The learning trajectory is structured into six parts: 1. introduction of negative numbers, 2. ordering of negative numbers, 3. subtraction with a positive subtrahend, 4. addition of negative numbers, 5. subtraction with a negative subtrahend, and 6. multiplication of negative numbers. Each part of the learning trajectory has the same structure. It starts with sequences of tasks using the induction extrapolatory method (Figure 1) in order to foster students' diagrammatic reasoning. Every sequence consists of six to eight tasks and shows a pattern that the learners are supposed to identify. The learners know these task sequences from learning arithmetic in primary school. Therefore, they know that the sequences have patterns and they are familiar with completing these patterns. For every sequence of tasks, the learners have to work on three tasks: The first task is to describe the identified pattern verbally using phrases like 'the minuend/subtrahend/difference remains constant/increases/decreases by one/two/...'. Thereafter, the learners have to complete the sequence of tasks according to the identified pattern. The last task is to transfer the tasks into a table, where they can further explore task relations. Based on the insights from their explorations, the learners either have to formulate a rule and consolidate this rule by working on further examples or they have to verify the given rule. These activities are based on Pierce's notion of diagrammatic reasoning. Students' need to manipulate diagrams according to rules that they perceive by exploring the structure of the diagrams. By formulating rules, they have to express the result of their explorations in general terms.

$$\begin{array}{rclcl}
 3 & - & 2 & = & \underline{\hspace{1cm}} \\
 3 & - & 1 & = & \underline{\hspace{1cm}} \\
 3 & - & 0 & = & \underline{\hspace{1cm}} \\
 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}} \\
 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}} \\
 3 & - & \underline{\hspace{1cm}} & = & \underline{\hspace{1cm}}
 \end{array}$$

**Figure 1: Sequence of Tasks at the beginning of the section**

In this paper, we focus on the subtraction of negatives (part 5 of the HLT). The first sequence of tasks in this section is shown in Figure 1. In this sequence, there are different diagrams in the sense of Pierce, which are on two different levels of the task sequence. On the first level, every task is a diagram in itself, because it represents the relation of the minuend, the subtrahend and the result. On the second level, the whole sequence is also a diagram because the single tasks are related and exhibit a particular pattern. In the case of the task sequence in Figure 1, the minuend of all the tasks is fixed (3) and the subtrahend is reduced by one from one task to the next. Consequently, the results increase by one from one task to the next.

In terms of the students' learning process, we hypothesize that the students have to work on diagrams on both levels when solving the tasks. First, they can solve tasks one to three in the sequence, which should be familiar to them from natural number arithmetic. Referring to the ideas of diagrammatic reasoning, these are manipulations on diagrams on the first level. In the next step, they need to explore the structure of the sequence on the second level. In other words, they have to investigate the properties and relationships of the second level diagram. After exploring the structure, they can complete the tasks four to six, which are new to them, by referring to the structure. These are also manipulations on diagrams on the second level. For learning, how to subtract a negative number from an integer, it is important to switch in between the diagrams on the different levels and relate to them once again as described above. The students have to recognize how the calculations of the tasks

including the subtraction of negative numbers are carried out. Relating to the idea of diagrammatic reasoning, this is the investigation of properties and relationships of the diagrams on the first level.

In summary, we hypothesize that the students' learning process related to the subtraction of negatives involves an interaction between the diagrams on two different levels. The students need to operate on diagrams on the first level, then refer to the structure of the diagram on the second level and get back to the diagrams on the first level in order to solve the tasks. By deriving the results of tasks that involve the subtraction of negatives from the structure of the diagram, they are able to get an insight into the algebraic permanence principle and thus could develop a formal understanding of the rule for subtracting negatives.

## Methodology

Data was collected in five 6<sup>th</sup>-grade classrooms in a German secondary school. The students worked on the HLT in pairs in a separate room. Altogether, we videorecorded eight pairs of students while working on the HLT.

In order to reconstruct the diagrammatic reasoning of the students, we use Toulmin's (2003) "pattern of an argument" as an analytic tool. Toulmin's core structure – or "first skeleton" as he puts it – of an argument has been used productively in mathematics education research to analyse students' reasoning (e.g. Fetzer, 2003; Reid, et al. 2008). The core structure of an argument is composed of three components: The *data* are the facts, which are the basis of the *conclusion*, "whose merits we are seeking to establish" (Toulmin, 2003, p. 90). *Warrants* are propositions like rules, principles and inference licenses. They are used "to show that, taking these data as a starting point, the step to the original claim or conclusion is an appropriate and legitimate one" (Toulmin, 2003, p. 91).

Arguments and diagrammatic reasoning are linked by the role of rules. Diagrams are embedded in a system which has rules and the manipulation of diagrams in the sense of diagrammatic reasoning is rule-based. The warrants in students arguments related to relationships and properties of a diagram should explicate the rules of the diagram as the students explored them. Therefore, the analysis of students' reasoning based on Toulmin's scheme provides an analytic tool to reconstruct the rules on which their diagrammatic reasoning is based.

In a first step, we reconstruct students' argumentation based on Toulmin's pattern of an argument. We further frame each argument in terms of the level of diagrams it relates to: level 1 or level 2. Finally, we draw conclusions about students' diagrammatic reasoning based on an interpretation of their argumentation.

## An example analysis of students' actual learning process

In this exemplary analysis, we focus on the learning process of two girls, Mia and Marlen. They are working together on the HLT. We are focusing on the beginning of the section "We subtract negative numbers" and especially on their work on the sequence of tasks shown in Figure 1. Due to space limitations, we can only analyze two short episodes from the whole learning process.

The episode in Table 1 starts at the beginning of the students' work. Their task is to describe the pattern of the sequence:

		level 1	level 2
8	Mia: It's decreasing in a). In a) the first [points on the minuends] remains constant and the second [points on the subtrahends] decreases by one.		D1
9	Marlen: But we also have to describe the ... The result decreases o... No...		C1a
10	Mia: Heh?		
11	Marlen: ... increases by one.		
12	Mia: No.		
13	Marlen: Sure, the result always increases by one.		
14	Mia: Decreases ... by one. There are negative numbers, Marlen.		C1b/ W1b
15	Marlen: No, look. Three minus two is one. Three minus one is two. Three minus zero is three. ...		W1c
15a	Marlen: ... Three minus one ...	D2	
16	Mia: ... minus one ...		
17	Marlen: ... minus minus one. That would be ... two ...	C2	
17a	Marlen: ... Then it's decreasing. Well, the difference first increases and then decreases, right?		C1c

**Table 1: First episode from the transcript 6b\_Subtraktion2\_1**

In line 8, students express data (D1), which is the starting point of their argument (The minuend remains constant and the subtrahend decreases by one). From this data they draw three different conclusions. The first conclusion (C1a) is that the results increase by one. This argument is not explicitly supported by a warrant. According to Fetzer (2003, p. 33), this is a simple inference, which has only data and a conclusion and no legitimation through a warrant. Their second conclusion (C1b) is that the results in the sequence of tasks decrease by one. It is legitimated by the warrant "There are negative numbers" (W1b). The last conclusion Marlen draws from (D1) in this episode is that the results first increase and then decrease (C1c). The warrant (W1c) is the calculation of tasks one to four in this sequence.

All arguments based on D1 in this episode are on the level of the sequence, i.e. on the diagram on the second level. Additionally, there is a simple inference on the task level, i.e. on level 1 (lines 15a and 17) with the task  $3 - (-1)$  as data (D2) the result "2" as the conclusion (C2). This simple inference is important, because it is one essential part of warrant (W1c), which supports to the conclusion (C1c) that the results first increase and then decrease.

Following the episode in Table 1, the teacher asks the students to reason, why the results first increase and then decrease. He further asks them to fill in the blanks in the task sequence. After they finished filling in the blanks, the following episode starts.

		level 1	level 2
27	Teacher: [...] Well, and if you recognize, after you have got up to the three. Did we have sequences of tasks, in which the results first increase and then decrease or vice versa?		D5
28	Both: No.		
29	Teacher: And what's the next result?		
30	Mia: Probably it goes on and on. ...		C5b
31	Marlen: Probably four.		C5a
32	Teacher: Right.		
33	Mia: ... Because here (points at another sequence) it is the same, but here the first summand changes.		W5b
34	Teacher: Yes .... It means, when continuing the pattern, the next result is ...		C5a
35	Marlen: ... four.		
36	Teacher: Right.		
37	Mia: Heh? It decreases by one. It decreases, Marlen.		
38	Marlen: But we didn't have a sequence so far, in which the results first increase and then decrease suddenly. It is a kind of pattern, but I don't understand why it is.		W5a

**Table 2: Second episode from the transcript 6b\_Subtraktion2\_1**

In this episode, the data of all conclusions is given in line 27: The results of the first three tasks in the sequence are “1”, “2” and “3”. The first conclusion (C5a) based on this data (line 31) is that the next result is (probably) four. This is a simple inference without a warrant. The second conclusion (C5b) in line 30 is justified by warrant (W5b) in line 33, which refers to another sequence of tasks on the same page. In line 34, the teacher repeats the conclusion (C5a), but now Marlen provides a warrant (W5a): She refers to other known sequences of tasks. There it never occurred that the results of the tasks first increase and then decrease or vice versa.

## Discussion and Conclusion

In our description of the hypothesized learning process, we argued that diagrammatic reasoning, which relates diagrams on two levels of the task sequence in Figure 1, is crucial for students' formal understanding of the rule for subtracting negative integers. The students have to work on diagrams on the first level to see the pattern of the diagrams on the second level. Referring to the pattern of the

diagram on the second level, they can solve the tasks (diagrams on the first level) which include manipulations on the new mathematical objects, i.e. negative numbers. Comparing the eight pairs of students reveals that most of them actually follow this hypothesized learning process. Only two pairs struggle with the sequence shown in Figure 1. Both of them are only working on the diagrams on the first level, i.e. they try to solve all the tasks before referring to the structure of the task sequence. As opposed to the pair of students described in this paper, the other pair is not sticking as consequent to the idea that instead of subtracting a negative number they can subtract the additive inverse.

However, the reconstruction of Mia's and Marlen's argumentation in the two columns behind the transcript reveals that the students work on diagrams on both levels, but not in the hypothesized way. The crucial point in their diagrammatic reasoning occurs in lines 15-17. We hypothesized that for a formal understanding, it is important to refer to the structure of the task sequence in order to derive the result of the task  $3 - (-1)$ . The analysis shows that the students conclude that the result of this task is 2 (C2 in line 17). Because of the missing warrant in this argument, it is not possible to reconstruct the rule of their manipulation on the diagram on level one. According to their reasoning, the inner relationship of this diagram on the first level is, that the difference of "3" and "-1" is "2". As opposed to our hypothesized learning process, the students do not infer the result of the task from the relationships of the diagram on level two, but vice versa. Their further reasoning reveals that the simple inference  $D2 \Rightarrow C2$  (lines 14-17) is part of the warrant for the conclusion that the results first increase and then decrease, which relates to the inner relationship of the level 2 diagram. Consequently, instead of inferring the rule for manipulating the level one diagram  $3 - (-1)$  from the relationships of the level two diagram, they do it the other way around.

With the intervention of the teacher they get the correct results for the 'new' tasks, but as a result of lines 15-17 the students do not understand why the results are correct (lines 29-30). From the point of view of diagrammatic reasoning, the students use the structure of the sequence to complete the tasks, but they are not able to recognize the rules for manipulating tasks comprising the subtraction of negative numbers.

The comparison between the hypothesized and the actual learning process shows that it is very important how students relate to diagrams on the different levels in their diagrammatic reasoning in order to develop a formal understanding of the rule for subtracting negative integers. The analysis of two students' reasoning revealed that relating the diagrams on the two levels other than in the hypothesized way might lead to inferences that violate the permanence principle. Therefore, students might need support in our HLT in order to relate the diagrams on the two levels in productive ways. As in our case, the support could be provided by the teacher. A different option is to redesign the task in a way that it will guide students more closely to consider the relation of the diagrams on the two levels. This could be achieved by splitting the task sequence into two parts, a familiar part (tasks one to three of the sequence) and a 'new' part (tasks four to six in the sequence). After solving the tasks in the familiar part, students are asked to analyze the structure of the task sequence and continue the task sequence accordingly. Based on their analysis they are asked to draw conclusions about the results of tasks four to six.

In our analysis, the theory of diagrammatic reasoning helped to identify the crucial obstacle in both, the hypothesized and the actual learning process. The in-depth analysis has proven to be very fruitful in order to better understand students learning processes related to particular task types. Based on the findings, it was possible to derive substantiated ideas for the redesign and the implementation of the task and thus, the inductive extrapolatory method. However, the analysis carried out in this paper does not provide evidence that a formal perspective rather than one focused on real-world scenarios is helpful in developing understanding in this area.

## “First you have to know it exists.”

### Cultivating teachers’ thinking about resource options

Helen Siedel

Visiting Research Associate, Wolfson College

Cambridge University, UK

[helensiedel@hotmail.com](mailto:helensiedel@hotmail.com)

*Professional development activity with a secondary school mathematics department in England aimed to further teachers’ knowledge of their resource options in order to better inform the resource choices they make and support their ability to use resources to design effective instruction. Participants conceptualized individual resources as representatives of resource types, drafted a model to represent types, and compared types using indices (exponents) as a focal topic. This paper reports on a study of that activity. Findings suggest that learning more about resource options assists and interests teachers and that using a focal topic to explore, characterize, and compare resources has merit. Organizing resources by type for use as a tool for finding resources and coordinating their use in a resource system appears beneficial, but would require work over time.*

*Keywords: Mathematics education, resources, curriculum resources, resource system, resource selection*

### Introduction

Resource options for teachers are burgeoning. However, despite calls for providing opportunities to develop teachers’ resourcing skills (e.g., Rolando, Salvador, & Luz, 2013), and the recognition that teachers choose to use multiple resource types even in countries where prepared curriculum materials such as textbooks have dominated (e.g., Webel, Krupa & McManus, 2015), little is known as yet about how to help mathematics teachers select resources advantageously on behalf of student learning. One question that arises is whether teachers are familiar enough with the full range of available resources to make well-informed selections. In order to select and use a resource, a teacher must first know that it exists, as suggested by the quote from a secondary mathematics teacher in England in the title of this paper. Unknown resources are effectively inaccessible.

Siedel and Stylianides (2018), in a study of secondary mathematics teachers in England, found that teachers with considerable autonomy and responsibility for resource selection did not know about or were not selecting several potentially useful types of resources. To investigate further, the authors introduced a construct called “the pool of possibilities” (p. 121) to represent all instructional resource options for a teacher population, including human, cultural, social, material and digital resources. Teachers in the study discussed here, the Resource Types study, had an opportunity to learn more about their resource options by exploring their pool of possibilities.

Although the pool of possibilities and the work teachers undertake to find resources in a pool of possibilities have received limited attention in studies of teacher-resource interactions, literature about teachers’ selection, adjustment and construction of resources was pertinent to the Resource

Types study (e.g., Pepin, Gueudet, & Trouche, 2017). One premise for the study was that knowledge of resource options, including familiarity with the range of resource types, supports what is described as teachers' "mathematics-didactical design capacity" (Pepin, Gueudet, & Trouche, 2016, p. 2), that is, their ability to use or construct resources to plan effective instruction. The "focal topic approach" introduced in this paper, for example, illustrates that examining and comparing a variety of resource types for a particular mathematical topic might augment teachers' knowledge of mathematics, of teaching, of student learning, or of resource features. Knowledge of options can thus support the development of other resources, regardless of whether a teacher chooses the options for further use.

The idea of "resource system," an "evolving notion" in mathematics education (Ruthven, 2018, slide 2), framed the study. When teachers interact with various resources in various ways, they typically acquire a collection of individual resources to support their work. As described by Ruthven (2018), a collection of resources becomes a resource system by application of an organizing principle intended to make the collection function more effectively. Often the organizers are teachers, who may seek to unite stand-alone resources in some way to produce a coherent whole, a resource system. Teachers in the Resource Types study were invited to organize resources using the principle that individual resources are representatives of resource types that can be usefully classified and related. Participants applied this principle to a wide range of individual resources and types of resources from their pool of possibilities, not all of which were familiar. The supposition was that identifying types of resources and classifying by types could, first, enable and motivate teachers to select from a wider range of options in their pool of possibilities by increasing the number of resources familiar to and thus accessible to them. Second, regardless of how teachers prefer to use or construct resources, knowing more about a variety of types, and comparing types, might support more advantageous resource selection and ultimately a stronger resource system.

The research question for this study was:

What sorts of professional development activities enable secondary mathematics teachers to draw on a wider range of resources when developing their resource system?

## Methods

The two-hour Resource Types session occurred in the final month of a nine-month pilot study about the mathematical symbol known as the minus sign, conducted with the mathematics department for 11 to 16 year olds at a state secondary school in the South East Region of England. All eight teachers in the department were present for the Resource Types session. At the inaugural session of the overall pilot, teachers were introduced to instructional resources as a topic of interest for their department that would be folded into the minus sign exploration; they also completed surveys about their resource use. Indices (exponents), the mathematical topic for the Resource Types session, was included in the pilot as one of the topics where the minus sign is known to be problematic.

The Resource Types session had two parts. Part 1 introduced the idea of classifying resources by type. In Part 2, using the "focal topic approach," indices (exponents) was a focal topic for comparing diverse resource types featuring content specific to that topic. Both parts included guided discussion. The full session was audiotaped using two recorders; slides used during the session were

posted afterwards. At the department meeting one week after the Resource Types session, participants completed a follow-up survey and had an opportunity to sketch their thinking about a typology for resource types. Participants were encouraged to add comments.

In Part 1, using the “list approach,” teachers worked in pairs to brainstorm categories for types of resources and began to organize the types, first using a list of sixteen familiar resources, then a list of twenty-two others, less familiar, and thirdly a proposed list of categories for resource types accompanied by commentary and questions. The department head, also a teacher participant, led discussion after the group had time with each list. Part 1 was open-ended and fast-paced, not intended to lead conclusively to any well-developed classification by types. Part 1 concluded with the group’s first attempt to graphically organize “types of resources.”

In Part 2, participants reviewed the treatment of indices in a researcher-selected set of resources representing types, in order to examine, characterize, and compare types. The set of types included two contrasting blogs, a research article, traditional curriculum materials, a site to design assessments, a book with rationale for mathematics procedures, a mathematics information site, and a mathematics educator’s website with teaching suggestions for numerous topics. These represent some types of resources not mentioned by most teachers in the Siedel and Stylianides study (2018).

Part 2 initially focused on two blog posts by Dan Meyer (dy/dan, 2015; dy/dan, 2016) because these exemplified the value of searching for resources using non-British mathematical terms (“exponents” rather than “indices”), contained rich user discussion that mentioned other resource types, included a “research into practice” example, and included a variety of teaching strategies and activities. Those posts and the research article (Cangelosi, et al., 2013) were characterized and compared as types. Due to time constraints, examination of the remaining types was brief.

The follow-up survey was administered at the department meeting a week post-session. Drawing on Guskey’s (2016) levels of evaluation for professional development, which also informed data collection and analysis for the session itself, the survey was designed to determine participants’ affective response to the Resource Types session, their learning about individual resources or about the idea of resource types, and whether as individuals or as a department they were likely to use what they learned. At that post-session meeting, as part of a separate activity, teachers were also invited to diagram or otherwise describe their current thinking of how types might relate.

## Results

Data were identified by researcher observation of the session, review of the audiotapes, and teachers’ written responses in the follow-up activity. Data from conversations in Parts 1 and 2 of the session were qualitative. Teachers appeared fully engaged throughout the session; there was evidence they were learning about individual resources and about resources as exemplars of types. Quantitative survey data (Table 1) and teachers’ written comments (Table 2) supported this.

During Part I, resources in the first of three lists participants worked with were familiar to most. They were asked to use the list to generate categories for resources from the new perspective of resources as types. They quickly generated categories that appeared to be based on what a resource facilitates, such as “problem-solving,” “worksheets and homework,” “develops ideas,” “direct

teaching.” With the second list, however, the resources were less familiar; much of that conversation consisted of teachers trying to learn about a resource in order to identify it by type. For example, someone familiar with a resource could describe it to others. This was an opportunity for participants to learn about the existence of a resource. Categories for types from this list included “technology” and “what level it addresses.” These were broader categories, less activity specific. The third list, a proposition of types, surprised teachers because there were many (twenty) types.

As teachers worked with the 3<sup>rd</sup> list, teachers remarked about some they had not thought of, such as “books.” Later, in Part 2, reviewing types of resources for indices, the group decided to purchase a book that was mentioned; they had not known about the book. Such incidents were evidence that participants were learning about previously unknown resources or broadening their range of types.

During Part 2, participants had an opportunity to evaluate the pre-selected set of individual resources representing a variety of types for the topic indices. Teachers thus learned about these individual resources, while other individual resources were mentioned in the discussion. For example, a discussion about an assessment site prompted mention of a forthcoming resource for UK educators associated with the assessment site. Most participants had not known of its existence.

Results from the follow-up survey, shown in Tables 1 and 2, indicate that as a result of the session, some teachers were already visiting online resources in the following week. One teacher, for example, went to a site providing information about mathematics to look up definitions. In the last comment of Table 2 (Teacher 8) the participant expresses an interest in using as wide a range of resources as possible, which would likely involve searching for new resources.

The tables indicate teachers were likely to use ideas about “types of resources” to organize their own interactions with resources or to consider relationships among resource types. The data in Table 1, from the follow-up survey, attest to interest in, ongoing thinking about, and discussion of resource types. Most teachers found the session useful; some had been actively engaged afterwards. Table 2 suggests that some teachers will continue using the teacher-student dichotomy they generated as the basis for a typology (Teacher 2). Comments in response to a question about what stayed with them after the session suggest that these teachers are likely to think about the benefits of classifying resources (Teacher 4), but are aware that there are many types (Teacher 3). Thinking of types promotes learning about their work with resources (Teachers 5 and 8) and, for some, relating them. It also indicates awareness of the difficulty of organizing by type (Teacher 6), with fewer categories a possible objective. Some want to pursue this further (Teacher 7).

Teachers’ attempts to graphically organize resources as types also contributed data. Asked to diagram the categories for resource types during the session itself, one pair proposed two unlinked central categories, labeled “teacher resources” and “student resources.” The group accepted this. They began to place other categories they generated from the first list as subcategories. At this point the visual resembled a pair of main idea webs. One teacher noted that a resource could also be “mixed,” with provisions for both teachers and students. A week later, at the department meeting where participants completed the follow-up survey, but as part of activity apart from the survey, teachers were asked to diagram or discuss their current thinking about how to diagram the relationship of resource types. Five teachers responded. Four used the teacher-student dichotomy,

however one of these drew an arrow from teacher to student, linking the two. Another drew three intersecting circles, as in a Venn diagram. These were labeled “teacher,” “students,” and “online;” directional arrows indicated two-way interaction. The teacher who did not use the teacher-student dichotomy instead began a main idea web with “resource” at the center and two ideas as subcategories. One was labeled “needed for”; the other was not yet labeled.

**Table 1: Affirmative responses to post-session survey items (N=8)**

Frequency of “Yes” responses to 14 questions	Statements to which they were responding
8	Found the session interesting
8	Learned something about resources
8	Thought about resource types later
6	Found the session useful
6	Looked for information as a result of something in the session
5	Thought about doing something different with learners as a result of the session
5	Noticed resources more explicitly
4	Discussed the session with colleagues
4	Went to a resource directly as a result of the session
4	Noticed the minus sign more explicitly
3	Learned some mathematics
3	Noticed indices more explicitly
2	Learned strategies for teaching
1	Did something differently with learners as a result of the session

**Table 2: Selection of teacher comments from post-session survey (N=8)**

Teacher 2	(Mentioned a site she went to) “I like this site as being a useful resource for teaching but it is not necessarily so for learning.”
Teacher 3	(What took root?) “The wide range of resources available”
Teacher 4	(What took root?) “It’s easier when resources are in categories and you know where to go for what”
Teacher 5	(What took root?) “Made me think about what resources I was using for what reason”
Teacher 6	(What took root?) “The difficulty in classifying resources”
Teacher 7	(What she planned to do) “Look online for resource categories & how to ‘type’ them”

Teacher 8	(What took root?) “Types of resources and how we use them in planning and teaching”
Teacher 8	(What took root?) “The need to include <u>all</u> categories including research”

## Discussion

This small study represents a first step towards explicit investigation of a pool of possibilities as a way to enhance teachers’ work with instructional resources. Results suggest that opportunities to classify resources by type can amplify teachers’ knowledge of their resource options, thus making more resources in their pool of possibilities available to them. Results also point to the complexity of organizing resources by type. More time would have been necessary for participants to fully classify resources and link the classification to the development of a resource system.

With respect to the research question, results seem to imply that the activities developed for the session were responsible for favorable results. However, other factors might account for what occurred with this particular group, who, as colleagues, represent an important resource in their pool of possibilities. These factors include: (1) participant teachers were a team who worked together daily with the same student population, were accustomed to and enjoyed working together on the types of activity in the Resource Types session; (2) two mathematical topics for the session, indices and the minus sign, were important to this group, and possibly a motivating factor; (3) the larger pilot in which the Resource Types session was embedded featured a monthly topic and accompanying materials that tacitly, but consistently, evidenced the idea that there are a variety of resources to explore for any topic, including resources not specifically for student activity. Participants were accustomed to exploring multiple types of resources for a topic.

Despite this, participants’ reactions to the activities in Parts 1 and 2 suggest that the “list approach” and the “focal topic approach” have the potential to influence teacher thinking in ways that support more deliberate selection from a wider range of resources. During Part 1, participant thinking evolved. With the first list, it seemed straightforward to organize resources by pedagogical activity, but the second list seemed to indicate that resources could be conceptualized various ways, and that organizing by type could be challenging. In response to the third list, of resource types, teachers were not in favor of having too many categories for types, even when, or perhaps especially when, they saw how many types there could be. Part 1 discussion showed that teachers’ thinking about the merits of classifying by types varied. Like many mathematics departments in England, this department had not adopted a textbook (e.g., Siedel & Stylianides, 2018); guided by the national curriculum, they were responsible for their own curriculum development and resources. One teacher wanted to use as many resource types as possible to guide searches, so that the department would not miss knowing about important ideas, new developments, or any potentially useful resources; the teacher also emphasized the importance of finding “research-based” resources. Another teacher was less interested in broad-based searching by types; this teacher was motivated by “what you do with it” or “what you want it for.” In a later session, this teacher defined a high quality resource as one where, “You stop looking! No need to look ... again as it does the job perfectly.”

As a result of the comparison of types for indices, a participant visited a resource she uses regularly to check its treatment of indices, particularly of zero as a superscript, exemplifying that the “focal topic approach” may influence teachers’ work with resources they already have. When one variable

that characterizes resources, the mathematical topic, is controlled for, it is easier to compare and comprehend other characteristics, such as the affordances and constraints of each as a type. At the same time, because each resource features the same topic, this activity may augment teachers' knowledge of the topic.

One way in which a typology of resource types for developing a resource system might affect student learning is by possibly reducing the variation in teachers' individual resource collections. Siedel and Stylianides referred to the existence of variable collections of resources within the same school as "plurality and variation" (2018, p. 130). If teachers' individual sets of resources include multiple resources, with sets varying considerably even among teachers at the same school, there may also be variation in opportunities for children to learn mathematics, known to be problematic in education (e.g., Morris & Hiebert, 2011). The question of whether or not they should all be using the same resources for a topic was posed to this group, but limited time did not allow discussion.

Two related questions for the mathematics education community emerged from this Resource Types study. The first concerns teachers' understanding of the expression "evidence-based." What types of resource can be considered evidence-based and how can teachers weigh these for resource selection? When comparing blog postings and the Cangelosi et al. (2011) research study, one teacher said the research article was evidence-based but the blog was characterized by opinions. The implication was that the research article had more worth. Would this mean that ideas developed from experience, such as long-term practice, are less trustworthy? What about the work of influential educators who guide mathematics teachers but may not be conducting systematic research? For their work to be trustworthy is formal review by other educators necessary? Teachers might benefit from opportunities to identify types but also to weight them.

The second, related question deserving attention in studies of teachers' resource skills is how to help mathematics teachers find research articles such as Cangelosi et al. (2011) that contain valuable information for mathematics teachers. Cangelosi et al. (2011) describes misconceptions about indices held by university students. The article includes activity that secondary mathematics teachers could readily implement to forestall similar misconceptions among their own students. Unfortunately, the inclusion of material in Search Engine Results Pages (SERP) seems to change over time. Cangelosi et al. (2011), for example, at one time appeared in the results of an online search for "negative exponents" and seemed to be openly accessible, but that no longer seems to be the case. Familiarity with the notion of open access articles and pre-publication copies may not aid teachers. Potentially helpful resources may be inaccessible, even when teachers know they are "out there." This becomes significant for questions about whether a resource exists for teachers.

Overall, the results of this study advocate for repeating the activities in a context outside of the pilot study, with more time to pursue the proposition that these activities might strengthen resource systems on behalf of student learning. The results suggest that in the process of classifying types of resources to develop a professional model for improving their resource systems, teachers can extend their knowledge of resource options in ways that benefit all of their work with resources.

## Alignment of mathematics curriculum to standards at high schools in Colombia

Silvia Solano<sup>1</sup>, Pedro Gómez<sup>1</sup> and María José González<sup>2</sup>

<sup>1</sup>Universidad de Los Andes, Faculty of Education, Bogotá, Colombia;  
[sp.solano10@uniandes.edu.co](mailto:sp.solano10@uniandes.edu.co); [argeifontes@gmail.com](mailto:argeifontes@gmail.com)

<sup>2</sup>Universidad de Cantabria, Spain; [mariaj.gonzalez@unican.es](mailto:mariaj.gonzalez@unican.es)

*The design of Mathematic curriculum in Colombia has been influenced by the curricular guidelines (MEN, 1998) and Basic Standards of Competence (MEN, 2006). These official documents have been the baseline to decide how to conduct the math curriculum parameters in schools. Specially, the basic standards of competence document provides teachers with a set of guidelines for what students are expected to know and be able to do, defining the intended curriculum. However, there is a lack of coherence between these parameters and what the teachers design in their school curricula. We analyzed the alignment between the mathematics curriculum of a sample of Colombian schools and the document of basic standards of competences at high schools in Colombia. We found an inadequate alignment between the schools' mathematics curriculum and the official document of basic standards of competence.*

*Keywords: Alignment, Mathematics curriculum, Standards*

### Law 115 of 1994 and curricular autonomy

The curriculum in Colombia has suffered many different changes or transformations based on political parameters or requirements. In 1994, the Ministry of National Education (MEN) stated the Law 115. This law organized the educational services in Colombia, through general rules. In this law, the government established the curricular autonomy of schools. This means that schools have autonomy to make and adapt their curricula. Also, the Ministry of National Education has proposed some guidelines in terms of learning expectations called Basic Standards of Competence (MEN, 2006).

### Basic Standards of Competence (2006)

Mathematical competences are related to mathematical thinking and mathematical systems. The standards are based on these mathematical thinking and systems. These guidelines contemplate the competences that a student must achieve when a cycle of two school years ends.

### Alignment to standards

In the past, the most common educational use of the concept of alignment referred to the match between an assessment instrument (or instruments) and a curriculum (Webb, 1997). Alignment does not only refer to a comparison between one assessments instruments with a curriculum, but extends to a set of assessment instruments or the assessment system. However, Webb has defined the alignment as “the degree to which expectations and assessments are in agreement and serve in conjunction with one another to guide the system toward students learning what they are expected to know and do” (1997, p. 12). An area plan is a curricular document that has the objectives, the

methodology, the distribution of time, and the evaluation criteria for a subject, in our case, the area of mathematics. The area plan becomes the roadmap that guides the implementation of the mathematics curriculum within schools. The alignment with standards is a characteristic of Colombian area plans. We assume the alignment with the standards as the measure to which the mathematics area plans approach the contents proposed in the standards. With this attribute, we seek to determine how much is covered of the subjects in the area plans according to what it is stated in the official document of the standards. For a specific syllabi and specific topics, the alignment should indicate to what extent that area plan meets the standards proposed to these issues.

## Methodology

We collected a sample of 212 syllabi throughout the country taking into account three main variables: geographical area (rural and urban), type of institution (public and private) and type of secondary education (academic and technical). In addition, we built code trees based on the didactic analysis carried out on three subjects of school mathematics. The topics chosen are the conic sections, the derivative and the descriptive statistics. The process of coding the 212 area plans consisted in identifying the text segments that allude to the proposed topics. Once these text segments were identified, they were assigned to label each one with a code of the code tree in N-Vivo program. Similarly, we coded the standards document as if this document were an area plan. After coding the documents, we proceeded to make a comparison between each area plan and the standards. Once the sources were compared, we proceeded to count the codes that each syllabi document shares with the standards document. We constructed a statistical variable with this measure. The value of this variable for an area plan is equal to the quotient between the number of codes that the area plan shares with the standards document and the total number of codes assigned to the standards document.

## Results

We found that the sample mean of the variable is 29,19%, with a standard deviation of 13,36% which means that there is a low alignment and a great variability in the alignment percentage of the area plans and the standards document. At 95% confidence, we found a confidence interval of the population mean of Colombian area plans of (27.31%, 31.07%). The area plans should be aligned to the curricular parameters and standards; however, we found evidence that these plans do not fit what the Law established causing a gap on secondary education, mainly on tenth and eleventh grades.

# The concept of function in secondary school textbooks over time: An analysis made with the Theory of Conceptual Fields

Patricia Sureda<sup>1</sup> and Laura Rossi<sup>2</sup>

<sup>1</sup> CONICET - UNICEN, Tandil- Bs. As., Argentina; [psureda@exa.unicen.edu.ar](mailto:psureda@exa.unicen.edu.ar)

*The purpose of this paper is to analyse how functions have been taught throughout 22 secondary school textbooks over the last 50 years. We have adopted a temporal perspective, as the books examined were published from 1953 to 2010. Firstly, the definition of concept (situation, meaning, system of representation) was the one proposed in the theory of conceptual fields, in order to analyse the concept of "function" taught in each book. Secondly, the books were categorized according to a focus on Sets, Analytical - Graphic or Hybrid. Finally, the meaning of function emphasized in each approach was analysed according to the representational system. The analysis showed that the meaning changed over time, as well as the difference in each representational system.*

*Keywords: Mathematics teacher resources, textbooks, high school teachers, Theory of Conceptual Fields.*

## Introduction

The conceptual field of functions is taught from the first up to the sixth grade of high school. Its importance lies in its increasingly broad field of application.

In high school, the knowledge that the teacher selects for his teaching practice is the knowledge that is in his textbooks. Thus, the book is an unavoidable framework for both, the teacher and the student, and generates much of the mathematical discourse manifested in the teacher's practice.

The analyses of the 23 books were divided in two parts. In the first part, the teaching of functions was classified in three categories, proposed by Sureda and Otero (2007): Approach of Sets, Analytical Graph and Hybrid. Then, we analysed the proposal through the term of "Concept" taking into account the Theory of Conceptual Fields (Vergnaud, 1990). Accordingly, the situations used in the books to propose the functions were analysed along with the tasks and their resolutions, inferring from them the set of Operational Invariants presented in each representational system. The Operational Invariants can be inferred as the textbook proposed the tasks simultaneously with the correct resolutions, its definitions, and explanations.

## Literature Review

Due to the variety of investigations related to functions, we only mention those analysed in books, or those focused on in the analysis of representational systems. The latter can be found in the work of Lavaque, Méndez, and Villarroel (2006), who analysed the instruction of the notion of function through a coherent articulation of Duval's representational registers.

With regards to the research related to the secondary level textbooks, the work of Cordero, Cen Che and Téllez (2010) is worth mentioning, who proposed the use of graphic representations presented in school books, in order to use them to understand the institutionalization of the concept of function.

$(y = 2x^2 + 4)$ . **RS Second Order Algebraic:** Algebraic procedure in which parameters are not initialized ( $y = ax + b$ ). **RS Analytical-graphic:** Graph on Cartesian Axes. **RS Verbal Written:** written linguistic forms. **RS Pictorial:** Refers to the construction of schematic drawings such as the Venn Diagrams.

This analysis allowed us to classify them in the three mentioned approaches (Sureda & Otero, 2007).

**Approach of Sets:** It is a teaching of the concept of function centred on the Theory of Sets. The study of the functions includes the teaching of ordered pair, Cartesian product, relations, equivalences, functions, set of departure and arrival, domain, image, etc. In this way, this approach is more precise and does not present ambiguities in the development of the concept of function. **In the Analytical-Graphic Approach,** the concept of function is determined through the graphical representation in Cartesian axes of a problem or concrete situation, in which a functional relation between variables is established. The analysis of the function and its properties is performed from the graph: domain, image, notable points, asymptotes, increasing or decreasing, etc. **The Hybrid Approach** has characteristics of the two already mentioned organizations. It establishes a relationship between variables, and also uses a set concepts such as set of departure and arrival, and allocation rules. However, it is problematic when giving meaning to the concepts it borrows from set theory.

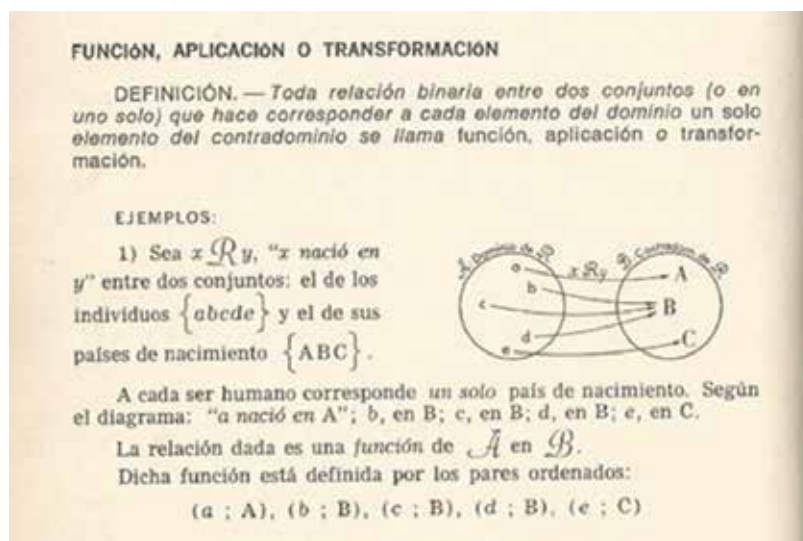

These three approaches allowed textbooks to be classified into three disjoint and exhaustive categories, since those textbooks which did not correspond to the approach of sets, nor to the analytical-graphic, were a combination of both.

## Data Analysis and Results

**Approach of Sets:** The books analysed which fit in the Approach of Sets are: **1)** *Arithmetic and Algebra 3*, Publisher Estrada (1953); **2)** *Mathematics 4 Commercial Course*, Eds. Estrada (1961); **3)** *Elements of Calculus Difference and Integral*, Eds. Alsina (1970); **4)** *Mathematics 3*, Eds. Estrada (1980); **5)** *Mathematics 3*, Eds. Plus Ultra (1987); **6)** *Mathematics II For the Aula Taller*, Eds. Plus Ultra (1988); **7)** *Modern Mathematics 2*, Eds. Stella (1970); **8)** *Directed study of mathematics 3*, Eds. A-Z (1989). These books were published between 1950 and 1989. The analysis is similar to the one made to the book *Mathematical 4 Commercial Course* published in 1961 (from Eds. Estrada), presented below.

**The reference [S]:** The textbook introduces the concept of function (figure 1) through the definition: "Any binary relation between two sets – or just in one set- that corresponds each element of the domain to a single element of the counter domain is called function, application, or transformation".

Then, various Venn diagrams are presented, in which three examples of relationships are indicated. In the example 1) the relation "x was born in y" is proposed (figure 1), indicated as a function. In example 2) the relation "a x corresponds to the desk y" is proposed, indicated as a function. In example 3) the relation "x is a multiple of y" is proposed, indicated as a non-function. Each example is accompanied by a Venn diagram in which the output sets  $A$  domain of  $R$  the arrival set  $D$  codomain of  $R$ ; and the relationship by the arrow  $x R y$ . Finally, the ordered pairs of the function are indicated.

**Figure 1: Definition of Function - Mathematics 4 Commercial Course, Publisher Estrada 1961**

**The signifier [I]:** The textbook uses the RS Verbal Written for the definition of Function; the Second Order Algebraic RS to define the sets and relationships of the example, and the Pictorial RP for the representation in Venn diagrams.

In short, the textbooks with this approach present the concept of function from the notions of ordered pair, cartesian product, and relationships. The sequence that these textbooks follow to accomplish it, is: theory - example - exercise. The Representation Systems used are: Verbal Written, Algebraic of Second Order and Pictorial. Thus, we can determine that another characteristic of the set theory is the relevance given to mathematical notation.

**The meaning [I]:** The Theorems and Concepts in Action that emerge from the concept of Function in this approach are the following. **RS Verbal Written:** A Function is a binary relation between two sets that corresponds to each element of the domain in a single element of the codomain - If a Relationship complies with the uniqueness and existence, it is a Function - The Domain of a Function is included in the Reach set - The Image is included in the Range of a Function. **RS Second Order Algebraic:** The expression of a function is  $y = f(x)$  - Given the sets  $A = \{a, b, c, d, e\}$  and  $B = \{A, B, C\}$ , the relationship formed by the pairs  $(a; A) (b; B) (c; B) (d; B) (e; C)$  is a function of A in B - The Domain of a Function is included in the Scope set - The Image is included in the Range of a Function. **RS Pictorial:** Functions can be represented by Venn diagrams - From each element of the set called Domain, a single arrow appears towards an element of the set called Codomain.

These Theorems-in-Action propitiate a static idea of the concept of Function. This can be seen in the examples and activities proposed. For example, the textbook presents the sets A and B by extension, and then defines the relationship between both sets. That is, the function can be defined by extension and there is no rule for assigning the variables.

**Analytical - Graphical Approach:** The textbooks analysed included in the Analytical - Graphical Approach are the following six: **1)** *Mathematics Bachillerato 2*, Eds. Anaya (1987); **2)** *Mathematics II*, Eds. Anaya (1989); **3)** *Mathematics 9*, Eds. A-Z (1997); **4)** *Mathematics 1*, Eds. Kapeluz (2004); **5)** *Mathematics 9*, Eds. McGraw Hill (1998); **6)** *Mathematics 3*, Eds. Puerto de Palos (2009). These textbooks were published between 1987 and 1998, yet there is one exception of 2009. The analysis

is similar to the one made in the textbook *Mathematics 3* published in 2009 by Puerto de Palos, presented below.

**The reference [S]:** The textbook introduces the concept of function (figure 2) by means of the definition: "*A function is a relation between two variables in which each value of the first corresponds to a single value of the second*".

Then, it presents a graph that represents the users of the Web worldwide, and interprets it. Thus, the textbook indicates that for each value of time (independent variable) there is a unique number of users (dependent variable). That is, 1574 million users are the image of the year 2008, and 2008 is the preimage of 1574. Then, the textbook defines the domain as all the values that can be taken by the independent variable, in this case all the years greater or equal than 1989 and less than or equal to 2008; and all the values that the independent variable can take as the image set, formed by all users greater than 0 or less than or equal to 1574 million.

**The signifier [I]:** The textbook uses the RS Written Verbal for the definition of Function and domain and image set; and the RS Analytical - Graph to represent the function.

Figure 2: Function Definition Book "Mathematics 3" - 2009, Edited by Puerto de Palos

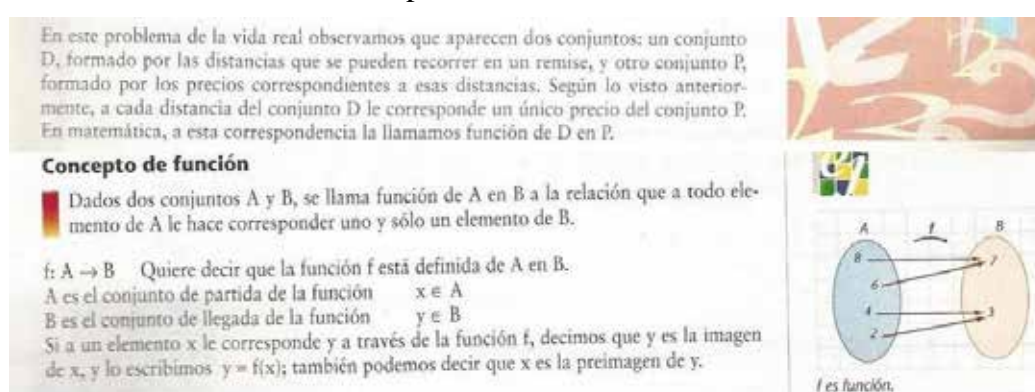

**The meaning [I]:** The Theorems and Concepts in Act that we reconstruct from the concept in this approach are the following. **RS Verbal Written:** *A Function is a Relationship between two variables in which each value of the independent variable corresponds to a single value of the dependent variable - The independent variable is  $x$ , which is represented on the abscissa axis - The dependent variable is  $y$ , which is represented on the ordinate axis - To find the characteristics of a Function, the problematic situation it represents must be taken into account.* **RS Analytical – Graph:** *A Function is represented through a graph in the Cartesian Axes – It is a Function if a single element of the vertical axis corresponds to each point of the horizontal axis - It is not a Function if the drawing of a vertical line from any point of the horizontal axis cuts the graph in more than one point.*

These Theorems-in-Action give a dynamic idea of the concept of Function. In short, the books of this approach propose some situations of everyday life through a graph in Cartesian axes, describing the relationship between variables as a function, and then analyse its characteristics such as the analysis

of variables, growth and decrease, maximum and minimum points, constant function, periodic function and zeros. In all cases, the definition is made in the RS Verbal Write and refers to a relation between variables that meet certain characteristics.

**Hybrid Approach:** The books analysed framed in the Hybrid Approach are the following: **1)** *Mathematics 2*, Eds. Santillana (1989); **2)** *Mathematics 3*, Eds. Santillana (1995); **3)** *Mathematics 8*, Eds. Santillana (2002); **4)** *Pythagoras 8*, Eds. SM (2004); **5)** *Mathematics, functions and Statistics*, Eds. A-Z (2005); **6)** *Functions I*, Eds. Longseller (2002); **7)** *Mathematics I*, Eds. Estrada (2004), **8)** *Elementary Functions to construct mathematical models*, Eds. Inet (2010); **9)** *Mathematics 4*, Eds. Estrada (2010). These textbooks were published between 1995 and 2010, yet there is one exception in 1989. The analysis is similar to the one made in the book *Mathematics 3* published in 1995 by Santillana, presented below.

**The reference [S]:** The textbook introduces the concept of function by means of a real-life problem relative to the rate of a taxi according to the kilometres travelled, and then solves it. Based on the problem, it establishes the following (figure 3): "In this real-life problem, we observe the presence two sets; set D, formed by the distances that can be covered in a taxi, and another set P, which is the price corresponding to those distances. As seen above, each distance D corresponds to a single price of the set P. In mathematics, we call this correspondence function of D in P".

**Figure 3: Definition of Function, Book "Mathematics 3" - 1995, Publisher Santillana**

Then, the formal definition of function is written, as well as the image and preimage, using elements of the set theory.

