 textbook: “(1) determine the possible values  $x_i$  for  $X$ ; (2) compute the probabilities  $P(X = x_i)$ ; (3) summarize them in a table”. This technique was linked with the fact that in most cases, the random variable took a limited number of values (in our test for example,  $X$  takes 4 different values), that could be presented in a table. In the Barbazo textbook, 104 exercises amongst 106 were about random variables taking a limited number of values. In the ECS textbook, in 20 exercises amongst 21 the random variable took its values between 1 and an integer  $n$ . To determine the distribution, the technique is consisted of finding a formula giving  $P(X=k)$  for  $1 \leq k \leq n$ . The associated technologies in the two institutions were provided by the definitions mentioned above. Thus the praxeologies were clearly different in each textbook.

Also the differences concerning the context lead, for similar types of tasks, to different responsibilities of the students in terms of modelling. In Grade 11, 19 exercises asked students to calculate an average payout or determine whether a game would be favorable or not to the player, with no intermediate tasks. For this type of task, the technique used was to select the appropriate random variable, and then determine its distribution in order to calculate the probability of a certain event. This modelling work is totally absent for ECS, although the proportion of exercises in the context of artificial situations is high. In these exercises, the random variable is always given and the types of tasks present are "determining the probability distribution" or "calculating its expected value".

### Students responses to the test

We recall here that the test started with three questions, concerning: the mathematical definition of a random variable, the explanation for a Grade 12 student of what a random variable is, and an example of random variable. These questions were directly linked with the theoretical block  $[q, Q]$ . Twenty-three of 44 students (52%) answered the first question, 33 of 44 students (75%) answered the second question, and 26 of 44 students (59%) answered the third question.

The answers were very often false or incomplete. The most common errors were confusion between the random variable and the probability distribution (which we expected, considering the definitions given in the textbook) and confusion between the definition of a random variable and its properties. In the first question concerning the theory, six students confused the definition of a random variable with its properties, and five students confused the random variable with the probability distribution. In the second question (in which students are expected to produce a technological discourse), three students confused the random variable with the probability distribution. In the third question, 11 students confused the random variable with the probability distribution.

The vocabulary and mathematical notations used by the students allowed us to distinguish two types of answers: theoretical answers in which we find a symbolic register with mathematical concepts and notations, and answers in relation to randomness in which we find a vocabulary in relation to randomness. Such answers contain ideas linked to chance, for example: “randomly draw a sample,” “results of a random experiment,” or “depends on chance.”

For the first question, students mainly gave a theoretical answer (19 of 23 students); only 4 gave an answer in relation to randomness. An example of theoretical response by student S2 is:

“A random variable is a law that associates a variable entity (price, size) with X.” (our translation)

The second question generated more diversity in the registers used by the students in their responses. We distinguish for this question a new type of response, in which students responded with a specific example of the use of a random variable. Almost a fourth of the students produced such a technological discourse, explaining in their answers how a random variable can be used (see the example below). These students seem to have incorporated the perspective of the official curriculum: random variables as tools for the modelling of random situations.

An example of this type of response by student S38 is as follows:

"it will be a question of insisting on the fact that a random variable is not fixed, it will allow specially to make calculations of returns, of profits. Know through expected value if it is relevant or not to play a game of chance. In order to be able to work on its expected value for example it will be necessary to draw up the law of probability (table of values)". (our translation)

Finally, on the third question, we were interested in the contexts in which students set their example. Eight of 26 students who answered this question gave an example in a real-life situation (e.g., the price of a chocolate bar, the price of a car, the life of a light bulb or the size of a plant) while four of 26 of students gave an example in an artificial context (e.g., a betting game, a die roll, or a drawing of balls from urns).

The students were more successful with the exercise than with the three preliminary questions. Thirty-seven of 44 students answered the first question that asked them to determine the distribution of a random variable (described by a text), 38 of 44 students answered the second question that asked them to compute the expected value of this random variable and interpret it, and 29 of 44 students answered the third question that asked them to study the influence of a change in the initial data on the expected value. Students who responded to these questions often offered a correct and well-justified answer.

Concerning the first question, a fourth of the students who answered used a technique involving the representation of the probabilistic situation with a diagram or a tree diagram. Questions of interpretation were often well addressed. Almost two thirds of the students who answered the second question gave a correct interpretation of the expected value.