**The signifier [Γ]:** The textbook uses the Written Verbal Representation Systems, Numeric, Analytical - Graphic and Pictorial to define and represent the function and concepts of image, preimage and domain.

**The meaning [I]:** The Theorems and Concepts in Act reconstructed from the concept in this approach, are the following. **RS Verbal Written:** *A Function is a specific relationship between two variables - The variable  $x$  is the independent variable - The variable  $y$  is the dependent - Each value of " $x$ " corresponds to a single value of " $y$ " - The Domain is the set of all the values that the independent variable " $x$ " can take - The Image is the set of all the values that the dependent variable " $y$ " can take - The Image is obtained by applying the Function to the elements of the Domain.* **RS Numeric:** *A function can be represented by a table - In the first column the values of the independent*

variable are located - In the second column the values of the dependent variable are located. **RS Analytical – Graphic:** A Function can be represented in Cartesian axes - The values of  $x$  are exemplified by the horizontal axis - The values of  $y$  are located on the vertical axis - The graph represents the points  $(x, y)$ , to draw the figure that represents the function - When drawing lines parallel to the  $y$  axis, they must cut the graph at a single point to be Function. **RS Pictorial:** Functions can be represented by Venn diagrams - From each element of the set called Domain, a single arrow appears towards an element of the set called Codomain.

These Theorems-in-Action give a dynamic idea of the concept of Function, yet they preserve elements of the Sets approach. In synthesis, in these books, the proposed situations correspond to a situation directly connected to a certain context, with its formula or chart and analysis, using elements of the two previous approaches.

## Conclusion

The analyses of the concept of function showed that - except for some few exceptions- the approaches usually corresponded to a particular set of years, and that the changes in the textbooks coincided with the dates in which national laws on education were sanctioned in the country. The Approach of Sets (1953-1990) prevailed in the period of Law 1420 of Education. Then, the Graphic Analytical Approach (1993-2006) was consolidated during the Federal Education Law (24.195), passed in 1993. Finally, the Hybrid Approach corresponds to the current period, coinciding with the last National Education Law 26.206 enacted in 2006. At the same time, the analyses of the textbooks showed that the Operational Invariants, about function changes according to the approach.

The **Approach of Sets** emphasizes the idea of a binary relation between sets that complies with existence and uniqueness (for example " $x$  was born in  $y$ "), but relegates the dependence between variables. However, the positive aspect of this approach is the fact that it uses a lot of the RS Second Order Algebraic, which allows to have the symbolic notation and rigor characteristic of Mathematics. In the **Analytical - Graphical Approach**, the idea of the function is built on the system of graphic representation, in which the written verbal language explains that a Function is a Relationship between two variables, and that each value of the independent variable corresponds to a single value of the dependent variable. The independent variable is  $x$ , represented on the abscissa axis, and the dependent variable is  $y$ , represented on the ordinate axis. This approach manages to link the use of functions with everyday life but loses mathematics in the process. Finally, the **Hybrid Approach** presents the functions as a relation between two variables, but tries to recover elements from the focus of the approach of sets, such as Range, ordered pair, etc. Likewise, this approach tries to make sense of the functions by linking them with everyday life, while at the same time there is an effort to recover the proper notations of mathematics. However, this effort is limited by the lack of elements typical of set theory, conditioned by its use.

Finally, the analysis of the reconstructed theorems-in-action for each RS showed that, as affirmed by Sureda and Otero (2013), the meaning of function changes according to the representational system. For it is not the same to think of functions as a relation that achieves "*from each element of the set called Domain a single arrow goes to an element of the set called Codomain*", to think of a Function

as a relation in which "each point of the axis horizontal corresponds to a single element of the vertical axis", or that can be represented by a formula. Moreover, not only there is a change in meaning, but also a change in the operative invariants linked to them that are characteristic of the RS. For example, RS Graph has a number of operative invariants linked to the scale, and to the location of the points in the plan, which the Venn diagram lacks. The meaning of a concept is much more than the systems of representation; however, it is impossible to conceptualize complex concepts without any representation system. Particularly in secondary school, it is essential to foster situations that demand the use of the different representation systems which constitute the concept.

# The potential of Problem Graphs as a representational tool with focus on the Hungarian Mathematics Education tradition

Eszter Varga

Eötvös Loránd University, Faculty of Science, Doctoral School of Mathematics, Budapest, Hungary; [evarga@bpg.hu](mailto:evarga@bpg.hu); [vargaesztermail@gmail.com](mailto:vargaesztermail@gmail.com)

*Keywords: Series of Problems, Hungarian mathematics education, teacher design capacity*

## Introduction

Capturing teachers' principles and working methods in instructional design can pose some challenges, as well as its representation and dissemination. In this work in progress, we suggest a new representation tool, the Problem Graph, that has the potential to reveal some of the Teacher Knowledge embedded in series of problems and task sequences. Problem Graphs are developed with dual purpose: as an analytical tool to explore the structure of existing resources through a priori analysis, and as a design tool that can help teachers plan their instructional sequences and long term learning trajectories. The potential of Problem Graphs in developing teachers' design capacity were also investigated in two pilot experiments with the objective of introducing them in teacher education and PD programs.

Initially, this work is strongly rooted in the Hungarian Mathematics Education tradition, but both the approach in question and the representation tool is relevant to the international community for its special handling of Mathematical Knowledge for Teaching (Ball et al., 2008).

## Background

My present and prospective work with Problem Graphs is a part of a large scale research project launched by the Hungarian Academy of Sciences.<sup>1</sup> The project focuses on the Hungarian "Guided Discovery" approach, that was experimentally implemented nationwide by a reform movement led by Tamás Varga in the 1960s and 70s (see Gosztonyi et al., available in pre-Proceedings of ICMI 24; Varga, 1988). This approach is highly recognized among Hungarian experts. The research project is assigned to describe the approach and examine its background as reflected in the recent theoretical frameworks as well as revisiting the reform and communicating it to both national and international audiences.

In a preliminary study, Gosztonyi identified Series of Problems as a characteristic aspect of teachers' work in the Guided Discovery approach. The research group started to analyze Series of Problems as a special type of resource, using the frames of the Documentational approach (Gosztonyi, 2018; Gueudet, Pepin, & Trouche, 2012). In this course of work, a need emerged for an efficient visual representation of the inner structure of Series of Problems, to which the graph representation came

---

<sup>1</sup>The poster is made with the financial support of the MTA-ELTE Complex Mathematics Education Research Group, working in the frame of the Content Pedagogy Research Program of the Hungarian Academy of Sciences (ID number: 471028).

up quite naturally as one of the possible answers. Problem Graphs were built to some of the examined Series of Problems and discussed in details with experts. In these structures, nodes represent the individual problems, while edges show the explored connections. The connections reflects Mathematical Knowledge for Teaching, one-way arrows show precedent-consequence relations. For the standards of further classification, the domains suggested by Ball et al. might be a good starting point, but this work is only at its first steps at the moment.

The poster will demonstrate that the name Series of Problems covers a notion that is more complex than a task sequence, and seems to be indigenous in the Hungarian tradition. Nevertheless, the graph representation can be an effective tool to support the analysis of other learning sequences independent from this cultural context.

Dealing with problem Graphs led to the idea that this type of work on set of problems could benefit teachers' professional development greatly, especially if conducted in groupwork. Planning on investigating this opportunity, we conducted two pilot experiments with 10 and 18 participating teachers. In both experiments, teachers worked in groups on the same subset of a Problem Field which was examined previously by the research group. During the sessions, the teachers built a Problem Graph from the selected problems, followed by a whole group discussion and a questionnaire in the second experiment.

## Poster Content

The poster will summarize some major principles of the Guided Discovery approach as a context. It will also give a working definition for Series of Problems. Limitations in space will not allow to provide full examples for Series of Problems, but some key problems will be highlighted. In the main part, Problems Graphs will be displayed, with one extensive example representing a Series of Problems from the field of Elementary Geometry in the center, with some specification of the connections. Graphs built by teachers from the same problems will also be presented, accompanied with some teacher responses from the questionnaires. This will allow us to draw some conclusion from the pilot experiment regarding the potential usage of the Problem Graph.

*With an interest on curriculum resources of mathematics teachers, this study works as part of an emerging research program of analyzing teachers' resource systems through their naming systems of resources in contrasting contexts. This study presents the preliminary analysis results of two cases from China and Mexico. Using a conceptual framework drawn on Documentational Approach to Didactics (DAD) and Cultural-Historical Activity Theory (CHAT), we explored teachers' resources within a linguistic and cultural background. Three key resources of each case were selected and analyzed for finding their features and links with the teachers' resource system. By contrasting the two cases, we find that naming system provides us a lens on teachers' resource system (both the content and structure), and evidences the influences from linguistic and culture contexts.*

*Keywords: Curriculum resources, mathematics teachers, resource system, naming system, international comparison*

### Introduction and research questions

In 2018, the Re(s)ources 2018 International Conference<sup>1</sup> was hold, dedicated to teachers' resources work analysis with reflections on DAD for the past ten years. A young researcher workshop session was organized (Gitirana *et al.*, 2018, p. 373) specifically for exploring secondary teachers' resource work by analyzing their lexicons in naming and describing their resources and their documentation work (Trouche, to be published). A name is a syntactic entity denoting an object, and "a naming system resembles a restricted database system that infers the object(s) referenced by a name" (Bowman, 1993, p. 795). In addition, considering the views of the teachers, and the influences from their own languages, cultural and institutional contexts, we refer to two cross-cultural comparative projects: the Lexicon Project (Clarke *et al.*, 2017), which investigates the pedagogical naming systems used by different research communities speaking different languages to describe the phenomena of the mathematics classroom; and the project of Remillard *et al.* (2014), which addresses the influences from cultural contexts and educational traditions.

We situated our study as part of the research program "contrasting naming systems used by teachers in describing their resources and documentation work: towards a deeper analysis of teachers' resource systems" (Trouche, to be published). Holding a similar concern of Lexicon Project on the cultural contexts and educational traditions through cross-cultural analysis, this program involves researchers from eight languages/cultural contexts (Algerian, Brazilian, Chinese, Dutch, French, Mexican, Turkish and Ukrainian) for a better understanding of teachers' resource work through documenting lexicons (naming systems) on resources employed by teachers. Particularly in this

---

<sup>1</sup> <https://resources-2018.sciencesconf.org>

study, to deepen the understanding of teachers' resource systems, two contrasting cases (Chinese and Mexican) are analyzed from two research questions: (1) How understanding teachers' resource system through their naming systems? (2) To what extent each case can illuminate the other one?

## Conceptual framework

The resource concerned in the project is from Adler (2000), anything with potential “to source again or differently” (p. 207) teachers' activities, “encompassing materials and also all elements intervening ‘upstream’ of teaching” (Gueudet, Pepin & Trouche, 2013, p. 1003). However in this study we focus more on the curriculum resources from Pepin and Gueudet (online first): all the *material resources* that are developed and used by teachers and students in their interactions with mathematics in/for teaching and learning, inside and outside the classroom.

This study is situated in the theoretical field of Documentational Approach to Didactics (DAD) and Culture-History Activity Theory (CHAT). DAD is an empirical approach to teachers' work and professional development through a lens of resource. The creative work of mathematics teachers' interactions with resources in their daily work is coined as documentation work (Trouche, Gueudet, & Pepin, online first). As a process of appropriation and transformation of resources, the interaction includes selecting, modifying and creating new resources, by individual or by a group of teachers working together, in- and out-of-class (Gueudet & Trouche, 2009). During these interactions, teachers develop *schemes of usage* that are attached to the resources for a same class of situations, and generate a document as outcome (resources + scheme of usage = document). A resource is never isolated, “each resource must be viewed as a part of wider ‘set of resources’” (ibid, p. 200), and the “set of resources” is named as his/her *resource system*. Originated from Vygotsky (1978), CHAT (Engeström, 2001) emphasizes that the dynamic of consciousness is essentially subjective and shaped historically by social and cultural experiences. The structure and development of human psychological processes emerge through cultural mediation, historical development, practical activity, and the three are interrelated (Cole, 1996). CHAT inspires us that individual teacher' documentation work could be situated into the cultural/social/linguistic contexts where they work in. Tools inspired by these two theories will be introduced in the following methodology part.

## Methodology

The naming system project adapts the methodology of *reflective investigation* from DAD, emphasizing the involvement of teachers throughout research with five principles: (1) long-term follow up; (2) in- and out-of-class follow up; (3) broad collection of resources; (4) reflective follow-up; and (5) confronting teacher's views on his/her documentation work (Trouche et al., online first). As a preliminary work, this study mainly takes the fifth principle. To differ the views of teachers from the researchers', we use the methodological tool of Reflective Mapping of the Resource System (RMRS) (Wang, 2018), where the teacher is invited to draw a RMRS by reflecting on his/her resources, and linking them into a structured way with his/her own naming and category of resources. RMRS emphasizes the teacher's views through his/her continuous reflections: the namings of resources and the structure of RMRS are all from teachers, and it could be incomplete with different versions, and improved along with the development of teacher's resource system, and teacher's deeper understanding on it.

This is a qualitative study performed through cases study. For feasibility and convenience reasons, we chose the teachers from schools associated to the authors' universities (in China and Mexico), which allows us to do further research with them. The criteria of the cases are: middle career mathematics teachers; from secondary schools in big cities (not from rural areas); with willingness to join our research and improve his/her teaching; "open minded" towards new resources.

Gao graduated in 1993, majored in education management (bachelor), then she started to teach mathematics in middle schools. She was the ex leader of mathematics Teaching Research Group (TRG) in her school, a school-based non-administrational professional group composed by teachers who teach the same discipline, where the leader is usually the most experienced teacher and in charge of organizing teachers' collective teaching research activities (Pepin *et al.*, 2016). She had two classes in grade 8 and 5 lessons for each class per week. In China, curriculum program is national. There are a limited number of textbooks edited under the control of the national government. Teachers cannot decide which textbooks to use, but they have diverse learning-aid materials as supplementary resources to choose.

For the Mexican part, Brenda is a high school mathematics teacher majored in mathematics (bachelor) and Earth sciences (master). During her bachelor study, she attended a mathematics teaching seminar. Then after graduated, she started to work as a volunteer in elementary schools teacher training. Till the interview, she worked as coordinator of mathematics in a primary school. In Mexico, private high schools can use the national curriculum -coordinated by the government- or the curriculum of the autonomous (public) university of the state where the school is located. Brenda works in a private high school, which follows (with some adjustments made by the school) the curriculum of an autonomous university.

Both of Gao and Brenda were interviewed concerning: (1) their working experience, current work and the teaching equipment conditions of their school; (2) their resources used in daily teaching, including the name, the content, the usage, the source, and the way to maintain and organize these resources; (3) an example of resources integration for a lesson preparation about functions (or algebra); (4) a RMRS by reflecting on her/his resources mentioned. The analysis of the interview was made following a common grid: with the interview transcription texts, we selected out the *names* of the *resources* most frequently mentioned by the teacher with personal features/preferences, and analyzed them combining the language and culture with the teacher's description on the usages, then situated these resources into the RMRS to infer the structure of teacher's resource system.

## Results

This section presents the results of each case.

### Selected resources from resource system in the Chinese case of Gao

In the Chinese case of Gao, a most frequently mentioned character is “题(tí)”. In Chinese language morphology, word is formed by a combination of characters. In Gao's interview, by combining with other characters, “题(tí)” forms into words like “习题(xí tí)” (exercise), “试题(shì tí)” (examination/test question), “例题(lì tí)” (example), “问题(wèn tí)” (question/ problem) etc. In Gao's case, the three selected resources (see in Table 1) are the sources of the “题(tí)”.

Naming in Chinese	Translated name in English	Description in English	Transcriptions examples
教辅材料 (jiào fǔ cái liào)	Learning-aid materials	The commercial textual materials (e.g. books) for students, with exercises or exam questions or knowledge explanations (available in bookstore).	“Before the new semester, I will go (to the bookstore) to check the new learning-aid materials.”
习题笔记 (xí tí bǐ jì)	Exercise note	The personal notes of Gao, in which she used for collecting the exercises she considered as valuable.	“I keep notes when I find valuable exercises, I made four (notebooks) last year.”
校本习题册 (xiào běn xí tí cè)	School-based exercise booklet	Booklet with exercises for the students, developed collectively by all the mathematics teachers inside Gao’s school (not for sell)	“This school-based exercise booklet was developed by me...which selected from my exercise notes.”

**Table 1: Three typical expressions on resource naming by Gao**

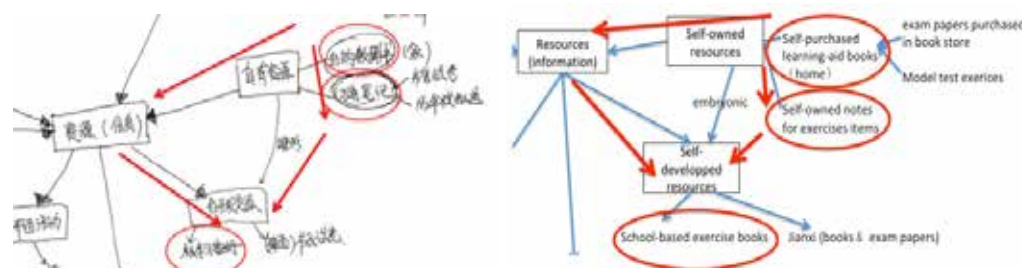

(1) Learning-aid materials (教辅材料, jiào fǔ cái liào) is a kind of printed and bound materials sold in bookstores, to “aid” learning. It generally contains examples, knowledge explanations and exercises. Gao knew the learning-aid material market well due to her experiences working as an author of a learning-aid book some years ago: “The learning-materials also have life-cycle, and have to be updated regularly”, so she visited the bookstore almost before new academic year, to see if there is anything new in the materials that she was following. She bought lots of learning-aid materials as her self-owned resources, and she had an awareness of following the trends of the learning-aid material markets, selecting and accumulating the valuable ones.

(2) Exercise note (习题笔记, xí tí bǐ jì) is a personal paper-pencil notes of Gao. She kept such habits for several years: after a whole day’s work, she liked to do exercises (e.g. from the learning-aid materials), and keeps the notes of the valuable ones. She also did the category of these exercises according to the contents (e.g. functions) or types (e.g. drawing). The source of the exercises is not limited to the learning-aid materials, but also from Internet. Many big professional websites/forums for mathematics teaching propose their enterprise applications with the popularization of smart mobile phone. Besides these apps, Gao used a social communication application “Wechat”, with which she can discuss and share resources (as file or picture) with colleagues, receive articles about exercises explanation, analysis on knowledge, information about exams, or even videos of other teachers’ lessons. She kept all the valuable information in her notes.

(3) School-based exercise booklet (校本习题册, xiào běn xí tí cè) is a series booklets developed collectively by the mathematics TRG in her school. As a teacher of grade 8, Gao was in charge of the two booklets in her grade. The booklets are sent to students as homework, consisted mainly with exercises, as Gao explained, “most of them were selected from my exercise notes.”

Crossing the three resources, there appears a chain: the learning-aid materials nourish her exercise notes (self-owned resource), which in return “re-source” her exercise booklets (self-developed

resource). This evidenced a kind of “resource cycle” in her resource system (Figure 1 left, the red circles and arrows were marked by the author according to Gao’s explanation in the interview).

**Figure 1: Part of RMRS of Gao (original left, and digital transposition by the researcher right)**

When situating these resources in Gao’s RMRS, we find the different roles of resources as “input”, “output” and “hub” (evidenced by the arrows). For the inputs, Gao had resources from learning-aid materials, feedbacks from students in their homework; for the output, she developed her self-owned resources into self-developed resources: her personal exercise notes worked as a hub. Gao selected exercises carefully for students, and kept their feedbacks as important resources. This could be referred to her education background (education management): “I pay much attention on students, and try to maintain good relationship with them, they will like mathematics if they like me.”

### Selected resources from resource system in the Mexican case of Brenda

Three selected resources of the Mexican case were presented in Table 2.

Naming in Spanish	Translated name in English	Description in English	Transcriptions examples
Manual (Versions for teacher/student)	Textbook	School textbook produced by the school, adjusted and improved by the teachers every year.	“Then we [teachers] use a manual, where we all see the same [contents].”
Diagramas (Figure 2a) / esquemas (Figure 2b)	Diagrams	A geometric drawing with which one gets the resolution of a problem, the relationships between different parts of a set or a system.	“I make diagrams to see what is my objective and what do they need.” “Then [at the end] those schemes, I give them copies of the scheme or I give them blank to be filled.”
Calendario escolar	School calendar	Teaching schedule designed institutionally to mark dates of activities at school. It is a reference for planning lessons.	“I need a calendar, because the time is very important; [we have] the normal calendar, the school calendar...”

**Table 2: Three typical expressions on resource naming by Brenda**

(1) Textbook (manual) is the resource that guides the development of the different topics that are addressed throughout the school year. The elaboration of each textbook (for each of the three secondary degrees) is based on the curriculum (another important resource not analyzed in this study)

of the largest university in the country and to which the school where the interview was conducted is incorporated. The work of (re)elaboration of the textbooks is directed by a coordinator of mathematics (who is also the teacher of the school). However, teachers are free to suggest and contribute any concerns or observations they may have. Table 2 shows how collaborative work guides the activity of teachers in a particular way: “...we all see the same”. In the use of the textbook as a resource, all stages of Brenda's documentation work (review, analysis of resources, adaptation, reorganization, implementation and reflection) are involved. It is also interesting to notice that in Spanish, “manual” refers to something “we have in hands” and something related and available to the usage, whereas quite different with textbooks. The translation makes one lose the meaning-production universe around.

(2) Two resources (diagramas/esquemas) in which Brenda emphasized its use, during the interview, were the use of diagrams/schemes. It is important to note that both words (diagram and scheme) were used by indistinctly to refer to the same resource: diagram (Figure 2). However, the term “scheme” is incorporated to show how the teachers name their resources in relation to their teaching activities. Brenda elaborated the diagrams according to her teaching contents. The diagramas were initially used as a way of learning by Brenda when she was a student. This stage is closely related to the analysis of the textbook (manual), as she pointed out: “I make diagrams to see what my objective is and what they [students] need to know for reaching that goal” (see in Table 2). Then, during the lessons, Brenda incorporated the resource as learning material for the students: “I give them copies of the scheme, or blank ones to be filled.”

**Figure 2: Part of RMRS of Brenda (original left, and digital transposition by the researcher right)**

(3) School calendar (Calendario escolar). In relation to the resources selected from the interview, the use of the textbook and the elaboration of diagrams are closely related to the teaching plan and lesson design. This includes both the textbook that will be addressed in each class and the elaboration of diagrams for each topic. These two resources are organized from a school calendar.

Crossing the three resources within her RMRS (Figure 2), they are all resources for her “lesson”. Brenda did not draw her RMRS centered on “resource” like the Chinese case. However, considering the particularity of the textbook she used, we can still infer that the textbook bridges Brenda’s individual documentation work with her collective work with others: The textbook is developed based on the university curriculum with the involvement of the school teachers, and as a teacher, Brenda worked as both user and usage feedbacks provider; To implement the curriculum and textbook, she adapted her personal learning strategy (diagram) into classroom teaching, and diffused it with other teachers through resources related to school calendar (teaching plan).

## Discussion and perspectives

Resource system is not easy to be inferred from or interviews. In this paper, we took a method of combining teacher's naming system and her/his RMRS, with two contrasting cases from different cultural contexts, China and Mexico, to have more elements (theoretical and methodological) to analyze teacher's resource system. Far more work need to be done for a deeper understanding on their resource systems. Although Gao and Brenda are two very different cases -in terms of their teaching activity and their sociocultural context-, one from public middle school and using national curriculum, and one from private high school using a university curriculum. However, by documenting the name/content/usage as well as their positions in RMRS, we can still find some features that allow us to develop and deepen our further analysis works.

Related to research question (1): In the Chinese case, the resource naming system showed an emphasis on “tí(exercise in English)”, and the three selected resources evidenced its position of central element in the teacher's resource system, linking both the teacher's personal working habits (taking notes) and the cultural context (exams-emphasized culture and huge learning-aid material markets) of mathematics education. In the Mexican case, the resource naming system evoked an adaption of personal choices (e.g. diagram adapted from learning teaching) and consideration on others' work (e.g. school calendar), mediated by a collective used/developped/revised manuel (textbook). For research question (2): Crossing the two cases, they are both following a fixed curriculum (national curriculum and local unified textbook in Chinese case, unified curriculum and textbooks produced by the university in Mexican case); they are both trying to integrated the supportive resources (learning-aid materials in Chinese case, disciplinary academic books in Mexican case); they are both organizing their resource work centered on students (selecting exercises from diverse sources and paying attention on their feedbacks in the Chinese case, adapting her own learning strategy, diagram, into classroom teaching in the Mexican case). Additionally, there are school-based resources involving the two teachers in both two cases: the school-based exercises booklets collectively developed by the mathematics TRG in the Chinese case, and the university-curriculum based textbooks developed and revised by the school mathematics teachers in the Mexican case. In the case of Gao, the different terms related to “tí(exercise) reveal a potential resource category from the teacher's view. In the case of the Mexican teacher, the ambiguity of naming the same resource in two different ways infers a more individual work of the teacher.

To summarize, analyzing teacher' naming systems on resources by actuating it within specific cultural contexts could be a promising method for us researchers to deepen the understanding on teacher's resource system. Due to the limited space, we were not able to analyze the mathemtics components of their resource system. As a beginning of this exploration, we hope that involving other cases and crossing with other projects will help us to go further in this direction.

<sup>1</sup>Instituto Politécnico Nacional, CICATA Legaria, Mexico; [mosanchez@ipn.mx](mailto:mosanchez@ipn.mx)

<sup>2</sup>University of Potsdam, Germany; [kuzle@uni-potsdam.de](mailto:kuzle@uni-potsdam.de)

<sup>3</sup>Norwegian Centre for Mathematics Education, Norwegian University of Science and Technology (NTNU), Norway; [kjersti.wage@matematikkenteret.no](mailto:kjersti.wage@matematikkenteret.no)

<sup>4</sup>Aalborg University, Denmark; [misfeldt@learning.aau.dk](mailto:misfeldt@learning.aau.dk)

*In this introduction, we briefly present the origin of a young Thematic Working Group 23 (TWG23) on implementation of research findings in mathematics education, and its development from CERME 10 to CERME 11. We then address the construct “implementation research” by looking at the model proposed by Century and Cassata (2016). Drawing from this model, we attempt to categorize the papers and posters of TWG23. In addition, we report on the results from two thematic discussions that focused on the topic of “Methodology in implementation research” and “Replication studies”. Lastly, we offer a collective, still in-progress definition of implementation research as a result of the summarizing discussion in the TWG23 during CERME 11.*

*Keywords: Implementation research, research findings, replication studies, innovation, change.*

### Origin of the Thematic Working Group 23

During five decades, the field of mathematics education research has generated a multitude of products, such as theoretical frameworks, concepts, didactic designs, solid findings, etc. Although the research community has always been concerned with the theory-practice relationship, it remains an open and a challenging problem how such products could be used and applied in practice. Many mathematics education researchers work on (large) developmental projects that rely heavily on previously documented research results. However, reporting on these projects in mathematics education scientific outlets have proven to be challenging, since such projects do not necessarily fall under the usual paradigms of research in mathematics education. Before CERME 10, this issue was identified. More concretely, there was no forum to discuss important issues related to implementation of research findings. For that reason, TWG23 was founded with the idea of being a forum dedicated to presenting and discussing empirical and theoretical studies focused on elucidating the enablers and general conditions that favor or inhibit the implementation of research products generated in our field in practice as well as reporting on research-based designs themselves. The original concern of the group was “*How can we apply and implement stable research findings in «real life»?*” and “*How can we bring the accumulated research knowledge into practice?*”

These questions remained to be in the focus of TWG23 also at CERME 11. We were embracing for papers and poster proposals addressing, from both empirical and theoretical perspectives, issues related to the implementation of research findings. In particular, we wanted to focus on a wide variety

of “good examples” of implementation of research findings and products into practice, aiming at improving the teaching and learning of mathematics at all educational levels. Moreover, we were interested in empirical research and theoretical discussions that address the challenges and possibilities of “implementation research”, as well as in-depth literature reviews that provide general and updated views of the state of development of this type of research in the field of mathematics education. Thus, the work of the group was organized around the idea of closing the identified “gap” and acting as a bridge between research and practice by focusing on multiple perspectives of implementation research.

## **Evolution of the TWG 23**

At CERME 10, the working group undertook initial attempts to make sense of the construct of implementation. In the call for papers for the TWG23 at CERME 10, the construct “implementation research” was operationalized rather broadly, as a wide range of different kinds of didactical design, from task design, (model) lesson design, teaching modules and courses to design of entire programs at all educational levels. Furthermore, “implementation research” was inclusively treated as research on aspects of developmental projects, intervention projects, as well as research on aspects of the development and use of educational media, such as textbooks, apps, software and learning platforms. However, the call for papers required to make explicit connections between the reported designs and findings or insights from mathematics education research. As a result, many examples of implementation of research findings in mathematics education were presented, including process models, determinant frameworks, classic theories, implementation theories and evaluation frameworks (Jankvist, Aguilar, Bergman Ärleböck, & Wæge, 2017). Many examples had been presented also at CERME 11, however, a new general theme in considering them have gradually emerged. At CERME 11, both the papers and posters as well as our discussions, reflected an effort to articulate more clearly what implementation research in mathematics education actually is, as well as the growing interest in theorizing it.

## **Understanding our emerging “paradigm” and its blind-spots and tacit assumptions**

It was apparent at CERME 11 that many of the contributions shared certain ideas of what implementation in educational situations is. The ideas were shared both in terms of terminology and in terms of key references. Two key concepts apart from implementation are worth mentioning, namely *innovation* as described by Rogers (1962) and his famous work on the diffusion of innovations, and central factors of “implementation” as proposed by Century and Cassata (2016). This means that many of us considered “implementation” as innovation that causes a change when enacted in ordinary practice, and that the change is stipulated by relationships between the nature of the innovation, influential factors and key stakeholders.

Furthermore, we internalized the Rogers (1962) idea that innovations spread through different user segments, from innovators that participate in developing and realizing the innovation, over early adopters to a majority who instantly or relatively soon take up the innovation, and then to the late majority – taking the innovation up late – and laggards who might never change practice.

The five factors that influence innovation proposed by Century and Cassata (2016), were actively used in a number of the contributions in the group, as a lens to study the implementation and implementability of initiatives. These five factors are: characteristics of the individual users, organizational and environmental factors, attributes of the innovation, implementation support strategies, and implementation over time.

Apart from referring to the Rogers' and Century and Cassata's (2016) "standard models" for implementation (as something that causes a purposeful change, related to factors and stakeholders) in the group discussions, we also spent some time investigating the downsides of looking at changes in the educational sector through this lens.

First of all, we observed that the "standard models" tend to fetishize the "manifestation" of a change as an innovation. Change in the educational sector is typically not caused by one "thing". Rather, it is better studied as an interplay between many factors and forces. The constant focus on "innovation" in our work and discussions might have a problematic downside here. Another problem with the term "implementation as enactment of innovation" is that it overplays the intentional aspects of educational change. Many changes come as organic developments rather than as purposeful implementations.

We also began understanding the implementation paradigm by drawing a parallel to Stein, Remillard, and Smith's (2007) phases of curriculum, which was brought to the discussion by Boris Koichu. In Stein et al.'s (2007) model, the curriculum can be seen as consisting of different categories, namely written, intended, enacted, and attained curriculum based on what phase of the teaching and learning process one is focusing on. If we replace the written curriculum with (stable) *research findings*, a new model emerges (see Figure 1). Thus, in this new model published research refers to the research findings available to the teachers. *Intended implications* refer to the set of objectives to be accomplished in practice on the basis of research findings. *Enacted implications* refer to various learning activities or experiences of the learners on the basis of research findings in order to achieve the intended implications. Lastly, *attained implications* refer to the implementation outcomes with respect to student learning on the basis of the intended and enacted implications.

**Figure 1: Phases of implementation of research findings into practice**

## **Introduction to the papers and posters presented at the TWG23**

Twelve papers and two posters were presented at CERME 11, all of them addressing a wide variety of topics and using different approaches. In this section we use the five categories proposed by Century and Cassata (2016) in order to present an overview of the works discussed in this thematic working group. Although not mutually exclusive, to some extent these categories allow us to group the works presented in the TWG23 according to their interests and perspectives.

### **Inform innovation design and development**

The research study by Ioannis Papadopoulos and Nafsika Patsiala falls into this category. They describe a pilot study, aiming at capturing the landscape of problem posing in a Greek grade four classroom. It is intended that the information produced by this pilot study informs and helps to setup a year-long intervention in the classroom aiming to develop the problem posing abilities of the students.

### **Understand whether (and to what extent) the innovation achieves desired outcomes for the target population**

Two papers belong to this category. The first work, by Inga Gebel and Ana Kuzle, presents a problem-solving innovation for students in grades 4-6 has been designed and evaluated. During the evaluation phase, the researchers analyze students' problem-solving solutions with respect to their fluency and flexibility, and present the (dis-)advantages of the innovation in regular mathematics lessons.

The second work is by Helena Gil Guerreiro, Cristina Morais, Lurdes Serrazina, and João Pedro da Ponte. These authors try to understand, in a context of teachers' collaborative group, how emphasizing multiple representations can contribute to the learning of the rational numbers by elementary school students.

### **Understand relationships between influential factors, innovation enactment, and outcomes**

Three of the papers presented in the TWG23 focus on identifying factors that influence innovation enactment. One of them was developed by Rikke Maagaard Gregersen, Sine Duedahl Lauridsen, and Uffe Thomas Jankvist, who focus on identifying the enablers and barriers for the implementation of the so-called *Swedish Boost for Mathematics*, which is one of the largest initiatives on improving mathematics teaching and learning in the Nordic countries in recent times.

The paper presented by Johan Prytz also analyzes the implementation of the Boost for Mathematics initiative, but this paper adopts a historical and comparative approaches. Through this perspective, the author shows the role that research and models of governance played in the New Math project in the 1960s and 1970s, and later in the Boost for Mathematics project.

Finally, the paper by Dorte Moeskær Larsen, Mette Hjelmberg, Bent Lindhart, Jonas Dreyøe, Claus Michelsen, and Morten Misfeldt describes a recent attempt to implement on a large-scale an inquiry-based mathematics teaching in Danish compulsory school. In their analysis, they identify critical factors for this large-scale implementation.

### **Improve innovation design, use, and support in practice settings**

Most of the works presented fall into this category. For instance, Tomas Højgaard and Jan Sølberg refer to a longitudinal project called KOMPIS (a Danish acronym that stands for "Competency Goals in Practice"). In particular, they present a two-dimensional content model derived from the KOMPIS project that aims at supporting competence-based curriculum development and teacher planning.

In turn, Morten Elkjær discusses the design of a dynamic online diagnostic tool aimed at assessing students' mathematical misconceptions in lower secondary school. The design of such online tool is

based on the application of research findings on mathematical misconceptions in algebra and numeracy when working with equations.

The implementation of notions from the inquiry-based mathematics teaching perspective (IBMT) is the focus of the work presented by Per Øystein Haavold and Morten Blomhøj. In particular, they discuss how the design of a four-year professional development project called SUM (A Norwegian acronym that stands for “Coherence through inquiry based mathematics teaching”), can support the implementation of research findings related to the IBMT approach.

The large-scale implementation of alternative models for multiplication is the focus the paper by Anna Ida Säfström, Ola Helenius, and Linda Marie Ahl. They make use of Vergnaud’s theory of conceptual fields to produce a teaching design where models in the form of iconic representations serve as a means for creating patterns that make multiplicative invariants and structures visible.

The work by Nina Ullsten Granlund reports on a professional development project where preschool teachers are offered theoretical tools – in particular Bishop’s theory of mathematical activity – so that they can think about their teaching in a structured and explicit way, but respecting the play-based tradition on which Swedish preschool education is based.

The last article located in this category is the one presented by Boris Koichu and Alon Pinto. They report on the TRAIL project (Teacher-Researcher Alliance for Investigating Learning), which is a co-learning project between mathematics teachers and mathematics education researchers. They illustrate how this project favors teachers’ adaptation of research procedures and ideas in their classrooms as part of participation in community educational research.

### **Develop theory**

The main emphasis of the works included in this category is in the conceptualization of the implementation of research findings. This focus is clearly reflected in the work of Uffe Thomas Jankvist, Mario Sánchez Aguilar, Jonas Dreyøe, and Morten Misfeldt. Taking as a reference implementation research frameworks from outside the field of mathematics education, they try to outline what an implementation research framework in mathematics education could encompass.

Finally, Andreas Lindenskov Tamborg argues in his paper that in order to synthesize the research results in implementation research as an independent sub-field in mathematics education research, there is a need for a consistent vocabulary. He then proposes to combine Century and Cassata’s (2016) definition of implementation research with theoretical notions developed in the realm of the documentational approach to didactics.

### **Results of the thematic group discussions**

During our sessions, we organized two thematic discussions. The first thematic discussion focused on the topic of “*Methodology in implementation research*”, while the second one concentrated on “*Replication studies*”. Below we mention the main ideas that were addressed during those group discussions.

## Methodology in implementation research

As of 2017, we as a community of mathematics educators interested in implementation research, got a forum to talk about and publish our “implementation” research, while analyzing our data from multiple perspectives. Here, different dependent variables can be considered: climate variables, learning variables, system variables or independent variables. Yet, in the wider community this type of research does not necessarily fall under the usual paradigm of “research in mathematics education”. As a consequence, it is not highly-recognized and often is not considered for publishing in high ranking peer-reviewed articles, due to different factors. That said, the following question naturally arises: “*What would count as a high-quality implementation research (recognized by the community and having impact in high-ranked journals)?*” In order to answer this question, we had small group discussions organized around the following questions:

1. What perspective of implementation research does each project follow? Ones identified, what is the purpose of one’s perspective?
2. How is innovation within each project measured and analyzed? What are methodological challenges faced by each “implementation” project?
3. Which of perspectives and purposes from (1) are closely aligned with the usual paradigm of “research in mathematics education”?
4. Which of these perspectives would count as high-quality implementation research? If so, why? If not, why not?
5. What implications would the decision from (4) have with respect to our methodology (e.g., instruments, units of analysis, such as products, processes, evaluation of particular factors, analysis)?
6. What challenges do arise in implementation research (e.g., related to data analysis, to ethical issues) and how could one go about them?

The discussions have shown that TWG23 is at its early stage where many fundamental issues are not yet completely clear. Both thematic discussions as well as the paper discussions made us enter a pathway towards formulating a more precise collective definition of the construct “implementation research in mathematics education” (see last section of this paper). Another issue identified was the complexity of implementation research, which consequently implies the variety of theories needed in order to inform it. Given the length limitation of publications in most of the high-ranked journals, it makes is extremely difficult to report on implementation research in its full complexity – although this is also the case for other types of research. Lastly, in our community implementation of research findings is still not highly recognized by many colleagues. Hence, we discussed the need of a community building and raising awareness with respect to potential of implementation research for the field mathematics education.

## Replication studies

The interest in replicating didactic designs and empirical studies has been present in the community of mathematics educators for several years. In the 1970s Phillip M. Eastman (1975) wondered why there were no more studies of replication in our field, while arguing for relevance of such studies. During the 1980s several reproducibility studies were carried out – mainly in the French teaching

community – focused on understanding the conditions that allowed a didactic design to be implemented with enough fidelity in different scenarios, preserving the effects in student learning.

Simply put, a replication study can be seen as the attempted repetition of a study or an experiment that has been published in a peer-reviewed journal or book. However, since in the social sciences there cannot be two identical qualitative studies (i.e., there is no duplication), the development of qualitative replication studies involves maintaining certain variables similar to the original design, such as investigating a similar population, using the same didactic design, or applying the same modes and categories of analysis or coding. This kind of replication is known as *conceptual replication* (Hüffmeier, Mazei, & Schultze, 2016). Yet, this characterization does not exclude the possibility of developing quantitative approaches to replication studies.

Lately, replication studies are gaining the attention of the mathematics education community (and beyond). An example of this is the working group on replication in mathematics education, which met for the first time at the PME 42 conference in Umeå, Sweden. Another indicator is that some specialized journals are beginning to receive and publish replication studies, for example the *Journal for Research in Mathematics Education* (JRME). However, despite its apparent importance, replication studies have found some obstacles to establishing themselves as an “accepted” type of study in our field. As expressed by Hugh Burkhardt (2013) “Replication, a key element in scientific research, is simply not sexy” (p. 225).

There are several arguments for this lack of “sexiness”. One is that the academic system privileges the publication of original and innovative works, and devalues works that are not perceived as novel. Additionally, some published research does not provide sufficient methodological and empirical details that allow them to be replicated (Schoenfeld, 2018).

With these ideas in mind, the second thematic group discussions revolved around the following questions:

1. Can replication studies be useful for the development of implementation research in mathematics education? If yes, in what way? If not, why not?
2. What characteristics should a replication study have in order to be useful for the development of implementation research in mathematics education?

Although there was no definitive answer to these questions, it did appear a feeling in the group that replication studies could help us identify conditions that allow (or prevent) certain innovations to be reproducible in different scenarios, or even help us investigate the effects of a particular treatment under different conditions or populations, which in turn would allow us to advance the implementation of research results. However, it was also acknowledged that for this type of development to happen in the field of educational mathematics different conditions must be in place. For example, it would be necessary to promote a culture of data sharing where the research protocols, data sets, and other elements on which the research is based are not only public, but also shared among researchers through data repositories.

## Toward a new definition of implementation research in mathematics education

In TSG23, we feel that we are witnessing the emergence of a new and vibrant research area within the field of mathematics education. In plan to continue looking for a common ground on what do we understand as implementation research in our future work, because once we have a more precise understanding of what implementation research is, we be able to think more precisely about what its methodological implications and challenges are. A first collective attempt to formulate a chain of definitions of the key concepts of “implementation” and “implementation research in mathematics education” was led by Boris Koichu at the last meeting of the group. At the end of this discussion, the group formulated the following proposal.

*Implementation* is a change-oriented process of adapting and enacting a particular resource (e.g., an idea, a tool, an innovation, a framework, a theory, an action plan, a curriculum, a policy) that occurs in partnership of two communities, *a community of the resource proponents* (CRP) and a *community of the resource adapters* (CRA). These communities differ but can intersect. At the beginning of the process, the CRP has the ultimate agency over the resource. The process of adapting a resource by CRA includes some of the following: (1) constructing an agency over the resource, (2) changes in ways of communicating, and (3) changes in practice. Accordingly, *implementation research in mathematics education* is research that focuses on aspects of implementation, as specified above, in the context of mathematics education.

As we progress in our work, we will certainly refine our working definition. However, we feel that the above proposal adequately captures many ideas and concerns discussed in the group at CERME 11 and that the journey aimed at further theorizing and characterizing implementation research in our field is worth taking.

# Identification and diagnosis of students' mathematical misconceptions in a dynamic online environment

Morten Elkjær

Danish School of Education, Aarhus University, Denmark; [me@edu.au.dk](mailto:me@edu.au.dk)

*Keywords: Formative assessment, implementation research, misconceptions, diagnostic test.*

This poster aims to present the ideas behind the design of a dynamic online tool to assess students' mathematical misconceptions in lower secondary school. These ideas and this tool are part of an industrial PhD project, which is a collaboration between the Danish School of Education, the doctoral candidate, and the company Edulab.

Edulab is a Danish private company that has developed an online mathematical learning platform for the Danish elementary school. In Denmark, 75% of elementary schools subscribe to this platform. In fact, every day Danish school students answer 1.5 million tasks on this online platform. This creates a unique opportunity to implement didactical research results regarding mathematical misconceptions directly into practice. The industrial PhD project aims to provide Edulab with an evidence-based tool to capture students' misconceptions, understood as concept images differing from the formal concept definition (Tall & Vinner, 1981). Thereby providing the teachers in lower secondary school with easily accessible formative assessment of their students in the fields of algebra and numeracy in working with equations. Cai et al. (2017) claimed that linking intervention with implementation through iterations of design research is a strong way for researchers to have an impact on practice.

From reviewing the literature on misconceptions, it concludes that the community knows a great deal about mathematical misconceptions and learning difficulties related to algebra, equations and numeracy in lower secondary school (e.g., Booth, McGinn, Barbieri & Young, 2017). Such research-based findings in combination with an online mathematics platform that communicates directly to the end user (i.e., the students) provides a unique opportunity to shorten the implementation time span between the research findings and the end user as was pointed out by Century and Cassata (2016). The project goal is to investigate: How can an online diagnostic tool for lower secondary school be designed, utilizing existing research findings on mathematical misconceptions in algebra and numeracy when working with equations?

To answer the question the aim is to design, and develop an online diagnostic test. Designing an online diagnostic test aimed at lower secondary school students is going to be an iterative process. The literature review will give rise to a categorization of algebraic misconceptions. The idea is to use the 'Concepts in Secondary Mathematics and Science' projects diagnostic tests (Hart, Brown, Kerslake, Küchemann & Ruddock, 1985) in algebra and number operations in a modernized, digital version in order to locate students holding misconceptions fitting this categorization. Based on the algebraic tasks the students have interacted with on the platform, it should be possible for machine learning algorithms to create a "platform behavior" fitting the categorization. It is worth noting that students having greater usage of the platform are a preferable choice for diagnosis in order to create a more precise platform behavior for the different categories of misconceptions. Design-Based Research (e.g., Barab & Squire, 2004; diSessa & Cobb, 2004) will pave the way for the knowledge

generated through iterations of the work with the diagnostic tests and the machine learning algorithms. The project's hypothesis is that math teachers in Denmark, based on collected data, have a unique opportunity to organize, plan and complete their teaching. The point of the continuous diagnosis of all students using Edulab's platform is to catch if students are using the platform as if they are holding one or more misconception(s). The teachers are provided with a formative assessment report, generated for each student that possibly holds misconceptions, describing the student's behavior and the misconceptions present. Thereby, providing an in-depth explanation of which algebraic concepts and processes in which the students' concept image is conflicting with the concept definition may give the teacher the opportunity to aid the student avoid further progress in constructing a deeper rooted and conflicting concept image. Lucariello, Tine and Ganley (2014) emphasize the importance of teachers having access to formative assessment regarding individual student's misconceptions in order not to impede the student's future learning. This formative assessment report should contain ideas and guidelines for how the teacher further teaches the student in the form of literature-based explanations of the origin of the diagnosed misconceptions, and how the concept image may be changed.

Ultimately, the industrial PhD project is looking to generate knowledge and perspectives on how mathematical online diagnostic testing together with mathematical online formative assessment can be implemented in order to help teachers, and thereby students in Danish lower secondary school.

## Implementation research in primary education: Design and evaluation of a problem-solving innovation

Inga Gebel<sup>1</sup> and Ana Kuzle<sup>2</sup>

<sup>1</sup>University of Potsdam, Germany; [inga.gebel@uni-potsdam.de](mailto:inga.gebel@uni-potsdam.de)

<sup>2</sup>University of Potsdam, Germany; [ana.kuzle@uni-potsdam.de](mailto:ana.kuzle@uni-potsdam.de)

*Problem solving is a binding process standard that is often neglected in school mathematics, and generally reserved for motivated and gifted students only. Researchers also call for the development of problem-solving competences, starting already in primary school to promote the habits of mind, that can be applicable in situations varying from challenges in school to those in life. Different questions emerge in this context. What tasks are suitable to reach all students? What might a differentiated problem-solving classroom look like that would attain to individual student needs? In this article, we present a problem-solving implementation research project. For this purpose, a problem-solving teaching concept with an accompanying type of task for primary education was developed based on both theory and projects on problem solving. The first results indicate positive outcomes with respect to meeting the requirements of practical suitability, and sustainability.*

*Keywords: Implementation research, problem solving, differentiation, primary education.*

### Introduction

New implementations in schools often involve different protagonists (e.g., teachers, students, researchers, policy makers), each contributing different expertise, but also having their own demands. Design-Based-Research (DBR) is a flexible methodology that aims to improve learning and teaching in naturalistic settings through iterative cycles of design, implementation, analysis and re-design, where both researchers and practitioners collaborate towards a common goal. Over time, this can lead to changes in the implementation, such as target group, material, teaching concept, which are then re-evaluated in the next cycle (e.g., Wang & Hannafin, 2005).

DBR is the basis for two research projects, namely SymPa and DiPa<sup>1</sup>, that focus on implementation of problem solving in school settings. In both projects, problem solving is regarded as an educational goal, namely development of students' problem-solving competences in a targeted manner by learning heuristics. In the context of the SymPa project, theory-based and practice-oriented materials were developed for motivated students in grades 4-6 (Kuzle & Gebel, 2016). Even though Kuzle and Gebel (2016) reported on variables, and conditions that favored and hindered the implementation of the material on the basis of two DBR cycles using the feedback from the students and the teachers, several crucial inhibiting factors unraveled once researchers themselves observed the implementation, and planned the lessons with the preservice teachers (Gebel & Kuzle, 2019). In particular, the teaching concept focused around systematical introduction of different problem-

---

<sup>1</sup> SymPa stands for *Systematic and material-based development of problem-solving competences*; DiPa stands for *Differentiated development of problem-solving competences*. In German: *Systematischer und materialgestützter Problemlösekompetenzaufbau* and *Differenzierter Problemlösekompetenzaufbau*, respectively.

solving heuristics, which inhibited individual problem-solving processes of the students. Though the problem-solving tasks allowed students to choose different problem-solving paths, the teacher guided the students to use a particular heuristic in focus. Consequently, these factors impacted student motivation. In addition, the teaching concept was not aligned with the typical lesson structure, which resulted in preservice teachers needing support when planning their lessons. Even though one could expect that motivated students are a homogeneous group, we experienced that the tasks did not necessarily invoke problem-solving behaviors. Thus, the problem tasks need to offer more freedom with respect to a problem-solving approach (e.g., subtasks with different levels of difficulty), but on the other hand challenge students to use their knowledge in a complex way.

Based on the above listed inhibiting factors, the SymPa project was further developed into the DiPa project. The main goal of the project is to make implementation of problem solving in primary school mathematics suitable, and sustainable by developing a problem-solving teaching concept aligned with the typical lesson structure, and a type of tasks that would address the individual needs of each student (Gebel & Kuzle, 2019). In the following sections, we outline relevant theoretical foundation used to develop criteria for differentiated problem-solving tasks, and the teaching concept for primary education, before showing how these got implemented, and report on the evaluation of the pilot study (initial DBR cycle). Leading questions for the evaluation are: To what extent does the teaching concept consider necessary differentiating approaches to problem solving? What are the differences depending on the level of performance comparing to fluency and flexibility? What are the (dis-) advantages of the innovation in regular mathematics lessons? As a result of the evaluation, we discuss the findings with respect to possibilities, and limitations of the teaching concept and the nature of the problem-solving task in the context of grade 5 mathematics. With regard to implementation research, this article provides an overview of the development of our innovation (i.e., problem-solving teaching concept and task), and the identification of the first core elements of the innovation (e.g., Century & Cassata, 2016). Detailed answers are not delivered at this time, but rather an insight into the first DBR cycle is given.

### **Theoretical foundation guiding the design process**

A plethora of research on problem solving undergoing since the 1970s identified several pivotal areas for a problem-solving curriculum. Here, we outline only a small portion of this research that was crucial for the project based on German standards' conception of problem solving (KMK, 2004).

#### **Learning problem solving**

Problem-solving competence relates to cognitive (here heuristic), motivational and volitional knowledge, skills and actions of an individual required to overcome a personal barrier in unfamiliar situations (e.g., Bruder & Collet, 2011; Schoenfeld, 1985). Thus, routine procedures are not sufficient to solve a problem, but rather heuristics may be helpful. *Heuristics* can be defined as

kinds of information, available to students in making decisions during problem solving, that are aids to the generation of a solution, plausible in nature rather than prescriptive, seldom providing infallible guidance, and variable in results. (Wilson, Hernandez, & Hadaway, 1993, p. 63)

In the field of problem solving there are two different approaches to learning heuristics. In an *implicit heuristic training*, it is assumed that the students internalize and unconsciously apply strategies they have learned through imitating practices of the teacher, and through sufficient practice. On the other hand, *explicit heuristic training* refers to making a given heuristic a learning goal, which is practiced step by step (e.g., Schoenfeld, 1985). For instance, Bruder and Collet (2011) pursued an explicit problem-solving training focusing around Lompscher's (1975) idea of "flexibility of thought". *Flexibility of thought* is expressed by manifestations of mental agility, namely reduction, reversibility, minding of aspects, change of aspects, and transferring. Untrained problem solvers are often unable to consciously access the above outlined flexibility qualities. In their research at lower secondary level, Bruder and Collet (2011) were able to show that less flexible students (e.g., students with difficulties in reversing thought processes or transferring an acquired procedure into another context) profit from explicit problem-solving training. Concretely, they were able to solve the problems just as well as more flexible students, who solved the problems intuitively. Thus, problem solving can be trained by learning heuristics corresponding to these aspects of intellectual flexibility in combination with self-regulation (e.g., Bruder & Collet, 2011; Schoenfeld, 1985).

### **Criteria for differentiated problem solving tasks**

In addition to the choice of the teaching approach, the problem selection is also a key factor for a successful development in problem-solving competences (e.g., Pehkonen, 2014). In the SymPa project we used different types of problems (i.e., open-ended, closed, subtasks with different levels of difficulty) (Kuzle & Gebel, 2016), but always oriented on the specific mathematical content as outlined by the mathematics curriculum (KMK, 2004). During the implementation, it became apparent that the subjective barriers of the students were very different: some tasks represented a challenge for some students, and for others there were routine tasks (Gebel & Kuzle, 2019).

Since differentiation is the core idea of the DiPa project, we developed specific criteria for our type of a problem-solving task, namely *Problem-based Learning Environments* (PLE), that address the previously mentioned drawbacks<sup>2</sup> and fit the framework of the DiPa project. In addition to the criteria of general learning environments (Wälti & Hirt, 2010), a heuristic core is the key aspect of the PLE, whereas the mathematical content is present, but not in the foreground. With a PLE, we refer to a collection of related problems, that are linked by certain guiding principles based on an intra-mathematical and heuristic structure, and fulfill the following criteria: accessible to *all* learners, *variety* of possible solutions and ways of thinking (use of different heuristics), high *cognitive activation potential*, independent activity by means of *enactive or iconic representations*, *implicit mathematical content*, and *social exchange*. In itself they offer more freedom; each student can decide independently in what depth he or she works on the PLE. With each subtask the students are compelled to use their knowledge in a more complex way. During this process they may use enactive or iconic material to support their problem-solving process.

---

<sup>2</sup> For the sake of completeness, it should be said that there are already problem-solving task formats in the literature that also consider individual approaches. For example, Pehkonen (2014) showed the potential of using problem fields to engage all students in problem solving.

## Problem-solving teaching concepts

A few teaching concepts exist that focus on a longitudinal development of problem-solving competences. Here, we report on the teaching concepts of Bruder and Collet (2011), Rasch (2001), and Sturm (2018), and their limitations for everyday implementation in primary school mathematics. The five-phase teaching concept of Bruder and Collet (2011) has been successfully implemented in the context of lower secondary school. The core idea of the teaching concept lies upon a long term systematical, and explicit training of heuristics through the phases of familiarization, explicit strategy acquisition, productive practice phases, context expansion, and awareness of the own problem-solving model. Even though this teaching concept has been empirically evaluated, its implementation in primary grades showed some limitations (Gebel & Kuzle, 2019), as was noted earlier. For that reason, we follow Rasch (2001) and argue for a less specific step-to-step teaching concept. Hence, we need a teaching concept, that would first allow all students (in primary school) access to problem solving in an intuitive manner, before explication of particular heuristics is initiated.

Sturm (2018) conducted a problem-solving training in primary school focusing on external representations. The teaching concept included three phases that spread over two mathematics lessons. During the first lesson the students solved a given problem intuitively, whereas the students' solutions with respect to used heuristics were made explicit during the second lesson, after the teacher gained insight into students' solutions between the two lessons (Rasch, 2001; Sturm, 2018). Taken the extensive analysis of students' solution, we find this structure difficult to implement in practice. Although the implicit (intuitive procedures) and explicit ideas (reflection of the solution path) of heuristic trainings were taken into account, we assume that due to implementation once per month, the students have difficulties recalling their problem-solving processes and therefore, the reflection process may be too abstract. Here, a 90-minute lesson, focusing on several different heuristics – and not just on external representations – may be more plausible.

Based on this limitations, and the results from the SymPa project (Gebel & Kuzle, 2019), the DiPa project pursues an alternative teaching concept (see Table 1), in which both implicit and explicit heuristic training are combined. Furthermore, its structure corresponds with a typical lesson structure, which may unburden teachers when planning their lessons. In addition, the second exploration phase represents a novelty. Other problem-solving teaching models (e.g., Rasch, 2001; Sturm, 2018) terminate after the third phase (explicit strategy acquisition), so that heuristic strategies are only transferred in the case of structurally similar tasks, which could represent an additional hurdle. Alternatively, in our proposed problem-solving teaching concept (see Table 1), the students have the opportunity to apply the heuristics even to the same subtask.

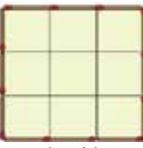

1. Introduction	The basic problem is presented. Comprehension questions are discussed in plenum.
2. Exploration I	The students work independently, and intuitively on a given PLE. They document their work on their worksheets. Teaching material on an enactive or iconic level creates differentiation opportunities.
3. Explicit strategy acquisition	The students gain an insight into the procedures of their fellow students. Relevant heuristics are discussed in plenum, and documented on a strategy poster.
4. Exploration II	The students continue working on the PLE, and apply the heuristics that were discussed in the phase 3.
5. Reflection	Students reflect on their problem-solving process by analyzing the heuristics they used, and changes in their approach. If necessary, new heuristics mathematical ideas are discussed in plenum.

**Table 1: Teaching concept for problem-solving lessons in the DiPa project**

## Evaluation: Data sample, instruments and procedure

The evaluation of the pilot study had several objectives: (1) to evaluate the teaching concept with respect to differentiation during problem solving, (2) to analyze students' problem-solving solutions with respect to their *fluency* (creating a large number of ideas) and *flexibility* (changing perspective and using different strategies) and in contrast to their level of performance, and (3) to present the (dis-)advantages of the innovation in regular mathematics lessons.

For this study, an exploratory qualitative research design was chosen. The study participants were two fifth grade classes ( $n = 40$ ) from one urban school in the federal state of Brandenburg (Germany) (Gebel & Kuzle, 2018). Main sources of data were student worksheets, and a semi-structured interview with the teacher.

<p><b>PLE: Paper squares</b> Tina has 12 matches and some paper squares. The side length of one square is as long as one match: </p> <p>Here you can see a figure with 12 matches and 9 paper squares.</p>  <p>The squares must meet at the sides. Therefore, the following does not apply:</p> 	<p>Task a) Can Tina lay a figure with 12 matches that includes 5 paper squares?</p>	<p>Task b) How many different figures can you find, which are laid out of 12 matches and include 5 paper squares?</p>
	<p>Task c) Can Tina also lay figures with 12 matches that include 6/7/8 paper squares? Which figures can you find?</p>	<p>Task d) Which figure includes the most and which figure includes the least paper squares? (<i>Use 12 matches.</i>)</p>
	<p>Task e) What is the minimum number of matches to enclose 10/11/12/... paper squares?</p>	<p>Task f) What is the highest number of matches to enclose 10/11/12/... paper squares?</p>
	<p>Task g) Can you find a relation between the count of paper squares and the highest number of matches? What is the minimal number of matches to enclose 100 squares?</p>	<p>Task h) Invent further tasks.</p>

**Figure 1: Problem-based Learning Environment “Paper squares”**

The research data were collected in a school setting during a 90-minutes lesson. The first author of the paper taught the lesson structured around the teaching concept, whilst the class teacher observed the lesson. The students were first introduced to the PLE “Paper squares” (see Figure 1). The students read introduction to the problem, and misunderstandings were discussed (phase 1). Afterwards, they worked individually on its different subtasks. Each student received its own working sheet with grids, and enactive material (e.g., matches and paper squares) (phase 2). In phase 3 a museum exposition took place; the students laid their worksheets on the table and got insight into the solutions of their classmates. Afterwards, we discussed clever strategies and noted them on a strategy poster. Before working on further subtasks or working again on the same subtasks using the newly noted strategies on the strategy poster (phase 4), they drew a red line to denote their work in the second exploration phase. At the end of the lesson, students' solutions were discussed in plenum. In addition, new strategies were noted on the strategy poster, and their mathematical discoveries were discussed (phase 5). The same procedure was used with the second fifth grade class. A semi-structured interview with the class teacher took place, and lasted about 45 minutes. It was used to assess the teaching concept, and the individual problem-solving behaviors of the students compared to regular mathematics lesson.

The student work on subtasks a) and b) was analyzed after all the data had been collected. As suggested by Patton (2002), multiple stages of the analysis were performed. For the within analysis each student was treated as a comprehensive case. The analysis procedure for both classes consisted

of counting the number of basic figures (see Figure 2), and their duplicates<sup>3</sup> on the basis of each student's worksheet, which provided an insight into their fluency. For the cross analysis the students were clustered into three groups based on their mathematical performance: high (grade 1), average (grade 2) and low (grade 3/4) achieving students, in order to compare the particular performance groups against each other. Both researchers coded the student data independently. Adjustments were subsequently made after which the interrater reliability was 100%.

## Results

Table 2 gives an overview of students' results during the first and the second exploration phase when working on the first two subtasks of the PLE. What is particularly striking here, is that the students from the group of low achievers ( $n_{3/4} = 6$ ), who again worked on subtasks a) and b), had a particular increase in the number of solutions in the second exploration phase (from 2,83 solutions to 9,5 solutions). Even though the sample size, and the orientation towards the mathematics grade represent limitations of the pilot phase, it can be assumed that especially low achievers profited from the explicit strategy acquisition phase. Those, who were less able to develop strategies on their own in the first exploration phase, were able to produce many different solutions in the second exploration phase due to insight into their classmates' solution, and discussion in plenum (Gebel & Kuzle, 2018).

	<b>n<sub>1</sub></b>	<b>n<sub>2</sub></b>	<b>n<sub>3/4</sub></b>
Data sample	11	19	10
Absolute frequencies of solutions (tasks a and b)	12,27	8,11	8,2
Students, who worked further on task b in exploration II	4 (3)	9	6
Absolute frequencies of solutions in exploration I	6 (7,67)	4,44	<b>2,83</b>
Absolute frequencies of solutions in exploration II	12,5 (10,3)	9,11	<b>9,5</b>

**Table 2: Results of the pilot study**

**Figure 2: Basic solution figures of the PLE "Paper squares"**

The analysis of the strategies used during the problem-solving process has shown to be a big challenge. The majority of the students were not able to describe their solution behavior in writing. Here, alternative research instruments are needed to discern student thinking when problem solving. Nevertheless, we recognized huge differences in the solutions between the sample groups. For example, figure "staircase" was found by average and high-achieving students only (see yellow figure in Figure 2). In addition, the students had lively discussions about the permission of reflected and rotated figures. The worksheets of the high- and average-achieving students showed tendencies towards systematical rotations, and reflections of basic figures. In the semi-structured interview, the teacher particularly emphasized that *all* pupils had access to problem solving. Moreover, they were able to work on the PLE at different levels: she observed different forms of representation, such as

<sup>3</sup> It was left to the student if reflected/rotated figures were to be documented, as this was not explicitly given in the PLE.

enactive material, iconic representations, written descriptions. Students' pervasiveness and perseverance during the lesson were also positively evaluated. In addition, she mentioned that – in contrast to SymPa teaching concept – the strategies emerged from the students' solutions and were not given by the teacher. Thus, the students started solving the problem intuitively followed by explicit strategy naming based on students' solutions. Her assessment of the second exploration phase is consistent with the analysis of the students' solutions. She saw a great benefit of it for the low-achieving students by getting insight into their classmates' solutions. Nevertheless, she stated that the students had difficulties describing their problem-solving processes in writing. Last but not least, the teacher asserted that all students had fun doing mathematics when solving the given PLE.

## Conclusion

Despite different endorsements for making problem solving a vital part of school mathematics (e.g., KMK, 2004), problem solving has not yet been fully implemented in school mathematics. In order to reach this goal, we need to understand what variables and conditions, such as tasks, teaching concepts support and/or inhibit a sustainable implementation in school settings. In the DiPa project we have consciously decided to establish problem solving in regular mathematics lessons in order to simultaneously (1) develop suitable practice-oriented materials, (2) to develop a sustainable problem-solving teaching concept for all students, and (3) to gain realistic insights into individual students' learning processes. The results have shown that a synergy of the teaching concept, and the PLE allows all students access to problem solving. Low-achieving students benefited the most, especially through the use of concrete material, the nature of the task, and the insight into classmates' solutions. With respect to fluency, difference between the high and average/low-achieving students was minimal. However, student flexibility was rather difficult to measure. So far, we used one PLE with two fifth grade classes from one school. Hence, the evaluation of our innovation is limited to these conditions. Nevertheless, they suggest the next step in our research, namely to conduct a study with a larger data sample using several PLEs over a longer period of time in a wider variety of settings. Our goal is to examine the development of the students' problem-solving competences as well as factors affecting this development. Here, we plan to videotape students during problem solving in order to obtain a holistic view of their problem-solving learning. This process will then guide our focus with respect to teaching and learning problem solving from both theoretical and practical points of view.

<sup>3</sup>Danish School of Education, Aarhus University, Denmark; [utj@edu.au.dk](mailto:utj@edu.au.dk)

*In this paper, we identify a number of implementation enablers and barriers in the Swedish ‘Boost for Mathematics’ (BM). Through an analysis of two selected BM modules’ use of sensitizing and prescriptive theoretical constructs from mathematics education research, we attempt to link the existence of enablers and barriers to identified policy dimensions of the BM. Besides the two modules on the web portal (the Lärportal), the study’s empirical data also consist of surveys of four involved teachers and interviews with two involved researchers and module designers. The analyses also make use of the innovation’s novelty and value, the degree of merit in how it is imparted and Rogers’ three determinant factors of an innovation.*

*Keywords: Implementation research, enablers and barriers, policy dimensions, degree of merit.*

## Introduction

This paper looks at one of the largest initiatives on improving mathematics teaching and learning in the Nordic countries in recent times, namely *the Swedish Boost for Mathematics* (from now on referred to as BM), which was implemented from 2012 to 2016. The BM was a national professional development initiative with the goal of enhancing students’ mathematics performance in Swedish primary and secondary school. The initiative was a reaction to continuously disappointing result in international tests, such as TIMSS (Bentley, 2008) and PISA (Utbildningsdepartementet, 2012). BM was designed and developed as a collaboration between the Ministry of Education and Research, the Swedish National Agency for Education, and the Swedish national resource centre for mathematics. The BM involved 260 municipalities, 37,000 mathematics teachers, and had a cost of Skr. 649,000,000 (Nyström, 2018). The BM has been evaluated in a handful of reports (e.g., Österholm, Bergqvist, Liljekvist, & Bommel, 2016; Ramböll, 2016). In this paper, however, we consider the BM from an implementation research perspective, meaning that we apply theoretical constructs from implementation research to address selected aspects of the implementation. process. From such theory, it is well known that the success of an implementation process to some extent depends on its enablers and barriers, i.e., people or factors that either enhance aspects of the implementation or somehow diminishes them (e.g., Nilsen, 2015). Like many other initiatives concerning the improvement of mathematics instruction and learning, the BM drew on and sought to implement research results and findings from mathematics education research. We thus consider the BM as an implementation program in a mathematics education context. The research question that we ask is: *What enablers and barriers for implementing mathematics education research results and findings in practice can be determined in the Swedish Boost for Mathematics initiative?* The study reported in

this paper and the empirical data that it builds upon stem from a master's thesis in mathematics education at the Danish School of Education, Aarhus University (Lauridsen & Gregersen, 2017).

### **Theoretical constructs related to implementation research**

First, we elaborate on our understanding of implementation and innovations, and then we introduce the terms and constructs applied in the analysis.

“Implementation takes place when an individual puts an innovation into use” (Rogers, 2003, p. 20). But what is an *innovation* in the context of mathematics education? If we view the BM as an implementation process, mathematics education research results are the innovations. Hence, a clarification of innovation is in order. In the original definition by Schumpeter (1934/1961), an innovation entails a valuable change in practice. According to Rogers (2003), an innovation, on the other hand, has to be considered novel, not necessarily in common understanding, but for the individual doing the implementation. We shall draw on both positions and define an innovation in the context of mathematics education as: Mathematics education research results that are subjectively novel and bring valuable changes into practice once implemented (Lauridsen & Gregersen, 2017) – taking into account that what is to be considered valuable is of course also to some extent subjective.

To determine enablers and barriers (see Nilsen, 2015) within the implementation program, we draw upon parts of Rogers' (2003) theory of diffusion of innovations. Rogers claims that there are three determinant factors for an innovation to be implemented: the *awareness-knowledge* of the existence of the innovation; *how-to knowledge*, which is knowing how to apply the innovation; and *experience of relevance* of the innovation. Each factor is influenced by an undefined number of variables, which either enable or barricade the implementation (Nilsen, 2015). The aim of analyzing enablers and barriers is to obtain insight, nuance and challenge the determinant factors. We also use Rogers' (2003) term *principles-knowledge*, which refers to understanding how and why the innovation works. Principles-knowledge is not a determinant factor but is seen as a valuable contributor to a successful implementation, hence in this context it can be seen as an enabler for implementation. To gain further insight into barriers and enablers, the BM's theoretical content is viewed as either *prescriptive* or *sensitizing* (Nilsson, Ryve, & Larsson, 2017). Prescriptive theories supply the teacher with actions that should be applied in practice, whereas sensitizing theories supply insights into learning processes. Sensitizing theories can be seen as a way to obtain theoretical principles-knowledge, and the prescriptive theories as a way to obtain theoretical how-to knowledge. This comparison allows us to connect theoretical content to the knowledge framework from implementation theory.

To classify the BM, we adopt the notion of *policy dimensions* by Trouche, Drijvers, Gueudet, and Sacristán (2013). They use this notion to classify the policies concerning implementations of technological developments in mathematics education. Our use differs slightly, however, as we consider implementations of mathematics education research results. Trouche et al. (2013) define three policy dimensions: *top-down/bottom-up* referring to the origin of the implementation process initiative; *offering access/supporting integration* referring to the extent to which the implementation process is supported beyond supplying access to the research results; and *collective/individual* referring to whether the process of implementation is conducted with colleagues or not. Trouche et

al. (2013) claim that bottom-up, supporting and collective policies promote implementation, yet in our understanding it must be the variables connected to a policy that act as enablers/barriers.

## **Educational background, research methods and empirical data**

In the BM, groups of mathematics education researches and mathematics teacher educators were asked to author modules for an online open-access resource platform, the so-called Lärportal (<https://larportalen.skolverket.se/#/>), which now contains more than 30 modules. A module contains eight segments, each working through a four-phase process: (A) individual preparation, where participating teachers read texts and watch videos; (B) collegial work, discussing text and preparing lessons/activities; (C) individual execution of lessons/activities; and (D) collegial evaluation of learnings and classroom experiences. Four didactical perspectives are common to all modules: Classroom norms/socio-mathematical norms; teaching by the mathematical competences, assessment of learning and teaching in mathematics; and routines and interaction in the classroom (Österholm et al., 2016). School leaders and counsellors were educated to support and guide teachers in the process (Skolverket, 2017). All Swedish mathematics teachers were granted attendance of two modules. After that, it was up to the individual schools to finance further participation.

The method of the paper is a case study of two selected modules within the BM program: “Algebra module grades 7-9” and the “Problem solving module, grades 7-9” (Skolverket, 2017). The main theoretical construct behind the algebra module is that of variation theory (Marton, 1981), although it also contains a range of topic specific constructs concerning the learning and teaching of equations, variables and formulas. The main theoretical constructs of the problem solving module are the “five step model” (Stein, Engle, Smith, & Hughes, 2008) for planning and conducting problem solving lessons and the “four phased problem solving process” (Skolverket, 2017) for organizing students’ problem solving.

The empirical data on which this study relies was gathered as part of the previously mentioned master’s thesis (Lauridsen & Gregersen, 2017). The data was obtained by three different methods:

- Coding of the module content in regard to whether texts and videos were communicated primarily in a prescriptive or sensitizing manner (Nilsson et al., 2017).
- Interviews with two representative researchers who participated in the development of the algebra module (Researcher 1) and problem solving module (Researcher 2), respectively.
- A questionnaire answered by four available teachers, three who had completed the problem solving module (Teachers 1, 2, 3), and one who had completed the algebra module (Teacher 4).

## **Policy analysis and coding of module content**

In regards to the three policy dimensions (Trouche et al., 2013) the dominant policies of the BM are top-down, supportive, and collective, which of the top-down policy is not considered favourable in an implementation process. Despite the top-down policy, the teachers’ workflow has been highly organized in consideration to teachers’ needs, in terms of influence and practical relevance. We also see this in the developers’ (Researcher 1 and 2) awareness on imparting content in the modules towards teachers. This indicates that a top-down policy under certain conditions can support and organize several enablers. The supportive policy of the BM appears, for example, in the financial

contribution to participating schools and in the teachers' access to counsellors. The financial support is limited to two modules, which lessens the extent of the support dimensions of the future use of the Lärportal. The BM was primarily influenced by a collective policy, which was central to the design of the Lärportal, with a few individual elements (Lauridsen & Gregersen, 2017).

The coding of the content in the algebra module determines that it mainly contained sensitizing theoretical constructs and only a few elements of prescriptive theoretical constructs. On the contrary, the problem solving module mainly contained prescriptive theoretical constructs and only a few sensitizing constructs. These conclusions were confirmed by Researchers 1 and 2 (Lauridsen & Gregersen, 2017). Please note that the article 'Programming and programming process' has been added to the Algebra module April 2018 and is not included in the coding. When comparing the questionnaires answered by the teachers, some interesting statements about their learning outcomes become apparent. Teacher 4 stated that she mainly developed how she teaches the concept of equality and the meaning of the equality sign. This is particularly notable as the main theory in the algebra module was variation theory (Marton, 1981). For this reason, we analyzed the algebra module for content on the equality sign and the conformity of the presented and used theoretical constructs. We found that there were only a few mentions of actual research results on students' difficulties and misconception on the concept of equality (Lauridsen & Gregersen, 2017). Kieran (1992) is cited, but the key findings on the need for experiences of complex arithmetic of the form  $ax + b = cx + d$  is left out. This fact leaves you wondering to what extent the changes in Teacher 4's practice may have been supporting her students' concept formation of equality. It thus becomes a question of merit concerning the accuracy in which research results are imparted to teachers, with which the definite findings and conclusions of the research are referenced in the text.

### **Implementation analysis – enablers and barriers**

In this section, we analyze the BM for influential variables related to the three determinant factors of considering them as enablers or barriers, and further relate them to the policy dimensions as well as the categorized module content.

Firstly, we analyze for enablers and barriers in relation to *awareness-knowledge*. Following Rogers (2003), access to mass media is a certain source to knowledge of the existence of the innovations. In the BM, the Lärportal represented a mass media where the teachers were able to achieve awareness-knowledge on a range of mathematics education research. In continuation of this, it may be of a certain importance that the content was conveyed to teachers in a way that was understandable and therefore also accessible. Both Researchers 1 and 2 stressed that it had been an important part in the development of the modules that communication was targeted the teachers as receivers in the Lärportal. This indicates that the ways in which innovations are imparted to the receiver may be considered an enabler of awareness-knowledge. In the section above, we noticed the importance of imparting innovations with a certain degree of merit, to support guidance of teachers. The question is whether the teachers really do achieve awareness-knowledge, if the presentation of the innovation is not communicated with a certain degree of merit, e.g., that the key findings are stressed when research is referred. Hence, the lack of merit of the innovation conveyed, may be regarded as a barrier of the awareness-knowledge and hereby also the following implementation process in the BM.

Secondly, concerning *how-to knowledge*, teachers may obtain such throughout the implementation process. The Lärportal is a major source of how-to knowledge. Teacher 1, 2 and 4 described using the Lärportal, as they searched for videos and written suggestions for classroom activities to find inspiration during and after the BM. Consequently, the access to a mass media, containing how-to knowledge, can be considered an enabler in the BM. When comparing the types of knowledge in the algebra and the problem solving modules, the latter module mainly contains how-to knowledge (cf. above). Teacher 1 and 2 both implied that they now use the five-step model (Stein et al., 2008) as well as the four-phased process (Skolverket, 2017) in their practice (cf. above), i.e., the main theoretical constructs of the module. This suggests that mass-media access to how-to knowledge such as task suggestions and videos of classroom examples may be considered enablers. Teacher 4 had not, in the same manner, implemented the main theory, variation theory (Marton, 1981), in the algebra module, but she had gained a new perspective on planning classroom presentations focusing on students' misconception. This implies that the teacher had gained some how-to knowledge through the planning and execution of the experimental practice in phase B and C as a way of implementing the principles-knowledge gained in phase A (cf. above). On this account, the experimental practice can also be understood as an enabler for how-to knowledge about the gained principles-knowledge and hereby for implementation. According to Rogers (2003), the more complex an innovation is, the more how-to knowledge is needed. This might be the case for Teacher 4. Complex theoretical constructs, such as variation theory, may become a barrier, when not supported with sufficient how-to knowledge. Another example of this is found in the lack of development of socio-mathematical norms (Yackel & Cobb, 1996), which is documented in an evaluation of the BM (Österholm et al., 2016). Researcher 2 confirms this:

Researcher 2: [...] it is very easy to say that these norms are important, but how should you act as a teacher to change them? The norms are not something you can get to grips with. My guess is that teachers have been presented with too few concrete examples on how to work with these norms.

Recall that the BM can be characterized as a collective policy. This entails that for the majority of the process, the teacher has access to an interpersonal source of how-to knowledge. This gives teachers access to colleagues' experimental how-to knowledge. Trouche et al. (2013) argue that collective policies can be a support for implementing a technology. The same argument seems to withstand when it comes to implementing research findings in mathematics education into practice. The collective processes in the BM may, therefore, be viewed as enablers for how-to knowledge.

Thirdly, we analyze enablers and barriers regarding the last determinant factor for implementation (Rogers, 2003), i.e., the subject's experience of *relevance* of the innovation. We do so based on two examples of the teachers' work with the two modules. The first example is based on that we previously made it clear how Teacher 4 continued the use of her new knowledge of the equality sign after having ended her work with the BM. Following Rogers (2003), this continuous use of the mathematics didactical knowledge is a sign of a successful implementation. In relation to relevance of the theoretical constructs, Teacher 4 expressed her experience of relevance of the didactical research concerning the equal sign: "...as it is so important and frequently used in mathematics" (our translation). Our second example is from Teacher 3, who verbalized:

Teacher 3: I do not think the Boost for Mathematics was a good “boost”. The information it provided was for example the kind of material that we had used in our school for several years [...]. There was no new and inspiring tasks to use, which was sad in the view of it all. (our translation)

We regard this as an expression of a lack of experience of relevance. Teacher 3 was already aware of the presented strategies and theories in her current practice. This is of course not the same as her considering the content of the problem solving module irrelevant, only it was not relevant to her. This indicates that if the teachers are not presented with anything new, i.e., no innovation, it can become a barrier for their experience of relevance of the BM. In our further analyses of Teacher 3’s questionnaire answers, we see no indication of a use of theories from the BM. Hence, for Teacher 3 the BM must be considered an unsuccessful implementation.

To understand the enablers and barriers of the teachers’ possibilities of having an experience of relevance, we examine the primary differences at the two modules. Recall from the previous section that the theoretical content in the algebra module was mainly sensitizing while it was mainly prescriptive in the problem solving module. It is relevant to consider the extent to which this might influence enablers or barriers in the teachers’ experience of relevance. Previously we illustrated the connection between prescriptive theory and how-to knowledge and sensitizing theory and principles-knowledge, respectively. In the second example, Teacher 3 primarily met prescriptive theoretical constructs in the module and thereby descriptions of phases and steps about how to teach problem solving. ‘Unfortunately’ Teacher 3 already had an existing practice built on these phases and steps. According to Rogers (2003), a principles-knowledge can contribute to a better understanding of why something works. This understanding of ‘why’ can qualify ‘how’ one does things in practice. Therefore, a sensitizing theory might possibly have contributed with an understanding as to why Teacher 3 already did as she did in her practice, and thus support further development. In this way, the principles-knowledge can become an enabler of the teachers’ experiences of relevance in the BM. In the first example, Teacher 4 primarily met principles-knowledge. This gave her an opportunity to understand why the teaching of the concept of equality is important and not just how she should teach it. This again indicates that principles-knowledge is an enabler for the teachers’ experience of relevance in the BM. As mentioned earlier, one of the policies of the BM was a top-down policy. In contrast to a bottom-up policy, this increases the probability of one encountering already known innovations that might already part of one’s daily practice. Based on the analyses of Teachers 3 and 4 and in the context of BM’s top-down approach, it might be an advantage that the teachers also acquire principle-knowledge, since principles-knowledge may act as an enabler of experience of relevance in the top-down policy context.

## Conclusion

In the analysis, we have identified a number of enablers and barriers in the BM and we have attempted to link the existence of these to the identified policy dimensions of the BM as well as the modules’ use of sensitizing and prescriptive theoretical constructs from mathematics education research.

In particular, the main findings concern implementation programs with a top-down policy. Within this policy we see that the experience of relevance is challenged if the content is mainly how-to

knowledge. We support this claim by the example of Teacher 3 not experiencing anything new in the BM. To accommodate this we argue that principles-knowledge can support the teachers' further insight into the innovation. Such understanding of 'why' may upgrade the quality of 'how' the teachers do things in practice, and make the content relevant for the teachers. Following this argument, we find that principles-knowledge enables the experience of relevance, which is determinant for implementation. With this in mind, we suggest that future mathematical education implementation programs with a top-down policy consider the content balance of how to-knowledge and principles-knowledge. Furthermore, it could be an object of investigation in the research community to understand the balance and synergy of knowledge-types in implementation programs.

In addition, the degree of merit that innovations are imparted with influence all three determinant factors. It can be argued that the importance of selecting relevant innovations and how they are conveyed is fundamental to avoid misguidance of teachers' practice. It becomes clear that success of implementation in a mathematics education context is not limited to Rogers' (2003) definition of an innovation merely being put into use; the implementation of the innovation must lead to a change for the better – not least as perceived by the end uses, in our case the teachers. We must take into account Schumpeter's (1934/1961) claim that an innovation should entail a valuable change in practice. This supports the need for defining innovations as subjectively novel, which bring about valuable changes in practice when dealing with implementation processes in mathematics education. Before determining content knowledge in implementation programs, conducting reviews and using solid findings (Education Committee of EMS, 2011), may be one feasible way to accommodate valuable changes.

**Abstract.** *In this paper, we aim to understand, in a context of teachers' collaborative group, how emphasizing multiple representations can contribute to the learning of the rational numbers by elementary school students. We report part of a Design Based Research, within which a learning path for rational numbers was constructed and implemented in grade 3 classes. Data was collected through audio recordings of the collaborative group sessions, written records of the teachers' and students' interactions, as well as photo records of classroom work. We analyse two tasks focusing on students' rational number learning of two classes, through discussion and reflection in the collaborative group. The results show that enactive and iconic representations, used as models in a recurrent way, support an intertwined understanding of symbolic representations. We conclude that the collaborative group work was essential to bring research into the classroom.*

**Keywords:** *Rational numbers, representations, elementary school, collaborative work.*

### Introduction

In mathematics education research, learning and understanding rational numbers is a very important and complex topic (Behr, Lesh, Post, & Silver, 1983; Tian & Siegler, 2018). This complexity relates to the multiple representations and meanings that rational numbers can assume. Although research provides clues about how different representations can be articulated, with understanding, at an early stage of students' learning (e.g., Moss & Case, 1999), its effective implementation in the work carried out in the classroom seems hard to reach. Thus, we seek to implement mathematics education innovations into practice within an implementation research perspective (Century & Cassata, 2016). In this paper, we aim to understand, in the context of the collaborative work of a group of teachers, how research-based ideas on emphasizing multiple representations and models (Guerreiro, Serrazina, & Ponte, 2018; Morais, Serrazina, & Ponte, 2018) may contribute to the learning of the rational numbers, by elementary school students.

### Multiple representations in learning rational numbers

When learning rational numbers<sup>1</sup>, students should realize that the same rational number might be expressed in different symbolic representations, such as decimal number, percentage or fraction.

---

<sup>1</sup> We use the term "rational numbers" to designate non-negative rational numbers.

Besides these, enactive and iconic representations (Bruner, 1999), actions and images, respectively, and oral and written language (Ponte & Serrazina, 2000), a supporting mode of representation at the early grades, should also be considered. These types of representations are considered useful in the development of students' conceptual understanding as they help them to track ideas and inferences when reflecting and structuring a problem.

Moving across different types of representations is essential for the recognition that each representation presents a different perspective of rational numbers, and students' understanding develops as the number of perspectives increases (Ponte & Quaresma, 2011; Tripathi, 2008). Gravemeijer (1999) reinforces that a model emerges when it is underpinned by representations. In this emergent modelling process, representations become models, as they allow a direct modelling of a contextualized situation and support the development of more formal mathematical knowledge (Gravemeijer, 1999). Consequently, learning rational numbers through models, at the elementary grades, may be a dynamic process required to co-develop representation and conceptual understanding.

Contexts, within which representations can be perceived as models, are fundamental to understand and establish complex and meaningful relations (Brocardo, 2010). The number line, with an implied measure meaning, and the *decimat* (Roche, 2010) that emphasizes a part-whole meaning, are useful representations that highlight the multiplicative structure of rational numbers. Post, Cramer, Behr, Lesh, and Harel (1993) highlight the role of representations in understanding rational numbers, relating it to the flexibility with transformations between and within rational number representations. Thus, students' flexibility in making transformations involving different representations can show their understanding of the rational numbers involved (Post, Wachsmuth, Lesh, & Behr, 1985).

Recognizing the same rational number across different representations is an outcome of a global coordination of representations, which in turn empowers mathematical reasoning (Duval, 2006). The transformations of representations, which support translation between different representations of rational numbers, are central in the mathematical activity (Duval, 2006), and the analysis of these transformations provides a lens to access students' mathematical reasoning processes, as solving strategies and justification (Mata-Pereira & Ponte, 2017).

## Methodology

This study follows a design-based research approach (Cobb, Jackson, & Dunlap, 2016). It focuses on two grade 3 classes (8 years old) students' learning. These classes belong to two teachers that participate on a collaborative group of five teachers, with the first author as a regular member. The group has been meeting weekly for about ten years to plan classes lessons together. In different ways, all teachers have connections to the research field, in which they seek to support their professional practice.

To face the demand of learning rational numbers in grade 3 (a national curriculum determination) with understanding, the group decided to construct a learning path, a trajectory for learning rational numbers, that promoted an active engagement of students in the construction of knowledge through meaningful tasks. Thus, along with the first author, the second author also integrated the group as invited researcher, with the purpose of sharing key ideas of ongoing studies to be discussed in the group (Guerreiro, Serrazina, & Ponte, 2018; Morais, Serrazina, & Ponte, 2018) and support the

construction, implementation and reflection of tasks. Together, teachers and researchers, collaborated for developing the learning path, meeting those students, with the aim of implementing theoretical ideas identified as key in the learning of rational numbers, understood as innovations (Century & Cassata, 2016). All the three teachers put the learning path into action, but only two, Hélia and Sandra, actively participated in all the sessions of collaborative group, thus being participants in this research. These sessions were held once a week, according to the school calendar, between February and June of 2018.

The need to intertwine different symbolic representations of rational numbers, supported by several representations used as models, like common batteries icons or status bars, but also the multibase arithmetic blocks (MAB) or the decimat, which make explicit the “ten-ness” of the base ten place value system (Roche, 2010). This was one of the guiding principles of the learning path constructed and implemented, within this design-based research. This path privileged the symbolic representations of percentage (Phase 1), decimal number (Phase 2 and 3), and fraction (Phase 4), using part-whole and measure meanings, according to the sequence presented in Figure 1.

**Figure 1: Implemented learning path of rational numbers**

Data was collected through audio recordings of the group sessions, collection of written records of the teachers, the written works of students (brought by the teachers for the sessions), as well as photo records made by teachers during classroom work.

We focus the analysis on two tasks, Task A and Task B, solved by students, which were carried out in Phase 3 of the learning path. Data analysis is centered on students' use of representations as models, and on how they use and relate different symbolic representations.

## Results

### Task A

Before task A, students were asked to fill and empty five bottles in order to establish relationships between their capacities, and associate labels written in decimal numbers to each bottle (Figure 2).

**Figure 2: Labeling bottles task**

Two bottles had the same capacity, and two labels represented the same quantity: 0.5 l and 0.50 l. At the group session when the work carried out in this task was discussed, the teachers identified the need to lead students to justify the equality between the representations 0.5 and 0.50:

Hélia: Now that we have finished [the task] the filling of the bottles and they realized that five tenths are equal to fifty hundredths but they don't know why. . . So, we could go from there...

Helena: To the equivalence with different representations.

. . .

Hélia: So, I will ask why fifty hundredths are the same as five tenths, because I want them to be able to justify...

Although Sandra suggested that the status bar could be used as a support representation for task A, the group discussed that it would be important to promote the use of the number line, recognizing the need to evolve to a more formal representation.

Sandra, referring to her students, suggested that the double number line could be presented with marks corresponding to tenths and, eventually, to hundredths:

Sandra: In my class... I usually focus their [students] attention on “Into how many [parts] is [the unit] divided? So, they are how many of how many?” That's why we came to this [suggested way to divide the number line] . . .

This suggestion stems from the fact that Sandra acknowledges that her students had already explored rational numbers mainly with a part-whole meaning, which had been associated with the fraction representation. Hélia recalls that her students used, above all, the decimal fraction with denominator one hundred, because percentage was a reference for them:

Hélia: When I call upon fraction it's always decimal fraction with hundredths . . . Because for them percentage is... Is their guiding line!

Thus, in anticipating how her students would relate 0.5 and 0.50, Hélia suggests that 50% should be already presented in the double number line:

Hélia: Let's just start by asking. They will realize that fifty is because it is divided... The percentages here... I think that it should be 50% already represented...

However, the group discussed that by dividing the number line in that way, in order to include other symbolic representations, could restrain students when choosing a representation to justify. Therefore, the group decided to present only the representation in decimal number to, on one hand, focus the question in this specific equivalence and, on the other hand, to allow the students to mobilize representations on their own.

The task implementation showed that the students used different kinds of justifications. Sandra mentioned that her students justified the equality between 0.5 and 0.50 by presenting arguments based on an enactive representation, related to what they had experienced in the labeling bottles task:

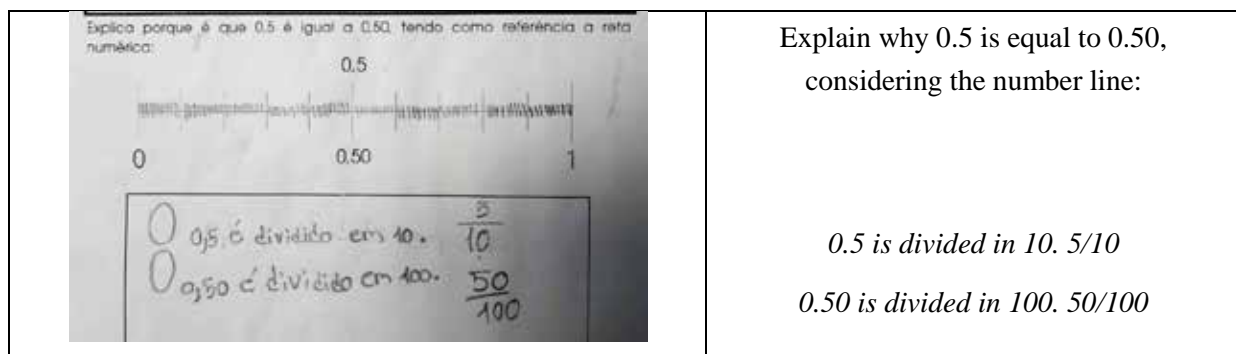

Sandra: They concluded that five tenths are equal to fifty hundredths because these bottles had the same capacity...

These arguments seem to show that, in this task, the students understood the symbolic representation of a decimal number as a label that identifies a certain amount of water, an understanding that is strongly linked to the context. The meaning that the students give to the decimal number symbolic representation was based on an enactive representation.

The arguments used by Hélia's students show an understanding of the symbolic representations involved without needing to refer to their experience in the task of labeling bottles.

Hélia: Almost all the groups [of students] concluded that in five tenths we have the unit divided in ten parts, and that in fifty hundredths we have the unit divided in one hundred parts...

The meaning that the students assign to the symbolic representation in decimals is supported by the interpretation of the number line and other representations, such as the decimal fraction (Figure 3).

**Figure 3: Written record of a student from Hélia's class – Task A**

In this way, the students seem to recognize the same number in different representations, which they mobilize to justify the equivalence between 0.5 and 0.50. In this phase of the learning path, in addition to the enactive representation of the bottles and the number line iconic representation, the decimat was another important representation for the understanding of the decimal number representation.

### Task B

In Task B, the students were asked to represent the shaded areas of the decimat, in percent, decimal number and fraction. The written record presented in Figure 4 illustrates how a student from Sandra's class used the decimat as a model, as the student gives meaning to this representation, using percentage to keep track of the relations established.

#### Figure 4: Written record of a student from Sandra's class – Task B

The student interpreted the decimat that she named as the larger rectangle, as 100%, associating each rectangle A to 10%. She identified half of 10% as 5%, which she justified by tracing half of a rectangle A. She interpreted rectangle B as 1%, justifying it with the division of 100, which she seems to relate to one hundredth, by 10. She also pointed rectangle C as “1000”, which seems to show that the student identified the relation  $1/1000$  of this rectangle with the larger one. Thus, the student seemed to have understood the relationship between each shaded area in the decimat.

Hélia agreed that this model allowed her students to visualize and mobilize different symbolic representations, facilitating their interrelation. This is evident when Hélia reflected on another task involving the decimat:

Hélia: For my students it was a systematization... This construction was essential. For example, my students looked at the decimat and most of them said that it was [shaded] 30%.