Finally, we note that these students (who were high-achieving at secondary school) were able to use a random variable for the modelling of a concrete random situation. They interpreted the situation to find the distribution of the random variable, used it to solve a question concerning an expected value, but were unable to produce the correct theoretical/technological discourse needed at tertiary level.

## Conclusion

The questions we studied here about the concept of random variable concerned on the one hand the differences between secondary and tertiary levels; and on the other hand how well prepared students were by their secondary school for the teaching proposed at tertiary level.

The textbooks' comparative study evidenced as expected that the practical block was more important at secondary school while the theoretical block was more important in the preparatory classes. The

definition of random variable given at secondary school was less general, and immediately associated with the definition of the distribution, which is central in the exercises. Similar types of tasks were found in preparatory classes, but they corresponded to different praxeologies. For example, techniques were different because random variables met at secondary school had a limited number of values, while random variables in preparatory classes had values between 1 and  $n$ . At secondary school, random variables are introduced as tools to study situations and the focus was on the distribution, represented by a table. In preparatory classes, in contrast, the concept of random variable and the associated theory became central.

The student responses to the test are coherent with the textbook study: they were able to use a random variable for the study of a given situation but did not seem to handle well the theoretical and technological aspects. In particular they confounded random variable with its distribution. The textbook analysis suggests that secondary school teaching is probably not a sufficient preparation for what is expected at tertiary level, and our small sample of students seems to confirm this. Even if the concepts are the same, students at tertiary level are likely to meet difficulties for connecting the new theoretical aspects with their previous knowledge.

Beyond these observations, similar to the results obtained by studies about the secondary-tertiary transition for other topics (Gueudet & Thomas 2018), our work raises theoretical and methodological issues. Concerning the theory, the importance of modelling within the theme of probabilities leads to questions about “modelling praxeologies”: how can the praxeology be described? Which kind of theory is involved in it? It is necessary to answer these questions, in particular, to design a teaching intervention in which modelling plays a central role, and theory is also present. Concerning the methods, we have observed that the analysis of textbooks can contribute to identify changes of praxeologies between different institutions. Nevertheless, identifying the theoretical and the practical blocks in a textbook is not always straightforward; different textbooks can have very different structures. We consider that this is a direction open for a further methodological work, especially important for transition studies.

Naturally the study presented here remains limited. In a further work we will consider the learning of probabilities by non-specialists in the first year of university, with the aim to propose a teaching and associated resources combining the modelling of real-life situations and theoretical aspects.

## Appendix: English version of the test given to the students

*Please answer this little test without consulting any document: the goal is to know what you remember, at the end of high school, about random variables.*

1. Give the mathematical definition of a random variable.
2. How would you explain what a random variable is to a senior student?
3. Give an example of a random variable.
4. Solve (on the back) the exercise below.

### Optimization of a profit:

The cost of production of a laptop computer by the company MARBIC is 950€ .  
This laptop may have a defect  $A$ , a defect  $B$ , or both the defect  $A$  and the defect  $B$ .  
The warranty allows repairs to be made at the manufacturer's expense with the following costs: 100€ for the defect  $A$ , 150€ for the defect  $B$  et 200€ for the defect  $A$  et  $B$ .  
We admit that 90% of the laptops produced have no defects, 4% have the only defect  $A$ , 2% have the only defect  $B$  and 4% have the defects  $A$  and  $B$ .

1. We denote  $X$  the random variable which, with each laptop randomly chosen, associates its cost price, i.e. its production cost increased by the possible repair cost.  
Determine the probability distribution of  $X$ .
2. Calculate the expected value  $E(X)$  of this random variable. What does  $E(X)$  represent for MARBIC? It's assumed that all laptops produced are sold.
3. (a) Can MARBIC hope to make a profit by selling 960€ each product?  
(b) MARBIC wants to make an average profit of 100€ per laptop. Explain how to choose the selling price of the laptop produced.