The use of this iconic representation was highly valued by the teachers as a “systematization representation”, as Hélia mentioned, considering the phase of the learning path in which it was used. Although the decimat representation is usually perceived as related to the decimal number representation, it supported and triggered other representations such as percentage.

#### Final remarks

Considering that the aim of this study was to understand how emphasizing multiple representations could contribute to the learning of rational numbers in the elementary school, this study shows that a work involving the interrelation of percentage, decimal number and fraction, is very promising in the initial approach of the learning of rational numbers.

We emphasize that the understanding of these symbolic representations, and their relations, is supported by the use of enactive and iconic representations (Webb, Boswinkel, & Dekker, 2008), in a recurrent way. Enactive and iconic representations were used as models, leading students into the establishment of relationships (Gravemeijer, 2004), between and within the same type of representation. Therefore, enactive and iconic representations allowed the emergence of symbolic representations with understanding.

Even though the learning path was constructed according to the sequence of symbolic representations, percentage – decimal number – fraction, the students mobilized the representation that they considered most appropriate to justify the equivalence relation. This ability shows an apparent confidence in working with rational numbers, considering the initial stage of these students' learning of this concept. In this way, a work focused on the understanding that the same number can assume different representations, not only symbolic, but also enactive and iconic, contributed to the students' conceptualization of rational number.

The fact that the Portuguese curriculum does not emphasize percentage at grade 3, as a rational number representation, could be considered an obstacle to the implementation of the intervention. However, the fact that the collaborative group was willing to develop a learning path comprised by key research findings overcame this obstacle. The teacher group already had a joint work routine prior to this study facilitated the sharing environment created. This was a factor that influenced the

effectiveness of this intervention. Those teachers used to plan and reflect together and, with researchers, they got confidence in constructing and implementing the learning path, a common aim that provided a desirable gateway for implementing research in the classroom. A discussion about how to echo this experience on a larger scale is still much needed to enhance its beneficial effects in new contexts (Century & Cassata, 2016).

We highlight the relationship between theory and practice in this study: theory found a way to support practice, identifying the guiding principles of this intervention, and practice provided clues for problematizing theory, necessarily refining those principles. On one hand, the learning path of rational numbers was constructed based on previous research, which emphasizes the crucial articulation among symbolic representations of rational numbers (e.g., Moss & Case, 1999; Ponte & Quaresma, 2011; Tripathi, 2008). On the other hand, the practice informed that not only this articulation is possible at the elementary school grades, but also that it benefits from a continuous work that embeds other types of representations.

*SUM is a four-year research and developmental project with the aim of contributing to coherence in children's and students' motivation for, activities in, and learning of mathematics throughout the educational system from kindergarten to higher education. The concept of inquiry is key in the project, and it involves the implementation of different types of theories and methods related to inquiry based mathematics teaching (IBMT) at three systemic levels: (1) The students' inquiry in and with mathematics. (2) The teachers' use of inquiry based mathematics teaching as a means for supporting the students' learning and inquiry into their own practice across a particular transition. (3) Inquiry into the interplay between the development of teaching practice and research in IBMT. In this paper, based on the project design and preliminary findings from the implementation, we discuss the project as an implementation of theory at these three levels, with a particular focus on level 2.*

*Keywords: Professional development, teacher collaboration, inquiry, mathematics.*

## Introduction

In this paper, we present and discuss how the design of a four-year professional development project called SUM can facilitate the implementation of research findings related to Inquiry Based Mathematics Teaching (IBMT) as a means for creating better coherence across important transitions in the educational system. Strategically, the project focuses on five transitions in the educational system where particular challenges with developing and retaining students' motivation for and learning of mathematics are evident in teaching practice and in research. The principles behind the design of the project are based on research findings in the mathematics education literature specifically related to IBMT. Therefore, this paper can be seen as a case study on how professional developmental projects can be a vehicle for implementation of theories in the practice of mathematics teaching.

The project design is based on a broad understanding of IBMT going back to the educational philosophy of Dewey (Artigue & Blomhøj, 2013). More specifically, in SUM we conceptualize and operationalize the inquiry concept at three different systemic levels developed by Jaworski (2004, p. 24): (1) the children's and students' inquiry in and with mathematics; (2) the teachers' inquiry into their own practice and their use of IBMT as a means for supporting students as learners; (3) inquiry into the interplay between the development of teaching practice and research in IBMT. These three levels of inquiry have formed the project design and structured the application. In that sense, as a research and professional development project, SUM is an implementation of a general theory of inquiry also used in other projects (Bjuland & Jaworski, 2009).

Coherence is another key concept in the project. In SUM, the fundamental premise and proposition is that we can help create and sustain coherence at each of the three levels through inquiry. However, as with the term inquiry, the term coherence takes different meanings at each of the three systemic levels. At level 1, the focus is on children's and students' motivation for, activities in, and learning of mathematics. The term coherence here refers to how students can make sense of mathematics,

maintain their joy of, and develop a deep understanding of mathematics. In other words, coherence means that students' experience mathematics as a meaningful, relevant, and consistent subject. However, we cannot expect students to develop these desirable characteristics on their own. Students need opportunities to develop productive habits and deep conceptual knowledge for creating and maintaining a joy of and to make sense of mathematics (Schoenfeld, 2014). This leads us to level 2.

At level 2, coherence refers to the teacher's practices and their knowledge and beliefs about IBMT and challenges related to students' learning in general, and across the particular transitions in the system of mathematics teaching in particular. For students to experience mathematics as a meaningful endeavor both in general and across transitions, teachers have to, among many things, create a learning environment that involves inquiry through investigative activities such as experiments, problem solving, and modelling. The aim of the project is that the teachers can develop mathematical and didactical competences, through inquiry into their own practice and IBMT, for a practice of teaching that provide students with these types of learning environments.

At level 3, the focus is on the coherence between the development of practices of teaching and research in mathematics education. Nearly all professional practitioners, including teachers, experience a gap between theory and practice (Schön, 1983). This dilemma is also closely related to what Nilsen (2015) calls determinant frameworks. Determinant frameworks describe and help identify types of determinants, which act as barriers and enablers that influence implementation outcomes. Determining barriers and enablers, both at a systemic and individual level, is a key element in creating coherence between research in IBMT and development of teaching practice

At each of the three systemic levels, coherence also refers to the issues related to academic transitions in mathematics. As students move through the school system, the mathematics instruction, opportunities to engage, expectations, mathematical concepts and ideas, classroom norms etc. are all likely to change – in particular in transitions between key academic levels. These transitions are a potential risk to students' academic progress, unless they are managed well (McGee, Ward, Gibbons & Harlow, 2003).

The basic premise of the SUM project, and central claim of this paper, is that IBMT has a potential for meeting these demands at the three systemic levels. In this paper we address the following research question with a particular emphasize on the implementation of inquiry at level 2:

*In what way does the design of the SUM project support the implementation of IBMT as a means for creating better coherence?*

To answer this question, we will explain how research related to IBMT has been implemented in the design of the project, and report on some preliminary findings that show how this design of the SUM project has helped create better coherence. In this paper we explain how inquiry is implemented – i.e. conceptualized and operationalized – in the design of the project at each of the three systemic levels, and how it can help create better coherence across academic transitions. Due to the limited scope of this paper, we then focus more closely on one of the systemic levels, and provide an example of how theory related to IBMT has been implemented at level 2. We highlight in particular a 3-phased didactical model that has been developed to help organize and design IBMT lessons. Finally, we present some preliminary findings from the project, and discuss how this implementation of inquiry at level 2 in the design of the project has helped teachers incorporate investigative activities in their own practice – and thus helped create a better coherence between teachers' practice of teaching and the intentions for the development of students' beliefs about mathematics and their mathematical learning.

## The organizational structure of SUM

However, a quick description of the project is needed. SUM is the acronym in Norwegian for “Sammenheng gjennom Undersøkende Matematikkundervisning”. In English, the title is “Coherence through inquiry based mathematics teaching”. The project is based at the Arctic University of Norway in Tromsø (UiT), and financed by The Norwegian Research Council for the period 2017- 2021. The SUM project is organized around five transitions in the educational system where students typically experience a discontinuity in their mathematics teaching:

Kindergarten (T1) ® Primary school (T2) ® Middle school (T3) ®  
Lower secondary (T4) ® Upper secondary (T5) ® University

The organizational structure of SUM is in accordance with what we know about effective professional development (PD). Research has shown that effective high-quality PD possesses a robust content focus, features active learning, is collaborative and job embedded, aligned with relevant curricula and policies, and provides sufficient learning time for participants (Desimone, 2009).

The SUM project has a robust content focus that is also aligned with current curriculum reforms in Norway. An important part of the work in the transition groups is to identify challenges related to the transition in question. These challenges are related to the learning of key mathematical concepts such as for example the number line as a model for natural, whole and rational numbers at the transitions T1-T3, or on how to support the coherence and progression across a transition with regard to particular mathematical competences such as for example mathematical reasoning or modelling competence. Such competences and deep learning of key concepts are playing a dominant role in an ongoing curriculum reform for mathematics teaching from primary to upper secondary level in Norway (Kunnskapsdepartementet, 2016).

The SUM project also has a clear focus on active learning, job-embedded collaboration, and sufficient learning time. For each of the mentioned transitions, a group of 8-14 mathematics teachers from school and/or kindergarten (as for T1) is formed. There are at least two teachers from each participating school. Each group is led by two or three mathematics educators from the project team at the university. Currently, around 55 teachers are participating in the project. For three consecutive school years each group work together on identifying and discussing challenges regarding students’ learning of mathematics across a particular transition. In collaboration and with support from the group leaders the teachers develop, implement and evaluate IBMT with the explicit aim of helping the students to overcome the identified challenges and to contribute to a better coherence across the transition in focus for the group.

It should be mentioned that SUM includes a particular focus on IBMT as a means for developing a cultural responsive approach for supporting the coherence in mathematics teaching for Sámi children. One of the transition groups consist of teachers at a Sámi school working at both T1 and T2.

## Implementing IBMT in the SUM project

As mentioned, the inquiry concept is coming into play differently at the three systemic levels. At level 1 and 2 it is in the form of IBMT, while at level 3 it is inquiry as part of the research process. The implementation of inquiry at each of the three systemic levels consists of a further conceptualization and operationalization, which is discussed below.

At level 1, inquiry means that students are learning mathematics through exploration in tasks and problems in the classroom. The aim is to help students develop and maintain the joy of, motivation for, and coherence in their learning. For students to experience mathematics as a meaningful endeavor, they need to, among other things, struggle with “important mathematics”. The term struggle

does not mean that students should waste time on extreme levels of challenges that lead to needless frustration. Struggle, in this context, means that students should expend effort, explore, investigate and make sense of problems and situations that are not immediately apparent (Hiebert & Grouws, 2007). This view of learning as a result of reflective inquiry and meaningful struggle is a key aspect of IBMT. In the SUM project, we put special emphasis on IBMT as a means for developing and maintaining the students' interests for and joy of working with mathematics, both in general and across the transitions. Through problem oriented activities the students should have the opportunity to experience the joy of solving problems, which they to begin with find challenging.

At level 2, inquiry means that teachers explore and reflect on the design and implementation of tasks, problems and activity in classrooms. The teachers use inquiry as a tool to explore teaching, alongside researchers and other teachers who offer both theoretical and practical support. The teachers also develop their practice through successive cycles of inquiry, working in their own classroom, interpreting a design they have produced in collaboration with researchers and other teachers (Jaworski, 2004). Through this inquiry into their own practice and IBMT, the aim of the SUM project is that the teachers can develop mathematical and didactical competences for a practice of teaching that provide students with learning opportunities that help them develop and maintain the joy of, motivation for, and coherence in their learning of mathematics – with a particular focus on challenges related to academic transitions. In the transition groups we present and discuss with the teachers a number of different activities spanning the options of IBMT at that particular transition. Together with the didactical structure presented below, these examples and the related discussion help the teachers in developing their own inquiry based activities.

At level 3, the focus is on how to facilitate interplay between developments of practice and research of IBMT. Here, inquiry is a tool used by both researchers and teachers for understanding the relationship between theory and practice. This is primarily accomplished through co-learning partnerships, in which researchers and practitioners are both participants in processes of using inquiry as a tool for understanding the relationship between theory and practice. Through a close collaboration in designing, implementing, and reflecting on IBMT, both teachers and researchers can develop a better understanding of each other's' worlds (Jaworski, 2004). The SUM project is designed for providing exactly such opportunities for collaboration over three school years between teachers representing different grade levels, and in some cases also different institutions, and researchers in mathematics education. In close collaboration the groups will go through the process of designing, testing and evaluating inquiry based courses three times each school year and nine times during the project. In that sense the design of SUM builds on what is known about developing IBMT in interplay with research (Boaler, 2008; Artigue & Blomhøj, 2013).

### **Implementing IBMT at level 2: The teachers' development of IBMT in their practice**

In the beginning, the work in the transition groups focus on level 2. The teachers need support for seeing IBMT as a didactical means for engaging the students in formulating and solving mathematical problems and using mathematics to describe and analyze real life situations. In addition, it is important for the teachers to see that such activities can motivate students and, at the same time, help them understand mathematical concepts and ideas that are essential for their mathematical learning across a particular transition.

The teachers need support for developing and teaching IBMT in their own classes. To that effect at the first seminar in the transition group, the teachers were introduced to a 3-phased didactical model for structuring inquiry based activities or courses. The model was exemplified with different types of inquiry based activities and courses relevant for the particular transition. The examples varied with respect to duration from one-lesson activities to 5-8 lessons courses, the degree of freedom given to

the students, and the degree to which the activities was stirred by a mathematical focus or by an extra mathematical problem or situation.

The 3-phased didactical model for structuring IBMT includes these elements:

**Phase1:** *Setting the scene for the students' inquiry work.* This phase could involve: telling a story, refer to or create student experiences to motivate the inquiry work; establishing a challenge or a problem in a context that makes sense for the students; creating classroom dialogues about the meaning of the situation; motivating the activity or problem—how could this be fun or interesting and important for life and/or mathematics?; establishing and communicating the didactic environment for the students' work, i.e. the temporal and practical conditions of the work; and presenting and arguing for the product requirements and assessment format.

**Phase 2:** *The students' independent (of the teacher) investigative work.* In this phase the students' should have: sufficient time, freedom, resources and support for their investigative work; support through dialogues with the dominant questions to groups or individual students being: What are you thinking?, How did you find out?, Why is it right?, What if ..?

**Phase 3:** *Supporting the students' learning of mathematics through sheared reflections in class.* In this phase the teacher should: let the students shear their experiences and results and related reflections; organize the students' presentation of their working process, products and results; facilitate classroom dialogues focused on the mathematical elements in the work; help systematizing the results for the class; pinpoint key ideas, concepts and methods in the students' work; try to build sheared mathematical knowledge in the class rooted in the students' work; use multiple mathematical representations and make connections to the students' previous mathematical knowledge.

This 3-phased model provide a good starting point for the collaboration among the teachers and between teachers and the researchers in the transition groups. The model was presented in the transition groups together with lists of essential student and teacher activities in each of the three phases. In addition, in each group some examples of inquiry based activities relevant for the transition in question were presented and discussed. The examples varied from relatively closed mathematical or practical problems over systems of connected problems forming a landscape of investigation to more open thematic investigations and modelling activities as illustrated in (Artigue & Blomhøj, 2013). Together, these elements supported the teachers in developing and planning inquiry based activities in their own teaching. At the transition groups meetings, the model structured the discussions and made it possible to focus on specific issues of IBMT at the transition in question. For instance, at the first meeting, the focus was on establishing a challenge or a problem in a context that makes sense for the students, and to set scene for the students' inquiry activities. This is in line with several other development projects on IBMT (see vol. 45, issue 6 of ZDM, 2013), where this or similar models has shown to be instrumental for the teachers' operationalization of IBMT.

A short example illustrates how the teachers used the 3-phased model. In this example, taken from upper secondary school, both the teacher and the students had little experience with IBMT. The students had been working on quadratic equations for a few weeks, and the teacher wanted to use IBMT in order for the students to get a better understanding of what each term in the equations meant. In one of the lessons, the teacher first set the scene by showing the students a visual proof of the identity  $(a + b)^2 = a^2 + 2ab + b^2$ . She then asked the students to make a visual proof of  $(a - b)^2 = a^2 + 2ab + b^2$ . During the second phase, the students' investigative work, she tried to provide constructive feedback that led the students in a productive direction. At the end of the lesson, the students were asked to present their solutions, and their findings were tied into how they could solve quadratic equations by completing the square.

This example illustrates how one of the teachers used the 3-phase model to implement, gradually, IBMT into her own teaching. Although this particular lesson is a structured and strongly guided example of IBMT, it is an example of how the 3-phased model helped the teachers to gradually include IBMT in their own teaching. The teacher expressed that the 3-phased model had helped her plan and implement IBMT when she first joined the project, as it had reduced the larger and more complex task of developing IBMT lessons into smaller sub-tasks in each of the 3 phases. In particular, the 3-phased model had helped clarify her role during an IBMT lesson.

## Research context and methods

The main research goal of the SUM project is to contribute to the further theoretical development of IBMT and researching its potentials and limitations for overcoming challenges in the practice of mathematics teaching related in particular to the five transitions. In order to fulfill this and other sub-objectives, several methods of data collection have been, and will be, employed. In this paper we report on some preliminary findings specifically related to the implementation of IBMT at level 2. More detailed analyses will be presented in later papers, with more specific scopes. The findings in this paper are based on preliminary analyses of focus group interviews and recordings of transition group meetings throughout the first year in transition group five (TG5).

TG5 consists of six mathematics teachers from three upper secondary schools, three mathematics instructors who teach mathematics at tertiary level, and two mathematics education researchers. Each meeting of TG5 during the first year of the project was recorded. The participants of TG5 was also interviewed in focus groups at the end of the first year of the project. These transition group meeting recordings and focus group interviews covered a large set of subjects and themes, but for the purpose of this paper we focused only on statements and discussions related to the teachers' exploration and reflections on the design and implementation of IBMT in their classrooms.

Both the transition group meeting recordings and focus group interviews were first transcribed, and then analyzed using an inductive qualitative content approach. For each interview and transition group meeting, we extracted all text components that captured some aspects of the design and implementation of IBMT in the teachers' own classrooms. We then formed categories, across the interviews and transition group meetings, which summarized the teachers' experiences and reflections. In the next section we report on some of the key findings from this analysis.

## Findings

We found that the 3-phased model, and the design of the SUM project in terms of inquiry at level 2, in general helped the teachers design and implement IBMT in their own lessons. There were several reasons for this, most of which were tied to specific challenges in designing or implementing IBMT.

One of the strongest findings was related to the design of IBMT. All of the teachers said they had little experience with open-ended activities and problems, and therefore found it difficult to design such activities themselves. One teacher said for instance that she "didn't know how to come up with problems and activities like the examples they were given in TG5". Other teachers expressed similar thoughts, and said it was difficult coming up with good tasks or activities that were open-ended, relevant for the content-specific syllabus, and also interesting for the students.

There were also several issues related to the implementation of IBMT lessons and tasks. The teachers found it slightly uncomfortable to give up control of the lessons, and allow the students to investigate and explore more freely. A majority of the teachers said that it was difficult to let students work on tasks and problems, without correcting the students. Three of the teachers even said that this lack of clear instructions and corrections could lead to students developing content-related misconceptions. They explained further that misconceptions had to be dealt with early and resolutely. Another

challenge, was the large difference in terms of skills and knowledge between the students. Some students struggled with even the most basic aspects of the IBMT lessons, while other students solved the more difficult tasks with a fair bit of ease.

However, in spite of the challenges related to the design and implementation of IBMT, all of the teachers in TG5 expressed that the 3-phased didactical model alleviated to some extent these challenges. The teachers agreed that it provided them with a more structured approach for designing IBMT for their own practice. Instead of tackling a large and intimidating challenge of designing full lessons of IBMT, the 3-phased model reduced a large and complex task to several smaller less complex tasks. Together with the examples of IBMT provided in the TG5 meetings, the 3-phased model simplified a large and abstract task into a set of smaller and more concrete sub-tasks. Furthermore, the teachers said that the 3-phased model helped them remind them about their and their students' role at each phase of IBMT. As one teacher said, "it was a nice reminder of what she should do and what the students should do, and it gave a nice partition of the lesson".

We also noticed that the teachers seemed to find the collaborative and job-embedded structure, and inquiry-focus, of SUM to be meaningful and productive. The teachers said that developing, implementing, and reflecting on IBMT, in collaboration with other teachers, provided them with a better understanding of what IBMT is and how IBMT lessons can be developed. The teachers expressed in particular that implementing IBMT in their own classes, made the activities more important and relevant as the teachers had an "ownership" of the lessons. Furthermore, a majority of the teachers said that discussing both the model and the examples of IBMT in the TG5 meetings helped them to better understand the key characteristics of IBMT and the purpose of it.

Summing up in relation to our research question, at level 2, the 3-phased model with concrete examples and the organization for the work in the transition groups seem to be instrumental for implementing IBMT in order to help creating better coherence in the participating teachers' practice across the respective transitions. Within implementation theory the 3-phased model for IBMT together with the organization of the transition groups can be considered as an innovation for implementing IBMT in the practice of mathematics teaching. Rogers (2003) identify three levels of knowledge, which has to be developed among practitioners—here teachers—as a necessary condition for a successful implementation of an innovation in relation a problematic in an existing practice. Concretized in relation to the SUM, these are (1) knowledge of and experiences with challenges regarding the students' motivation and learning in mathematics teaching across the transitions; (2) knowledge about how to use the 3-phased model for planning, conducting and evaluating IBMT; (3) knowledge about and experiences with cases where the 3-phased model has been effective as a didactical means for supporting students' investigative activities and their learning of mathematical concepts and methods. So far, we have some evidence that the transition group meetings have enabled the teachers to share experiences with and to reflect about challenges regarding coherence in the students' motivation for and learning of mathematics across the transition in question. The 3-phased model has been instrumental for structuring the presentations and discussions of IBMT in the transition groups. Also, the model has shown to be a tool for the teachers in designing and implementing IBMT in their own practice. It is still to be seen if the teachers will reach the third level of knowledge and experience IBMT as an effective didactical means for improving the students' motivation for and learning of mathematics across the transitions.

Large developmental projects running over several years and with funds for establishing close collaboration between selected teachers and researchers is one very important way in which theories can come into play in the development of teaching practice – as support by Rogers (2003). Therefore, it is relevant to analyze the role and function of theories from mathematics education research in the design of such research based developmental projects. In this paper, we have analyzed how elements

of theory related to IBMT come into play in the SUM project at the systemic level focusing on the teachers' experimental practice and their related reflections.

# Competencies and curricula: Danish experiences with a two-dimensional approach

Tomas Højgaard<sup>1</sup> and Jan Sølberg<sup>2</sup>

<sup>2</sup>Department of Science Education, University of Copenhagen, Denmark; [jans@ind.ku.dk](mailto:jans@ind.ku.dk)

*Curricula around the world make more and more use of goals trying to capture different kind of processes for the students to master. In Denmark, these ambitions have most recently been described in terms of subject specific competencies. However, bringing such ambitions into the actual teaching practices has proved challenging. KOMPIS was a longitudinal project aimed at developing and examining ways of dealing with some of these challenges in lower secondary Danish classrooms in collaboration with teachers. In this paper, we present aspects relevant to mathematics curricula. As a key point of this analysis, we present a two-dimensional content model derived from KOMPIS that proved useful in supporting competence-based curriculum development and teacher planning. We argue that curriculum descriptions of competency objectives need to be clear and distinct as well as independent of subject matter to be operational.*

*Keywords: Competence, mathematical competencies, the KOMPIS project, two-dimensional content framework.*

## Introduction

KOMPIS is an acronym for KOMPetenceMål i PraksIS, which is Danish for “Competency Goals in Practice”. It was a longitudinal research and development project conducted in the years 2009-2012. The project was based on collaboration between teachers, teacher educators and researchers working to implement competency-oriented teaching in mathematics, science and Danish language classes for grades 7-9. A number of these model and concepts were subsequently incorporated into the national curriculum (Undervisningsministeriet, 2014).

In this paper, we focus on the curricular aspects of the KOMPIS project within mathematics by analyzing the following question: *How can we describe curriculum in a way that enables teachers to structure their planning in a manner that focusses on competency development?* Firstly, the background for KOMPIS is briefly described. Secondly, we describe the two-dimensional content model for mathematics education that was developed for and challenged by the experimental teaching conducted during the KOMPIS project. Finally, we describe the experiences regarding planning and organizing of teaching and the conclusions drawn from these experiences regarding curriculum development.

## Background

In Denmark, as well as in many other countries, competencies are used more and more to describe curriculum goals. Internationally this is partly due to the initiation of what has since been called the Bologna process, aimed at making transfer of educational merits between countries of the EU easier

(European Ministry of Education, 1999). To accomplish this a unified description of educational standards was needed, and it was decided to describe these standards in terms of competencies.

Alongside this political process, there has been theoretical and practical development of competencies as an educational concept. One of the most significant developments was the appointment of a workgroup called Description and Selection of Competencies (DeSeCo). In their final report, they formulated a well-conceived and holistic definition of the term and presented their recommendations for “key competencies for the good life and the well-functioning society” (Rychen & Salganik, 2003).

### Syllabusitis

Analytically, another educational approach to the concept of competence can arise from asking the question (cf. Blomhøj & Jensen, 2007, pp. 46-47, which this and the next section is based on): What constitutes a subject, e.g. mathematics? “Mathematics is the subject dealing with numbers, geometry, functions, calculations, etc.” is not a rare type of answer.

What, then, does it mean to master a subject? With reference to the above, it is tempting to identify mastering mathematics with proficiency in mathematical subject matter. However, this belief if transformed into educational practice is severely debilitating for students’ ability to make reason of the subjects and to apply them in future contexts. The debilitating effect is potentially severe enough that the phenomena has been given a name that evokes images of a disease, namely syllabusitis (Jensen, 1995; Lewis, 1972). A curriculum infected by syllabusitis tends to focus only on the ability to reproduce subject matter and therefore fails to set an appropriate level of ambition and puts the teachers in a position where they struggle to cover the prescribed subject matter.

### The KOM project, competency and mathematical competencies

The issue of syllabusitis was one of the main issues to be addressed by the Danish so-called KOM project, running from 2000-2002. The core of the project was to identify, explicitly formulate and exemplify a set of mathematical competencies as independent dimensions in the spanning of mathematical competence (see Figure 1) (Niss & Højgaard (to appear) provides a presentation and analysis of the project and an English translation of the original report).

**Figure 1: A visual representation – the “KOM flower” – of the eight mathematical competencies presented and exemplified in the KOM report (Niss & Højgaard, to appear)**

Such a set of mathematical competencies has the potential of replacing the syllabus as the focus of attention when working with the development of mathematics education, simply because it offers a vocabulary for a focused discussion of what it means to master mathematics (Jensen, 2007). Often when a syllabus attracts all the attention in a developmental process, it is because the traditional specificity of the syllabus makes us feel comfortable in the discussion.

The definition of the term “competence” in the KOM report (Niss & Jensen, 2002, p. 43) was semantically identical to the one we use: Competence is someone’s insightful readiness to act in response to the challenges of a given situation (cf. Blomhøj & Jensen, 2003). In definite form, a mathematical competency is consequently defined as someone’s insightful readiness to act in response to a certain kind of mathematical challenge of a given situation.

### The initial KOMPIS analysis

Following the approach of the KOM project, the endeavour to incorporate subject specific descriptions of competencies in mathematics curricula should primarily be guided by an attempt to fight syllabusitis. In this perspective, it was important to focus on the interplay between subject specific competencies and the subject matter traditionally described in the syllabus.

### A two-dimensional content model

In the KOM report the proposal for such an interplay is to separate subject specific competencies and subject matter areas as two independent dimensions of content (Niss & Højgaard, to appear). Subsequent research and development work prior to the KOMPIS project (Jensen, 2007) supported the importance of such an approach to curriculum development, and added the general hypothesis that a goal oriented (yearly) planning is supported by a curriculum that is systematically developed for enhancement of transparency, offering itself as a thinking tool for the teachers. The model in Figure 2 was a proposal for such a transparent representation of the core of the by then (2009) newly revised National Standards for mathematics (Undervisningsministeriet, 2009).

In a curricular perspective, the defining point of such two-dimensional content models is that the subject specific competencies can function as “the missing link” between the overarching purpose of an education and a concrete syllabus, by pointing out what types of challenges the students must be able to act in relation to.

Competency \ Subject matter area	Numbers and algebra	Geometry	Statistics and probability
Math. thinking comp.			
Math. problem handling comp.			
<b>Math. modelling comp.</b>			
Math. reasoning comp.			
Math. representation comp.			
Math. symbols and form. comp.			
Math. communication comp.			
Math. aids and tools comp.			

**Figure 2: A two-dimensional model for description of the content of grade K-9 mathematics teaching (Højgaard et al., 2010, p. 15)**

## **The KOMPIS project and the methodological approach chosen here**

The experimental teaching included 16 teachers from four schools together with three university researchers and three teacher educators split into three subject groups—math, science and Danish. The groups had three-hour meetings at alternating schools once every month to discuss the teachers' experience and reflections regarding their competency-based lesson plans and the teaching they tried out between meetings. Furthermore, all participants met (including representatives from the municipality) twice a year for full-day seminars to exchange experiences across subjects.

Our participation in this longitudinal experimental process gave us access to knowledge and ideas from the different participants, and to follow the developmental processes among the teachers on an ethnographic basis. In this paper we report on our analysis of how the two-dimensional content framing influenced two aspects of these processes; planning and organization of teaching.

Hence, the “implementation element” of the paper in the sense described by Century & Cassata (2016) is the two-dimensional model displayed in Figure 2, used as a tool for helping teachers to plan and organize a teaching focused on the development of certain mathematical competencies.

## **KOMPIS experiences regarding planning and organization of teaching**

The common distinction between planning and organization of teaching is useful for describing some of the results of the KOMPIS project. Following Larsen (1969) we consider planning of teaching as the process of making decisions regarding the content of the teaching, whereas organization of teaching deals with selecting appropriate (relative to the content and the learning ambitions associated with it) teaching methods and making decisions regarding the course of the teaching.

### **Planning competency-oriented teaching**

In this sense of the phrase, planning of teaching inevitably boils down to an endeavor with one dominating dimension: Time. Since time is a scarce resource when teaching takes place within a formal educational system like compulsory schooling, it is of little surprise that the two-dimensional content model in figure 2 acted as a systematically induced challenge to the planning of the teaching. One of the consequences of this approach is that it makes didactical considerations necessary when planning from a two-dimensional content structure to a one-dimensional yearly teaching plan. Planning of competency-oriented teaching is ideally about creating a connection between the two dimensions in such a way that the work with a given subject matter area can be explained and motivated by development of competencies, which make the students able to handle new types of situations or known situations in a more competent way. This often requires more prolonged and successive teaching time making it necessary to plan teaching in modules wherein the students get to build a chosen competency.

This approach can be modelled by dividing the year up into modules and deciding early on which areas of subject matter, competencies or combination of the two to focus on, cf. the modelling of this approach in figure 3. This model can function as a planning and reflection tool for teachers as well as a model that teachers can use when they discuss what the objectives of a given teaching session is with colleagues and students (Højgaard, 2010).

**Figure 3: The two-dimensional model used as a tool for planning of teaching by creating modules of some weeks in duration, each appointed with explicitly stated learning objectives consisting of subject specific competencies and/or objectives related to specific subject matter**

Hence, an important part of implementing competency objectives in teaching turned out to be linked to planning for extended periods of time, where students and teachers could focus on a few selected competency objectives. KOMPIS was designed to ensure that teachers included such periods in their yearly planning from year two of the project. When the mathematics teachers involved were interviewed subsequently, they assessed the explicit use of the model in figure 3 as a planning tool as both challenging, constructive and meaningful. Challenging because the representation of the competencies as a separate dimension in the model forced them to be explicit about their ways of thinking and working with this new kind of objectives. Constructive because the model turned out to be a comprehensible thinking tool when planning their teaching, not least by explicating the role of the competencies in their answer to the fundamental planning question posed above: When are the students to learn what? Meaningful because they experienced the mathematical competencies as a way of making some of their more fundamental ambitions as mathematics teachers explicit.

### Organizing competency-oriented teaching

Following the planning approach by dividing the year up into modules, the dominant organizational approach used by the teachers in the KOMPIS project was project work where the students could concentrate on a selected competency objective. In the mathematics group, Tomas followed one teacher closely. She deliberately and explicitly organized the project work modules with the following general characteristics:

- The teacher decided on a given mathematical competency objective to focus on for the project period.  
*Six projects were oriented towards the mathematical modelling competency and two towards mathematical reasoning competency.*
- Approximately, one week was spent on helping students develop an understanding of the given competency objective.

*An example of this was that in the first project focusing on mathematical reasoning, where the teacher let the students spend the first week gaining different experiences with mathematical reasoning by alternating between short tasks that required students to use mathematical reasoning and group discussions about their reflections. This led to the development of a model that presented the students ideas about central elements involved in mathematical reasoning (Sølberg, Bundsgaard, & Højgaard, 2015).*

- c) Once the class had reached a common understanding of the given competency, each project group was required to come up with relevant problems involving the given competency. They then spent the rest of the allotted time—most often two weeks—working on problems through which they developed the given mathematical competency.

*For example, one group of students chose to work on the mathematical reasoning involved in solving and producing Sudokus, while another group worked on developing simple mathematical proofs.*

The process ensured that students and teacher reached a mutual understanding of a competency objective before the students were challenged to find ways of developing it. Such an approach turned out to be supported by choosing one and only one competency as the guiding learning objective for each project work. From this perspective, the important attribute of the two-dimensional content model is the separation of competencies and subject matter areas, so it is for the teacher to decide whether the learning objectives for a given module should come from a mathematical competency, a mathematical concept or a combination of the two. In previous one-dimensional Danish curricula a mixing of the two types of learning objectives were the dominant approach chosen.

Another advantage of employing a set structure was that the students became familiar with the template. After the first couple of projects, they did not need as much instruction during the project work and gradually gained significant ownership of the process.

## **Curricular perspectives**

Applying a teachers' perspective on curriculum, there are at least two important perspectives regarding the use of competency objectives to be derived from KOMPIS. *Firstly*, the project confirmed that teachers require help in formulating learning objectives to be able to plan teaching explicitly aimed at building student competence. To formulate such more specific learning objectives, however, there is a need for *clear and distinct* competency descriptions in the curriculum. At the same time, to avoid syllabusitis it is necessary to be able to distinguish between competencies and subject matter as two independent dimensions of content descriptions. The model in figure 2 demonstrates how this could be achieved for mathematics, and we propose that similar two-dimensional models of content could be generated for other subjects.

*Secondly*, being able to formulate competency-oriented learning objectives can help teachers plan their school year in a way that allows them to maintain focus on a *few key subject specific competencies* and thereby create the necessary conditions for sustained development of both teacher and student competencies. In addition, being able to focus on a few learning objectives at a time enables the students to better understand the meaning behind the learning objectives which in turn enables the students to pursue them more independently.

## Final remarks

One of the goals behind the KOMPIS project was to experiment with curriculum development from a teacher's perspective. We wanted to engage teachers in developing an approach to competency-oriented teaching that was not only meaningful but also practical for teaching. To make a long story short, our experience from this longitudinal study is twofold (Højgaard, 2012): Firstly, one of the main advantages of using a two-dimensionally structured competency perspective is that it inherently fosters reflections among teachers about the essence of the competencies involved. Secondly, such reflections promote the implementation of the more ambitious kind of work processes that mathematics education aims for as long as the teachers involved (as has been the case in the KOMPIS project) get the necessary time and support to learn how to use the two-dimensional structure as a developmental tool. Hence, KOMPIS indicates that there is significant promise from a teachers' perspective in applying the two-dimensional model presented here for mathematics teaching.

The experiences from KOMPIS have come to influence the subsequent national curriculum revisions. The two-dimensional model has been incorporated into the current curriculum for mathematics (Undervisningsministeriet, 2014), and at the time of writing (2018) it is being revised to emphasize this approach even more. Thus, Danish mathematics teachers are now officially encouraged to use the two-dimensional model in planning their teaching.

*Although there have always been investigations in the field of mathematics education that concern implementation research, it is not yet clear how to structure such a research area. In this paper, we take a step towards this. Taking as reference frameworks elaborated in other fields where implementation research is more advanced, we attempt to outline what an implementation research framework in mathematics education could encompass. We illustrate this with an example of implementing the Danish innovation of the mathematics competency framework (KOM).*

*Keywords: Implementation research; innovation; theory of change; value.*

## Introduction

Implementation research has received an increase in attention within mathematics education during the last few years (e.g. Cai et al., 2017; Jankvist, Aguilar, Ärleback, and Wæge, 2017). But the discussion of implementation is neither new in educational research in general, nor in mathematics education in particular. Already Fullan and Pomfret (1977) remarked that “implementation is not simply an extension of planning and adoption processes. It is a phenomenon in its own right.” (p. 336). Even if the discussion of implementation has been around for some time, both the work presented and carried out during CERME 10 and the recent discussions in JRME (e.g. Cai et al., 2017) illustrate clearly that there is still a large potential indeed in addressing initiatives within mathematics education from an implementation research point of view. However, it is not at all clear how exactly to do this. Hence, we first need to ask ourselves which existing implementation research frameworks that are applicable to which initiatives in mathematics education as well as how and why? The purpose of this paper is to take some initial steps towards addressing this big question. As a reference point we take implementation frameworks from other research fields to try to sketch an implementation research framework in mathematics education. Then we “test” it on an illustrative example of the decentralized implementations of the Danish mathematical competencies framework—KOM—in selected mathematics programs of the Danish educational system.

## Implementation research frameworks

Within the context of health science, Nilsen (2015) proposed a taxonomy of three aims for the use of theoretical approaches in implementation science, and five categories of theories, models and frameworks. The first aim of theoretical approaches is to *describe and/or guide the process of translating research into practice*. Process models lay out specific steps to implement research into practice, and thus provides practical guidance in planning and carrying out implementation. The second aim concerns *understanding and/or explaining what influences implementation outcomes*. Three different types of frameworks and theories are found to support this aim. The first type is the determinant frameworks that identifies barriers and enablers, which influence the implementation outcomes as well as specifying the relationships between barriers and enablers. The second type is

the classic theories, which are theories that originate from fields outside of implementation science, but may be applied to understand some aspects of implementation. The last type related to this aim are actual implementation theories, which are those developed with the sole purpose of explaining aspects of implementation. The third and last aim concerns *evaluating implementation*. This aim can be supported by the category of evaluation frameworks that may provide a structure for evaluating implementation.

In their review of implementation research within education, Century and Cassata (2016) offer the following (working) definition:

Implementation research, by our working definition, is the systematic inquiry of innovations enacted in controlled settings or in ordinary practice, the factors that influence innovation enactment, and relationships between innovations, influential factors, and outcomes. Thus, frameworks that inform the organization of implementation research address two main concerns—how to conceptualize and describe the innovation itself, and how to identify and organize the contexts, conditions, and characteristics that influence innovation enactment (influential factors). These two fundamental concepts—(a) characteristics of the innovation and (b) influential factors—are basic elements of varied theories of change and a key part of most recent research syntheses or metaframeworks depicting innovations in context. (p. 181)

This definition builds on two other terms, the meaning of which will have to be explained as well; namely those of innovation and change. Century and Cassata (2016) operate with a definition of *innovations* as “programs, interventions, technologies, processes, approaches, methods, strategies, or policies that involve a change (e.g., in behavior or practice) for the individuals (end users) enacting them” (p. 170). More traditionally, an innovation is oftentimes considered to be new ideas creating economic value (Darsø, 2012), or as the middle part of the CIE (Creativity, Innovation and Entrepreneurship) model for value creation and change (Paulsen and Harnow, 2012). However, the dependence on economic bottom line thinking makes this definition difficult to apply to educational situations. Nevertheless, if we instead consider innovation as changes of practices and technologies for the better, then we set ourselves free from the problem of economy as the core goal for innovation. This however leaves open what kind of normative change for the better that we should value in innovation. We should ask what (kind of) value and for whom. The definition of educational innovations provided by Century and Cassata (2016) focuses on *the change for end users* (e.g. teachers and students) and simply views innovations as the object of implementation research. While this is indeed an important perspective, we suggest that the notions of value and stakeholders are critical; an innovation is only an innovation if it creates value for some stakeholders (Krainer, 2014), but the stakeholders do not necessarily have to be the end users. Value can be for the society in general, for educational administrations, school management, etc. We thus define educational innovations as *change in educational practice that are valued by some stakeholders*. However, in order to conceptualize any change, it is necessary to acknowledge that change may take place at different levels (at the individual level, classroom level, school level, etc.), but also that change is mediated by people and institutions who can adopt, modify or even reject the intended innovation implementation. Thus, as pointed out by Century and Cassata (2016), a question that lies at the heart of the implementation research is: “what does it take for people, organizations, and systems to change?” (p. 178).

To address a question like that in the context of mathematics education, we need to draw on a wide range of conceptual and methodological tools from within and outside the field. For example, to try to identify and organize the conditions that influence innovation enactment at the classroom level, it would be important to understand the intentions and individual motives that a mathematics teacher has to adopt or not an educational innovation. Research on curricular implementation in

mathematics education has shed some light on this type of issues (e.g. Remillard and Heck, 2014). If we refer to change beyond the classroom and on a larger scale, say at the institutional level, it could be useful to resort to studies on organizational change from different disciplines such as medicine (Rohrbach, Grana, Sussman and Valente, 2006) and management science (Burnes, 2005), which can provide us with theories and methodological approaches to help us understand how to produce large-scale change behaviors in school systems. Here studies on mathematics education with an institutional perspective could also be useful (e.g. Castela, 2004). On a wider scale, Rogers (1962) has developed a frequently cited theory describing how innovations are spread across a social group (see for example Koichu and Keller, 2017). He distinguishes several groups of adopters; innovators (adopting a new technology instantly), early adopters, early majority, late majority and laggards (who adopts very late). Rogers shows that the distribution of adoption is similar to a normal distribution with the bulk of people in the early and late majority category. Implementation is obviously related to how people adopt. If you aim for mainstream implementation of an innovation, when it is only adopted by innovators, you are bound to fail.

### **Five factors that influence implementations**

The identification of the factors that influence innovation enactment is a fundamental component of implementation research. For years educational researchers have tried to identify the variables that influence the implementation of educational innovations; these variables can be classified in the following five spheres of influence (Century and Cassata, 2016).

*Characteristics of the individual users:* The change that an educational innovation is aimed at generate, it is mediated by the people involved in the implementation process. Hence, it is important to know their individual characteristics. We distinguish between (a) *characteristics of the individual in relation to the innovation* (mathematical background, experience using the materials or resources involved in the innovation, etc.) and (b) *characteristics of the individual that exist independently of the innovation* (willingness to try new teaching methods, attitudes towards new artefacts in the classroom, etc.).

*Organizational and environmental factors:* In the case of an innovation implemented in a mathematics classroom, organizational factors refer, on the one hand, to the characteristics of the setting itself (number of students, characteristics of the physical space, access to material resources, etc.), and on the other hand to the collective beliefs and behaviors of the members of the class (identity, sociomathematical norms, didactic contract, etc.). Environmental factors refer to those outside the organization, but which have an influence on how an innovation is adopted and implemented (economic conditions, educational policies, priorities of government agencies, etc.).

*Attributes of the innovation:* The attributes of the innovation can influence its implementation, however, it is important to distinguish between the *actual* attributes of the innovation (objective characteristics) and the *perceived* attributes of the innovation (subjective characteristics perceived by the user). Of course, the perceived attributes may vary from user to user.

*Implementation support strategies:* It is important that an innovation initiative comes accompanied by an intentional and planned support for the final users and their institutions. Such support strategies can be professional development, specific resources, etc.

*Implementation over time:* Another factor that influences the implementation of an innovation is time. Thus, it becomes relevant to study innovation endurance over time: how can we promote that an innovation, besides being adopted, is preserved over time until it is routinized? It is in this branch of the implementation research where longitudinal studies will become essential to answer questions like the one previously stated.

## The KOM framework - an “implementation story”

As an illustrative example of an implementation, we take a historical and chronological look at the Danish mathematics competency framework, referred to as KOM, which was first published in Danish (Niss and Jensen, 2002), and later in an English translation (Niss and Højgaard, 2011). This framework has heavily influenced mathematics education in Denmark, where it has been implemented in primary and lower secondary school through the so-called “Fælles Mål” (common goals) (Undervisningsministeriet, 2014), and in both the technical stream (htx) and business stream (hhx) of upper secondary school—to a lesser extent in the classical stream (stx)—in the mathematics teacher education program as well as in some of the mathematics-related programs in tertiary education. On an international level, KOM’s competencies descriptions were an integral part of the PISA assessment framework for mathematics from approx. year 2000 through 2018. The description has also been influential in mathematics programs in several countries’ (see Niss and Højgaard, in progress). Now, in itself the KOM framework constitutes a normative text, which is not directly translationable/implementable in the various mathematics programs. But KOM’s competencies description, with its eight distinct yet interconnected mathematical competencies, was never meant as a standalone. It must be implemented together with a curriculum for the mathematics program at a given educational level. One distinct feature of the KOM approach is its matrix thinking that links specific competencies to various mathematical areas, i.e. competencies in the rows and mathematical areas, e.g. algebra, geometry, in the columns of a matrix. From an implementation perspective, however, KOM makes up an interesting case.

When published in 2002, KOM was supplemented with an implementation support strategy of meetings and seminars debating specificities of the framework and the value of placing development of mathematical competencies as the key feature. But besides this, the implementation support strategies must be characterized as ad hoc and rather scattered. Still, KOM’s competency description was adopted by a large part of the teacher educators in Denmark. It was implemented in the national standards for compulsory school, partly between 2003 and 2006 and more thoroughly in 2009. Furthermore, it was implemented in the teacher education standards in 2012 and in upper secondary school in 2013 and again in 2017. In 2012 the impact of the competencies framework was evaluated as part of a general evaluation of the national standards (Danmarks Evalueringsinstitut, 2012), showing that teachers were neither using the standards nor the eight competencies to a very large extent. In 2014 the K-9 curriculum was reformed towards an outcome-oriented curriculum, and the competencies were now embedded in this structure (“Fælles Mål”). Furthermore, the number of competencies was changed from eight to six. A transformation that was heavily criticized by the people behind KOM (see e.g. Niss, 2016). As of now, the overall structure of the output-oriented curriculum is being debated again and will be partly rolled back. Nevertheless, for the eight competencies this transformation actually appears to have increased their impact and the outreach of the KOM framework. These days more teachers do seem to know more about the competencies than before; partly due to timing in terms of adoption and partly because the 2010 reform made everyone aware of the curriculum/standards and hence the competencies. As mentioned above, such awareness concerning KOM does not seem to be present at the classical stream of upper secondary school, stx, which is by far the largest of the three upper secondary school programs. Why is this? The answer to this question—we believe—is to do with environmental (and institutional) factors as well as the characteristics of the different individual users.