# Participation of female students in undergraduate Mathematics at the University of Malawi

Levis Eneya<sup>1</sup>, Lisnet Mwadzaangati<sup>2</sup> and Mercy Kazima<sup>3</sup>

<sup>1</sup>University of Malawi, Faculty of Science, Malawi; [leneya@cc.ac.mw](mailto:leneya@cc.ac.mw)

<sup>2</sup>University of Malawi, Faculty of Education, Malawi; [lmwadzaangati@cc.ac.mw](mailto:lmwadzaangati@cc.ac.mw)

<sup>3</sup>University of Malawi, Faculty of Education, Malawi; [mkazima@cc.ac.mw](mailto:mkazima@cc.ac.mw)

*Keywords: Undergraduate mathematics, female students, student performance, student retention.*

## Rationale

In line with declarations to improve the education and literacy of women, Malawi, like many other African governments, has implemented various policies and action plans to improve access and participation of girls in both primary and secondary education. Since 1994 the government has progressively promoted a policy of 50:50 for selection of girls and boys to secondary schools (Ministry of Education, Science and Technology [MoEST], 2001). This policy has been accompanied by several gender reforms and interventions by the government and Non-Governmental Organizations (NGO's) to support the participation of girls in secondary schools, including school fee waivers, cash transfers, and building of additional hostels for girls in boarding secondary schools. Furthermore, the MoEST developed a National Girls' Education Strategy aimed at strengthening and improving girls' access and participation at all levels of education (MoEST, 2014). Despite these interventions, female students' access, success and retention in mathematics and science continue to be a challenge throughout secondary and higher education (Mbano & Nolan, 2017) sectors. This might be because the interventions mainly focus on improving general performance of the girls in schools and not necessarily focusing on girls' participation in mathematics and science subjects. We have not found any studies that have been conducted to find out how these female students sustain themselves both academically and socially during tertiary education in the absence of the interventions they were offered during primary and secondary education. This is important because after access to university, retention of the girls is necessary. Therefore, the purpose of this study was to examine the participation of female students in mathematics courses at the University of Malawi, and to explore possible strategies that would support and sustain participation of female students in mathematics at university.

## Methodology

The study adopted a mixed method approach using quantitative and qualitative techniques to investigate how female mathematics students cope academically. Quantitative methodology involved a desk study that analysed secondary data regarding female students' access, performance and retention in mathematics courses. Three cohorts of all students enrolled into Bachelor of Science and Bachelor of Education Science programmes in 2013, 2014 and 2015 were followed to their completion in 2016, 2017 and 2018, respectively. Qualitative methods involved interviews and focus groups discussions with 41 female mathematics students to gain in-depth insights into their views and experiences regarding access, participation and retention of female students in mathematics. Data analysis for quantitative data used Microsoft Excel to calculate frequencies and percentages. For qualitative data, responses were coded and categorised into themes that were not predetermined.

## Findings

### Retention

Results from desk study indicate that 15.1% of potential female mathematics majors at second year (compared with 24.7% for males) proceed to take at least two mathematics courses at years three or four due to various reasons including lack of support systems and planted fear resulting from, among other issues, negative correlation between entry grades and semester grades.

### Motivating factors to continue with Mathematics

When asked about what motivated them to study mathematics, and what will compel them to continue with the subject, students gave several reasons including: scoring good grades, having role models, learning the practical use of mathematics in the industry, and wanting to be role models to other girls. However, the most prominent response was the encouragement from fellow students and lecturers.

### Strategies and support that would help the learning and better performance in mathematics

When asked about strategies and the support that they think would help them in the learning of mathematics, all students (100%) mentioned tutorials for practice, while other strategies ranged from availability of teaching and learning materials (75%), conducive learning environment (50%), motivation talks (25%), and use of YouTube (10%).

### Implications

The study is ongoing, such that results after interviews with male students and lecturers will be reported in a separate poster or paper. However, the following implications can be drawn from the results this far:

1. The mathematics department need to introduce support systems for female mathematics students.
2. The department need to enhance and increase frequency of mathematics tutorials.
3. The department need to work together with stakeholders for continued policy interventions for female mathematics students.

### Acknowledgment

# Supporting the use of study skills in large mathematics service courses to enhance students' success – one example

Frank Feudel<sup>1</sup> and Hans M. Dietz<sup>2</sup>

<sup>1</sup>Humboldt-University of Berlin, Germany; [feudel@math.hu-berlin.de](mailto:feudel@math.hu-berlin.de)

<sup>2</sup>University of Paderborn, Germany; [dietz@upb.de](mailto:dietz@upb.de)

*Many university freshmen have difficulties in first year mathematics courses due to inappropriate study skills and learning strategies. In large mathematics service courses the effect of poor study skills is even worse because individual support is hardly possible. Past research shows that it is not sufficient to introduce new study skills because students often do not use these; they need first to be supported when working with them. In this paper we describe one possible support with a coaching program for a tool that aims to assist students in learning mathematical concepts. We describe the aims, the design, and the implementation of the coaching program supporting the students' work with the tool provided, as well as some evaluation results concerning reported students' benefit from the program, their attitudes towards the tool, and the frequency of use of the tool at the end of the coaching.*

*Keywords: Study skills, methodological support, mathematics for non-mathematics degree, coaching for study skills*

## Introduction and embedding of the research

Many students have problems in their first year mathematics courses at university due to insufficient study skills (Anthony, 2000). Empirical evidence suggests that promoting study skills in tertiary mathematics courses might lower students' difficulties in learning university mathematics (see, e.g., Cornick, Guy, & Beckford, 2015; Mireles, Offer, Ward, & Dochen, 2011). Teaching study skills is in particular successful if respective programs are integrated into the regular course (Hattie, Biggs, & Purdie, 1996). Hence, the second author, a mathematician, developed a methodological support program named CAT (Checklist, Ampel [=Traffic Lights], Toolbox) and, in 2010, integrated it into his course 'Mathematics for economics students' at the University of Paderborn. This program consists of several tools addressing different study skills (for details see Feudel & Dietz, 2019).

Past research, however, also showed that many students fail to use study skills and learning strategies taught to them or just do not use them at all (Anthony, 1996; Dembo & Seli, 2004). In a joint previous research project at the Centre for Higher Mathematics Education in Germany, the authors of this paper identified five additional reasons for such failure: 1) perceived time and effort required to use the methods provided, 2) difficulties in working with them, 3) perceived unhelpfulness of the methods, 4) perceived lack of benefit from them, 4) insufficient understanding of them, 5) using personal methods, and 6) no need (see Feudel & Dietz, 2019 for more details).

To address these problems, the authors developed a coaching program for one of the tools of the CAT program, the 'Concept Base' that aims to help students learn mathematical concepts. This tool was chosen because the authors conjectured that a suitable coaching program could address the two

main reasons for not using it: ‘perceived time and effort compared to the benefit’ and ‘difficulties when working with the methods’. These two reasons are also described (not verbatim but in terms of the content) as important reasons for not using study skills taught or optional resources provided in literature (Dembo & Seli, 2004; Guthrie, 2010). The ideas behind the coaching program to address these reasons for the non-use of the Concept Base can be also probably transferred to other study skills or optional resources provided in mathematics courses.

### Short description of the *Concept Base* tool

The tool was conceived as a study skill that should help students learn mathematical concepts. The ‘Concept Base’ is a system of various categories that students should attend to in order to make sense of a mathematical concept. These categories include: the definition of the concept, examples, non-examples, visualizations, statements involving the concept and applications. The category system was developed by the lecturer H. Dietz of the course based on his teaching experience. But these categories are also labeled as crucial in didactic literature for gaining understanding of mathematical concepts (Tall & Vinner, 1981; Vollrath, 1984).

The lecturer H. Dietz advises the students to attend to the Concept Base categories for each mathematical concept taught in the course. He also points out that the knowledge of the categories is also required in the exam. Further, he recommends the students to write them down for important concepts, for example for the ones covered in more than one lecture. These written Concept Bases may also serve as summaries when preparing for the exam later in the semester. The students can download an empty template from the course homepage as support (Figure 1).

Keyword/ Name of the Concept: Symbol:	
Definition:	
Examples:  Non-Examples:  Visualization:  Important statements:  Applications:  Further Annotations:	

**Figure 1: Template of a Concept Base (scaled down from one page)**

A written ‘Concept Base’ as a summary of aspects of a mathematical concept is also closely related to the idea of a ‘concept map’ by Novak and Cañas (2008) that organizes knowledge related to mathematical concepts. However, the latter focuses more on linking different concepts while the ‘Concept Base’ focuses on categories crucial for gaining an understanding of a single concept (for acquiring an adequate concept image in the sense of Tall & Vinner, 1981).

## **Framing of the coaching program to support the use of the Concept Base**

As pointed out in the introduction, the majority of the students did not use the tool ‘Concept Base’ after its introduction in the course in 2010, although the lecturer advised them to do so. To address two of the reasons identified in prior work on reasons for not using the Concept Base (Feudel & Dietz, 2019), specifically ‘perceived time and effort required for the creation of the Concept Base compared to its benefit’ and ‘difficulties when trying to create Concept Bases’, the authors designed a coaching program addressing these problems in the winter semester of the academic year 2016-2017. Its goal was to help students overcome difficulties with the tool ‘Concept Base’ and see its benefit, so they might use it on their own.