The characteristics of the individual users in the various institutions are quite different. Danish K-9 mathematics teacher educators are mainly educated at the Danish School of Education, where they are exposed to and thus become accustomed to an educational approach that relies heavily on the competency framework (e.g. Højgaard and Jankvist, 2015). In their future professions at the

university colleges, these teacher educators thus often come to act as enablers for the implementation of KOM, not least in relation to the teachers that they educate. The K-9 mathematics educational system, however, is a big ship to turn since it is comprised of teachers of all ages educated under various different educational paradigms and reforms. Hence, as mentioned above, the prevalence of awareness of the eight competencies was a lengthy process. One indicator of this is the fact that many teachers reacted negatively against the PISA 2012 assessment in mathematics, despite the fact that the 2012 PISA mathematics framework was perfectly aligned with KOM and thus also the national standards of 2009. Yet, as part of these standards, an explicit matrix structure between the competencies and mathematical areas was developed for each grade level. This has played a major role in the implementation of KOM in K-9.

When it comes to the upper secondary stx mathematics teachers, they oftentimes hold a master's degree in mathematics from a university mathematics program. Their teachers at the university typically hold a PhD in some area of mathematics, and hence are not necessarily very well versed in the area of mathematics education research, including the competency approach. This of course serves as a barrier for the implementation of KOM in stx. The reason that the situation is a bit different in the two other streams of upper secondary school, as mentioned above, is most likely to do with the fact that the mathematics teacher population there has a more varied background, e.g. at htx several teachers have a background as engineers. Another identified barrier is to do with the lack a matrix structure in the stx curricular documents. Although these do mention a selection of KOM's eight competencies, then mainly do so on a rhetorical level, i.e. the various competencies are not linked to actual mathematical areas and concepts. To a much larger extent this is done in the curricular documents of both htx and hhx (for a further discussion, see Niss and Højgaard, in preparation).

Implementing the KOM framework has taken time. As described above different stakeholders have adopted the framework to different degrees. Even though all these stakeholder groups are distributed across Rogers' (1962) different adoption-types, it is still possible to distinguish groups that overall are moving faster than others. The teacher educators, for instance, have adopted KOM much faster than the K-9 teachers. However, in the case of the K-9 teachers time seems to work for the implementation of KOM, even though adoption is slow. The 2014 K-9 reform was timewise in a place where the innovators and early adopters was already using the competencies framework. This is to say that the timing was working for the competencies, and the curriculum reform thus acted as a catalyst for the early and late adopters to embrace the framework. In the case of the stx teachers, we are less sure to what extent the adoption and implementation will progress over time. KOM has the learning of mathematics at its core, and hence it should be relevant for this population of teachers as well. Still, the lack of an implemented matrix structure in the curricular documents of stx, which, as described above, is an essential attribute of the innovation, does not hold a lot of promise. Due to the stx curricular documents' use of the competency terms only on a rhetorical level, the actual attributes of KOM and the stx teachers' perceived attributes may simply not be aligned.

## Discussion and analysis

Referring back to Nilsen's framework as presented above, the analysis of the implementation of KOM in Denmark mainly addresses the second aim of understanding and explaining what influences implementation outcomes. Here both aspects of what Nilsen refers to as determinant frameworks are in play, as the project identified certain barriers and enablers which influence the implementation outcome. Century and Cassata's (2016) description of factors that influence implementation (see above) was useful alongside Rogers' (1962) focus on stakeholders' adoption. Hence, these implementation research frameworks have provided us with some general perspectives

of where to look and focus our attention, but in themselves they are not detailed enough for cases such as KOM - or any case of mathematics education, we predict. In particular in relation to Nilsen's first and third aim, the description of the implementation process and the evaluation of implementation, one thing that the general frameworks often cannot supply us with is a *theory of change*. Which on one hand can guide the process of implementation and on the other hand is used to evaluate the success of an implementation. The parameters on which to measure change may oftentimes be found within theoretical constructs from mathematics education itself. Let's exemplify.

In mathematics education there are of course many different kinds of innovations, but for the sake of simplicity let us distinguish two. One type concerns that of implementing normative frameworks such as KOM, which in a sense call for a philosophical or cultural change in mathematics programs as to what it means to master the subject. Another type are the grand scale initiatives as for example the Swedish Boost for Mathematics (BM), which offered a further education program to the majority of Swedish mathematics teachers. Although the BM did include a framework, involving e.g. didactical contract, socio-mathematical norms, etc., it was in itself not a framework such as KOM is. This means that when assessing qualitative aspects of the implementation of the innovation, KOM becomes its own theory of change, whereas BM does not. We are not claiming that this necessarily is a problem; only that we should be aware of this when discussing implementations in mathematics education. Another difference is that the implementation of the BM was top-down, whereas many of the local implementations of KOM were more bottom-up. Also, the difference in scale of the two implies that the evaluations of them may be of different nature. While the BM was often evaluated on quantitative terms, e.g. how many schools and teachers participated, etc., KOM to a larger extent was only evaluated on qualitative terms. The qualitative theory of change parameters of both KOM's and BM's evaluative frameworks come from within mathematics education research, while the quantitative parameters of BM's evaluation do not necessarily do so. Nilsen's (2015) framework also includes theories which focus on change from other fields than implementation science, the category of classic theories. However, this category concerns something different than what we call a theory of change, since we regard a theory of change to be something that is locally developed in conjunction with the framework being implemented. The benefits of the close relation between innovation and evaluative framework is that we set us free from binary and simple evaluative categories. In a sense, it is like choosing between relevance and accuracy/circular inference (begging the question/circular argument) in the evaluative frameworks.

## Concluding remarks

Century and Cassata (2016) provided us with a definition of implementation research that has been useful in our effort to begin to explore how implementation research in the field of mathematics education might look. However, this conceptualization of implementation research is not exempt from criticism, nor from competing visions in the conceptualization of this area of research. For instance, one could point out the fact that the conceptualization made by Century and Cassata does not take into consideration—at least explicitly—the role of adopters in the implementation process of an innovation. A conceptualization like this runs at risk of positioning innovation as an imposition for the adopters, who may perceive it as an external element and alien to their own didactical ecosystems. To address this issue, we could consider complementing such conceptualization with other already existing theoretical frameworks from the field of mathematics education. For example, a documentational approach could help us to consider the process through which an innovation can be reshaped and transformed by the adopters.

Thus, although implementation frameworks can be useful to focus our attention on key elements of an implementation process and even to conceptualize them, in the case of mathematics education some of these key elements will be of a general nature, while others may be of a more specific nature and connected to mathematics education. Thus, it is feasible to suggest that the implementation research in mathematics education needs to be based on a bricolage of different constructs and theoretical frameworks typical of research in mathematics education, in combination with constructs from implementation of research in other disciplines with a longer research tradition in this regard. However, there is a lot of work to be done to achieve such integration of theoretical frameworks and constructs. A natural step in this effort may be to begin to identify and organize the already accumulated research in the field of mathematics education that addresses aspects of implementation.

## **Implementation through participation: Theoretical considerations and an illustrative case**

Boris Koichu and Alon Pinto

Weizmann Institute of Science, Israel; [boris.koichu@weizmann.ac.il](mailto:boris.koichu@weizmann.ac.il); [alon.pinto@weizmann.ac.il](mailto:alon.pinto@weizmann.ac.il)

*This paper explores a particular model of implementation of research: teacher adaption of research procedures and ideas in their classrooms as part of participation in community educational research. The TRAIL (Teacher-Researcher Alliance for Investigating Learning) project seeks to guide the design and conduct of co-learning partnerships between mathematics teachers and mathematics education researchers. In TRAIL, mathematics teachers actively participate in formulating research goals and designing research tools, and then collect data in their classrooms and analyze together the shared data corpus. In the first part of the paper, we present theoretical underpinnings of implementation through participation in TRAIL. In the second part, we examine implementation through participation in an illustrative case, in which a group of teachers designed and explored classroom situations aimed at promoting student questions in the classrooms.*

*Keywords: Co-learning partnerships, student questions, design and implementation.*

### **Introduction**

Implementation of educational research in practice is tricky. On one hand, it is customary to conclude a research paper with suggestions regarding possible implications for practice. For example, when a study includes an intervention component, the researchers may recommend teachers to implement the intervention principles or activities in their classrooms. Or, when a study results in identification of strategies that students engage with, in the context of a mathematical task, the researchers may invite teachers to get acquainted with these strategies in order to better prepare themselves to possible scenarios while enacting similar tasks with their students. On the other hand, it is widely recognized that existing strategies for applying research-based suggestions in practice are far from being satisfactory (Burkhardt & Schoenfeld, 2003). As Kieran, Krainer and Shaughnessy (2012) point out, “[t]he primary responsibility of teachers is *to teach* their students, not to read research papers, and there is some evidence that most teachers don't read such papers very often” (p. 366, emphasis in the original). The scholars then review prevalent strategies by which researchers attempt to familiarize teachers with research findings in various professional development settings and conclude that these strategies, as widespread as they are, have their significant limitations, partly due to the implied view of teachers as recipients or alumni of educational research.

An alternative approach for bridging between research and practice builds on the notions of teachers as stakeholders in educational research, co-producers of professional knowledge, or potential co-producers of scientific knowledge (Kieran et al., 2012; Krainer, 2014). The rationale for this approach stems from in-depth analyses of what teachers may be expected to take to their own practice from mathematics education research. For example, Bishop (1977, cited in Kilpatrick, 1981) points out that teachers can borrow from researchers their procedures, the data and some of research-produced theoretical constructs and models. Even (2003) suggests that mathematics education research is

relevant for teachers as means for gaining insights into teaching and learning that might not be gained through practice, such as: “mathematical knowledge is constructed in ways that do not necessarily mirror instruction” or “knowing is a ‘slippery’ notion” (p. 38). Teachers are more likely to gain access to these kinds of ‘products’ of research as participants in research. Additionally, viewing teachers as co-producers of professional and scientific knowledge rather than recipients of research findings is well aligned with the notion of learning as an active process. It is well documented that students are more likely to succeed in implementing new knowledge when they are actively engaged in co-constructing it. By the same principle, teachers are more likely to implement new knowledge of mathematics education if they are actively engaged in producing it (Taylor, 2017; Wagner, 1997).

The goal of this paper is to draw on the view of teachers as active participants in educational research and present a particular mechanism of research implementation, in which teachers act as partners of mathematics education researchers. In what follows, we unpack this mechanism, first theoretically and then by means of an illustrative example of an authentic study aimed at findings ways to promote meaningful student questions in mathematics lessons. This example demonstrates how teachers can adapt methods and ideas from past research as tools for inquiring into and reflecting on their practice.

## **Theoretical considerations**

To conceptualize and study implementation through participation, we developed a theoretical-organizational framework called TRAIL - Teacher-Researcher Alliance for Investigating Learning. TRAIL consists of a system of theoretical premises and heuristics for guiding the design and conduct of research-practice co-learning partnerships aimed at generating and implementing new knowledge in mathematics education. In this section, we provide a concise outline of the TRAIL framework (for a more detailed discussion, see Koichu & Pinto, 2018).

## **Underpinnings**

The TRAIL framework draws on theoretical constructs and ideas developed in three bodies of the professional literature: the literature on mathematics teacher inquiry, the literature on modes of research-practice partnership and the literature on Citizen Science.

The literature on mathematics teacher inquiry tells us that different types of inquiry are (or at least should be) inseparable parts of teaching as a professional occupation (Menter, Elliot, Hulme, Lewin, & Lowden, 2011; Watson & Barton, 2011). We learn from the literature that the term *teacher inquiry* is used broadly, so that it embraces mathematical modes of inquiry, practitioner educational research, and other forms of inquiry that teachers engage with in their daily work, when preparing to the lessons, conducting them or reflecting on them. For the purposes of this study, we draw on Menter et al.’s (2011) in conceptualizing *teacher inquiry* as a systematic effort to develop and disseminate new knowledge or understanding in an educational setting carried out by someone working in that setting, in collaboration with practitioners working in similar settings and with education researchers.

The literature on research-practice partnerships tells us that different forms of interactions between teachers and researchers have different pragmatic, moral and political expectations and implications for the involved parties. Particularly relevant for this article is a co-learning partnership, as described by Wagner (1997). In co-learning partnerships, researchers and practitioners join forces to inquire

together and aid one another in order to learn something new and worthwhile about their worlds and themselves. The goals, methods and principles of inquiry are negotiated openly to maximize the learning and professional growth of both sides. Therefore, co-learning agreements essentially reduce asymmetry in the roles of the researchers and practitioners. Such agreements make the border between conducting research and implementing it somewhat blurred.

Finally, the TRAIL framework is informed by the literature on Citizen Science (CS). CS is a rapidly growing form of conducting scientific research that involves members of the public in association with scientists to collectively gather, categorize or analyze large quantities of data in order to address real-world problems (Bonney et al., 2009). We learn from Bonney et al. (2009) that an option to engage different participants in the same study at different levels of participation should be thought through when planning a CS project. We also learn, from Wiggins and Crowston (2011), that CS projects can be conducted by local communities that collaborate with researchers as consultants who assist the members of the community to turn their concerns into researchable questions and to construct feasible procedures for pursuing the questions and disseminating the results.

In the case of interest, the teachers were engaged in a research cycle that included design and implementation of classroom activities inspired by past research and by the participants' experiences. The teachers were encouraged to participate in research not only for personal professional growth and improvement of their practices, but also for the joy of being part in producing new knowledge. Likewise, the researchers (the authors of the paper) were interested not only in pursuing their research agenda with the help of the teachers, but also in refining the agenda so that it would be aligned with the teacher-participants agendas.

### **The TRIAL framework**

Based on the described underpinnings, we have formulated, in Koichu and Pinto (2018), the TRAIL premises and heuristics. Four premises are particularly relevant to the concerns of this article.

*Professional Growth through Involvement in Research premise:* Active involvement in the various stages of educational research generates opportunities for teachers to enhance their abilities to engage effectively in inquiry, noticing and reflection as part of the day-to-day practice.

*Authenticity premise:* Teachers' engagement in research is more likely to produce positive effects if conducted in the context of an authentic educational research rather than an exercise in doing research. Accordingly, it is advantageous for teachers and researchers to take part in research that is drawn by questions of potential importance to both communities.

*Choice premise:* Teacher participation in educational research can be stable and productive if the teachers can choose in which research projects to take part, in what capacity and to which extent.

*Shared Agency premise:* Alliance of the communities of teachers and education researchers can be stable and productive if the opportunity to share the agency over the partnership is available for both communities. This means that individual members of each community are to be involved in the partnership in ways that can advance their peculiar goals and needs, including the needs to contribute, develop professionally and have room for expressing personal creativity.

A relevant subset of TRAIL design heuristics is as follows.

- The research goals and questions that underlie TRAIL partnerships are openly negotiated and deal with issues that have the potential to resonate with dilemmas and challenges that mathematics teachers encounter in their daily work at the level of a class, a small group or an individual student.
- TRAIL partnership must have “clear utility” for practitioners that can be convincingly communicated without heavily relying on the scientific literature in which the research is situated. In a similar vein, a TRAIL partnership must have “clear utility” for researchers, that is, have the potential to yield insights of importance to the education research community at large.
- TRAIL partnerships enable teachers to be involved as research assistants or researchers, but not as objects of research. However, both teacher-participants and researcher-participants can be objects of a study about aspects of TRAIL.
- TRAIL partnerships employ accessible data-collection and data-analysis procedures. We call a research procedure accessible if it can be mastered by an interested individual with no background in education research after a brief training period, and if its use requires reasonable time and effort. Examples include: conducting a questionnaire in a classroom, writing a reflective summary of a lesson, or responding to a summary by another participant.
- TRAIL partnerships offer channels of interaction among the participants as well as channels for providing feedback on contributions of the participants. For example, a teacher who contributes a summary of her lesson to the shared database of the project will obtain structured feedback on his or her contribution from the fellow participants and from the researchers.
- TRAIL partnerships comply with the ethics codes for conducting educational research. In particular, the shared databased of a TRAIL partnership should consist only of properly anonymized data.

### **An illustrative case**

A group of 25 experienced high-school mathematics teachers participated in a 60-hour professional development program (PD hereafter) during the 2017-18 school year. Broadly speaking, the PD’s goals were to enhance their participants as leaders of their school communities. About 1/3 of the PD’s time, and the final assignment, were devoted to designing and conducting a pilot TRAIL study.

### **From researchers’ perspective**

At the first meeting with the participants, we briefly introduced the project and offered the group the following question: Suppose your school hires a professional mathematics education researcher in order to help you improve your practice, what questions about your teaching or your students' learning would you like to ask him or her to explore? The teacher responses were highly diverse. For example: *“What can mathematics education research offer for my teaching?”*; *“How can I help my students to deal with the stress of matriculation exams?”*; *“How to teach in a heterogeneous class?”*; *“What is the validity and reliability of the tests that I offer in my classes?”*; *“How can I encourage my students to be more independent?”*; *“How can I know if my students really understand me?”*; *“Which questions do I ask in my lessons and how these questions affect student learning?”*; *“How can technology help me in teaching trigo?”* The rest of the meeting consisted of the negotiation towards a short list of research topics that would be researchable and of interest for both the teacher-participants and the researcher-participants. We chose to inquire into two topics: (1) the roles of questions asked during

the lessons and (2) indicators of student “understanding”. By the end of the meeting, each teacher-participant enlisted herself in one of two sub-groups that corresponded to the two chosen topics.

The second meeting was conducted in two sub-groups. We prepared for each group a three-page document for orienting the teachers of how the chosen topic can be explored. Each file consisted of a brief literature review and elaborated summaries of two studies chosen by us as examples. A study used in both documents, by Leikin, Koichu, Berman and Dinur (2017), discerned different types of questions (e.g., *elaboration questions* and *clarification questions*). The study also exemplified how transcripts of task-based classroom discussions can be analyzed according to the types of the questions students ask in order to gain insight into the understandings students develop. The paper contained four classroom episodes; two episodes in the context of proving in geometry, and two – in the context of exploration of functions. A common characteristic of the episodes was that the student questions have not been elicited but arose spontaneously. The feasibility of designing such situations in the teacher-participants classes was discussed. The discussions in sub-group (1) converged to the realization that teachers ask much more questions than students do and that creating situations rich with the student questions is a challenge that can be handled in a variety of ways. The discussion in sub-group (2) resulted in realization that students' understanding cannot be assessed directly but ways of understanding can sometimes be induced from student questions and responses. An additional discussion at that meeting was about data-collection tools. We considered a videotaped episode from VIDEO-LM study (Karsenty & Arcavi, 2017) and discussed affordances and limitations of videotaping, audiotaping and making notes.

For the third meeting, we prepared a draft of a research program based on the inputs from the second meeting. The sub-groups were reunited. The document included the following questions:

RQ1: How do experienced mathematics teachers construct in their lessons situations that are rich with student questions? What are characteristics of these situations?

RQ2: What types of questions do students ask in these situations?

RQ3: How can student questions be used as indicators of their ways of understanding of the material taught?

The document also included our suggestions for the next steps, including a time schedule. The first stage was to refine and agree upon the research program. At the second stage, each teacher was required to plan one or more classroom activities that would be appropriate for addressing the above research questions and discuss her ideas with peers in an online forum. The third stage consisted of the individual data collection: each teacher was required to enact his or her ideas in a classroom and document three classroom episodes. It was up to each teacher either to try the same activity in three classes or enact three different activities in the same class. The fourth stage was planned as a group discussion, at the next meeting, of the classroom experiences. It was also planned to discuss at that meeting how to create the shared database of the study and how to conduct data analysis. The last two stages consisted the data analysis and writing final reports.

This plan was fully realized. Each stage was supported by a corresponding document prepared by us and shared with the teacher-participants. Of note is that the program was devised so that it left room

for teacher choices. In particular, it left room for choosing individually appropriate mathematical content and context. The teachers were also encouraged to choose two out of three research questions to address and two out of three data-collection tools. It is also of note that the agreed program left room as to whether to implement the research procedures from the studies considered as examples or to devise their own procedures in spirit of the considered examples.

### **From teacher-participants' perspective**

The concluding task of the PD was a term-paper assignment in which the participating teachers presented findings and conclusions from their analysis of data collected in one lesson activity they designed, and one lesson activity designed by another participant. An analysis of the teachers' products is beyond the scope of this paper, yet in this section we provide a glimpse into one aspect of research implementation, as reflected in the reports of two teachers: Michelle and Libby.

Both Michelle and Libby included in their reports elaborated reflections on their goals, dilemmas and decisions while enacting the research program. Michelle noted in her introduction that she was always curious to find out to what extent teachers' professed values and beliefs, including her own, actually shape teaching practices and learning environments in the classroom. Accordingly, she chose to explore RQ1 and RQ3, recognizing an opportunity to investigate this issue in the context of a belief that was collectively endorsed by the PD teachers: students would gain a deeper understanding of the material taught if they ask more questions in lessons. She specifically looked to examine whether other teachers' reflections on their practices and on student learning will be aligned with this professed belief. To this end, she chose to analyze interventions of a teacher who was teaching at the same grade level she was teaching, believing she would be more sensitive to implicit considerations and assumptions guiding the other teacher as she was designing and conducting the intervention. Similarly, while analyzing her own intervention, Michelle discussed in length her own considerations and assumptions. Thus, Michelle drew on the research literature and the research questions to reflect on and inquire into her practice and her colleagues' practice in accordance with her own agenda.

In the introduction of her term paper, Libby notes that she generally agrees with Leikin et al. (2017) that student questions are instrumental in the development of understanding, but that after reading the paper she was left wondering whether "silence [...] could also be considered as a form of student-teacher interaction", and what would silence afford in terms of student questions. In her assignment, Libby wanted to investigate this issue by comparing the affordances of different teaching approaches to student questions. Accordingly, she designed three lesson episodes, one in which she would "restrain as much as possible from intervening in the classroom discussion", one in which she would "try to guide students towards answers [...] without providing the solution", and one where she would "take up the reins" and "be the center of discussion". While presenting her analysis of these episodes, Libby noted that she found the categorization between *elaboration questions* and *clarification questions* proposed by Leikin et al. (2017) was insufficient for distinguishing student questions in the data she collected. Accordingly, she suggested refining the category elaboration questions into two sub categories, and illustrated this refinement in her analysis.

Michelle and Libby's reflections on their decisions throughout the term-paper assignment indicate that they drew on research methods and constructs in their inquiries. They interpreted the agreed in

the group research questions in light of their own goals for professional growth, and made consequent decisions regarding data collection and analysis. We consider this a particular case of implementation through participation, as discussed in the next section.

## Concluding remarks

In the literature on implementation research in education (e.g., Century & Cassata, 2016), the word “implementation” is sometimes paired with such objects as “innovation”, “program” or “reform” (as in “implementation of an innovation”). Such collocations frequently imply co-existence of two distinctly different agencies, creators of an innovation or a program and those who put it into practice. Tensions and issues related to alignment and coordination between these agencies are repeatedly pointed out (e.g., Penuel, Fishman, Cheng, & Sabelli, 2011). Simultaneously, there are voices (e.g., Century & Cassata, 2016; Penuel et al., 2011) that treat implementation of an innovative idea as a multiparty enterprise. We join these voices by presenting and illustrating the TRAIL framework.

TRAIL is a theoretical-organizational tool for devising and conducting co-learning partnerships between teachers and researchers. As illustrated, teacher-participants in a TRAIL study typically consider the products of past studies critically, and draw on them mainly as a resource supporting reflection on and inquiry into their practice. Thus, in TRAIL, the distinction between practitioner inquiry and implementation of research in practice is blurred, and teachers act as co-producers of new knowledge rather than as consumers of the existing knowledge (Kieran et al., 2012). Of note is that while only a few of the participating teachers referred explicitly in their works to the research literature they had been exposed to, many teachers stressed in their feedbacks the importance of exposure to and active participation in educational research to their professional growth.

In summary, this paper illustrates some of the theoretical and practical considerations underlying implementation of research products through teacher participation in research. More precisely, we treat *implementation of research* as active adaptation of research ideas and procedures by practicing mathematics teachers while being involved in doing authentic educational research, in collaboration with mathematics education researchers. We put forward an idea that past research products are likely to influence practice (also) when they are adapted rather than adopted, and when implementation is not the goal but a means on the way to resolving pedagogical problems of importance to the teachers. To this end, the implementation of research products can be seen as intertwining ideas developed by others with one's own experiences and ideas.

## Acknowledgement

This study is supported by a research grant from the Abramson Family Center for Young Scientists. We wish to thank Yonah Amir and Abraham Arcavi for their advice and encouragement, and the participating teachers for their collaboration, dedication and creativity.

*In this paper, we describe and discuss a recent attempt to implement inquiry-based mathematics teaching in Danish compulsory school. After a description of the project and an example of the teaching sequences involved, we will introduce a framework for understanding implementation issues in mathematics education, and use this framework to discuss the problems and potential that our project might encounter when it is considered part of a larger implementation of inquiry-based teaching in Danish mathematics education. We found at least three critical factors for implementation: stakeholders, teacher resources, and the balance between well-prepared and more open teaching materials.*

*Keywords: Implementation, inquiry-based mathematics, teacher development.*

### Introduction: Implementation and inquiry – a story of potential without impact

This paper addresses the implementation of inquiry-based teaching in mathematics. The idea of developing an investigative and problem-oriented approach to teaching mathematics is not new. Even though the discourse around inquiry-based mathematics teaching only dates back to the late 1990s (National Research Council, 1996), the goal of refocusing mathematics education to practice where students are actively investigating and developing mathematical content at play dates back much further (e.g., Dewey, 1938; Freudenthal, 1991; Papert, 1980). Crucial for bringing about changes to mathematics education is dissemination of experiences and processes to a larger group of schools and teachers. This calls for large scale and long-term capacity building providing pedagogical support for teachers so that they can develop the repertoire of skills and understandings required to teach for inquiry-based mathematics. Furthermore, a sustainable impact depends on a good balance of internal and external resources and support (Krainer & Zehetmeier, 2013; Schoenfeld & Kilpatrick, 2013).

More recently, several European development projects have focused on articulating, testing, and implementing inquiry-based approaches to teaching mathematics, science, and engineering (<http://www.primasproject.eu>, <http://www.fibonacci-project.eu>).

These projects have generally reported positive results showing the potential of inquiry-based approaches to teaching mathematics. However, despite the fact that Denmark participated in a number of these projects, the findings have not given rise to significant changes in the teaching of mathematics

at scale (Mogensen, 2011; Østergaard, Sillasen, Hagelskjær, & Bavnghøj, 2010). With this in mind, the Danish government has initiated a three-year project called KiDM (Quality in Danish and Mathematics Education) focused on developing the quality of teaching in both mathematics and first language (Danish).

One of the goals in the KiDM project is to identify and investigate the enablers and constraints for a large-scale implementation of inquiry-based mathematics teaching. This will be addressed in the present paper, where we describe the inquiry-based activities from KiDM and report on how they are received by the teachers, in order to plan and support the implementation. Using a framework for implementation research (Century & Cassata, 2016), we then try to pinpoint important stakeholders and factors that support, hinder, and alter the implementation of the activities of KiDM. In order to discuss problems, potentials, and relevant foci for KiDM as a large-scale implementation project.

### **Description of “Better Quality in Danish and Mathematics” (KiDM)**

KiDM is a three-year, design-based research and development program named “Kvalitet i Dansk og Matematik” (Better Quality in Danish [first language] and Mathematics); its aim is to make the teaching in Danish compulsory school more inquiry-based. The program involves (1) surveying the literature on inquiry in teaching mathematics and Danish, (2) developing inquiry-based teaching activities for a four-month mathematics teaching approach for 4<sup>th</sup> and/or 5<sup>th</sup> grade implemented at 107 schools, and (3) testing the effect of the intervention with a Random Controlled Trial. The control schools and intervention schools are randomly selected with respect to geography, size and ethnicity. They participated with 2-4 classes each, the intervention concerns all lessons in mathematics for a whole semester. The control schools only participated in the tests.

### **Initial investigations and design principles**

The literature survey (Dreyøe, Larsen, Hjelmberg, Michelsen, & Misfeldt, 2018) as a preliminary investigation of KiDM, was conducted to gain insight into the most important issues and main concerns associated with Inquiry Based Mathematics Education (IBME). A systematic search of six of the highest-ranked journals led to five important themes/issues: 1) The literature survey stresses that *communication in the mathematics classroom* should be facilitated as open, inquiring, and related to the students’ activities with a starting point in the students’ prior knowledge. 2) *Mathematical skills and competences* are critical to participation in inquiry-based teaching. The modeling view of problem activities especially holds the greatest learning potential for students in inquiry-based teaching. Inquiry-based teaching has a positive impact on students’ mathematical creativity. 3) The students should be allowed to *move in and out of the mathematical domain*, and hence it is important to use a wide spectrum of activities in teaching. This requires students to be flexible thinkers and prepares them to cope with situations outside of school. Furthermore, the literature survey contained examples of and knowledge about both 4) *tools and resources for planning and implementing inquiry-based learning*, and 5) *professional development and collaboration*. In relation to planning (4), the literature survey suggested that teachers should try to predict the students’ answers and prepare general and specific questions to scaffold, extend, and promote the students’ ability to generalize mathematical ideas. Regarding development and collaboration (5), it is worth noting that any change

to a teacher's approach is a lengthy process. By utilizing pre-planned teaching units, one can contribute to a teacher's ability to reflect on how IBME differs from his/her own approach to teaching.

Apart from surveying the literature, we also interviewed six supervisors in mathematics prior to developing the specific designs in KiDM (Michelsen et al., 2017). Diplomas (60 ECTS) in mathematics supervision have been available since 2009, and many schools have a local supervisor in mathematics who initiates changes and supervises fellow teachers. The supervisors are organized in a national network. The interviews revolved around similar themes and to the need for supporting teacher-teacher and student-student collaboration – “We need time to cooperate inventing and exploring”.

From the above, we formulated three principles which implications were important for the didactical intervention of the design for KiDM:

- Principle 1: An exploratory, dialogical, and application-oriented teaching method with room for student participation increases the effect of the student's understanding of mathematical concepts and develops appropriate ways of working.
- Principle 2: In order to enhance motivation and learning, we prioritize that the students' experience of the teaching and the content should be meaningful both from an internal mathematical perspective and from the perspective of the situation of application/inquiry.
- Principle 3: An exploratory, dialogical, and application-oriented teaching approach with room for student participation increases the possibility of implementing mathematical competences.<sup>1</sup>

To assess the students' development of mathematical concepts and mathematical competences related to inquiry-based teaching, a pre- and post-test was used in intervention schools and control schools; student and teacher surveys were also conducted focusing on changes in the students' motivation and experiences and the teachers' extent of implementation and experiences, respectively.

### **The intervention**

The inquiry-based mathematics intervention was developed in collaboration with school teachers, supervisors in mathematics, teacher educators, researchers, and professors in an iterative process during which the intervention was tested in a number of cycles in special development schools. The intervention was then tested in a pilot study in 14 schools and adjusted before the actual program began. The program runs for three subsequent semesters in the years 2017-2018. The results for the entire program are expected in 2019.

The KiDM intervention consists of a website that contains a detailed teacher's guide and accompanying student pages with various student activities that take into consideration students' prior experiences, students' opportunity for participation and appropriate ways of working with exploration, applications and mathematical competences especially communication, reasoning, and

---

<sup>1</sup> Mathematical competences (Niss & Højgaard, 2011) is a key concept in the Danish curricular standards.

modeling (principle 1, 2 and 3). In addition to activity descriptions, the teacher's guide also contains specific instructions on how the activities should be introduced, what hints can be given along the way, and how the collective discussion should be designed. The activities are designed to be open for the pupils to engage in mathematizations on a number of different levels. One example of such an activity is to count the number of books in the local library, where the pupils are invited to develop strategies for addressing this question in a structured manner. In Figure 1 we see the activity "How many knots?", where students produce their own data sets by tying knots on a string. The students start by tying as many knots as they can in one minute. Afterwards, every student must count how many knots each have made. In groups of 3–4, students must make charts of the numbers. The assignment is: "If a man comes through the door and asks how many knots a student in this class can tie in one minute, what could you tell him?"

**Figure 1: Strings from the activity "How many Knots?"**

In the above example, the students' participation is crucial; they create and use their own data. In a meaningful, explorative way of working they get the opportunity to reason about the data, communicate their result by developing their own model.

All supervisors and teachers in the intervention are required to participate in three project meetings during the semester; they are also required to participate in three group meetings with all school mathematics teachers. All the meetings are clearly facilitated in detail on the website, where short video clips are viewed and discussed in the group meetings. Finally, there is an evaluation sheet that must be completed after each meeting. The group meeting focuses on the establishment of IBME teaching, the action phase in IBME teaching, and the validation phase in IBME education. For instance, the teachers and the supervisors reflected on the validation phase of the lessons they have tried out. The supervisor in mathematics is essential for the implementation by arranging, facilitating and evaluating these structured meetings. Lastly, the intervention teachers, supervisors, and, if possible, the headmasters participate in an all-day introductory meeting focused on the intervention, including both didactical and practical organization of the project, and an all-day evaluation meeting at the regional university. During the intervention, one teacher educator or one researcher will visit the school; this visit may focus either on observation of lessons or participation in a group meeting or project team meeting. The schools receive a stipend for each class participating in the project to cover expenses.

### **KiDM as an implementation project**

In the following section, we will provide some concepts from implementation research and try to use them as a lens to investigate KiDM as an implementation project. We build on the definition of

implementation research from the work of Century and Cassata (2016,) as: “systematic inquiry regarding innovations enacted in controlled settings or in ordinary practice, the factors that influence innovation enactment, and the relationships between innovations, influential factors, and outcomes” (p. 170). Century and Cassata (2016) provided a description of important factors for the implementation of educational innovations. These factors are related to (1) *the users*, (2) *the broader organization*, (3) *the actual innovation*, (4) *the strategies supporting its implementation*, and (5) *the timewise dimension* of the implementation. In relation to the individual end users, we should be aware that the changes that educational innovation aims for are mediated by the people involved in the implementation process and aimed at their “change”. Century and Cassata (2016) distinguished the characteristics of individuals that build on their relation to the innovation (such as prior experience with the approach) from the characteristics of individuals that exist independently of the innovation (such as willingness to try new things). What Century and Cassata (2016) referred to as organizational and environmental factors are both characteristics of the specific setting (e.g., the classroom, the colleagues at the school) and to the broader ecology it sits in (e.g., the municipality or school district). Furthermore, these factors can also be completely outside the specific school or district (e.g., national policies). We can also distinguish between the actual and the perceived attributes of the innovation. This distinction highlights the difference between the explicit blueprints and detailed plans and the subjective (and often diverse) experiences of using these plans. The last factor that Century and Cassata (2016) discussed is implementation over time. Time is always a factor in the implementation and diffusion of practices and innovations.

### **Methods and data**

The supervisors were responsible for the local implementation of the KiDM project and they were in charge for the evaluation sheets developed by the project, concerning implementation of KiDM, e.g. the explication of the teacher guide and inquiry-based teaching in general, e.g., key issues and challenges. To understand the status and challenges of KiDM as an implementation project we use the lens from Century and Cassata (2016). In the following section, we use the five factors from above to analyze our project. By reviving and coding the free-text information from the supervisors' evaluation sheets that the local supervisors wrote as part of the documentation of the group meetings and project meetings. The sentences (i.e., citations) were categorized first individually by the first and second author of this paper according to the five factors but also in connection to enablers and constraints in implementation. Afterwards the coding was discussed in the whole group.

### **Characteristics of individual end users of KiDM**

The end users of the KiDM project are teachers of mathematics, supervisors in mathematics at the participating schools, and students. Intervention schools were randomly selected according to a number of parameters, and therefore, we assume that we consider all types of mathematics teachers. However, there was a request that teachers had mathematics as their main subject and teaching experience in mathematics. This request was not met for all schools. Another request was that the school provide a coordinator who is a supervisor in mathematics. Some schools were unable to fulfill this, and their coordinators were participating teachers or the headmaster. We take into consideration the heterogeneity of the teachers by being very explicit with detailed plans in the teacher's guide.

However, in terms of explication, there were still challenges, “It is very hard for a teacher who doesn’t have math as their main subject to read the teacher’s guide”. In a similar vein, “Preparation of the activities is hard work. We are only two educated math teachers in a group of six teachers, so we have to do most of the work”. Others found the material to be very explicit, “The didactic description is very thorough. A teacher who doesn’t have math as their main subject would be able to teach if he had the time and opportunity to read the description”.

The teachers are a critical part of the end users and the data we currently have suggest that one important aspect of the project’s ability to satisfy this group is to provide enough information so that the instructions are clear (since inquiry-based approaches are new to some of the teachers) while not providing so much information that the workload becomes too great.

### **Organizational and environmental factors**

The project is funded by the Danish Ministry of Education and supported by the Danish Union of Teachers. The school receives a stipend, which covers extra time for preparation and participation in meetings; this is important for the participants, “We have spent a lot of time reading the teacher’s guide. If there had been no extra time given in the project, we would not be able to use such an extensive teacher’s guide”.

The intervention is planned in accordance with the national curriculum, yet some of the participants questioned the extent of this, “Do we meet the needs for the National Test?” and “Are the curriculum in play equivalent to half a year’s work?”

As described above, the supervisors play an important role at most of the participating schools since they organize the meetings and local progress in the project. The project meetings are important for cooperation and for shift in collective attitudes: “We have cooperated far more than we have ever done”, “Wonderful to ‘nerd’ with mathematics at the meetings”, and “It has been liberating to be able to engage in discussions about mathematics and didactics at the group meetings”.

The important organizational factors are economic resources/time, legislative support, and collaborative structures. Furthermore, we can see that the supervisors in mathematics becomes critical as the person who plans and facilitates the activities.

### **Attributes of the innovation**

The degree of specification of what teachers and students must do in KiDM is high. The operationalization is not left to the teachers to perform by themselves. This tight scaffolding can be seen as critical to the success of KiDM. On the homepage, the teachers have access to a teacher guide that includes specific questions to ask in all phases of the activities, the aims of the activities, and agendas for all project meetings and group meetings. The agenda includes questions for discussion, links to short videos to watch and discuss, and tasks to solve and discuss. The teacher’s guide has some flexibility in the material, for example, to differentiate between 4<sup>th</sup> and 5<sup>th</sup> grade or to include students who are especially talented in mathematics.

The teachers in the project have varying attitudes toward this detailed and tight operationalization; some teachers said that having a very strict teacher manual helped them in the beginning, but at the end of the intervention, some of the teachers did not follow the manual entirely.

### **Implementation support strategies**

The implementation strategies in KiDM are very broad. One important strategy is the meetings held at the local schools, where the focus is on discussion, operational planning, and professional development among mathematics teachers at the school. There were various comments about the idea that the teachers in the project must present their work at the larger mathematical group meeting at the local schools – “It does not work. You cannot involve the entire school in something that three teachers participate in” – but most of the teachers responded very positively about these meetings – “We have discussed teaching and reflected about teaching and learning much more than we usually do. We hardly ever say, ‘How about page 87?’” The supervisor has an important role in these meetings because he/she must facilitate these meetings. If these meeting are not successful, it will affect the implementation at the school. The supervisor in mathematics can therefore be seen as a *change agent*. In addition, the KiDM teachers are given more time than usual for their lesson preparation and their extra meetings, which can also be considered an implementation strategy in the hopes that this additional resource can support further development of teachers.

### **Implementation over time**

It is not yet possible to determine whether the teachers’ methods of inquiry-based teaching have been implemented, as the project is still ongoing. At this point, it is not possible to determine whether the teachers are at a specific developmental stage (from awareness to initial adoption to sophisticated innovation), but some teachers have stated that they already have ideas for how they will implement an inquiry-based approach in the future: “We have applied for a workday where all the math teachers will try to formulate a strategy for how to implement inquiry-based mathematics” and “All classes from the 1<sup>st</sup> to the 5<sup>th</sup> grade receive one extra hour per week. This hour must be used for inquiry-based mathematics”. However, there are other variables that also come into play, such as the involvement of school leadership: “It is a turning point, the head of school is interested”, or “We don’t have a final agreement for the continuation of the work with the head of school yet”. The involvement of the mathematics group at the school is also important over time: “Despite the skepticism at the start (from the teachers not participating in the project), everybody is much more positive about the project as well as discussing didactics topics at the meetings”.

### **Implementation as core stakeholders, resources, and an act of balancing**

In answering our question about enablers and constraints for KiDM considered as a large-scale inquiry-based project in Denmark, we see at least three factors that are critical, namely core stakeholders, balance, and resources. The first is the existence of core stakeholders in this change; Denmark is lucky to have a relatively newly educated group of supervisors in mathematics that can act as such. In a survey initiated by the Danish Ministry of Education (Mogensen, Rask, Lindhardt, Østergaard, & Rostgaard, n.d.), supervisors seem to be very influential in implementing government initiatives. The supervisors and group meetings are crucial organizational factors in KiDM. Hence, the supervisors in mathematics have the potential to act as change agents in future large-scale implementations. The second factor that we see as critical is the existence of time and money to support the work. This is stressed repeatedly by the participants. However, rather than just providing more money to the schools, we can see that the visibility of the project resources for the teachers

involved is critical, at least in our case. Therefore, necessary resources should be available to the end users (in this case, the teachers). The last factor is that of *balance* between well-prepared material/structures and the freedom to change and modify. In this project, we have been quite precise about what has been prepared, and this has worked particularly well when teachers and supervisors adopted the approach and made it their own.

These three themes have been in the way that we describe the envisioned output and evaluation criteria of the project and hence as a part of the theory of change of the project.

# Towards a common understanding of implementation research in mathematics education research

Andreas Lindenskov Tamborg

Aalborg University, Department of learning and Philosophy; [alt@learning.aau.dk](mailto:alt@learning.aau.dk)

*Keywords: Implementation research, documentational genesis, implementation frameworks.*

## Introduction and aim

By reading the papers from TWG 23 in CERME 10, implementation research in mathematics education research appears to integrate diverse sub-fields from the community such as students' proportional reasoning, teachers' professional development, and curriculum design (Jankvist, Aguilar & Wæge & Ärleback, 2017). Often, these fields are defined by different research objects, core questions, ongoing discussions and mainstream theoretical and methodological approaches. This is also evident in the papers where the research object being studied is reflected in the choice of theoretical framework, for example, a study of the implementation of proportional reasoning draws on theory of proportional reasoning (Ahl, 2017). This characteristic has several substantial benefits. Firstly, the domain-specific theories developed within sub-areas of mathematics education research have been refined for decades to study the specific objects or processes for which they are developed. Secondly, whether implicit or explicit, domain-specific theories within mathematics education research often involve concepts and a vocabulary to investigate and articulate implementation matters (Jankvist, Aguilar, M. S., Wæge, K., & Ärleback, 2017). The use of different theories originating from diverse sub-fields, however, represents a threat in accumulating a solid foundation of knowledge. The aim of this poster is to show that explicitly relating domains-specific theories to implementation research can contribute in overcoming this potential pitfall while simultaneously preserving the advantages of using domain-specific and well-established frameworks. For this poster, I will illustrate how the documentational approach to didactics' (DAD) (Gueudet & Trouche, 2009) perspective on implementation can be articulated by taking an outset in Century and Cassata's (2016) definition of implementation research.

## Theoretical frameworks

Century and Cassata (2016) define implementation research as:

(...) the systematic inquiry regarding innovations enacted in controlled settings or in ordinary practice, the factors that influence innovation enactment, and the relationships between innovations, influential factors, and outcomes. (Century & Cassata, 2016, p. 170)

This definition involves four central elements, namely enactment, factors of influence, innovation and outcome. *Enactment* refers to a given end user's usages of what is being implemented. The *innovation* is what is being implemented, and it might appear in the form of a concept, training program, technology, etc. *Factors of influence* are what affects the enactment and may be attributes of the end user, organizational/environmental factors etc. Finally, *the outcome* is the result of implementation. It is a central point of Century and Cassata (2016) that these four elements are conceptualized and investigated differently in implementation research, as the aim, context and

theoretical approach of a given research question shapes the understanding of these concepts differently.

Central concepts in a framework called DAD can be considered an interpretation of the four elements in this definition of implementation. DAD is developed to study mathematics teachers' appropriation and usage of resources and considers the result of teachers' combination of resources, usages, and knowledge a document (Gueudet & Trouche, 2009). The framework draws on an understanding of resources as "a range of (...) human and material resources, as well as mathematical, cultural, and social resources" (p. 210). Teachers' work with resources is considered dialectic, where usages and resources mutually affect each other (Gueudet & Trouche, 2009). A *document* is defined as the combination of resources, usages, and knowledge. In DAD, teachers' enactment of digital learning platforms are goal-oriented appropriation and usage of resources. The innovation may be the resource, which a teacher use. The outcome may be considered the documents that are produced, and the implications that these might have for teachers' teaching and pedagogical work. In DAD, the influencing factors can be considered emerging instrumentations and instrumentalizations, which may be caused by resources, students, and teachers' interpretation of the learning platform or the like. Moreover, implementations of innovations are considered a bidirectional process where the user may affect the innovations, but the innovation may also affect the user. To synthesize the research results in implementation research as an independent sub-field in mathematics education research there is a need for a consistent vocabulary. In this poster, I have suggested using Century and Cassata's definition of implementation research to create common grounds. Using such an approach can synthesize results generated from diverse frameworks that are otherwise difficult to integrate.

# Capturing Problem Posing landscape in a grade-4 classroom: A pilot study

Ioannis Papadopoulos<sup>1</sup> and Nafsika Patsiala<sup>2</sup>

<sup>1</sup>Aristotle University of Thessaloniki, Greece; [ypapadop@eled.auth.gr](mailto:ypapadop@eled.auth.gr)

<sup>2</sup>Aristotle University of Thessaloniki, Greece; [npatsiala@eled.auth.gr](mailto:npatsiala@eled.auth.gr)

*In this pilot study, grade-4 students in a Greek primary school are invited to pose problems in three different situations (no feedback, peers' feedback, teacher's suggestions). The aim was to capture the problem posing landscape of the classroom in terms of the complexity of the problems the student pose in these situations. The posed problems were examined in terms (a) of mathematical complexity in the sense of the number of semantic relations they involve, and (b) of linguistic complexity. The findings give evidence that as the students become progressively aware of the initial problem's attributes, they start to pose more complex problems by increasing both the number of problems that involve at least 2 semantic relations and the number of linguistic instances.*

*Keywords: Problem posing, primary school, mathematical complexity.*

## Introduction

Problem posing has been recognized as an important intellectual activity in school mathematics and integral part of a balanced mathematics curriculum (Hansen & Hana, 2015). The truth is however, that in the school setting students are merely asked to solve problems rather than pose (Stoyanova, 2003), and therefore they often face difficulties in posing mathematical problems (Silver & Cai, 1996). Even though research findings support that students are capable of posing interesting and important mathematical problems (Cai, Hwang, Jiang & Silber, 2015) most of these problems are mainly cognitive undemanding and textbook-like (Crespo & Sinclair, 2008). This contradiction makes apparent the potential role of an intervention and many research studies (Crespo, 2003; English, 1998) seem to agree that a proper intervention might help students to learn posing problems given that they already have experience in solving problems similar to those they are asked to pose and actually this highlights also the teacher's role in this process.

In this paper, we make a preliminary effort to capture the problem posing landscape in a Greek grade-4 classroom in terms of the complexity (mathematical and/or linguistic) of the generated problems in a variety of situations. The findings will feed the design of a year-long intervention aiming to foster the students' problem posing abilities. Thus, our research question is: How the level of complexity in the problems posed by primary school students varies according to the setting in which the problem posing takes place?

## Literature Review and Theoretical Framework

'Are students able to learn to pose problems?' If yes, what is the proper way to achieve that? Brown and Walter (1983) claim that problem posing can be taught. For each problem students can ask what kind of information the problem gives us (known), what kind of information is unknown and what

kinds of restrictions are placed on the answer. Then many new problems can be generated if the solvers remove, change or loosen the restrictions. In essence, solvers are asked to list the attributes of the problem, to take an attribute and ask “What-If-Not” that attribute.

Exploring students’ problem posing performance is not new (English, 1998; Silver & Cai, 1996). Research findings reveal that even primary school students are able to pose good/meaningful mathematical problems. Lowrie (2002) claims that through a supportive and motivating learning environment, grade-1 students increasingly generated more sophisticated problems that were open-ended in nature. Gade and Blomqvist (2015) worked with grade-4 and grade-5 students who posed problems in three different stages (formulating written questions, problem posing in dyads and posing problems to one another) using slips of papers. Through these three stages, remarkable progress was made so as in the problems posed by the students as well as in the way they used the slips of papers. Chen, Van Dooren and Verschaffel (2015) implemented a training program aiming to develop grade-4 Chinese students’ problem-posing abilities. After the implementation, the problems generated from the students were significantly better proving that elementary students can be taught to pose better and meaningful problems. Cifarelli and Sevim (2015) connect the development of the problem posing abilities with successful problem solving. By focusing on episodes of two grade-4 students they explain how both problem posing and solving coevolve during the solution activity and also how the development of problem posing abilities contributed beneficially in the students’ problem-solving abilities, too.

According to the literature the problems posed by students can be more interesting when they have been previously solving similar problems themselves, when the posed problems are addressed to people outside the classroom and when they are prompted by informal instead of formal symbolic contexts (Crespo, 2003; English, 1998). Winograd (1997) working with fifth-grade students found that they were highly motivated to pose problems that their classmates would find interesting or difficult without losing their interest during the process of sharing posed problems. Problem posing is rather redefining the way students learn mathematics since they are actively engaged in the learning process by being encouraged to set questions and generate problems instead of being passive receivers of knowledge (Brown & Walter, 1983).

The problems posed by the students can be evaluated on the basis of three criteria (Silver & Cai, 2005): Quantity, Originality and Complexity. Quantity refers to the number of the generated problems. More specifically, the number of the mathematically correct problems may be indicative of the progress the students accomplished. Originality refers to the number of unusual responses and thus rareness is a way to measure it (they refer to these answers as atypical or original). The third criterion, complexity, can be examined at least from two different perspectives: the mathematical and linguistic complexity. Linguistic complexity focuses on linguistic structures (presence of an assignment, relational and conditional propositions in the statement of the problem). Mathematical complexity is related to the mathematical structure found in the posed problems and one plausible way to measure it is by enumerating distinct semantic relations using a classifications scheme of arithmetic word problems developed by Marshall (1995). This includes five categories of relations: Change, Group, Compare, Restate, and Vary. The Change schema applies when an initial quantity changes over time (increase or decrease). The Group schema relates to a situation where a number of small quantities are combined into a larger one. The Compare schema involves situations where two

things are contrasted with an emphasis on the relation between them (greater, smaller, more, less, etc.). Restate schema involve situations where there is a relation between two variables at a given frame only (e.g., exchange rates). Finally, Vary schema involves a fixed relationship between two variables that persists over time (e.g., relation between euros and cents).

Mathematical complexity has attracted the interest of several researchers on problem posing. According to Silver and Cai (1996) the complexity of the problems posed by the students tend to increase when students generate sequences of chained problems using the results of the simpler problems to pose more complicated ones. Ellerton (1986) comparing the problem posing abilities of high- and low-ability students found that high-ability students generated more complex problems. Finally, it seems that certain interventions influence the quality of the generated problems (Crespo, 2003; English, 1998). English (1997) conducted an intervention to grade-5 students and found that after the program the students posed a greater number of problems that were also more complex.

## **Design of the study**

This study is the first in a series of small pilot studies aiming to capture the landscape of Greek primary students' problem posing abilities. The students were asked to pose problems in three different settings to compare the variation on the complexity of the problems posed in each setting. Apart from the first setting, the following two settings were developed during the implementation taking into consideration the students' answers. Eighteen grade-4 students from a private school participated in this study. The intervention took place in parallel to the normal teaching of mathematics in the sense that an hour per week is dedicated in math tasks aiming to develop students' mathematical thinking. The students had no prior experience on relevant problem posing activities.

In the first phase, the students were given the starting sentence of a potential problem: "Peter has 75 cents..." and they were asked to complete the problem in as many as possible different ways without having to solve their problems afterwards. Silver and Cai (2005) consider this kind of activities appropriate for assessing students' problem posing abilities. The teacher did not give any clue about the operations or the mathematical concepts the students could involve in the produced problems. This session was followed by a whole class discussion and the students had the chance to present their examples. One of the students presented an example that initiated the second phase of the study. In his example he actually dropped an attribute of the problem using a "What-If" approach and produced a problem that attracted the attention of his peers. The attribute was the kind of currency and his question was "What if instead of euros the currency was lev?" (the currency of the adjacent country of Bulgaria).

Based on his suggestion the students were asked to pose new problems in the same spirit using the same "What-if" technique of their classmate even though they did not have similar experience before (2<sup>nd</sup> phase). No discussion on the notion of listing and dropping attributes took place. Again, a whole discussion followed the session and the students presented their problems.

Finally, during the third phase, certain attributes were explicitly provided to the students by the teacher. More precisely, the teacher asked them to pose problems by considering certain attributes such as the total number of coins, the kind of the coins/currency and the value of coins.

The problem in its incomplete form makes apparent one attribute in an explicit way: the total amount of money. Therefore, students are left to involve and negate more attributes that could potentially be part of the problem such as the number or the kind of coins.

The students' worksheets with the problems they generated during the three phases constituted the data for this study. The written responses were analyzed based on the assessment tools developed by Silver & Cai (2005) and Marshall (1995). According to these tools, the responses are organized in three major categories depending on whether the questions included in the problem were mathematical, nonmathematical or whether there was merely a statement in the problem rather than a question. Then, the mathematical questions were evaluated on their solvability (solvable and nonsolvable). Finally, the solvable ones were examined for indications of mathematical and/or linguistic complexity. We determined how many of the five semantic structural relations (Marshall, 1995) co-existed in each problem. Problems that involved a larger number of semantic relations are considered more mathematically complex compared to those that involve less relations. A comparison followed across all the three phases. All the responses were evaluated independently by the two authors and validity and reliability were established by comparing sets of independent results, clarifying categories until agreement.

## Results and Discussion

### Phase One

As already mentioned, during the first phase of the study, the students were given the first sentence of a problem and were asked to pose as many as possible problems without feedback neither from their classmates nor their teacher. Each student posed one or two problems. Table 1 summarizes the results of the first phase. All the mathematically complex problems are distributed further according to whether they involved 1, 2 or 3 semantic relations. Moreover, sometimes linguistic and mathematical complexity might co-exist in the same problem and this explains why the partial sums in Table 1 are not in agreement with the total number of solvable problems.

Total number of Responses: 23						
Nonmath Questions: 0	Math Questions: 22					Statements: 1
	Solvable: 19				Nonsolvable: 3	
	Math Complex. 19			Ling Complex. 2		
	1 relation	2 relations	3 relations			
	8	8	3			

**Table 1: Results of Phase-1**

As it can be seen, in this phase most of the responses (19 out of 23) were solvable problems exhibiting to a certain degree mathematical and/or linguistic complexity. The problems more or less copy the problems the students are familiar with and are included in their mathematics textbooks. Mainly they were problems including 1 or 2 relations that could be solved in one or two steps using more the addition and/or subtraction operations (instead of multiplication or division). One example with 1

relation was: *Peter has 75 cents. He gave 30c to one poor child and later he gave 7c to another. How much are left?* (1 relation, Change). Another example including 2 relations was: *Peter had 75c. His grandmother gave him 95c but later took 25c from him. His grandfather gave him two more euros but took 125c from him. How many euros will Peter have?* (Change, Vary). This problem combines addition/subtraction to find partial results (Change) but at the same time the concurrent use of cents and euros involves converting cents to euros and vice versa (Vary) which means that multiplication and/or division (depended on how the problem will be solved) are also necessary. Another example of mathematically complex problem which exhibited three semantic relations (change, group and vary) exhibiting at the same time linguistic complexity was: *Peter has 75c. At New Year's Eve his dad gave him 87€ and 46c. In March he bought 8 gums per 27c each. In April he bought an ice cream for 36€. Two weeks ago, he bought a skateboard for 19€ and 29c. a) How much money did he spend on February in order to have 75c now? b) How much € did all the gums cost? and c) How much did he spend for all of them?* The solver has now to interpret the existing information. 'New Year' refers to January and the chain of expenses refer to the period from January to May (the 'two weeks' is related to the time the session took place in school. It was during May). However, February is not mentioned. The initial amount of money is interpreted as the money Peter owns and the end. So, it is a multistep problem involving almost all the four operations and requires thought and interpretation of the information provided by the statement of the task.

There was finally an instance (1 out of 22) the students made a statement. That was: *Peter had 75 cents. He wants to buy a toy for 100€.* It is obvious that the student did not pose any question. During the whole classroom discussion one student posed the question (addressing it rather to the teacher than his classmates): *'What if instead of euros the currency was lev? Would you be able to solve the problem?'*. As already has been mentioned this question initiated the next phase.

## Phase Two

During Phase 2 the students were invited to generate new problems in the spirit of the 'What-if' approach exhibited by their classmate in the previous phase. There was not any explicit reference to the list of the problem's attributes and their negation. The results of this phase are summarized in Table 2.

Total number of Responses: <b>21</b>						
Nonmath Questions: <b>1</b>	Math Questions: <b>18</b>					Statements: <b>2</b>
	Solvable: <b>16</b>				Nonsolvable: <b>2</b>	
	Math Complex <b>16</b>			Ling Complex <b>0</b>		
	1 relation	2 relations	3 relations			
	<b>8</b>	<b>7</b>	<b>1</b>			

**Table 2: Results of Phase-2**

Most of the students' responses were solvable problems (16 out of 21). There was only one problem asking a question that was considered nonmathematical: *Peter has 75 cents. What if he loses all of his money and cannot buy anything?* Furthermore, no linguistic complexity was detected in the students' responses in this phase.

What is interesting is that almost all the students followed the instruction to use the ‘What-If’ approach but actually they copied the problem of their classmate in the sense that they just focused and/or negated the attribute of currency. For example: *Peter has 75 cents. What if Peter had a friend from Japan and he wanted to trade yen with 75c?* (restate). Or in another example: *Peter has 75 cents. What if his money was alien money. If an alien cent has the same value as 9€ and wants to buy a wallet which costs 49€, how much change will he get?* (restate and change). In these responses, the students engage the potential solver with currency conversions (which means true statements for a short period of time), and the solution of the posed problem relies heavily on the relationships between the two currencies. During the whole classroom discussion, the teacher shifted the focus on identifying and negating more attributes of the problem and this initiated the third phase of the study.

### Phase 3

During this phase of the study, certain problem’s attributes were provided to the students such as the number, value and kind of the coins and they were asked to consider them in order to pose new problems. The results of this phase are summarized in Table 3. An example of a ‘What-If’ approach considering the kind of coins was: *Peter has 75 cents. If he only has 5c coins, how many coins are in his pocket?* (vary). It looks like a common problem. However, the choice of division as the necessary operation to solve the problem is not met frequently in the students’ responses. An example of a moderate complex problem in this phase is: *What if there were also 7€ and 16€ coins and Peter has in his pocket sixteen 7€ coins and three 16€ coins. He spent 5.27€ and then lost 3.25€? How many euros are left? How many cents are they?* (Change, Vary, Group). The solver must be familiar with this new element of the weird coins that is not common at our linguistic repertoire and then must relate euros with these new coins and depending on the strategy there will be necessary to use multiplications and/or divisions for the interplay between euros and cents.

Total number of Responses: <b>32</b>						
Nonmath Questions: <b>1</b>	Math Questions: <b>31</b>					Statements: <b>0</b>
	Solvable: <b>29</b>				Nonsolvable: <b>2</b>	
	Math Complex <b>29</b>			Ling Complex <b>8</b>		
	1 relation	2 relations	3 relations			
	<b>9</b>	<b>16</b>	<b>4</b>			

**Table 3: Results of Phase-3**

The students’ awareness of the attributes of the problems seems to stimulate both the number and the quality of the posed problems. There was a noticeable increase in the number of the problems (almost 1,5 times more). More precisely, the number of problems that include at least 2 relations was 20 out of 29 problems. This increased number of semantic relations (Silver & Cai, 1996) indicate the presence of mathematical complexity. Furthermore, in this phase, there was a significant number of instances (8 problems) exhibiting a sense of linguistic complexity: *Peter has 75 cents. Is it possible to have only 2c coins?* The linguistic element in this problem is that its question differs significantly from the ones posed in the first two phases. The word “possible” must be interpreted correctly given

that the participants are grade-4 students and a certain language competency is required to negotiate phrases such as “at least”, “possible”, “the more” that are included in mathematical problems.

## Conclusion

The purpose of this (first among others that will follow) pilot study was to capture the landscape of problem posing in a Greek grade-4 classroom in order to setup a year-long intervention in the classroom aiming to develop the problem posing abilities of the students. The students were invited to pose their problems in three different setting and the results give evidence that given certain circumstances grade-4 students can pose interesting mathematical problems. Almost all the students were able to pose mathematical questions. Only a couple of statements or nonmathematical questions were identified. Moreover, the complexity and the sophistication of the generated problems tend to increase along with the evolution of the sessions.

During the first phase of the study, students posed without any external influence a series of solvable problems. Most of these solvable problems included one or two semantic relations resembling textbook like problems dealing with the four operations and specifically addition and subtraction which is in accordance with Crespo and Sinclair (2008). There were also a few instances of three relations or linguistic complexity signs that were identified in some of the answers.

In the next phase of the study, a “What-if” technique was used by one of the students who negated the currency attribute of the problem. This was an opportunity to invite students posing new problems under the light of this new approach. The situation was more or less similar to the previous one, and the posed problems were merely mimicking the one posed by their classmate. So, the students did actually drop the attribute of currency not as an action of negating the structural elements of the task but as a way to follow an example that seemed to be successful. No signs of problems’ linguistic complexity were identified.

During the final phase of the study, the students became aware of certain attributes that were highlighted by the teacher. This awareness seemingly helped the students to increase the number of posed problems increasing at the same time the number of the involved semantic relations per problem. Also, more evidence of linguistic complexity emerged.

Given the lack of any relevant experience on problem posing and its strategies the students were able to take advantage of the feedback provided during the whole classroom discussion either from their peers or their teacher. This feedback actually shifted their attention to specific attributes of the task. It is very interesting that the students’ answers determined the design of the next two phases. This study, being a pilot one, feeds the design of a future intervention aiming to create a class environment that will encourage students to raise questions and pose problems. This small-scale study encourages the idea that a systematic teaching on problem posing may develop students’ posing abilities which is in alignment with English (1997).

# Models of school governance and research implementation.

## A comparative study of two Swedish cases, 1960–2018

Johan Prytz

Uppsala University, Department of Education, Uppsala, Sweden; [johan.prytz@edu.uu.se](mailto:johan.prytz@edu.uu.se)

*This paper concern the role of research and models of governance in two Swedish reform programs: the New Math project in the 1960s and 70s and the Boost for Mathematics project in the 2010s. This historical comparison study aims to deepen our understanding of how research results in mathematics education are implemented in Swedish schools today. Theory and results from implementation research are used to pinpoint and justify the choice of the object of analysis. The analysis focuses on the role of research and the researcher in the preparation of the two projects. The main sources are reports and governmental decisions concerning the two projects, but sources also include material used in these projects.*

*Keywords: Governance, Educational change, Educational research, Innovation, Implementation.*

### Introduction

Between 1960 and 2018, the policy of governance of Swedish schools has shifted from being primarily centralised to being primarily decentralised (Prytz, 2017). To a great degree, this shift meant that teachers had more autonomy to choose what teaching methods and teaching materials to use. For example, since 1994, the national curriculum does not provide guidelines about teaching methods. About the same time, the review of textbooks was abolished. However, little is known about how this overall change in governing policy has influenced how research findings are implemented in schools.

In Sweden, the development of research on mathematics education has paralleled the change from centralisation to decentralisation. The number of researchers has increased greatly and mathematics education has become an established field of research at most Swedish universities. However, this does not entail that research in mathematics education did not exist in the 1960s – it did. However, in the 1960s research was conducted to a large extent by the central school authorities rather than by researchers in universities. Perhaps it is not entirely correct to refer to this enterprise as research, but there was cooperation with researchers and the methodologies were similar to those found in educational research today.

The study presented in this paper deepens our understanding of how research results in mathematics education are implemented in Swedish schools today. To this end, this paper compares two historical cases: The New Math project (1960–1975) and The Boost for Mathematics project (*Matematiklyftet*) (2011–2016). The two projects differ in many respects, but they also share some characteristics: both projects were run by central school authorities and both emphasised teachers using research findings to develop teaching strategies. The analysis is descriptive and concerns how the implementation of these projects was prepared. The analysis and the research question address the function of educational science as a base of knowledge for designing teaching innovations.

More precisely, I describe different phases in the preparation process and the role of research in this process. Further details are presented in the section ‘Theory and method’.

The paper contains five sections: ‘Theory and method’, ‘Contribution to previous research’, ‘The New Math project’, ‘The Boost project’, and ‘Conclusions and discussion’. ‘The New Math project’ and ‘The Boost project’ sections include a short background of each project as well as a more detailed description of the role of research in each project. In ‘Conclusions and discussion’, the two projects are compared with each other and I discuss the role of research and modes of governance.

## **Theory and method**

Innovation is a key concept in research about implementation as it is the innovation that is to be implemented (cf. Century & Cassata, 2016; Fullan & Pomfret, 1977). This paper concerns the preparation of the innovation. In an early overview on research about implementation and education, Fullan and Pomfret (1977) note that this phase can be determinant for the rest of the implementation process.

In a more recent overview, Century and Cassata (2016) discuss research about implementation and education and how innovation relates to knowledge. In an educational setting, knowledge can come from two sources: research and practice. This paper focuses on how educational research or science has functioned as a base of knowledge when innovations were designed; in brief, I call this the function of research.

In comparative historical studies in education and other subjects, it is imperative to have a common unit of comparison (Bray et al., 2007). In my analysis of the function of research in the two projects, the common unit is the researcher. The basic question of this paper is formulated as follows: How did researchers prepare the innovations? For example, the researchers can design the innovation by compiling results from other researchers outside of the project or the researchers can design the innovation by doing their own experiments or trials.

This analysis relies on official reports about the New Math project and the Boost project and teaching materials. However, when discussing the New Math project, I do not refer to the original sources but to a previous study, Prytz (2017), which includes an analysis of the New Math project in Sweden.

In addition, I analyse the organisational factors influencing the function of research. According to Century and Cassata (2016), these factors can influence the implementation of an innovation. In particular, I am interested in how policies of governance (centralisation or decentralisation) and scientific policies influenced the role of the researchers: How extensively have researchers been pursuing policies of governance and science?

As to the historical context of governance of each case, I have not done my own analysis but have relied on extensive previous research. Of course, there are different views on certain aspects, but there is strong agreement about the overall narrative: from about the mid-1970s up to about 2000, the policy of governance of the Swedish school system changed from mainly centralised to mainly decentralised. In all three areas of governance (economical, judicial, and ideological), the general

ambition was to give local actors the power to make decisions (e.g., local politicians, headmasters, or teachers). We also find this overall narrative in university textbooks and in research papers (see Prytz 2017 for an overview).

### **Contribution to previous research**

Focusing on methodology, this paper shows how historical studies can be used in research about implementation and education. Historical comparison is a rarely used methodology in research about implementation and education as evident in its lack of mention in quite old as well as more recent international overviews (cf. Century & Cassata, 2016; Fullan & Pomfret, 1977). The lack of historical comparisons is also evident in the field of mathematics education, where implementation research is a fairly new topic. For example, historical studies about implementation have not been an issue at the previous CERMEs.

A principal argument of doing historical comparisons is that they provide perspectives on contemporary phenomenon, a view that cannot be attained through the study of contemporary sources alone. Typically, historical comparisons help bring into relief what is stable and what is not (cf. Tosh, 2000). This study found that the role of educational research and the researchers preparing reforms co-vary with basic policies of governance. This co-variance can be a problem if we believe that research should be autonomous and follow its own logic.

This paper also contributes to the research about the Boost project. As with this study, Boesen et al. (2015) focused on design and planning to examine how the project was informed by research. However, Boesen et al. considered how references were made to different types of research publications, whereas my study focuses on the role of researchers. Another difference is my historical perspective and my comparisons of policies of governance. The Boost project has also been evaluated two times and a third is on the way. One of the evaluations (Österholm et al., 2016) uses a scientific approach. Not in any of the evaluations, the preparation of the program and the role of researchers are considered; the focus is on the outcome.

### **The New Math project**

The New Math can be seen as an international reform movement that aimed to innovate and improve school mathematics from year 1 to 12. The innovations were supposed to be based on contemporary science: The content of the teaching should be updated to reflect the advancement of the scientific discipline of mathematics, and teaching methods should be based on modern psychological and pedagogical research. By the end of the 1950s, the movement had accumulated great momentum. Internationally prominent researchers supported the project, including the mathematician Jean Dieudonné and the psychologists Jean Piaget and Jerome Bruner. In addition, international organizations such as OECD and UNESCO contributed by funding conferences and publishing reports (Prytz, 2017).

Quite early, Sweden became part of the movement. In the late 1950s, representatives from Sweden attended the international conferences on the New Math. In the early 1960s and in cooperation with other Nordic countries, except Iceland, development began on a new curriculum based on New

Math. The project was initiated, financed, and driven by central school authorities. These preparations lasted until 1968 (Prytz, 2017).

The role of the researchers during the preparations of New Math in Sweden was to lead and work in a research-like enterprise gathering and analysing extensive empirical data. The development of the innovations, which largely concerned the development of textbooks, was an extensive enterprise. The testing of new textbooks involved thousands of students in the Nordic countries. In addition, teachers completed questionnaires that addressed how teaching had progressed and how the material could be improved. In one part of the project, a new type of textbook based on New Math went through five rounds of development and trials. At the end of another part of the project, trials with experimental groups and control groups were conducted that lasted for two or three years. These trials ended with knowledge testing. The tests indicated that the new material was functional and which groups of students were served best by the new material (Prytz, 2017).

A central component of the New Math was set theory. The idea was that set theory, already from year one, should form the basis of all other areas of school mathematics, such as arithmetic, geometry, algebra, and statistics. The inspiration came from the scientific discipline of mathematics, where set theory functioned as a basis for other parts of mathematics. In school mathematics, however, it was not just a question of adding a common ground for the content of the courses; set theory also had an educational or methodological purpose. It was supposed to create clearer connections between the various topics, both for teachers and for students. In addition, explanations and illustrations should be based on concepts from set theory. Interestingly, concepts from set theory alone did not fill this role. The 1969 curriculum also emphasised the number line and images of numbers as positions on a number line (Prytz, 2017). Thus, the New Math project brought not only a general theory about teaching and learning, but also detailed guidelines about how teachers should communicate with students.

It was in connection with the methodological ideas about set theory that Piaget and Bruner were of particular significance. They argued that there are similarities between mental structures and mathematical structures, which they thought should be used in teaching. The idea was that a stronger focus on structures would provide better understanding, which in turn would result in better learning. Set theory, but also the number line, would provide a structure to create better learning. For this reason, set theory, along with the number line, should primarily be seen as a methodological innovation that concerned all parts of school mathematics (Prytz 2017).

However, Piaget's and Bruner's theories should be considered hypothetical guidelines. Few studies provided specific guidelines for how to design teaching. In the final report about the Nordic New Math project, we see only a few examples of these types of studies. A centre piece of that report is the development phase and the trials of new types of textbooks (Prytz, 2017).

In the 1970s, the reform was being implemented. The new curriculum based on the New Math was ready in 1969 and it took effect in 1970. By and large, all teachers in mathematics in year 1–9 received further education in New Math. A large majority of the textbooks followed the new curriculum (Prytz, 2017).

## The Boost project

The Boost project was an in-service training program for teachers and was prepared between 2011 and 2012 and was launched in 2013. The final decision about launching the program was taken in 2012. It ended in 2016 although much of the material is still accessible through the central school authority's website. It was a major program as 76% of all mathematics teachers (1–12) followed the program (Source B). At this point, we can spot a great difference in comparison with the New Math project: the time allotted for preparations.

Unlike the international New Math movement, the Boost project was an all Swedish enterprise. The justification of the project was that the results of the Swedish students had decreased for about 15 years, according to national as well as international evaluations. This was clearly stated in the final government decision to start the Boost project (Source A). The results in PISA and TIMSS had indeed decreased significantly, especially in the ten years before the Boost project. In fact, the decrease was greater than in any other country.

The same government document identified the cause of the problems. On the basis of several investigations, the document concluded that students mainly worked alone with the textbook and too little of the teaching were led by teachers, limiting the possibilities to learn about reasoning and argumentation (Source A). This view of the problem was reflected in the overall aims of the project. The aims were to change the culture of teaching and develop a new in-service training culture (Source B). Neither the justification nor the aims of the project had any direct connections to the new curriculum that was launched in 2011.

The Boost project was administered by the central school authorities in co-operation with the national centre for mathematics education at Gothenburg University (Source A). To ensure scientific quality, the work to develop the educational material, so-called modules, was distributed among several university departments with research in mathematics education (Source B).

The basic principle for organizing the program was peer learning among teachers with support from external experts. Experts in this case were researchers at the university departments. However, experienced and highly skilled teachers led the peer learning sessions with the teachers (Source A). These experienced and highly skilled teachers received special training at the university departments for eight or nine days. As I understand it, the researchers' main responsibility was the teaching material and the special training of the highly skilled teachers.

The choice of a peer learning program was justified by a reference to a report issued by the Ministry of Finance (Åman, 2010). In turn, the author of that report referred to another report (Timperley, 2007) issued by the Ministry of Education in New Zealand, an international overview of research on teacher training. The report clearly recommended peer learning, but it provides no explicit recommendations about how researchers, or experts, and teachers should interact. However, the report implied that this relationship is crucial since it emphasised the importance of the content of the teacher training program; in fact, this was considered more important than anything else.

This leads us to the teaching material and how it was developed by the researchers. The material, or modules, comprised scientific articles in mathematics education along with films, audio clips, web

texts with instructions, and questions for lesson activities and peer learning (Source B). Each module covered one topic (arithmetic, geometry, etc.) in the curriculum. In addition, each module focused on four areas: abilities, formative assessment, interaction, and socio-mathematical norms.

The scientific articles in the modules included different types of texts: an international overview of each topic and the four areas mentioned above and articles about Swedish mathematics education. The later type of texts was by no means dominant (Source C). My point here is that the research results presented to the teachers largely did not stem from research on Swedish students and teachers.

One major role of the researcher was to use information from previous research to produce the modules. To secure high quality material, each module was also reviewed by several other researchers. According to the final report about the project, there were no trials of the modules with teachers before they were published and used (Source B). However, in the same report, it is stated that there were follow-ups (school visits, interviews, and surveys) after the publication and these resulted in revisions of the modules (Source B). To what extent and for how long these follow-ups lasted is unclear. Another report noted that there was a test round with 300 teachers in the autumn of 2012. The program was then launched in the autumn of 2013 (Source B). Thus, it appears there was only one round of trials where the teachers could provide the researchers with feedback.

## **Conclusions and discussion**

The role of the researchers in the New Math project and the Boost project fits the narrative of an educational system that changed from a centralised to a decentralised system. In the New Math project, the state-financed researchers applied one specific theory about cognition and learning to find out what is efficient teaching in all subtopics for all school years. This research ended in detailed guidelines about how to teach all parts of mathematics such as how to explain new concepts and what type of illustrations or pictures should be used. These guidelines were then dispersed through the national curriculum. Thus, the decision about what is good teaching was centralised and the researchers were supposed to deliver detailed guidelines about teaching that all teachers were to apply. In the Boost project, much of the decisions related to learning and teaching were decentralised. The researchers did not have to apply one specific theory on cognition and learning. Moreover, the role of the researchers was not to provide more definitive answers, for example, through guidelines in the national curriculum about what is an efficient teaching practice. Moreover, the idea of peer learning theory, which was the overarching theory of the Boost project, is that teachers, with support from researchers, should develop their own teaching strategies. Another aspect of decentralisation was that the teachers choose to study two of several modules. Thus, the teachers decided which part of their teaching needed most development. As I see it, the role of the researchers in the Boost project was to gather a smorgasbord of teaching solutions the teachers could choose from. Thus, in both projects, the researchers were operating according to the policy of governance of each period.

Now we turn to the issue of pursuing scientific policies. The New Math project was driven according to one explicit general theory about cognition and learning mathematics. However, this theory was hypothetical as it did not deliver concrete solutions about how to teach. In practice, this meant

developing and testing teaching and support material, not the least of which were textbooks, for six years. During this time, new material was tried in five development cycles. The project involved thousands of teachers and students, and the material was also tested with experimental and control groups after two or three years of teaching. Important to notice is that the many years of testing were relevant from a scientific point of view since little empirical research results were available to develop the New Math project. In the Boost project, the situation was different. Time for development was brief, about a year, and the material given to the teachers, the modules, was tested just once and with few teachers. That is, rather than relying on results from trials (i.e., applying a more empirical and inductive mode of reasoning), the researchers had to work in a more deductive fashion (i.e., take and derive solutions from previous research results).

I am not saying the Boost way of preparing materials for teachers is unscientific or ineffective, but I am questioning if it is optimal. Are we today in the position to replace or drastically reduce the type of preparations we see in the New Math project? The methods applied in the New Math preparations still are relevant for development projects and they are a part of normal research methodology. Moreover, is it possible to derive functional material, both with respect to design and content, in a brief period from research results that in many cases do not stem from studies on Swedish students and teachers? If we consider the overview on implementation research by Century and Cassata (2016), their view seems not to include positive answers to these questions:

It is not uncommon for developers to be unsure about which elements are indeed most critical [...], and there is a tendency for innovation creators to identify the majority of components as “very important” [...] and to hold holistic views of their innovations (i.e., as “packages”), leading to component descriptions that lack specificity. [...] For these reasons, researchers are encouraged to use multifaceted approaches to identifying innovation components that combine information from developers and other experts, from end users, from observations of innovations in practice, and from reviews of artefacts, such as practice guides and other program materials. (Century & Cassata, 2016, p. 182)

This passage indicates that the development of the innovation should take some time to identify and develop core components in different ways. In fact, the preparations of the New Math reform fits this passage quite well since it combined information from developers, experts, and users as well as observations of innovations in practice.

So, why was the Boost project prepared in this way? Why was not more time and resources allocated to researchers and the development of the material? I suggest this decision, at least in part, was related to a policy of governance – i.e., decentralisation. This policy does not fit the idea of researchers in a central position deciding what is good material for all teachers. Moreover, the absence of more precise material, which Century and Cassata (2016) are asking for, is less of a problem if teachers are supposed to make decisions on their own. Here it is important to notice that the scientific report referred to in the planning of the Boost project that recommended peer learning (Timperley, 2007) gave no explicit recommendations about how researchers and teachers should interact. However, the report did imply that this relation is crucial since it emphasised the importance of the content of the teacher training program.

In the future, I think researchers as well as politicians and school administrators should consider the relation between governance and research more closely as they plan major development projects. To a great degree, they are probably interested in the same goal: to change the behaviour of teachers and students. However, their means to achieve the goal may or should not always be the same.

*The research literature provides plenty of examples of epistemological analyses of multiplication and descriptions of the complexity of the conceptual field of multiplication. Nevertheless, multiplication is often introduced as repeated addition, although decades of research have identified this pedagogical choice as leading to persistent problems in students' conceptualisation of multiplication. In this paper, we describe a teaching design that aims to implement theoretical and empirical research results regarding multiplication in classroom practice. Within our design, models in the form of iconic representations serve as a means for creating patterns that make multiplicative invariants and structures visible. The teaching we have designed is currently tested in a mid-scale randomized controlled trial and in a large-scale professional development project.*

*Keywords: Multiplication, primary school, models, implementation.*

## Introduction

Multiplicative structures constitute a vast part of compulsory school mathematics. The importance of the concept of multiplication for students' possibilities to develop mathematical competence cannot be overstated. When multiplication is introduced in school mathematics, children start a journey that should take them to advanced mathematical knowledge about fractions, ratio, rate, slope, similarity, trigonometry, probability and vector spaces. In addition, physics and social science are heavily reliant on multiplicative reasoning and proportional relationships, e.g., statements of equality of ratios  $a/b = c/d$ . Hence, multiplication is a fundamental concept, and it is therefore crucial to learn from educational research and to implement gained insights into classroom practice.

Up until today, research has gathered extensive knowledge on students' understanding of multiplication (e.g., Clark & Kamii, 1996; Fischbein, Deri, Nello & Marino, 1985; Harel & Confrey, 1994; Larsson, 2016; Thompson & Saldanha, 2003). We know that concepts preferably develop over long periods, through experience of a large number of situations (Vergnaud, 1988). We also know that the "whole number bias" leads students to a solid belief that *multiplication makes bigger* and that multiplication is synonymous with *repeated addition*. However, we do not yet know how to transform research results about students' understanding of the properties of multiplication into classroom practice in order to obviate the whole number bias. In this paper, we will describe an ongoing project, aiming to bridge the gap between research findings and teaching practice through an innovation (Century & Cassata, 2016): a carefully designed teaching sequence implementing alternative models for the introduction of multiplication. The implementation is carried out in Sweden, where multiplication traditionally is introduced in school year 2, at age 8–9 years. Research on the effects of the implementation is an integral part of the project.

## **The whole number bias**

The whole number bias is “a tendency to use the single-unit counting scheme applied to whole numbers to interpret instructional data on fractions” (Ni & Zhou, 2005, p. 27). This bias may be a result of an unchallenged presentation of multiplication as repeated addition with whole numbers. The consequences of a biased conceptualisation have been long known. Bachelard (1938) concluded that knowledge that has been formed and tested for validity in action tends to form a consolidated belief concerning the nature of the concept. When the concept is later challenged in new situations, assimilation might be more complex than if initial knowledge was absent. This is why an introduction of multiplication as repeated addition may become an epistemological obstacle for students. Fischbein et al. (1985) conclude that:

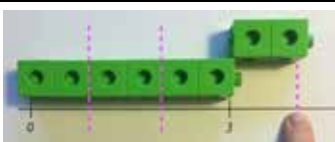

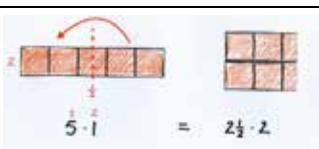

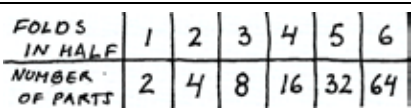

The initial didactical models seem to become so deeply rooted in the learner’s mind that they continue to exert control over mental behavior even after the learner has acquired formal mathematical notions that are solid. (p. 16)

There are two misconceptions of the properties of multiplication specifically linked to the whole number bias: conceptualising multiplication as an additive relation rather than a multiplicative relation, and a belief that a product will always be bigger than each of its factors. As long as multiplication is limited to whole numbers, these misconceptions will not constrain children’s reasoning, and are therefore unlikely to be challenged. However, as soon as children are introduced to multiplication with fractions and decimals their conceptualisation will no longer be sufficient. Products such as  $\frac{1}{2}$  times 5 cannot be calculated as repeated addition, and the law of commutativity, which could be helpful in this situation, is difficult to explain in terms of repeated addition. Furthermore, a firm belief that multiplication makes bigger will undermine the children’s possibilities to interpret situations with operations like  $0.22 \cdot 1.20$  (Bell, Swan & Taylor, 1981), since the answer is less than 1.20, which is not compatible with a conceptualisation of multiplication built on additive reasoning with whole numbers. In summary, conceptualising multiplication as repeated addition works when dealing with whole numbers but will become a misunderstanding of multiplicative properties when extended to rational and real numbers. This is a strong argument for finding alternative ways to introduce multiplication, and thereby avoiding the whole number bias.

## **Alternative models for introducing multiplication**

The complexity of multiplication is reflected in the body of research, and might be one reason why innovative designs are scarce in both research and practice. The efforts to describe dimensions and aspects of multiplicative knowledge are diverse, and show less agreement than, for example, the literature on additive knowledge (Nunes & Bryant, 1996). In Vergnaud’s (1988) terms, multiplicative structures can be seen as a conceptual field, consisting of situations, invariants and symbolic representations. Compared to additive structures, multiplication embraces a much more diverse family of situations. Already in the simplest case, with two factors, multiplication unifies qualitatively different situations, which can be both one-dimensional, like scaling, and two-dimensional, like one-to-many correspondence, area, intensity and Cartesian products (Harel & Confrey, 1994; Nunes & Bryant, 1996; Vergnaud, 1988). In line with the theory of conceptual

fields, our teaching design comprises both activities focused on situations and activities focused on invariants, with care taken to link established symbolic notation to both types of activities (see Table 1).

Week 1		Factorization (multiplicative grouping) of numbers with lattice models. Regrouping of lattices.
Week 2		Connecting lattices to symbolic notation for multiplication and division. Constructing the multiplication table by sorting lattices by factors.
Week 3		Placing numbers on number lines by measuring with skips and cubes. Discovering proportional relationships.
Week 4		Measuring number lines with halves. Equating different numeric expressions for multiple halves.
Week 5		Regrouping lattices by halving and doubling. Multiplication with half-integers.
Week 6		Exponential relationships and associativity in the context of repeated folding (inspired by Empson & Turner, 2006).
Week 7		Equal grouping situations: partition, quotation and one-to-many correspondences.
Week 8		Proportions: double, half, times four and fourth.

**Table 1: Overview of the sequence of multiplicative activities. Week 1–5 focus on investigating multiplicative patterns and structure, while week 6–8 focus on modelling multiplicative situations**

However, since classifications of multiplicative situations, including examples of classroom activities, have been thoroughly described elsewhere, we will focus this paper on the use of models in the form of iconic representations, and how such models may aid the discovery of invariants. Since multiplicative situations can be both one- and two-dimensional, we have chosen to use both one-dimensional number lines and two-dimensional lattices as models.

A coherent conceptualisation of multiplication requires an appreciation of multiplicative invariants across situations. In other words, one has to recognise patterns in different situations as manifestations of the same structure. Within the implementation, patterns and structure (Mulligan & Mitchelmore, 2013) has proven to be a useful terminology for conveying the importance of invariants to teachers, and for describing the purpose of activities where patterns are created and described. Seeing patterns calls for experience of a breadth of cases, rather than focusing on one particular situation at the time. Therefore, the first five weeks focus on exploring specific models of numbers (see Table 1).

From the perspective of embodied cognition, Lakoff and Núñez (2000) argue that arithmetic is a conceptual blend, resting on four conceptual mappings from concrete situations. These mappings, or metaphors, each contribute to the concepts of number and arithmetic in their own way, implying that no single metaphor can reflect these concepts in full. Our lattice models are related to the first two of the grounding metaphors: object collection and object construction, while number lines are related to the latter two: measuring with a stick and movement along a path. There is a particularly close relationship between multiplication and measuring. Both simple proportions and area build on two important ideas: unitizing and norming (Lamon, 1994). Unitizing is described as the ability to construct a reference unit or a unit whole, and norming is then to interpret a situation in terms of that unit. In other words: creating a measure and then using it for measurement. This idea is also mirrored in verbal expressions on the form “two threes”, where the number three becomes the unit six is measured in.

We will now describe how lattices, number lines and verbal expressions are used as models in our teaching design. In particular, we will detail how these models convey important properties of multiplication.

### **Lattice models**

Lattice models are in many situations exchangeable with arrays, but they do have some advantages. In arrays, each unit is separated from the others and pictured as indivisible. In lattices, the units are placed in a continuum, which makes the idea of dividing units by adding new lines attainable. Furthermore, open arrays are visually closer to lattices than arrays. Within our teaching design, both interlocking cubes and drawn grids are used to create lattice models. The activities using interlocking cubes could often be done in the same way with arrays of tickers or other objects, but that would make the step to drawn grids larger. By using cubes and grids of the same size ( $2 \cdot 2$  cm), the two representations are easily compared, and lattices of both kinds can be used in the same systematic arrangements.

Lattices can be seen as ‘bar models for multiplication’, in that they provide a way to represent different multiplicative groupings of numbers, just as bars can represent different additive groupings. Within the design, the class has previously worked with finding number bonds to ten by building ten bars and naming them “\_ + \_”. Multiplication can then be seen as a *different* way to group numbers (see Figure 1). Our choice of introducing multiplication by lattices hence introduce multiplication not as an additive relation, but as something different than addition. The criteria for multiplicative groupings are easily established by discussion in class, distinguishing proper lattices

from other shapes. The existence of different lattices for a number calls for expressions of the form “ $\_ \cdot \_$ ” to be introduced as names for lattices. Finding different lattices for each number then becomes an explorative activity, leading to discussions of which lattices are the same (commutativity), and why some numbers have more lattices than others (primes and composite numbers) (Week 1, Table 1). Hence, important multiplicative invariants, which are hidden when multiplication is conceptualised as repeated addition, are made visible already in the first activity.

**Figure 1: Bars and lattices as two different ways of grouping numbers**

Arranging lattices according to products reveal that multiplicative groupings do not form a pattern as simple as for additive groupings. Finding patterns in lattices therefore requires more careful instruction. Directing attention to lattices of twos leads to the discovery of even numbers and could be generalised to multiples of other numbers. This idea will inspire to a different arrangement of the lattices, focusing on factors rather than products. Building lattices of twos, threes, fours, etc. and ordering them in rows will result in the multiplication table (Week 2, Table 1). The table will spark a new exploration of patterns in the products, and the lattices will provide a means for explaining those patterns. For example, you can see two copies of the product in the second row in the corresponding product in the fourth row (a basis for the distributive law and powers), and that the products in the second column are the same as the products in the second row, because the lattices in the column are just rotated versions of the lattices in the row (commutativity).

Using interlocking cubes facilitate successive adding and subtracting of columns and rows, which are mainly additive strategies. However, they also allow for multiplicative regrouping of numbers. When comparing the two twelve lattices  $6 \cdot 2$  and  $3 \cdot 4$ , you can split one of the lattices and rearrange the parts, in order to see how one lattice can be regrouped into the other (Week 1, Table 1). Paper grids enable generalisation of such multiplicative regroupings to half-integers (numbers of the form  $n + \frac{1}{2}$ ), since paper can be cut and arranged to illustrate e.g.,  $2 \cdot 5 = 4 \cdot 2.5$ . This immediately gives rise to multiplications where the product is smaller than one of the factors, such as  $4 = 8 \cdot 0.5$  (Week 5, Table 1). The model hence enables the discovery of cases where multiplication does not make bigger, within the first weeks of introducing multiplication.

### Number lines

Number lines are important tools for arithmetic reasoning. Approximate use of empty number lines can both aid and communicate reasoning even in complex arithmetic problems. However, for empty number lines to be meaningful, one needs to be aware of the properties of linearity, closely linked to multiplication. Within our design, the class will use a variation of number lines, which put different properties of linearity in the fore.

During choral counting, a number line with markings and numbers, placed on the wall, is often used for pointing at numbers while skip counting (e.g., 0, 2, 4, 6, etc.). In some activities, a floor number

line is used. This number line has evenly spaced markings, with every fifth marking a little longer than the others, and a collection of number cards which can be placed in different ways in different activities. Every placement of two numbers raises the question of where other numbers should be and leads to discussions of equal spacing of numbers. In week 3 this is done with 0, and 1 or 2 in different positions (see Table 1). When starting with 1, the situation is a pure one-to-many correspondence, while starting with 2 requires more complex proportional reasoning. When justifying a proposed placement of numbers, or figuring out a placement, the children walk along the line, taking e.g., two-steps or three-steps. When documenting the work, teachers use verbal expressions and symbolic notation e.g., “you take three two-steps, so it’s three twos, we write  $3 \cdot 2$ ”. A similar activity is done with semi-empty number lines on paper, where only markings for specific numbers are present, e.g., 0 and 3. The task is to place markings for the missing numbers between 0 and 6, using interlocking cubes as a measuring tool. This activity is also provided at different levels, with some restricted to pure one-to-many correspondences.

As in the case with the lattice model, these activities are easily extended to fractions, starting with halves. Walking in regular or half-steps to different numbers creates an opportunity to introduce multiplication of fractions in an intuitive context. Since multiple double or triple steps were called twos or threes and represented as  $n \cdot 2$  or  $n \cdot 3$ , it makes perfect sense to call multiple half-steps halves and represent them as  $n \cdot \frac{1}{2}$ . Documenting the number of each type of step it takes to reach different numbers will result in a pattern with a proportional structure: the number of half-steps is always twice the number of regular steps (Week 4, Table 1). After whole class exploration of these patterns on the floor number line, children work in pairs to place half-integers on empty number lines, using interlocking cubes as a measuring tool, this time with 1 cube =  $\frac{1}{2}$ .

### **Verbal expressions**

In relation to both lattices and the number line, care is taken to use sustainable verbal expressions of the form “two threes” and “five halves”. As emphasized by Thompson and Saldanha (2003), there is a principal difference between “two threes” and “add three two times”. It is possible to generalise the first expression beyond integers, to e.g., “one and a half threes” or “one and a half third”, while “adding three one and a half time” is harder to conceptualise. Phrases of the first form mimic phrases used in measurement, making a number the measuring unit: “one and a half threes” – “one and a half meter”. While such phrases are used to discuss both models, they relate to each model a bit differently. Each phrase, e.g., “three twos”, labels a certain way of walking to a number or a series of skips to a number, which is different from what “two threes” labels. In contrast, both expressions can be linked to the same lattice, and the corresponding ways of seeing the lattice are made explicit, pointing out the three twos and the two threes in this six lattice.

### **Implementation of the alternative models for multiplication**

Taken together, our design covers a variety of advanced aspects and properties within the first weeks of the introduction of multiplication. The handling of advanced content is made possible by the highly structured material organising the teaching of each week in a cycle with six phases, including whole class discussions as well as pair work and individual documentation. This cyclic teaching structure has been previously described and tested in preschool (Sternier & Helenius,

2015). The material developed for the implementation of the design includes explicit instructions on what the teacher should do and say in each phase, and in reaction to different student actions and reasoning. Each activity also contains a detailed description of the mathematical concepts and procedures involved, as well as the purpose of each activity in relation to children's learning. Activities, as well as instructions, were tried and evaluated by small groups of teachers during the development of the material, increasing the quality and functionality of the design. Thorough testing of the activities is important for the teachers' trust in the material, which is particularly important due to the high level of prescription in the design.