The design of the coaching program was based on the ‘Decoding the disciplines’-model by Middendorf and Pace (2004). The model consists of seven steps that are important for a successful implementation of subject-specific study skills and working techniques into a university course. It was developed by faculty members of different disciplines at Indiana University at Bloomington on the basis of similar problems they had experienced when trying to implement study skills and learning strategies in university courses. The seven steps are:

- 1) Identification of students’ difficulties
- 2) Identification of strategies that experts of the subject (here: the lecturer as a mathematician) would use to overcome these difficulties
- 3) Demonstration of the strategies in the course
- 4) Exercise of the demonstrated strategies with the students including feedback
- 5) Motivation of the students to continuously use the strategies provided
- 6) Evaluation of the effectiveness of the strategies provided
- 7) Sharing of the knowledge acquired

In our case the recognition of the students’ difficulties by the lecturer, the development of the Concept Base and its implementation into the mathematics course were exactly steps 1-3.

Steps 4)-6) were realized in a systematic manner with the coaching program that was developed, implemented, and evaluated. Although students had practiced creating Concept Bases in the course tutorials that accompanied the lecture before 2016, the frequency and the intensity of its use varied across the tutorials because there was no mandatory guideline.

## **Design and implementation of the coaching program**

The program consisted of two parts: I. one workshop to practice the creation of Concept Bases (Step 4 of the ‘Decoding the Disciplines’-model), and II. submitting four written Concept Bases for further practice including feedback (still Step 4) and for motivating further regular use of the Concept Base (Step 5 of the model). The workshop was carried out after the Concept Base was introduced in the lecture in December 2016 by the first author and another tutor of the course who was familiar with the Concept Base. The second phase, the submission of the Concept Bases, took place afterwards during the second half of December 2016 and during January 2017, and was also conducted by the first author.

**Participants of the coaching:** Due to capacity restrictions only 50 participants could take part in the program (workshop + submission phase, 48 finished both). They volunteered to take part by writing an email to the first author (a randomized design was not possible due to ethical reasons, but the participants did not receive a reward). Hence, when evaluating the coaching, one has to take into account that these students were willing to work and to invest time for their study program.

### **Detailed description of the two parts of the coaching program:**

*Part I - the workshop:* The workshop had several aims:

- 1) Clarifying the benefit of the Concept Base to the students
- 2) Providing different suggestions how Concept Bases can be created
- 3) Helping students to overcome first difficulties when creating Concept Bases

It consisted of four phases:

1. Explanation of the benefit of Concept Bases by the leaders of the workshop
2. Creation of a Concept Base for the concept 'preference relation' on a poster in groups of 4-5 students (supported by the leaders of the workshop if questions occurred)
3. Comparison of the different Concept Bases in a poster session with discussion
4. Revision of the Concept Bases based on the discussions in Phase 3

Afterwards, pictures of the Concept Bases that had been created in the workshop, were taken and sent to the participants via email as stimuli for creating their own Concept Bases.

These activities were meant to address three problems found out in previous research causing the non-use of the Concept Base. First, the reason 'difficulties with creating a Concept Base' was directly addressed by helping the students during the workshop. Second, the reason 'perceived lack of benefit' was addressed by communicating one main benefit of the Concept Base explicitly right at the beginning: the possibility to use it as summary when preparing for the exam. And third, the reason 'use of own methods' was addressed. It had been found out that students felt constrained by the template in Figure 1. Hence, the adaptability of the 'Concept Base' according to the students' own preferences was underlined by (1) emphasizing that the important aspect of a Concept Base is the categories and not how they are arranged on the paper, (2) by motivating the students to extend their Concept Bases by further categories if needed (e.g., by a personal concept definition, Tall & Vinner, 1981), and (3) by providing lots of different examples of Concept Bases in the workshop.

*Part II: Submission of four written Concept Bases with feedback:* The aim of this phase was to continuously support the students when creating Concept Bases to further reduce the difficulties with the tool. In addition, the authors wanted for the students to get more experience creating Concept Bases and become more time efficient, which could address the reason 'time effort' for not using the Concept Base.