The teaching design has been implemented in an intervention research project covering 15 weeks in grade 2, where the multiplicative part covers 8–9 weeks. The project is a randomized controlled trial with 28 participating teachers in grade 2 (14 using our material, 14 in a control group). Data from the pre- and post-tests are currently being analysed. In a parallel project we are developing similar teaching sequences for grades 1 and 3. Including sequences dealing with additive structures and number, the complete material will cover most of the area of number and operations for grades 1–3. These sequences will also be tried and evaluated by small groups of teachers during development, together with auxiliary professional development material. In collaboration with 5 municipalities, we will implement the teaching design together with professional development for around 500 teachers starting in the fall of 2020.

### **Closing reflection**

The literature on the downsides of relying on multiplication as repeated addition is substantial. Still, teaching experiments with alternative models for multiplication are sparse, one example being Nunes, Bryant, Evans, and Bell (2010), who report on two studies covering only a few sessions. Also among teachers and textbook authors the dominance of repeated addition as the model for introducing multiplication persists. Fishbein et al. (1985) suggest that this model is chosen because it fits the mental requirements of children in the first years of schooling. It is simply hard for teachers to resist building on addition, since it is a concept that children are already familiar with at the time when multiplication is introduced. However, as seen above, multiplication in fact has several complementary roots that are not additive, such as measuring and one-to-many correspondence (Lamon, 1994; Nunes & Bryant, 1996). Many of these roots are intuitive for children and can hence be used as alternative bases for introducing multiplication.

According to Century and Cassata (2016), there are three key foci for implementation research: the innovation, the aligned outcomes, and the influential factors. This paper has described the innovation of an ongoing, large scale implementation project: a teaching sequence introducing multiplication by means of deliberately chosen models for making multiplicative patterns visible and comparable, which in turn inspire discussions where multiplicative structures are explicated. The analysis of test results in the randomised controlled trial will reveal to what extent this innovation achieves the desired outcomes, while the grade 1–3 project will provide opportunities to study the influential factors, as well as to further develop the innovation.

# Implementing theories for preschool teaching with play-based pedagogies

Nina Ullsten Granlund

Stockholm University, Sweden; [nina.ullsten@gmail.com](mailto:nina.ullsten@gmail.com)

*The play-based Swedish preschool is facing new challenges due to demands from the Swedish Schools Inspectorate to evaluate how the teaching of mathematics is carried out in practice. This demand has evoked a dilemma for the preschool teachers that find it unclear what teaching in a preschool means. A professional development project was set up, aiming to implement theoretical tools from research into preschool mathematics teaching. The project started in 2016 with 45 teachers over a duration of seven months. An integral part of the project is to conduct research on the impact of the preschool teachers' conceptualization of mathematics as a subject, and what counts as a mathematical situation. The participating preschool teachers collected video recordings of mathematical situations from their respective practice. The professional development is an ongoing project, the impact of the implementation of theories are currently being researched.*

*Keywords: Preschool mathematics teaching, play-based environment, professional development.*

## Introduction

The Swedish preschool is facing new challenges, it has a tradition of caring and educating and is built upon a playful custom of will on behalf of the child. The preschool is not organized in formal lessons and its curriculum does not define any subjects like mathematics or biology, but suggests a thematic way of arranging the practice so that the learning goals found in the curriculum can be met in line with the principles of social pedagogy (Bennet, 2005). Yet, since the national curriculum for preschools was introduced in 1998, some of the goals have been obviously concerned with mathematical matters and these goals were sharpened in 2010 and has now again in 2018 been slightly revised (Skolverket, 2018, valid from 2019).

Having particular goals for mathematics means that the children's learning cannot just be expected to happen through general everyday activities, but must be planned for by the preschool teachers. In previous national curricula, there has been no explicit mentioning of teaching, despite that teaching has been the overarching term used in the Education Act to describe the goal directed processes aiming for learning and development. Since 2018 however, teaching is an explicitly mentioned concept in the revised curricula (Skolverket, 2018). The changes in terminology, and perhaps also policy, came after the Swedish Schools Inspectorate expressed that there is a problem with an overall unclarity about what teaching in preschool means and how it should be done (Skolinspektionen, 2016). The dilemma is that in the play-based tradition, the organization of learning is quite different from a typical school setting. For example, children's own initiatives are much more foregrounded than the time children spend in situations that are guided by a teacher (Helenius, 2018). When the concept of teaching is imported from school to preschool, the play-based tradition is endangered. Voices have been raised, indicating that the teaching of mathematics might be particularly prone to act as a trojan horse for importing values and beliefs on teaching from school that might not necessarily fit very well in a play-based preschool practice (Fosse, Lange, Hope Lossius & Meaney, 2018).

The present paper reports on a professional development (PD) project aiming to offer the preschool teachers<sup>1</sup> theoretical tools for how they can think about the mathematics taught and how to think about the teaching in a structured and explicit way, that still respects the play-based tradition. Research on the effects on the teachers is an integral part of the project.

## Implemented theories in the PD project

When the play-based pedagogy of Swedish preschool works at its best, it integrates a play-based pedagogy with learning of mathematics in accordance with the curriculum goals. This can not only be done by planning regular teaching activities, since it would affect the preschool activities in a direction away from play in favor of formal schooling. Teaching must thus also be organized by means of planning the environment and using spontaneous situations in deliberate ways. A theory of play-based preschool teaching must account for that. At the same time, preschool teachers have difficulties verbalizing what constitutes teaching acts. Preschool teachers tend to not regard themselves as teaching teachers (Skolinspektionen, 2016). Therefore, a theory for play-based teaching should help the teachers to structure the type of work that is involved in play-based teaching by explicating particular components of such teaching (Helenius, 2018). A structured way of thinking about teaching can be a tool for teaching in a more deliberate way. This is a way to give teachers concepts and words for discussing with colleagues and plan their teaching in a play-based environment.

## Theorizing preschool teaching

A structured way of viewing the complexity of mathematics preschool pedagogy is through defining three dimensions of teacher action, with respect to mathematical pedagogy: pedagogical explication, teacher participation and situational planning (for more information see Helenius, 2018). They are not suggestions of normative categories, but examples of how the complex pedagogical practice of teaching preschool mathematics could be explicated.

First, in a *dimension of pedagogic explication* of the teaching and learning of mathematics, two different ways of including mathematics can be identified. One way is a classical teaching situation, where the participants know that the activity concerns the learning of some specific mathematical content. Following Walkerdine (1988), such situations are called pedagogical with respect to the mathematical content (Helenius et al., 2015; Walkerdine, 1988). The other way is when the situation is fundamentally about something else, but some mathematical activity is included in the situation. Such situations are called instrumental. In this theorization the child's experience of a situation as instrumental rather than pedagogical does not mean there are not pedagogical intentions from the teacher's point of view. For example, as exemplified in Helenius (2018), a teacher's decision to make a robot available to children have pedagogical intentions, but children playing with it are not thinking of it as a situation which they are supposed to learn mathematics. Teachers can make an active choice of explicating the mathematical content of a situation or not. This choice can be made beforehand, in planning, or on the fly, when a teacher observes a mathematical situation that she chooses to either act on by shifting the children's focus to the learning of some mathematics, or not. Similarly, when children act on their own, with no teacher involvement, in a situation that contain mathematics, the learning may or may not be visible for the children. Thus, when the children perceive the situation as being about learning something mathematical, that situation is 'pedagogical'.

---

<sup>1</sup> We include all employees who work with teaching in the participating preschools, although not everyone has a formal teacher education.

Second, a *dimension of teacher participation* is quite obvious for children in preschool because they spend a lot of time conducting activities without any teachers involved. They know when the teacher is arranging activities, or not. The unarranged situations can provide children with opportunities to use mathematical knowledge and participate in mathematical activities. Therefore, time spent in preschool with no pedagogue involved can contribute to children's mathematical development in important ways. The same is true for time spent outside preschool, but the difference is that teachers can influence the mathematical content as well as children's experience of mathematics in situations in the preschool environment. One obvious example is planning specific activities that the teachers ask the children to do. But, there are also more subtle ways, such as planning and modifying the environment, in and around the preschool facilities so that it stimulates mathematical activities. For example, children can play with a programmable toy robot, only available to children for their free play.

This third *dimension of situational planning* relates to what Ginsburg, Lee and Boyd (2008) calls "teaching moments" or "acting in the moment", in contrast to formally planning learning situations in Swedish preschool mathematics pedagogic discourse. It is of course important for teachers to use the option to plan situations where they participate themselves. Planning has a distinct advantage in giving the teachers time to predict what may happen in a situation, and prepare for different possibilities. But mathematically interesting situations can also occur outside planning. It is important to acknowledge that situations that are not directed by the teacher also allow for play in situations where children may use mathematics. Moreover, preschool teachers can affect what happens during "free time" in many ways. This is also a part of the planning. However, preschool teachers have choices concerning what situations they want to plan and which to deliberately leave unplanned.

The Schools Inspectorate evaluation of the preschool 2015-2017 points out that preschools see that children learn a lot from playing but they also found that teachers have a strong belief that children should not be disturbed when playing. This can lead to overlooking possibilities for learning and development. The evaluation also observes that mathematics mainly occurs in planned activities lead by an adult. The theory presented above attends to this dilemma by using the tool of documentation. If a teacher notices interesting activities in free play, these can be noted and documented and the teacher can later plan for how the experiences gained in the documented situations can be reused later. This can be done either by retrospectively challenging the children that were in the original situation, but also by using ideas from the documented situation for a planned activity with other children.

### **Theorizing mathematical activities**

One aspect of the theory above is using mathematics instrumentally. Therefore there is a need for a conceptualization of mathematics that views mathematics as something that can come out of practical problem situations, that is, a conceptualization that does not only view applications of mathematics as something you do with mathematics that is already learned or known. Moreover, a conceptualization of mathematics that is to be useful for preschool also needs to bridge everyday mathematics with formal mathematics, preferably in a rather seamless way. It has previously been argued that one theory that fulfils these requirements is Bishop's theory of mathematical activity (Bishop, 1988b; Helenius, 2018; Helenius et al., 2015; Johansson, 2015).

The background for Bishop's work is anthropological. By studying the use of mathematics in different cultures, he concluded that mathematics, just like rituals and cooking, occurs in all cultures. He also found that mathematics is different depending on where and in which culture it is evolved. And yet, certain regularities also occur in these studies and Bishop (1988a; 1988b) characterizes these in terms of six distinct mathematical activities that he claims are found in every culture and can be seen as the roots of mathematical thinking. The descriptions below are from Bishop (1988a; 1988b):

- Counting: The use of a systematic way to compare and order discrete phenomena.
- Measuring: Quantifying qualities for the purposes of comparison and ordering, using objects or tokens as measuring devices with associated units or ‘measure-words’.
- Locating: Exploring one’s spatial environment and conceptualizing and symbolizing that environment, with models, diagrams, drawings, words or other means.
- Designing: Creating a shape or design for an object or for any part of one’s spatial environment. It may involve making the object, as a ‘mental template’, or symbolizing it in some conventionalized way.
- Playing: Devising, and engaging in, games and pastimes, with more or less formalized rules that all players must abide by.
- Explaining: Finding ways to account for the existence of phenomena, be they religious, animistic or scientific.

The purpose of basing the view of mathematics on a theory is that through an increased awareness and knowledge about the role of mathematics in everyday context, the teacher can in a more deliberate way consider several options when planning for situations where children can develop knowledge in mathematics. This may lead to using a wider class of situations in a more systematically way, adapted to children’s interests, needs, experiences and qualifications.

The project's theoretical framework is focused on a mathematics based on the six mathematical activities of Bishop (1988a; 1988b), which is well established in the curriculum (Skolverket, 2018).

## **Implementation of the theories through professional development**

The project is now running for the third time in a medium-sized Swedish city, where you can find approximately 40 preschools for children aged 1-5 years. The first round was carried out from May to December 2016. Two preschools participated. The participants were 45 teachers, with different educational backgrounds. The second round run with four preschools during August 2017 to March 2018.

Both theories that the PD is built on have the potential to be normative in the sense of putting restrictions on what preschool teachers believe are the sanctioned ways of teaching mathematics. This is a dilemma from an implementation point of view, because if a point of both the theories and the PD is that it should be helpful for describing and improving existing preschool practice rather than to introduce normative ways of thinking about this practice.

To avoid such normativity, we tried to make the PD itself very tightly tied to the existing practice of the participating teachers by using videos produced by the participants of their practice as a basis for discussion. The recordings were done as a response to loosely formulated tasks concerning, for example, what mathematics might mean or what type of mathematics the teachers should focus on. As an example, one of the early tasks was: *Videotape one planned mathematical situation and one situation that is not planned but where you think there is some mathematics going on.* The recording from this task was then analyzed by a researcher before the next session with the aim of explicating examples of Bishop’s activities as well as examples of the three dimensions of preschool teaching described above. The submitted material represented choices made by the teachers themselves. Moreover, the loose phrasing also created a large variation in the interpretations of what was considered interesting mathematical activities to submit. This variation was intended, and when the videos were discussed at the next session, the discussion leader (the researcher involved in the project)

could ground the presentation of Bishop's six activities in the variety of mathematical activities already present in current preschool practice (even if all of the activities did not show up in the videos, and some therefore had to be pulled out of Bishop's hat).

Moreover, the set of videos could also be used as a basis for discussion when planned and unplanned situations were good, if the mathematics was pedagogical or instrumental and how teacher participation might have affected the situations. In other words, even these first set of videos could be used as an introduction to all three dimensions in the theory of play-based teaching.

In subsequent assignments, the teachers were asked to do more and more pedagogically complex things, like planning for a situation that characterized by a particular combination of the dimensions in the theory of play-based teaching.

Other questions that were discussed in the sessions concerned progression: Watch a videotaped situation and analyze what mathematics occurred in the situations. Think about this in terms of progression. Are there more basic ways of dealing with the mathematical ideas and concepts that are visible in the situation? What would constitute a more advanced way of dealing with those concepts? How an activity that would bring children toward a more advanced way of dealing with the same mathematical ideas could look?

In total, for each PD group, the PD included three such sessions and associated tasks distributed for half a year. This is not much, but it has to be taken into account that preschool teachers have much less time for both planning and competence development than school teachers. In addition to the PD-pedagogy described above, in between the sessions with the researcher, the preschools also got support from a local school developer and the teachers were also given time to discuss the different issues of the project on every workplace meeting (approximately once a month).

## **Researching the effect of the implemented educational theories**

Discussions with the teachers indicate that they find the six activities of Bishop to be both easy to understand and helpful for identifying different mathematical activities. The framing of activities as planned and unplanned, but still being mathematical situations, may at a first glance be a relief for the teachers. The project is all about creating mathematical situations that stimulate and challenge the children with different kind of questions and it is built on the curiosity and interest of the children. The teachers seem to be happily provided with teaching tools for framing their profession.

Still, these indications must be consolidated in a proper study. To investigate if the teachers' perception of teaching and mathematical activities has been improved by the project, a systematic data collection was carried out during the fall of 2018. The methodology is built upon using documentation from the PD rounds, new submitted video material, and interviews with teachers that will be analyzed in relation to the theoretical perspectives used in the PD. During the first two rounds of the PD project, we have collected data in the form of videotapes from planned and unplanned mathematical activities that the teachers encounter between the monthly meetings. We are now about to analyze the impact of the implementation of theories for theorizing preschool teaching and for theorizing mathematical activities. Because the objective of the PD was to help the teachers develop an elaborate and structured way to view (think and talk about, analyze, plan, etc.) the play-based mathematics teaching in preschool, the research question I ask is: Do the teachers that have completed the PD display an elaborate way of discussing mathematics learning activities in preschool? The term 'elaborate' will here be taken to mean using concepts (though not necessarily terminology) from the two theories that form the basis of the PD when discussing preschool activities. To evaluate this question, the following method will be used. A sample of five teachers will be asked to submit new

videos and documentation responding to the same set of tasks that were given during the PD. Using a stimulated recall methodology, the teachers will be asked to discuss both the old and new videos. Stimulated recall is a method very well suited for situations where you record the activity, using sound or video (Calderhead, 1981). The participants are given the chance to see or listen to what was recorded and are given the chance to make comments, either freely or guided by interview questions. The recorded material is a way of stimulating, or challenging, the respondent's way of thinking when it comes to the filmed or recorded episode (Haglund, 2003). By using the pedagogical documentation from the project, which consists of the filmed planned and unplanned educational activities, as well as notes taken during the activities, the purpose is to go back and investigate teachers' own perception of their conceptualization about mathematics, and the teaching of mathematics in preschool. By also including new material, teachers are given the chance to also reflect on developments of their practice. Progress will be coded both in terms of if teachers after the program can analyze and talk about a depicted situation in a deliberate way in line with the theories used in the PD, and in terms of if teachers can suggest a larger and more relevant spectrum of alternate teacher actions, or ways of challenging the children in depicted situations. This part of the methodology has previously been suggested by Lembrér, Kacerja and Meaney (2018).

## Concluding reflection

The quality of the pedagogy is of great importance for the learning of children. Pedagogical quality depends on how the teachers structure their work. By clarifying the special ingredients of the mathematics in Swedish preschools, as well as the role of the preschool teacher, I claim that quality can be improved. This is the intention of the described PD project.

In the PD project, participating preschools teachers can work with how to think about teaching and how to think about mathematics as a subject to be taught in preschool. The hypothesis is that an increased awareness of what mathematics is and what can be categorized as mathematical situations will be used by the preschool teachers for developing the teaching. As described above, the implemented theoretical tool for framing teaching preschool mathematics is the six mathematical activities of Bishop (1988a; 1988b), for sorting, planning and connecting different elements in the different activities. A theoretical tool for framing the planned and unplanned situations is given by Helenius' (2018) three dimensions for theorizing preschool teaching.

This paper has described a project aiming to implementing theories from research into preschool teaching practice. Next, we will evaluate the impact of our PD project by conducting research on the participating preschool teachers' conceptualization of mathematics as a subject, and mathematical situations as planned or unplanned activities. Data will be collected after the third round of the PD project, making research on the implementation of theories an integral part. By the time of the conference CERME 11, we will be able to report on the impact of the project.

### Introduction

This Thematic Working Group explicitly welcomed papers from a variety of different theoretical approaches and methodological frameworks addressing the role of representations of different types in teaching and learning processes, in particular those involving visualization (considered here as defined by Arcavi (2003)). From its first appearance at CERME10 when it was made up of 24 participants from 13 countries with 16 accepted papers and 2 posters, at CERME11 TWG24 grew: there were 31 participants (authors, co-authors, and some other participants), from 16 countries with 18 accepted papers and 4 accepted posters. The structure of the working sessions allocated for discussion of each paper or poster was designed to stimulate interaction and collaboration among participants: each paper or poster was allocated to a working session in which a same or similar theme was addressed (to the extent possible); all participants were asked to read all papers ahead of time, concentrating on those they found most appealing; presenting authors were asked to prepare a short presentation, followed by open questions and a brief analysis of how the work presented contributed to the open questions in the TWG's call for proposals. After the short presentation by the presenting author, a general discussion was initiated and conducted for a total of 30 minutes for papers and 15 minutes for posters. The last session was completely devoted to summing up the main issues that had emerged from the group discussions. The four themes are: 1) theories, language and categorizations used to study representations (theories, language and categorization), 2) embodied and enactive perspectives on the use of representations in mathematics education (embodied and enactive perspectives), 3) forms of representation implemented through technological approaches (technological approaches), 4) pedagogical implications in the choice and use of representations in the teaching and learning of mathematics (pedagogical implications).

### Theories, language, categorization

The researchers in TWG24 did not share a common theoretical framework for the use of the term representations. We see the diversity as a source of strength of our community, as different theoretical emphasis may illuminate various aspects of teaching and learning mathematics. We do share the need for having an explicit theoretical stance towards what is representation in our research.

The role of theory for the researchers in the group varied. Some articulated a theoretical perspective for designing tasks (e.g., Günster; Johnson et al.; Tabach & Koichu), while others view theory as a tool to guide their data analysis (e.g., Miragliotta; Lisarelli, Antonini & Baccaglini-Frank).

Some of us consider as representation what is accepted as such by the mathematical community (e.g., Duijzer et al.), while others see them as a collection of inscriptions produced by students for a given

mathematical situation (e.g., what Dahl called ‘self-invented representations’). We discussed tensions that might arise, during the learning process, between students’ unique-created representations and the need for students to be familiar and work with classical representations.

The group also discussed the issue of internal/external representations: we cannot directly access internal representations, hence it is difficult to assess; across papers and posters there was variation in the extent to which internal versus external representation was theorized. This methodological-theoretical issue is important to acknowledge, even if we do not see a direct way to resolve it.

Moreover, discussions highlighted a general move away from dichotomous categories of representation towards continuous spectrums, in both research design and analysis of data.

The advance of technological tools and our ability to design complex and dynamic learning environments seems to be increasing. Our theoretical language, however, is not yet well-enough developed to allow consistent “talking about” dynamism in representations. This might be a challenge to handle in the coming years. For example, do we have a theoretical language allows us to differentiate between representing a mathematical phenomenon with dragging a finger over a touch screen, versus representing the same mathematical phenomenon with ones’ whole body?

### **Embodied and enactive perspectives**

In our call for papers we explicitly noted that ‘representations’ should be interpreted broadly to encompass pictures, gestures, sounds, stories, metaphors and more (as well as more conventional classroom formats). Several presenters included material on the embodied and enactive representations employed by diverse participants (children and adults, from very high to very low mathematical attainment, with and without disabilities) within a wide variety of mathematical topics and contexts (educational, professional and recreational).

Several papers considered the salience of how hands, in particular, are used in embodied mathematical thinking. Miragliotta’s work on geometrical predictions analysed both discursive and gestural aspects of older school and university students’ geometrical problem-solving activity, highlighting the interplay both between language and motion, and perception and reasoning processes. One of the foci of Finesilver’s microgenetic case study of a teenager with severe numeracy difficulties was the significance of the regular pattern of hand movements in ‘dealing’ out units into equal groups. In keeping with the emerging theme of continua, this motion aspect, along with mixed-mode representation, enabled transition from concrete to graphic representation. In contrast, Wille and Schreiber focused not on informal gesture but the communication of mathematics in sign language, with a comparison of how explanations of geometrical terminology function in a visual signed language versus a spoken mode of communication. The subsequent discussion clarified that while sign language should be considered distinct from gesture, it may be productive to consider a continuum between them.

The intertwining of enaction and language was also considered by Arnoux and Soto-Andrade, with a focus on the significance of metaphor in understanding and representing mathematics. Their paper on moving between concrete and abstract forms also addressed affective concerns, and highlighted the way that metaphors may be particular to communities based on local phenomena and experiences. Meanwhile, O’Brien and de Freitas presented research from one particular community; that of those

engaged in textile arts who, while they may not consider themselves to be ‘doing mathematics’, are creating complex haptic and visual representations of mathematical patterns. Their *fibre mathematics* includes technical-aesthetic considerations of topological dimension and connectivity as well as space, mechanics and computation.

This year’s working group took a particular interest in the relationships between different representational forms, and discussion of enactive aspects also arose in the various discussions on graphical representations of time (Lisarelli et al.), motion (Duijzer, Van den Heuvel-Panhuizen, Veldhuis & Doorman), and relationships between quantities (Johnson, McClintock & Gardner). The discussions considered the different characteristics, affordances and limitations of creating moving representations with one’s hands, manipulating external physical objects, and elements displayed on a screen. There was particular interest in how changing the subject of operation (objects, the environment, oneself) could affect perception of mathematical relationships.

The embodiment and enaction of mathematics can work in many different ways. However, being so fundamental to human experience, it may particularly help learners to ground concepts and form connections between mathematical ideas that they tend to see as isolated.

### **Technological approaches**

A number of contributions presented studies in which different forms of technology were used to create or interact with representations of mathematical concept. Indeed, through technological artifacts, representations can become both dynamic and interactive. For example, Duijzer, Van den Heuvel-Panhuizen, Veldhuis and Doorman studied students creating distance-time graphs by describing their own movements in front of a motion sensor; Lisarelli, Antonini and Baccaglioni-Frank analyzed students’ written discourse about an experience in a dynamic interactive digital environment in which functions were represented in one dimension, as dynagraphs; and Johnson McClintock and Gardner explore students’ transfer of covariational reasoning intertwined with their creation and interpretation of dynamic graphs on the Cartesian plane. Dynamism – seen as interactive, controlled motion – can be very useful for learning about particular mathematical concepts related to functions: covariation, input-output relationship, effect of parameters.

The studies also suggested that dynamical software influence students’ practice and, afterwards, their drawings and verbal representations. This seems to be the case both when the whole body is involved and when only some parts of the body are used to interact with the technological artifact. For example, when a student walks in front of motion sensors and software captures and represents whole body movement, new expressions emerge such as “walking the graph” (e.g., Duijzer et al.). However, also after experiencing covariation in one-dimensional dynagraphs students use arrows in their drawing to describe movement, and words such as ‘motion’, ‘then’, ‘before’, ‘dragging’ (e.g., Lisarelli et al.). Furthermore, studies suggested that interacting with technological artifacts that produce dynamical interactive representations may also change the way students think of mathematical concepts (Duijzer et al.; Lisarelli et al.; Johnson et al.; Miragliotta; Tabach & Koichu). The group discussed how these could eventually become psychological tools as in the case of “dragging” (e.g. Baccaglioni-Frank & Antonini, 2016).

The use of dynamic representations was also discussed within the proposal of a theoretical framework providing the foundation to design tasks aimed at promoting students’ functional thinking (Günster).

Finally, a different technological approach to representations was provided by O'Brien and de Freitas who used the loom to unpack the relationship between making, mathematics, and technology.

Much work remains to be done regarding how to employ technology's full potential in learning trajectories (including those for other topics than the ones discussed), and on how to foster the development of these experiences into formal mathematics.

## **Pedagogical implications**

Representations play a vital role in mathematics teaching and learning. However, as researchers, we experience a constraint in communicating our findings in 'snapshots' – we noticed how many studies begin as small scale endeavors. Thus, researchers need ways to scale up from small scale studies and to bring what we are learning to teachers and their students. During the presentations and discussions, the group attempted to establish connections between representations and the pedagogical implications in the choice and use of such representations. For example, Milinkovic, Mihajlovic and Dejjic found that students who managed to solve mathematical problems were able to connect different mathematical representations. However, in mathematics classrooms, teachers generally stimulate algebraic/symbolic representations to solve mathematical problems more than other types. Pressures may exist for teachers to move quickly to help students have swift ways to solve problems and represent processes promoting one of the representations more than others, and these pressures may prematurely curtail students' intuitive approaches when engaging in problem solving.

Some discussions focused on how teachers should be able to use incorrect answers as an opportunity for mathematical investigation. While some teachers may prefer to ignore or dismiss an incorrect answer and focus on teaching correct ways to represent mathematical problems, others decide to use an incorrect strategy to engage in a class discussion. Tabach and Koichu used the potential of incorrect strategies for the solution of a problem with a novel method, namely in a "who is right" form in which students are given scenarios and asked to pick their sides (if any) for the correct solution of a problem. Okumus and Dede introduced students misleading representations without letting them know that graphs tweaked information. Alternatively, some may prefer to be more explicit and provide specific representations (e.g., Hough et al.; Böcherer-Linder et al.). Teachers pedagogical decisions will influence how these tasks move students' thinking forward or how they will hinder their learning.

*We are interested in exploring from an enactivist perspective the role of metaphor and representation in the emergence of the abstract from the concrete and also in sense making of abstract mathematical notions. After introducing our theoretical framework, we present and comment on some illustrative examples, explored with several cohorts of learners, which include both prospective mathematics secondary teachers and first year university students studying science and the humanities.*

*Keywords: Metaphor, Representation, Enaction, Concrete, Abstract.*

## Introduction

We claim that representation and metaphor (between which we distinguish, see below) play a key role in the teaching and learning of mathematics. More precisely, in this paper we focus on the ways in which *metaphorising* and *representing* can foster the emergence of abstract concepts from concrete a-didactic situations (Brousseau, 1998) and backwards, making (concrete) sense of abstract concepts. We argue, moreover, that taking advantage of such concrete situations can afford insights and motivations for classical abstract mathematical notions, which are friendlier to the learners than the traditional approach where such notions are quite often “parachuted from Olympus”. Indeed, many mathematical concepts emerge as procedural computations, which are not supposed to take a meaning by themselves. Every time a new representation, or metaphor, is found for such a “procedural” concept, this results in a deeper understanding, and quite often in new questions and results. A very famous example is that of complex numbers, invented as “impossible” numbers to solve cubic equations, whose now classical geometric representation via the complex plane was only found two centuries later. Other examples, like the metaphor of “arithmetic geometry,” are now at the base of important mathematical research programs. We argue that it is important to help students develop such representations explicitly, rather than treating them as trivial side-products of teaching. It is however a big challenge to figure out under which conditions representing and metaphorising foster mathematical thinking processes as hypothesised above.

We intend here to pursue our recent research on metaphorising, representing and enacting (Arnoux & Finkel, 2010; Diaz-Rojas & Soto-Andrade, 2015; Soto-Andrade, 2007, 2014, 2018), by presenting and commenting some non-obvious examples of enactive metaphors and representations of mathematical concepts and their use in a-didactic situations (Brousseau, 1998). The contextual background of our examples involves several cohorts of learners in Chile and France, mainly prospective secondary mathematics teachers.

## Research questions

We single out a couple of research questions, among those involved in our research:

1. Which sorts of metaphorising and representing can foster the emergence of abstract notions from concrete situations and convey a better grasp of them for the students?
2. How can teachers support, in a friendly manner, learners in developing their representational and metaphorical competences?

## Theoretical background

### Metaphorising and Representing in cognitive science and mathematics education

Metaphorising and Representing nowadays play undoubtedly a key role in cognitive science and mathematics education. See Goldin (2014) and Soto-Andrade (2014) for related comprehensive surveys. Notice that we prefer to focus in on *metaphorising*, a verb denoting a process, rather than on *metaphor*, a noun denoting an object. Indeed, what is a metaphor for someone may not be a metaphor for someone else, and for yet another person it could be a representation instead (see below). What we observe is actually the *process* of metaphorising carried out by someone, a cognitive subject.

Regarding metaphorising (“looking at something and seeing something else”, in metaphorical terms), widespread agreement has arisen in cognitive science that our ordinary conceptual system, in terms of which we both think and act, is fundamentally metaphorical in nature (Gibbs, 2008; Johnson & Lakoff, 2003). In mathematics education metaphor typically appears not just as a rhetorical device, but as a powerful cognitive tool, that helps us in grasping or constructing new concepts, as well as in solving problems in an efficient way and user-friendly way (English, 1997; Lakoff & Núñez, 2000; Sfard, 2009; Soto-Andrade, 2007, 2014).

Although in the literature the same object is sometimes described either as a representation or as a metaphor, here we draw a distinction: we *re-present* something given beforehand, usually to explain concepts already constructed, but we *metaphorise* to try to fathom something unknown or to construct a concept. Recall that Lakoff and Núñez (2000) highlight the intensive use we make of conceptual metaphors that appear – metaphorically – such as inference-preserving mappings (arrows) “going upwards” from a rather concrete ‘source domain’ into a more abstract ‘target domain’, enabling us to fathom the latter in terms of the former. Then representations naturally appear as arrows going the other way around, downwards from the more abstract domain to the more concrete one (Soto-Andrade, 2014).

Indeed, our approach to the learning of mathematics emphasises the *poietic* (from the Greek *poiesis* = creation, production) role of metaphorising, which brings concepts into existence. For instance, we bring the concept of probability into existence when, while studying a symmetric random walk on the integers, we look at the walker (a frog jumping on a row of stones in a pond, say) and we see it *splitting* into two equal halves that go right and left instead of being equally likely to jump right or left (Diaz-Rojas & Soto-Andrade, 2015). This ‘metaphoric sleight of hand’ which turns a random process into a deterministic one, allows us to reduce probabilistic calculations to deterministic ones, where we just need to keep track of the walker’s splitting into pieces: The probability of finding the walker at a given location after  $n$  jumps is just the portion of the walker landing there after  $n$  splittings.

In the same vein, imagine that one is trying to figure a struggle between two producers A and B for a consumer market, who each month – as a consequence of intensive marketing strategies – entice consumers of the other brand to change their choice, say 20% of consumers of A going to B but only

10% conversely. If one is familiar with jumping frogs, one could metaphorise the evolution of the market as the random walk of a frog between two rocks, tagged A and B, with corresponding transition probabilities. However, someone who is more familiar with market struggles would rather metaphorise the frog's random walk as a market evolution, to benefit of his/her economic intuition.

It can be argued that we often introduce new concepts via metaphor, but giving a new meaning (and often, just meaning) to a concept that has already been taught involves a representation. We may have *internal representations* (Goldin & Janvier, 1998; Goldin, 2014) which are operationally equivalent to metaphors, as the ways a cognitive subject has of figuring out concepts unfamiliar or still opaque.

## Methodology and experimental background

Our methodology relies mainly on qualitative approaches like participant observation techniques and ethnographic methods (Brewer & Firmin, 2006; Spradley, 1980).

Regarding our experimental background, several cohorts of students have participated in preliminary tests at the University of Aix-Marseille, France: 60 first year university students majoring in science and humanities in a mathematics course in 2015-2018 (usually organized in 10 groups of 6) and 40 fifth year teacher students in 2 mathematics courses, of 20 students each, in 2016-2018 (usually organized in 5 groups of 4 each).

At the University of Chile, in Santiago, three cohorts of prospective secondary school mathematics and physics teachers (45 students each, on the average), in a one-semester yearly course in elementary number theory, have been involved in our teaching and learning following a metaphoric and enactivist approach, from 2016 to 2018. Working most of the time in random groups of 3 to 4, (defined by blind picking of coloured Lego cubes from a bag) they were observed and monitored by the teacher and an assistant as participant observer or ethnographer (Spradley, 1980; Brewer & Firmin, 2006).

Since we were especially interested in evaluating the impact of our approach on the student's engagement and problem solving and problem posing abilities, we observed mainly: their level of participation and horizontal (peer) interaction, the emergence of "research questions", i.e. questions they ask themselves, to be tackled by themselves (not questions addressed to the teacher to ask for a clarification or explanation) and (idiosyncratic) metaphors, arising spontaneously or under prompting, accompanying gestural language of learners and teacher, expression and explicit acknowledgement of affective reactions. Snapshots of their written products in problem solving activities were taken and processed in a worksheet, also for evaluation purposes, and some videos of their enacting moments were recorded.

## Illustrative examples and case studies

We present and discuss here a couple of paradigmatic examples, regarding concrete ways to introduce and motivate in a friendly way Pythagorean triples as well as arithmetical congruences. In fact, we could describe them under the same roof as arithmetic in a discrete "modular universe": a 2D pixelated, grid-like one (the lattice  $\mathbb{Z}^2$ ) in the first case, and a 1D cyclic one (the polygon  $\mathbb{Z}/m\mathbb{Z}$  formed by the integers modulo  $m$ ) in the second case. For other examples, related to computer science (finite automata) and probability, see Arnoux and Finkel (2010), Diaz-Rojas and Soto-Andrade (2015) and Soto-Andrade (2018).

### Example 1: Pythagorean triples, with Lego bricks

This activity has been carried out at the University of Aix-Marseille, in several contexts, with the cohorts described above: first year science and humanities students and fifth year teacher students (last year of teacher initial formation in mathematics).

It has been tested informally in the last two years, using qualitative monitoring by an assistant, and posterior evaluation by the participants; we are setting up now an interdisciplinary team (mathematicians, didacticians and cognitive scientists) to study it more in depth in the framework of a methodology unit next year.

We give to groups of 4 to 6 science and humanities students or teacher students one  $16 \times 16$  horizontal plaque, two elementary  $1 \times 1$  bricks, and one  $1 \times 16$  brick. The question is: *for which positions on the plaque can the small bricks be connected by the long one?* See Figure 1, showing a  $8 \times 8$  plaque, two  $1 \times 1$  bricks in a good position, and a  $1 \times 8$  brick superposed on them; it is of course cumbersome to explain this in writing, but the real model leaves no room for hesitation.

**Figure 1: Linking brick for Pythagorean triples**

By construction, the plaque is endowed with a discrete grid (a metaphor for  $\mathbb{Z}^2$  with the canonical metric, points being the centres of the small circles and  $1 \times 1$  bricks playing the role of dots); no explanation of this is needed. But some time is needed to understand that the long brick can only be set on the pair of small bricks if the distance between these two bricks is an integer multiple of the unit distance: after half an hour, most groups discover the concept of Pythagorean triples as implied by this situation (they all know the Pythagorean Theorem, but not Pythagorean triples). This exercise is very rich. It works well, because all the distances are quadratic numbers, hence, if they are not integers, they are quite far from an integer: *at small distance*, there are only exact solutions, no “near-solutions”. It is also very engaging for students, because it is concrete. It evolves naturally into finding the classical Babylonian solutions (it may be pertinent at that point to present the famous Plimpton 322 tablet). One can then ask to find non-trivial rational points on the unit circle; students usually start by trial and error, and come first to the conjecture that there are no such points. It takes some time to make the relation with the previous question; this can be continued with a geometric parametrisation by the rational lines through the point  $(-1,0)$ , which makes the link with the quadratic equation, and, via elementary geometry, with the formula for sine and cosine as a function of the tangent of the half-angle: these formulas appear as a reformulation of the Babylonian formula. Most students seem surprised to see that there can be links between very different domains of mathematics. This can be taken to much more elaborate questions, like the number of triples within a bounded distance, and in fact to difficult research questions. One remark is that, in our experience, it is not important whether or not the students have already studied these notions: in the case of prospective teachers, they are always surprised by the exercises, and do not immediately link them to notions they know quite well, but in an abstract way.

## Example 2: Congruence mod $m$ and dynamical systems

We report on some developments of our metaphoric enactive approach to arithmetic congruences, with third year prospective maths and physics secondary teachers taking a one semester course in elementary number theory, in 2016, 2017 and 2018, at the University of Chile. Since congruences mod  $m$  are unavoidable in this course, we wanted to motivate them or make their study friendlier. To this end, following a radical enactivist approach (Proulx & Maheux, 2017; Soto-Andrade, 2018), we just proposed a *situational seed* first and let the action emerge freely.

From our theoretical perspective, taking into account the previous mathematical training of our teacher students, at secondary school and also in most courses of their initial formation, we could predict a “metaphoric deficit” in their understanding of arithmetical congruences. Eventually they will be able to recite the definition and calculate, but without having a favourite metaphor (or representation) for them, and also with no appreciation of their usefulness. Notice that if they metaphorise the integers mod  $m$  as a finite “shadow” of the integers, they might easily have the idea that a necessary condition for a property to hold for the integers is that it holds for its projection onto their arithmetical shadows, something much easier to investigate. So, if a Diophantine equation is solvable (in the integers) its shadow should be solvable in the shadow integers mod  $m$ . In this way, they get necessary conditions for a Diophantine equation to be solvable, which allows them to prove unsolvability in several cases.

Indeed, we found that although our prospective teachers know by heart the definition of congruence mod  $m$  in the integers, when we ask them how they imagine, metaphorise or visualise congruence mod  $m$  or which are their internal representations for it in the sense of Goldin (2014), they are at a loss. After a while, some of them think of kangaroos, rabbits, frogs, jumping on the integer line, or they begin to paint the integers in different colours (five colours for congruence mod 5). Slowly the metaphor emerges in several groups, of winding the integer number line on a polygon, e. g. a pentagon for congruence mod 5. They naturally carry out a spiral-like winding on the plane to begin with. If nobody suggests a different way, we ask them what they do when they want to wind up a long garden hose. They realise then that it is smarter to wind it in 3D, cylinder like. From there they come to visualise congruence mod 5, say, as a helical winding of the integer line above a regular pentagon. They metaphorise then this congruence relation as a covering space! Typically, however, this helix does not remind them of the intuitive construction of the imaginary exponential that they were exposed to in Calculus 1, where the real line was wound around or above the unit circle. Our enactivist theoretical perspective emphasises *processes and dynamics* more than (the more traditional) *objects and static structures*. So setting the integers mod  $m$  as a stage, for instance  $m = 12$  (or even  $m = 6$  or 7, for simpler examples of different nature), we prompt the students to wonder what interesting phenomena may arise in these universes with just 6, 7 or 12 sites, where they can add and multiply.

Among other ideas, they can look at the transformation  $M_2$  given by multiplying by 2, for example, which when iterated launches a *dynamical system* in the integers mod 12. The students try then to study the generated dynamics, something more natural for those who have developed a systemic perspective on phenomena, more often biology and physics students or humanistic students than mathematics students. Working for an hour, in random groups of 3 to 4 (defined by blind picking of coloured Lego cubes from a bag), a class of 30 to 40 students dutifully iterates  $M_2$  and tries to

*represent* the phenomenon. They explore then  $M_3$  and so on. See Figure 2, which shows some drawings by the students, for  $m = 7$  and  $m = 12$ . More generally, they investigate the dynamics spawned by the multiplication by an integer  $k$  in the integers mod  $m$ , discovering its variegated (forward) orbit structure. They metaphorise idiosyncratically these orbits as forward trajectories and they see fixed points, sinks, attractors, 2 – cycles, 3-cycles, etc., and become able to figure out the “fate” of different integers mod  $m$ . They begin to conjecture on the number of orbits, or the number of  $n$ -cycles for a given  $n$ . Level of engagement and participation is high, as well as their horizontal interaction, where several ideas and approaches meet. Some of them want to find an arithmetical explanation of this dynamic geometric behaviour. Others do not. But we suggest everyone to look at this geometric phenomenon with arithmetical eyes and vice versa. Most of them draw pictures, but others just write down numbers and tables, and compare. We prompt them to exert some hermeneutical effort (Isoda & Katagiri, 2012), so that all try to understand other’s viewpoints. In this way, some predict the existence of an “ubiquitous orbit” for some  $k$  for prime  $m$ . The students are quite excited and motivated by this challenge when working in small random groups, where horizontal interaction is fostered. Quite often some groups want absolutely to show the teacher and assistant their progress so far. Each group summarises its findings in a report on a sheet of their notebooks, which is photographed by the teacher and assistant. Samples of their work are shown in Figure 2. These reports are evaluated, and a huge worksheet is set up with the corresponding grades.

**Figure 2: Orbit structure for  $M_k$  ( $k = 2, 3, 4, 5$ ) in the integers mod 7 and mod 12**

At the end of the course each student gets a grade in group work which is only taken into account if it is higher than the average the grades in the usual compulsory traditional tests taken by the student during the course. Interestingly, in our courses the percentage of (the non-compulsory) student attendance is much higher than the average (80 to 85% against 50%).

Overall, we see that students previously exposed to traditional teaching show a severe metaphorical and dynamical deficit, remaining confined in the arithmetic-algebraic realm. However, progressively, most of them turn out to be able to open up to geometric and dynamical insights, even though initially they remain tied to the purely arithmetical approach that they are more familiar with. At the end of the work session consensus arises on the importance of being able to “change register” and move seamlessly between the arithmetic-algebraic realm and the geometric-visual one. Most students seem surprised to discover, in this way, links between domains of mathematics usually perceived as being far apart, like arithmetic and dynamical systems.

## Discussion and open ends

We have shown how Pythagorean triples can be concretely embodied and enactively explored and also how a dynamical systems approach can make the arithmetic modulo  $m$  more lively, visual and motivating.

Our examples show that concrete embodiment of abstract mathematical notions and properties, before or instead of their “abstract parachuting”, may bear a dramatic impact on the level of participation and engagement of the students in otherwise unappealing tasks. Such impact is also seen on their mathematical performance and their ability to put forth their own research questions, like investigating the “fate” of various numbers mod  $m$  or wondering about an arithmetical explanation of the dynamical phenomena observed in the universe of integers mod  $m$ .

Our didactic activities are not staircases to climb sequentially but a rather highly intertwined space to explore, where moving flexibly among several representations or metaphors is a must for a meaningful and fruitful mathematical experience.

Our examples also show that representations and metaphors appear sometimes deeply intertwined in a circular relationship, so that it may be somewhat artificial to try to separate them. If we focus in on *metaphorising* and *representing* it may very well happen that in a class, some students are metaphorising while others are representing.

Also, quite often the teacher will be striving to represent – in a friendly way for the students – a notion that she is familiar with (maybe in a rather abstract way though), while students will be metaphorising the same notion, which they hardly fathom. This is visible in our preliminary example of the frog’s random walk: the teacher will be eventually representing the probability of finding the frog in a given stone after  $m$  jumps by the portion of the frog landing there, while the students will be metaphorically just constructing this probability as the frog’s portion landing in this stone.

The same holds for Pythagorean triples and arithmetical congruences. Some arithmetically minded students may realise for the first time that Pythagorean triples may be embodied as an integer fitting phenomenon on a grid and that congruence modulo 5 may be represented by winding the integer number line over a regular pentagon. Other students may discover arithmetical congruences, which they ignored or felt to be an esoteric notion, with the help of this enactive geometric winding. Notice here the emerging connection between arithmetical congruences and geometric congruences.

A recurring observation in all our examples, is the surprise that arises among the learners when they realise hitherto hidden connections between realms of mathematics which seemed to lie far apart. Furthermore, it appears that usual problem solving, as found in the literature, tends to neglect the important role of metaphorisation and representation, as a learner’s first reaction when tackling a problem that looks opaque to him or her. Not only because this may allow him or her to solve an otherwise unyielding problem but also because it may allow him or her to “see” a solution, turning a hitherto blind calculation into pellucid insight.

The various metaphors we have presented here are only a sample; there are many others, in analysis, probability, computer science, etc. Invariably, when these metaphors are presented or emerge, they attract the attention of students, and make for a motivating and meaningful classroom experience. They may be however hard to find, so a systematic “catalogue” of them would be most commendable.

# **“He’s so fast at drawing” – Children’s use of drawings as a tool to solve word problems in multiplication and division**

Heidi Dahl

Norwegian University of Science and Technology, Norway; [heidi.dahl@ntnu.no](mailto:heidi.dahl@ntnu.no)

*This paper examines how young pupils (age 8–9) use drawings as a tool in exploring multiplicative situations. Analysis shows that drawings play an important role in their problem-solving process. Drawings are mainly used as information holders and as a tool to organise calculations for problems with a relatively easy structure; in problems with a more complex structure, drawings are more frequently used as a tool for reasoning. The results show no connection between the degree of abstraction in the drawing and the sophistication of the calculation strategy.*

## **Introduction**

Representations are central to all mathematical activity and are needed both to construct understanding and to communicate mathematical ideas. Throughout the history of mathematics, conventional notation, symbols, figures and diagrams have been developed and agreed upon by the mathematical community in order to serve these purposes in an efficient manner. However, Greeno and Hall (1997) claim that, when a child is about to explore a mathematical concept for the first time, nonstandard representations can be more useful than formal ones. Self-invented representations can help pupils to keep track of ideas and connections they have already discovered, and can assist them in organising their work. Moreover, encouraging pupils to create their own representations will provide opportunities to consider the advantages and disadvantages of different forms of representation, and to use those representations as tools to build conceptual understanding.