This phase was implemented as follows. The students were asked to create a Concept Base for four concepts: 1) monotonicity, 2) derivative, 3) convexity, and 4) Cartesian product of sets. The first three concepts were simultaneously taught in the lecture. The Cartesian product had already been taught at the beginning of the semester. This concept was chosen to motivate the students to also create Concept Bases for the concepts taught before the introduction of the tool in the course.

The first author provided feedback to the students on each of the four Concept Bases. The feedback had one quantitative and one qualitative component. The quantitative component was a list of aspects of the concept the authors expected the students to know. If an aspect on the list was found in the student's Concept Base it was marked with a check. Otherwise it was marked with a cross. In this way students could get an idea of the scope of the concept. In the qualitative feedback the students were given methodological hints for future Concept Bases, for example to structure the Concept Base on the basis of its categories. Mathematical mistakes in the students' Concept Bases were marked as well. The feedback gave the students ideas about what to include concretely in Concept Bases, and to help them become more efficient in their creation.

## Evaluation of the Concept Base coaching

For the 6<sup>th</sup> step of the 'Decoding the disciplines' framework we carried out an evaluation. In order to find out (1) to what extent the Concept Base coaching was helpful to the students, (2) to what extent they saw the benefit of the Concept Base before and after the coaching, and (3) whether the students used the Concept Base on their own in the following semester, several data was collected:

1. Data from a questionnaire administered to the coaching participants in January 2017 (N = 48)
2. The results of the final exams (in February 2017) of all students from the course (N = 821)
3. Data from one follow-up question administered in the next semester in June 2017 (N = 357)

*1) Questionnaire for the coaching participants:* The questionnaire comprised of two blocks of questions.

I. To find out if the coaching program and its components (workshop, submission of four Concept Bases) was helpful to the students the questionnaire contained 10 Items with statements about the perceived helpfulness of the coaching program. An example is 'The Concept Base coaching helped me to get a better understanding of the concepts, to which a Concept Base had to be submitted.' The answers format was a 1-6 Likert-scale (1='Do not at all agree' to 6='Totally agree'). The items can form a scale 'perceived helpfulness of the coaching program' ( $\alpha = 0.778$ ). Furthermore, the survey contained two items asking if the time for the participation was well invested.

II. To find out if the students saw a benefit of the Concept Base before and after the coaching the questionnaire contained a question asking about the perceived benefit of the Concept Base before and after the coaching program. The students could choose from several options that had been identified in previous research (Feudel & Dietz, 2019). Sample options were 'better understanding of the concepts' or 'summaries for the preparation of the exam'. Multiple answers were possible.

*2) Consideration of the results of the final exam:* To get an idea if the coaching might have had a positive effect on the students' performance, we also looked at the exam results. To mediate the effect that the participants were probably more motivated, we generated two special groups for the comparison of the exam results by asking all students of the course the following two questions<sup>1</sup>:

---

<sup>1</sup> These questions were administered in January 2017 and were part of a larger survey about the tool 'Concept Base' not described in detail here because the focus of the paper is on the coaching.

‘Would you participate in the coaching program if it was offered next semester again?’

‘How often do you use the Concept Base?’ (answer format was a 1-6 Likert-scale from 1=‘never’ to 6=‘every week’)

We suspected that students who would agree on the first question and did not take part in the coaching were probably as motivated as the current coaching participants. With the second question we wanted to find out if the coaching really made a difference (and not just the use of the tool alone). Finally, all students were asked for their final grades in mathematics at school to find out if better results might only be due to better initial mathematical qualification.

3) *Follow-up question in the next semester:* In the following semester all students in the subsequent lecture “Mathematics for economics students II” were again asked the question ‘How often do you use the Concept Base?’, in order to find out if the participants of the coaching continued using the Concept Base on their own.

### Some results of the evaluation

*Results concerning the perceived helpfulness of the coaching program by the participants:* Many participants found the coaching program helpful. The parameters of the 10-item scale ‘perceived helpfulness’ mentioned above ranging from 1=‘not at all helpful’ to 6=‘very helpful’ are:  $\bar{x} = 5.08$ ,  $\tilde{x} = 5.3$ ,  $s = 0.58$ . The distribution of the answers to one sample item is shown in Table 1.

<i>The Concept Base coaching helped me to get a better understanding of the concepts, to which a Concept Base had to be submitted.</i>