When entering a new mathematical domain, such as multiplication and division, a simple word problem will be a mathematical problem for a pupil. Carpenter, Ansell, Franke, Fennema and Weisbeck (1993) claim that modelling, either through the use of counters or by drawing, is a natural problem-solving strategy for most kindergarten and primary-grade children. However, older pupils seem to abandon these meaningful approaches in favour of more mechanical and algorithmic ones, and may even consider arguments based on drawings as a form of cheating (Crespo & Kyriakides, 2007). To help pupils build upon and extend their intuitive modelling skills, it is worthwhile to look more closely at how primary-grade pupils use self-invented representations in problem solving in different content areas. The research question for this paper is thus: *What kind of drawings do third-graders produce when they explore a multiplicative context, and what are the function(s) of these drawings in the problem-solving process?*

## **Background**

### **Young children’s knowledge of multiplication and division**

Multiplicative thinking is fundamental for understanding more complex concepts such as ratios, fractions and linear functions. According to Steffe (1994), a multiplicative situation is characterised as one where “it is necessary to at least coordinate two composite units in such a way that one of the

composite units is distributed over the elements of the other composite unit” (p. 19). Depending on the situation, at least four different multiplicative structures can be distinguished: equal groups, multiplicative comparison, rectangular area and Cartesian product (Greer, 1992). Each structure gives rise to problems in both multiplication and division. Multiplication is often introduced prior to division, but research shows that young children spontaneously relate them and do not necessarily find division more difficult than multiplication (Bakker, van den Heuvel-Panhuizen & Robitzsch, 2014; Carpenter et al., 1993; Mulligan & Mitchelmore, 1997). However, multiplicative reasoning differs significantly from additive reasoning in terms of complexity. It is therefore not surprising that multiplicative thinking takes time to develop (Clark & Kamii, 1996). Despite this, it is widely documented that children are able to solve word problems in multiplication and division long before they receive any formal instruction in this domain. Mulligan (1992) found that most third-grade pupils are able to solve multiplicative word problems using a wide variety of strategies, and Carpenter et al. (1993) established that this is the case even for kindergarten children who have been exposed to such problems over some time. In a more recent study, these findings were sustained and extended by Bakker et al. (2014), who found that first-grade pupils are not only able to solve word problems, but to some extent are also successful in solving bare-number problems.

Young children’s strategies for solving multiplicative word problems can be classified as calculation strategies and modelling strategies (Mulligan & Watson, 1998). Calculation strategies involve increasingly sophisticated counting methods such as direct counting, rhythmic counting and skip counting, additive strategies based on repeated addition, and multiplicative strategies. Modelling strategies involve the use of physical objects or drawings. Kindergarten children almost always use direct modelling (Carpenter et al., 1993), while primary-grade children tend to use calculation strategies for small-number problems, but revert to modelling for problems involving larger numbers (Mulligan, 1992). Teachers need to assist pupils in widening their repertoire of calculation strategies. Mulligan and Mitchelmore (1997) suggest that a first step to achieve this is to help pupils to model different semantic structures so that they successfully can apply direct counting. Thereafter, pupils can be encouraged to use the equal-group structure to develop more efficient addition strategies, before these strategies are transferred to other structures. When pupils are able to use repeated addition across different semantic structures, the idea of a multiplicative operation can evolve.

### **Problem solving and the use of drawings**

Polya (1985) describes a four-step approach to problem solving: understand the problem, devise a plan, carry out the plan and look back. Pupils might, of course, move back and forth between these phases before they reach a solution to the problem. The use of representations in general, and drawings in particular, has been highlighted as a tool in the problem-solving process (e.g. van Essen & Hamaker, 1990; Polya, 1985). Van Essen and Hamaker (1990) claim that by translating a word problem into a picture, pupils are forced to pay attention to the given relationships in the problem. Furthermore, some problem characteristics may be more easily inferred from a drawing because they become more explicit, while drawings also relieve working memory. Yet, research on children’s use of drawings in early-years mathematics is still limited (Bakar, Way & Bobis, 2016). Some studies focus on drawings as a product, and look for (possible) relationships between the abstractness of pupils’ drawings and their success in mathematical problem solving. The findings of these studies are

mixed, but there seems to be a tendency towards stating that pupils using iconic (or schematic) drawings are more successful than pupils using pictographic drawings (e.g. Crespo & Kyriakides, 2007; Veles & da Ponte, 2013). Bakar et al. (2016), however, found no such trend in their study. An *iconic* drawing contains only simple lines and shapes to embody the intended object, while a *pictographic* drawing has realistic depictions of the objects involved in the problem (Bakar et al., 2016). It is also important to determine the *mathematical matching*; that is, to what extent are the word problem and the drawing informationally equivalent? (Ott, 2017)

When it comes to viewing drawing as a process, Stylianou and Silver (2004) examined the use of representations by expert mathematicians in problem solving. They found that mathematicians consider drawings as a legitimate tool for reasoning and argumentation, and they use visual representations actively and for different purposes during the problem-solving process. Drawings can be means to understand information, recoding tools, tools that facilitate exploration, and monitoring and evaluation devices (Stylianou, 2011, p. 271). In a follow-up investigation involving middle-school pupils, Stylianou (2011) detected that pupils' use of representations resemble the experts' use in many ways. However, the use of representations as a monitoring tool is fairly limited and not very sophisticated. She recommends that teachers make pupils explicitly aware of the purposes of the representations they use, and that pupils are given opportunities to discuss and negotiate the meaning of various representations. In addition, pupils need to “develop the habit of exploring [a representation], generalising and abstracting from it, and using it as a springboard for connections among tasks and content in mathematics” (p. 277).

## Methodology

### Context and data collection

This study is part of a larger project entitled “Language Use and Development in the Mathematics Classroom” (LaUDiM), a video-based intervention project where two teachers from different primary schools and university researchers work together on planning and discussing teaching sequences. The empirical data for this particular study is drawn from a teaching sequence in one of the schools where the aim was to provide pupils with experience of different multiplicative situations. The teaching sequence consisted of two consecutive sessions, two days apart, and took place when the pupils had just entered third grade (age 8–9). In the Norwegian curriculum, multiplication and division are introduced and formalised during grades three and four, meaning the pupils in this study had not received any formal teaching on these subjects prior to this particular teaching sequence.

The pupils worked in pairs to solve word problems in multiplication and division. The context for all tasks was preparation work for a fictional school party. The teacher encouraged the pupils to write arithmetic problems or to produce drawings, but she gave no examples of what to write or draw. On the first day, two randomly chosen pairs of pupils were videotaped. In addition, a hand-held camera was used to capture glimpses of the pupils' work. On the second day, three pairs of pupils were videotaped. There was a partial overlap in terms of the pupils videotaped on the first and second day. The pupils' written work was also collected.

## Data analysis

As the research question for this paper focuses on how children use drawings in their problem-solving process, only video recordings showing the entire process of solving a given problem were considered data material. When looking through the recordings, 15 episodes were identified, where an episode is defined as “one pair of children working on a particular task, from the time they read the problem until they move on to the next task”. These episodes, together with the corresponding written work, constitute the data material for this study.

The first stage of the data analysis involved watching and transcribing all episodes. The drawings were categorised as mainly *iconic* or mainly *pictorial* (Bakar, 2016), the *mathematical matching* (Ott, 2017) was examined and the *solution strategy* (Mulligan & Watson, 1998) was identified. In the next step, the episodes were re-watched several times with the purpose of identifying the functions of the drawings. A more detailed description of the production and use of drawings, in the form of pointing, making additional markings and so on, was added to the transcripts, and an inductive analysis was conducted. Examples of questions asked about the material are “in what phases of the problem solving is the drawing produced and/or used?” and “how is the making and the use of the drawing linked to the solution strategy?”. Polya’s (1985) description of the four phases of a problem-solving process served as a tool for structuring this work. The analysis yielded several parameters, such as problem structure, abstractness, mathematical matching, solution strategy and different uses of drawings. The analyses of the 15 episodes were compared and contrasted with regard to these parameters to look for possible interrelationships.

## Findings

### Pupils’ drawings

One or more drawings are produced in all 15 episodes. Two of the drawings can be seen as mainly decorative as they do not resemble the mathematical structure. Figure 1 provides an example of a decorative drawing related to the problem of how many eggs one needs to make twelve portions of muffins, given that one needs four eggs for one portion. The pupils begin by drawing three rows of four eggs, which seems to resemble the equal-group structure of the problem, but then they add three more eggs to each row. After counting a total of 21 eggs, the pupils erase the additional eggs and decide to draw the entire baking process, from the beating of the eggs to ready baked muffins.

**Figure 1: A decorative drawing**

Of the thirteen remaining drawings, three are categorised as pictographic, and the rest as iconic. Figure 2 provides examples of both a pictographic and an iconic drawing of the problem of how many tables are needed for twenty-four people if there can be six at each table.

**Figure 2: A pictographic and an iconic drawing of the table problem**

All of the pictographic drawings are produced by the same male pupil. One girl initially starts to draw pictographically (using coloured pencils), but is encouraged by the teacher and her peer to change to an iconic drawing:

Teacher: Stop for a while. This is very nice, and it works well, but can it be done in a different way so that you don't have to draw every one? There is still a lot remaining.

Peer: Draw circles.

Girl: Can write 6.

The drawing produced in this episode is seen as the drawing on the right-hand side in Figure 3.

The iconic drawings still relate to the given context, as eggs, muffins and cookies are drawn as circles or dots, tables and trays drawn as circles or quadrilaterals, and pencils drawn as tally marks. This might suggest that classifying drawings from pictographic to iconic on a continuum, is more fruitful than seeing it as a dichotomy. All drawings, apart from the purely decorative ones, are considered to have a high degree of mathematical matching. As one can see in Figure 2, both drawings show the right number of people for each table, and twenty-four people in total. Three of the drawings involve number symbols as an important element. Figure 3 shows two of those, both produced in relation to the problem of how many pencils there are in twenty boxes, given that there are six pencils in each box. The pupils are successful in solving the word problems, barring minor counting errors, in all but two of the episodes. The two episodes where the pupils fail to solve the problem are the ones where only a decorative drawing is produced.

**Figure 3: Drawings with number symbols for the pencil problem**

### Pupils' strategies and use of drawings

The pupils' solution strategies are dominated by direct counting. For the multiplication tasks, there are only two examples of more advanced strategies. One is seen in the drawing on the left in Figure 3, where a strategy based on doubling is used; for the other drawing in Figure 3, the pupils count by ones, tapping a finger rhythmically six times for each box of pencils. The other example of a more advanced strategy is seen when a pair of pupils work on the problem of how many muffins there are on seven trays if there are ten muffins on each tray. They draw an iconic picture of all the trays and all the muffins, before they count ten muffins on each tray, simultaneously writing  $10+10+10+\dots$  on the paper. They reach the answer of 70 muffins with no further counting or visible reasoning.

For the multiplication problems, the drawing is usually produced immediately after the pupils have read the text. This indicates that they instantly visualise the problem situation and use the drawing as an information holder. In cases where the pupils struggle to understand the problem, they call for a teacher to help them re-read the text and explain particular words. When the drawing of all objects is completed, the pupils use the drawing as a calculation tool. Usually, the drawing is used to execute a counting plan, but in one case it acts as a means to develop a more advanced doubling strategy, as seen in Figure 3. There are instances where the pupils count one by one, even though the video recordings reveal that they master more advanced strategies. We see this, for example, in connection to the problem of finding the total number of muffins on a tray consisting of five rows with seven muffins in each row. The pupils first find the answer by direct counting, but later they write the addition problem  $5+5+5+5+5+5+5$  and skip count to 35.

For the division problems involving smaller numbers, such as the table problem (see Figure 2), all pairs use direct counting in groups of six. For the division problems involving larger numbers – 48 cookies being distributed equally between four tables – one pair use direct counting to distribute one cookie at a time until there are no cookies left. In the other two episodes involving this task, the pupils state that there will be ten cookies for each table and then divide the remaining eight cookies. One of these pairs draw all the cookies (first ten on each table, then adding two more), while the other pair write number symbols after performing calculations in their heads. Figure 4 shows the corresponding drawings for this problem.

**Figure 4: Drawings of the cookie problem**

The use of drawings in solving division problems differs somewhat from the use of drawings for multiplication. The actual calculations are more often made based on the numbers, not on the drawing. Nevertheless, the drawing is important for reasoning and for devising and executing a calculation

plan. This is exemplified by the following short extract from an episode related to the cookie problem. A pack of cookies has been drawn, with the number 48 above, as we enter the situation (drawing is seen to the far right in Figure 4):

- Pupil 1: You have to draw four tables with people. No, just four tables without any people. (*P2 draws four tables*)
- Pupil 2: We have to divide those by four. (*P2 points to the pack of cookies*)
- Pupil 1: Yes, that is what I plan to do. Ten. (*P1 points to each of the tables*) 11, 11, 11, 11. (*P1 points to each of the tables*) 12, 12, 12, 12. (*P1 points to each of the tables*)

This extract demonstrates how the drawing offers a visual support for the mental calculations by giving meaning to the numbers and the operation.

## Discussion and implications

It is not surprising that the pupils successfully solve word problems, as this result has emerged in previous research (e.g. Bakker et al., 2014). Somewhat more surprising is that there is no evidence in the material showing that iconic drawings are used in a more sophisticated way than pictographic drawings; rather, the opposite is true, but the data material in this study is rather limited.

When it comes to pupils' strategies and use of drawings, the amount of drawing and counting is striking. The pupils are not discouraged by higher numbers, such as 20·6; as one girl exclaims about her partner in relation to the pencil problem: "He's so fast at drawing". This supports the impression that even though the pupils are capable of using more advanced strategies, they prefer drawing and direct counting. One hypothesis is that the pupils in this particular class are used to showing their thinking, and that they consider drawings more suitable for this purpose than number symbols. Overall, they appear to regard drawing as a legitimate way to reason and argue, a view that needs to be acknowledged and nurtured by the teacher (Crespo & Kyriakides, 2007). Another hypothesis is that drawing serves as a form of confirmation for the pupils. Because multiplication and division are a new school topic for them, they need to model the situations in order to fully grasp the meaning of the numbers and the relations between them. There is therefore no rush for the teacher to push for more advanced strategies at this point; instead, they can use the pupils' work to discuss, compare and contrast the different multiplicative situations and possible ways to represent them. As claimed by Carpenter et al. (1993), children who are taught to approach problem solving as an effort to make sense out of problem situations, may come to believe that learning and doing mathematics involves the solution of problems in ways that always make sense. (p. 440)

# Functional representations produced and used by students during their introduction to the concept of derivative: a window on their understanding processes

Sarah Dufour

Université du Québec à Montréal, Faculté des sciences de l'Éducation, Montréal, Canada;

[dufour.sarah.2@courrier.uqam.ca](mailto:dufour.sarah.2@courrier.uqam.ca)

*This article is about student understanding processes during their introduction to the concept of derivative that were constructed as part of a doctoral dissertation. The observation of these understanding processes is made from the standpoint of representations in the sense of Duval (1993) and Hitt (2006). More specifically, two aspects of the models of the comprehension process are underlined. First, the fact that students can sometimes work well in different registers, but that they can not necessarily do a proper coordination of these representations is put forward. In addition, the particular role played by the verbal register is also discussed.*

*Keywords: Understanding process, derivatives, representations, teaching experiment.*

## Introduction

The concept of derivative is the subject of many scientific studies in the field of teaching and learning mathematics. The work of Biza and Zacharides (2010) on the concept of tangent is an example of documented difficulties that students in the calculus course may encounter. Or the work of Sierpiska (1985) around the concept of limit is also a landmark for all those who are interested in the learning and teaching of concepts in differential calculus. Other researchers shed light on factors that may explain these difficulties and have proposed possible solutions to help students overcome these difficulties. For example, Zerr (2010), Haciomerogolu, Aspinwall, and Presmeg (2010), among others, provide insights into the elements that lead to a so-called “conceptual” understanding of the concepts of differential calculus. Among these authors, Zandieh, at the turn of the 2000s, proposes a theoretical framework for the analysis of students’ understanding of the concept of derivatives. But, as Zandieh (2000) mentions, this schema does not comment on how and why students are approaching the concept of derivative in a certain way. In addition, Hähkiöniemi (2006) also proposes a diagram that identifies elements that can allow students to deepen their understanding of the derivative. However, this schema is based on the observation of the students after they have seen the concept in class. The observation of students in action, engaged into a process of understanding the concept of derivative, which is new for them, could allow to add a new dimension to these models.

This article, based on Dufour’s PhD (2018), reports on a study that aims to model the students’ understanding of derivative with regard to the process aspect of this understanding and the implementation of an analytical framework to observe and describe these processes. It is not possible to detail the models obtained in the thesis in this paper. However, this article exemplifies two elements in relation with the representations used by students, that seems for us, key moments in the understanding processes of students of the derivative.

## Theoretical Framework

An orientation on the concept of understanding must be taken in order to accurately model one or more understanding processes. Among the studies about differential calculus, some mentions the different representations of mathematical concepts as part of a solution or as a possible explanation to the students' difficulties (Eisenberg and Dreyfus, 1991; Biza and Zachariades, 2010). By insisting on this particular aspect of representations, it was possible to detail the model in depth in this sense. Two visions on the representations, one in continuity with the other, are gathered. First, Duval's theory of registers of semiotic representations (1993, 2006) puts forward important cognitive activities related to representations in different semiotic registers. Actions on and with representations, which are essentials, especially in the case where we are interested in introducing a new concept to students, are described by Duval. These actions are *recognition*, *treatment* (to process or manipulate), *production*, *conversion* and *articulation* (coordination). *Recognition* makes it possible to recognize a concept by a given representation. *Processing* makes it possible to modify a representation within the same register in order to obtain a new representation. *Production* produces a representation related to a certain concept. The *conversion* makes it possible, from a given representation, to produce a new representation in a different register from the one of departure. This action is more complex than the others since it requires to recognize the rules of two registers. Finally, the *articulation (coordination)* between representations in different registers is, for Duval, a cognitive activity related to the conceptual apprehension of a mathematical object. Beyond being able to produce a representation in a register or to convert a representation to a new register, it is a question of being able to go back and forth in different registers according to what is recognized as necessary (Duval, 2006) to carry out a mathematical activity.

The representations described by Duval are part of different semiotic registers which are described by a set of rules of conformity (Duval, 1993), and which are the subject of a certain consensus in the mathematical community. By this rather strict definition, we place Duval's representations in the category of institutional representations. However, as the objective of the research presented here is to learn about the "process" aspect of student understanding, a vision of representations that particularly considers intuitive representations of students is necessary. The concept of functional representations of Hitt (2003) describes intuitive representations in construction. Functional representations make it possible to associate representations produced or manipulated by students to a certain register, although the latter do not completely respect the rules established in this register.

Thus, along with the theoretical framework, an analytical framework is drawn up to describe the students' processes of understanding when they are introduced to a new mathematical concept into the classroom. Indeed, we can now describe these processes by the actions taken by the students on and with representations belonging to different registers of representations and having a certain nature: institutional or functional. On the other hand, it is advisable to specify the different registers likely to be encountered during the observation of the mathematical activity of the students. Due to the nature of the targeted concept, the derivative, which belongs to the mathematical domain of analysis, the registers of representations are: graphic, tabular, verbal (whether written or oral), algebraic and numerical.

## Methodology

Two key elements were taken into account in the choice of a methodology for this study. First, the observation of students understanding processes will be in the form of constructing one or more models of these processes. The chosen methodology must therefore be consistent with this central objective. In addition, the goal also installs the research in a particular context of teaching sessions designed to encourage the use of different representations. The Teaching Experiment (TE) was ideal for this project. Indeed, this methodology aims to document, through the production of a model, the mathematical development of students by observing, among other things, their learning process and their conceptions in a teaching context (Steffe and Thompson, 2000).

The theoretical position on understanding of this research, in particular Hitt's (2003) perspective suggesting these student's representations evolve through interactions with the teacher and other students, sets a particular context for the TE. It is therefore inspired by the position of Cobb (2000), among others, that the TE took its shape in this project. Cobb supports the need to conduct a TE in the classroom through the individual and social aspects of learning, which is consistent with the position taken in this research. However, a completely natural classroom context would have made the fine observation of the different representations used difficult. A "hybrid" form that lies between the individual interview outside the classroom and the natural classroom context is used. A TE with a small group of six students, which allows for individual, team or large groups work with the teacher-researcher and spans over five sessions, has been put in place.

The teaching sessions were videotaped and a journal was written before and after each session. The videotapes were translated into transcripts that were analysed with specific regard on the representations produced and used by students. The analysis of the transcripts and students' productions took place in four steps, or iterations, inspired by Powell, Francisco and Maher (2003)'analysis model. Table 1 resumes the different layers of analysis.

Layer of analysis	Description
First	<ul style="list-style-type: none"> <li>Identify key moments in the student's understanding process in order to use these moments as a basis for building the other sessions.</li> <li>Record the privileged or used registers of representations in the session.</li> </ul>
Second	From the transcripts (coding) : <ul style="list-style-type: none"> <li>Identify the different representations used, produced or processed by the students.</li> <li>Identify some actions on these representations by the students.</li> <li>Add comments on the transcripts.</li> </ul>
Third	From the coded and commented transcripts: <ul style="list-style-type: none"> <li>Write, as a story, the development of the session by dividing it into key moments.</li> <li>For each of these moments, identify and interpret, from the perspective of the theoretical framework, the representations used or produced by the students and the actions taken on these representations.</li> <li>Support these interpretations with excerpts from transcripts of the sessions or figures from students' productions.</li> </ul>
Fourth	From the story written before: <ul style="list-style-type: none"> <li>Identify the moments that are directly related to the concept of derivative.</li> <li>Highlight from these moments the elements that can be part of the description of the process of understanding students.</li> <li>Support this analysis with excerpts of transcripts of the sessions or figures from students' productions.</li> </ul>

**Table 1: Layers of analysis**

## Results and Discussion

The TE put in place and the many layers of analysis allowed us to build two collective models (for two teams of three students) of understanding processes of the concept of derivative during its introduction to students around 18 years old. Since the models take the form of a follow-up text revealing the different representations produced and used by the students and especially the way in which they have used and modified them during the different interactions between them and with the teacher-researcher, it is impossible to report the whole of them in this article. We will instead offer some excerpts that seem particularly rich to better understand the understanding processes of students with a particular focus on the necessity of a coordination between different registers. The first excerpt illustrates the ability of students to produce and process representations of a concept in different registers without being able to demonstrate a real coordination between the registers. The second emphasises the particular role of the verbal register in the understanding processes of students.

### Production of Representations in Different Registers Without Achieving Coordination

First, during the fourth session, a problem of bacterial proliferation was proposed to students through a scenario in words and a table of values. The question posed in this problem was to identify when an antibiotic administered to a patient allows the reduction of the bacterial population present in the patient. We are particularly interested here in the work of Guillaume, J  r  mie and Antoine's team (see figure 1 showing Jeremie's work).

Temps ��cou�� en heures depuis la prise de l'antibiotique (t)	0	2	4	12	14
Nombre de bact��ries dans la population (b(t))	1 000 000	1 025 200	1 044 800	1 067 200	1 058 800

Handwritten calculations below the table:

- Between t=0 and t=2:  $12600$  (difference),  $23200/2$  (derivative estimate)
- Between t=2 and t=4:  $9800$  (difference),  $19600/2$  (derivative estimate)
- Between t=4 and t=12:  $2600$  (difference),  $22400/8$  (derivative estimate)
- Between t=12 and t=14:  $4600$  (difference),  $(8400)/4$  (derivative estimate)

**Figure 1: Treatment of the Table of Values and Numerical Representations (Dufour, 2018, p. 152)**

The three students were able to produce, from a few treatments on the table of values, verbal representations of the situation that are related to the concept of derivative (see Table 2, translated from Dufour, 2018). Table 2 shows the representations and actions made by the three students during their work on this problem. These representations and actions are also interpreted in this table.

Although these functional representations are incomplete or even erroneous, the students associated them with the concept of derivative. They could thus had used the recognition of this concept (derivative) to produce algebraic representations implying the concept of derivative at a point which would be null and which could had allowed them to solve the problem. Unfortunately, this conversion did not take place and the students finally found another way to answer the question, but this solution is not what interests us here.

Type of representations and actions on these representations	Student	Interpretations
<b>Conversion from TR → NR (Tabular representation) → Numerical Representation)</b> From a table of value, calculations of different average rates of change. (see figure 1)	Jérémie	Jérémie makes a good use of the data in the given table to calculate the rate of change on different intervals. However, he doesn't go further on the interpretation of what he could do with this new information.
<b>Conversion NR → VR (verbal representation)</b> Because I asked, he produces a VR for his calculations (average rate of change) which is <b>“means” (VR)</b> .	Jérémie	Although this VR is <u>incomplete</u> , Jeremy is not wrong. Indeed, his various calculations can be associated with the concept of mean in the sense that he obtains a number of bacteria produced/dead for each hour in this interval, that is to say, a number of bacteria produced each hour if the same number of bacteria was produced every hour over this interval. This is an incomplete VR in the sense that it does not identify NRs as “rates of change” (VR), which is an important conversion for the rest of the problem and especially for the process of understanding the derivative.
<b>Conversion NR + VR → VR + VR</b> Conversion from the average rate of change calculated (NR) and the verbal representation “mean” (VR) to the verbal representations <b>“slope” (VR)</b> and <b>“variation” (VR)</b> .	Guillaume	Guillaume uses the representation “slope” to talk about what Jérémie calculated (average rate of change). These two VRs can indeed designate the same concept. It can be emphasized that the term “slope” is more often used with reference to the graphic register which is not necessarily the case here, although some links with the graphical register are formed later.
<b>Conversion NR + VRs → VR</b> Conversion from the average rate of change calculated (NR) and the verbal representations “mean” (VR), “slope” (VR) and “variation” (VR) to the verbal representation <b>“derivative” (VR)</b>	Antoine	Antoine continues the discussion by introducing the term “derivative”. It is true that what Jérémie calculates (average rate of change) is not very far from the concept of derivative (instantaneous rate of change). Recall that what distinguishes these two concepts is that the average rate of change is related to a given interval or secant line to the function involved. Whereas the instantaneous rate of change (derivative at a point) is related to the rate of change for a value of the independent variable in particular or the rate of change of a tangent line at a point of a function. Therefore, the use of the RV “derivative” is erroneous in this case.
<b>Conversion NR + VR → VR + VR</b> Conversion from the average rate of change calculated (NR) and the verbal representation “derivative” to two verbal representations: <b>“The derivative between 12 and 14” (VR)</b> and <b>“the tangent between 12 and 14” (VR)</b>	Antoine	Antoine goes further by producing the VR “the derivative between 12 and 14” and the VR “the tangent between 12 and 14”. For the same reasons as those raised above, these two VRs are erroneous. Indeed, a derivative or a tangent line can't be associated with an interval of this kind. In this case, Antoine should have used the representations “average rate of change” or “secant line between 12 and 14”, for example, so that the different representations in this discussion are coordinated coherently.

**Table 2: Representations Produced by Students and Our Interpretations (Dufour, 2018, p. 157)**

Later, the teacher-researcher directly suggested to the team to use the concept of derivative to solve this problem. At this point, the three students produced algebraic representations of the derivative at a point such that the derivative at this point would be zero (see Figure 2 for an example). They even managed to manipulate these representations to find that famous moment when one can observe a change of growth of the function.

$$\lim_{h \rightarrow 0} \frac{f(t+h) - f(t)}{h}$$

$$\frac{-200(t+h)^2 + 14000(t+h) + 10^6 - (-200t^2 + 14000t + 10^6)}{h}$$

$$\frac{-200(t^2 + 2th + h^2) + 14000t + 14000h + 10^6 + 700^2 - 14000t - 10^6}{h}$$

$$\frac{-200t^2 - 1400th + 700h^2 + 14000t + 14000h + 10^6 + 700^2 - 14000t - 10^6}{h}$$

$$\lim_{h \rightarrow 0} \frac{-1400th - 700h^2 + 14000h}{h}$$

$$\lim_{h \rightarrow 0} (-1400t - 700h + 14000) = 14000$$

$$a = 14000$$

$$b = 0$$

$$y = 14000x + b$$

$$y' = 14000$$

Figure 2: Treatment of an algebraic representation of the derivative of a function by Guillaume (Dufour, 2018, p. 166)

What is interesting to observe here is the completely parallel use of the different registers. Indeed, their work in “closed vases” did not allow them to coordinate coherently the different representations they can produce and thus achieve a better understanding of the concept of derivative. However, their use of the derivative in the algebraic register to solve the problem might suggested that once the concept was identified, which they had done verbally before (see Table 2), they could had completed the problem by processing an algebraic representation. Although their functional verbal representations were not completely adequate, the students identified them as the derivative. They could had allowed them to move to an algebraic representation as they did later at the request of the teacher.

### The Particular Role of the Verbal Register in the Coordination of Different Representations

According to the position on the understanding adopted in this article, to understand, one must coordinate different representations of various registers. However, beyond this necessity, the models constructed make it possible to identify the verbal register as being a central element of this coordination. In fact, the register is at least a mirror that can reflect the understanding of students. Indeed, it was often when the students were brought to produce such type of representations that we can observed if the coordination between the representations was coherent or not. The representations in this register sometimes revealed to students themselves that they cannot articulated representations in different registers.

As an example, some of the functional verbal representations showed in table 1 are not coherent with the concept of derivation such as “the derivative **between** [an interval]”. Other functional verbal representations produced by the same student later such as “the slope of a derivative is a tangent” and “the derivative **line** is the **slope** of a tangent” are also examples of incoherent representations of the

derivative. This kind of functional verbal representations let us realized that, even if some representations were coherent and complete in their own register (algebraic for example), the concept of derivative still provoked a confusion to the observed students. Even more important, when the students were asked, by the teacher-researcher or by their colleagues to explain what they were doing in a certain register (often algebraic), they, themselves, realized that they often cannot explained or justified the representations they produced or used. This was, then, a key moment for them in their understanding process.

Another example appeared when the students had to identify in different registers the concept of rate of change to be able to go through their idea of using derivative to solve a problem. Some examples of this difficulty were observed during the TE sessions. One of them was when we proposed a problem from Selden, Mason and Selden (1989) (see figure 3).

Find values of  $a$  and  $b$  so that the line  $2x+3y=a$  is tangent to the graph of  $f(x) = bx^2$  at the point where  $x=3$ .

**Figure 3: Problem proposed to the students during the fifth session**

The students, in both team of three participants, were able to identify in the verbal register the need to equal the rate of change of the given linear function and the derivative of the given function  $f$  for  $x=3$ . However, they were not able to articulate the verbal representation to a coherent algebraic representation. It needed some interventions from the teacher-researcher to finally be able to coordinate these representations. In this case too, the verbal representation was important for two reasons. First, it sheds light on the fact that the students were able to recognize the usefulness of the derivative. Second, it helped to determine that the problem was not directly the concept of derivative, in that case, but that it was the concept of rate of change. This coordination of different representations of the concept of rate of change seemed to be confusing for students. We must precise that if the concept of derivative is new for them, they work with the concept of rate of change since at least three school years. However, it seemed that this concept in particular still is of high importance in the understanding process of the derivative.

## Conclusion

The few examples given above are only some of the important elements that the construction of models of understanding processes of the concept of derivative made it possible to underline. The use of representations in different registers in a rather parallel way than in a coordinated way had been observed several times during the construction of the understanding processes models. Certainly, this step, working in close vases, may be inevitable and part of a deep understanding process of the concept. However, it must certainly be considered in teaching by attempting to provoke, not only representations in a variety of registers, but treating them in a coordinated manner. It's about emphasizing how these various registers are related to each other. The verbal register seems appropriate to allow such disclosure of the links between the registers.

*Making connections between variables and proficiently constructing graphical representations is key to higher-order thinking activities within mathematics and science education. In our research, we make use of a learning environment informed by embodied cognition theory to promote students' graphical understanding. In the teaching sequence offered to fifth graders, students created distance-time graphs describing their own movements in front of a motion sensor. In a pretest-intervention-posttest design, we investigated whether task-related bodily movements enhanced students' understanding of graphs of motion, as reflected in their competence in interpreting and constructing graphs. Preliminary results point to important links between students' motion experiences and their ability to reason about the relationship between distance and time as represented in graphs.*

*Keywords: Graphs, primary mathematics education, embodied cognition, motion, modelling.*

## Introduction

Students' difficulties with understanding graphs is a much-studied topic. Such difficulties become especially apparent when graphs include a time-dependent variable, as for example in distance-time or speed-time graphs. Then, students can be prone to focus on surface characteristics of the graphs, such as the slope and interpreting it as an indication of moving up or the height and viewing it as an indication of highest point (e.g., Glazer, 2011). However, good understanding requires that students discover the deeper connections underlying the represented data and start to think about the relationship between multiple variables and "their pattern of covariation" (e.g., Leinhardt Zaslavsky, & Stein, 1990, p. 11). According to Friel et al. (2001) students have to develop *graph sense*, which "develops gradually as a result of one's creating graphs and using already designed graphs in a variety of problem contexts that require making sense of data" (Friel, Curcio, & Bright, 2001, p. 145)".

Developing graph sense can be seen as higher-order thinking. It implies reasoning about graphs, including interpreting, constructing, changing, combining, and comparing graphs (e.g., Boote, 2014). In order to foster students' understanding of graphs and related reasoning, we designed a teaching sequence in which students are given ample opportunities to experience firsthand how their own bodily movements are represented as a graph. The idea that bodily experiences can be beneficial for learning, is captured within the theory of embodied cognition.

## Theoretical background

Embodied cognition theory states that when we interact with our physical environment valuable perceptual-motor experiences are acquired through which our cognition is shaped. This makes our

acting body one of the most important factors for learning (e.g., Wilson, 2002). According to embodied cognition theory this learning does not only include the acquisition of lower-level cognition (e.g., motor development) but it also incorporates the acquisition of higher-level cognitive processes (e.g., language and mathematics) (e.g., Barsalou, 2010). Evidence for the idea that thinking and learning are embodied has inspired researchers to incorporate bodily movements in educational environments in order to improve student learning. Often this involves activities in which students are instructed to make whole- (or part-)bodily movements, or to observe movements (e.g., Ruiter, Loyens & Paas, 2015). Whereas all these bodily experiences are considered to be embodied, some researchers argue that activities in which the whole body partakes have some additional benefits. For example, the body might become a mathematical object itself (e.g., *being a number, being the graph*) and, in a more collaborative vein, the body might become an object for collective sense-making (Kelton & Ma, 2018; Ma, 2017).

Embodied learning environments supporting students' understanding of graphing change are based on the premise that providing students with valuable bodily experiences that are immediately linked to the target concepts could alleviate students' difficulties with graphs representing change over time (e.g., distance-time graphs). In the context of modelling motion, this would imply a strong grounding of the concept of change in experienced (own) motion. For a recently carried out literature review (Duijzer, Van den Heuvel-Panhuizen, Veldhuis, Doorman, & Leseman, 2019), embodied learning environments supporting students' understanding of how to graph change were characterized on the degree of bodily involvement (own and others/objects' motion) and immediacy (immediate and non-immediate). Immediacy refers to whether a learning environment deals with on- or off-line cognitive activities. Off-line cognitive activities become grounded through embodied mechanisms such as mental simulation or imaginative activities (e.g., Barsalou, 2010). For example, when students walk in front of a motion sensor and see the graph of their own movements appear in real-time on the screen of the computer, the activity is "on-line" and the experience immediate. When students obtain this graph of their own movements at a later stage, the activity is "off-line" and hence the experience non-immediate. The review unveiled that learning environments making use of students' own movements immediately linked to their representation were most effective in terms of learning outcomes. These learning environments often made use of motion sensor technologies to immediately track a dynamic event as a line in a graph. This immediate link between one's own movement and a graphical representation of this movement was found to be an important mediating factor of these embodied learning environments.

Although over the past couple of decades much research has been published showing that one's own motion experiences might be helpful in learning motion graphs, practical applications are still scarce. Most of the research investigating the role of perceptual-motor activities on primary school students' understanding of graphical representations of motion has been done with individual students, looking at micro processes of development (e.g., Ferrara, 2014). We wanted to shift this accentuation a bit and investigate how the use of embodied learning environments translates to whole classrooms. In doing so we built on work done by others. For example, Deniz and Dulger (2012), showed positive effects of an inquiry-based instruction condition enriched with real-time graphing technology in which fourth graders were asked to replicate given motion situations. The other instruction condition

used traditional laboratory equipment (i.e., a bottle of water with a hole and measuring tape). In the traditional laboratory condition students were allowed to move as well, but the immediate real-time link between motion and graph was missing. Considering these findings, it could be argued that having the opportunity to move, as well as immediately seeing your movements reflected as a graphical representation is helpful for learning about graphs of motion for students of this age. Therefore, we further explored this issue by contrasting a group of students participating in classroom activities including immediate whole-bodily movements with a group of students participating in regular classroom activities, without having the experience of moving yourself.

### **Current study**

In this study, we investigated the effects of an intervention, comprising a teaching sequence including immediate task-related whole-bodily movements, on students' understanding of graphing change. Our research question was: *What is the effect of a classroom intervention including students' own whole-bodily movements on students' ability to interpret and construct motion graphs?* We hypothesized that an intervention in which task-relevant bodily movements were made, would result in better learning and test performance on interpreting and constructing graphs than an intervention in which students were not given this opportunity.

### **Method**

To answer the research question, we set up a quasi-experiment in a classroom setting with a pretest-intervention-posttest design containing two experimental conditions in which students were offered a teaching sequence on graphing change in motion and a control condition in which the students did not get this teaching sequence. Instead these students received a teaching sequence (similar in intervention duration and time of intervention) on probability to take into account the effect of having an intervention on students' learning gains. The first experimental condition was embodied, meaning that the students were allowed to move around freely, while in the second experimental condition, the non-embodied one, the students did not have this opportunity. Therefore, the main difference between both conditions was the dynamicity of the movement presented to the students as well as the opportunity to physically experience the target concept of graphically represented motion.

### **Participants**

Participants were 218 fifth-grade students (94 female, mean age = 10.29 years,  $SD = 1.46$ ) from 9 classes of 8 Dutch elementary schools. The classes were randomly divided over three conditions: embodied experimental condition ( $n = 70$ ), non-embodied experimental condition ( $n = 68$ ), and control condition ( $n = 80$ ). The research was conducted in accordance to the ethical guidelines of the Institutional Review Board of the faculty of Social and Behavioral Sciences at Utrecht University.

### **Procedure**

The participants in the experimental conditions participated in a teaching sequence of six lessons on graphing change in motion, participants in the control condition participated in a teaching sequence of six lessons on probability. The students received the teaching sequence at different time periods throughout the year, see Figure 1. All participants took four identical macro tests at fixed time points

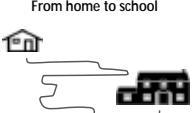

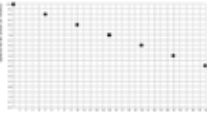

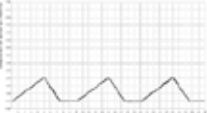

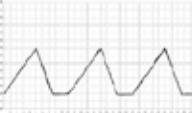

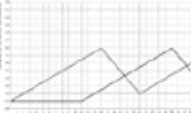

spread over the year and six micro tests which were administered after each lesson. All lessons on graphing change were given by the same teacher, the first author of this paper.

Condition	N Classes (students)		Phase 1 (October-November)		Phase 2 (January-February)		Phase 3 (April-May)	
1	(n = 21)	M1	Lesson 1-6	M2		M3		M4
	(n = 22)	M1		M2	Lesson 1-6	M3		M4
	(n = 27)	M1		M2		M3	Lesson 1-6	M4

**Figure 1: Research design**

### Teaching sequence

The main learning objective of the teaching sequence was to foster students' understanding of motion graphs. In the lessons we focused on graphs representing dynamic situations, where distance changes over time. The teaching sequence started with an activity in which students were asked to develop their own representation of a familiar motion event (i.e., their journey from home to school). After this, students received motion situations involving the representation of motion as discrete graphs, followed by the representation of motion as continuous graphs. Throughout the remaining part of the teaching sequence students were asked to draw graphs of given motion situations and reconstruct possible events from continuous graphs. See Figure 2 for an overview of the instructional sequence.

Informal graphs	Discrete graphs	Continuous graphs			
<b>LESSON 1</b> Motion: reflecting and representing	<b>LESSON 2</b> From discrete to continuous graphs	<b>LESSON 3</b> Continuous graphs of 'distance to' (1)	<b>LESSON 4</b> Continuous graphs of 'distance to' (2)	<b>LESSON 5</b> Scaling on the graphs' axes	<b>LESSON 6</b> Multiple movements and their graphical representation
					

**Figure 2: Overview teaching sequence**

In the embodied experimental condition, the teaching sequence was enriched with students' own motion experiences. These motion experiences varied in extent and duration over the different lessons. In the first lesson, students had to enact two slightly differing motion situations by walking along a straight line. The non-embodied experimental condition practiced this exercise differently.

They received the motion situations on the digital blackboard, as well as on paper, and had to discuss these in small groups without enacting them. From the second lesson onwards, motion sensor technology was used in the embodied experimental condition. In the second and the sixth lesson the whole classroom was involved in these activities, whilst in the third till the fifth lesson students worked together in smaller groups. This gave each student the opportunity to physically experience how their movements related to the line in the graphical representation. Again, students in the non-embodied experimental condition performed the same tasks, but without enacting the movements themselves.

### Motion sensor technology

In order to provide the students with an immediate link between a dynamic situation (moving in space) and its graphical representation (restricted to distance to a point over time) we included two Motion sensors, developed by CMA, in conjunction with Coach6 Software (Heck, Kedzierska, & Ellermeijer, 2009). The tool was connected to the digital blackboard (Lesson 2 and Lesson 6) or to laptop computers (Lesson 3-5). The motion sensor was set to provide a single graph representing the distance between the sensor and the nearest object over a 30 second period. Moving backwards in front of the sensor, resulted in an increase of distance between the sensor and the student, while moving forwards resulted in a decrease of distance between the sensor and the student. To familiarize students with the motion sensor they were asked to replicate a distance-time graph of a back-and-forth movement (see Figure 3 on the left), which resulted in student created graphs (see Figure 3 on the right). In Lesson 3 till Lesson 5, students had many individual opportunities to move in front of the sensor. In Lesson 2 and Lesson 6, most students observed other students who were walking.

**Figure 3: Given graph of a back-and-forth movement (left) and graph produced by a student in front of the motion sensor (right)**

### Measures

The paper-and-pencil macro test was administered to the students in order to measure their understanding of motion graphs as an indication of domain-specific mathematical higher-order thinking. Students completed five problems that assessed their knowledge of graphing. The test consisted of three graph interpretation items and two graph construction items. Two example items are shown in Figure 4. Four items could be answered correctly or incorrectly (i.e., a score of 1, 0). One item could be answered correctly, partially correctly, or incorrectly (i.e., a score of 1, 0.5, 0). This resulted in a possible maximum score of 5 and a minimum score of 0. We also coded students'

answers on their level of reasoning. We included four levels of reasoning. For this paper, we only look into students' correct or incorrect answers.

**Figure 4: Items macro test**

## Analysis

A mixed 3 (condition: embodied experimental, non-embodied experimental, control) x 4 (time of testing; pre-, post, and/or follow-up) staged comparison design with repeated measures was used. For now, we will focus on the tests administered before and after taking part in the intervention, see Figure 1. Our dependent variable was students' achievement on the mathematical higher-order thinking test.

## Results

In this paper we only provide the descriptive statistics of student' scores on the graphing motion test based on the correctness of the students' answers. Table 1 shows the pre- and post-test graphing motion scores for students in each of the three research conditions. On average the students in the intervention conditions increased in their understanding of motion graphs, regardless of whether they received an intervention on motion graphs. However, the embodied experimental condition showed higher gains from pre- to posttest ( $M_{\text{dif}} = 1.33$ ), when compared to the non-embodied experimental condition ( $M_{\text{dif}} = 0.62$ ), and the control condition ( $M_{\text{dif}} = 0.25$ ).

Phase	Intervention condition	Macro test				
		Pre-test		Post-test		Gain score
		<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M<sub>dif</sub></i>
1	Embodied experimental	1.21	0.94	3.20	1.15	1.99
2	Embodied experimental	2.70	1.38	3.73	1.17	1.03
3	Embodied experimental	2.65	1.60	3.70	1.37	1.05
Total		2.24	1.50	3.57	1.25	1.33
1	Non-embodied experimental	1.88	1.26	3.31	1.04	1.43
2	Non-embodied experimental	3.50	1.11	3.52	1.29	0.02
3	Non-embodied experimental	2.90	1.39	3.40	1.28	0.50
Total		2.74	1.42	3.36	1.25	0.62
1	Control condition	1.58	1.03	1.74	1.36	0.16
2	Control condition	2.50	1.51	2.70	1.41	0.20
3	Control condition	2.02	1.51	2.46	1.45	0.44
Total		2.06	1.41	2.31	1.45	0.25

**Table 1: Descriptive statistics of the students' macro test scores for the three conditions**

## Discussion

Based on the descriptive statistics of students' scores on the macro test we found that students who participated in a six-lesson embodied teaching sequence on graphing motion showed higher gains in their understanding of motion graphs than students in the non-embodied experimental condition or in the control condition. Moreover, students' dynamic interaction with the, by motion sensor technology created, graphical representation of their own movements indicates that the embodied learning environment contributed to their understanding. In particular, this is in line with studies which have found that immediate own motion experiences are effective for learning (e.g., Duijzer et al., 2018). Moreover, our results do not only support the findings of previous research that incorporated motion sensor technology, but they also add to our knowledge of using embodied learning environments in whole classroom settings. As such, our results extend earlier findings of Deniz and Dulger (2012).

Classic theories of cognitive science assume the creation of mental structures to guide or develop mathematical understanding. Another perspective is the embodied perspective taken in the current study. According to Nemirovsky, Kelton and Rhodehamel (2013), mathematical understanding is constituted on the basis of perceptual and motor experiences. In line with this, we assume that the mathematical understanding that arose in our students was strengthened by the graphical representation of their own movements immediately created by the motion sensor. Hence, students' mathematical understanding of motion graphs became grounded in their sensorimotor experiences (i.e., continuous transformations of whole-bodily activity) that they gained when moving in front of the motion sensor, while sharing and discussing their experiences with other students.

*Recent research yielded empirical evidence for a unit square being a useful visualization of Bayesian situations. However, most of the studies in the research field of visualizing Bayesian problem situations were conducted in well-controlled experimental settings with university students as participants. Therefore, we focus in this paper on a training study with 38 eleventh graders in school about visualizing statistical data with a unit square for coping with Bayesian problem situations. Firstly, we outline some theoretical and empirical basics concerning research about Bayesian situations and a unit square as a facilitating visualization tool. Afterwards, we present a short training sequence in using the unit square effectively. We report on methods, implementation and results of a pilot study in school. The promising results were discussed at the end.*

**Keywords:** Bayesian reasoning, visualization of statistical data, unit square, school training study.

## Introduction

According to Arcavi (2003) it is an important task of mathematics education research to investigate visualizations as specific graphical representations of mathematical objects in a theoretical and empirical way. Thus, we focus in our ongoing research about the unit square as a powerful visualization of Bayes' formula on theoretical and empirical insights. The unit square is shown in Figure 1 visualizing a Bayesian situation which are situations where the Bayes' formula could be applied.

**Figure 1: Bayesian situation and visualization with the unit square**

Given for example a Bayesian situation as described in Figure 1 the unit square would look like as displayed in Figure 1 in the right side. All essential information is represented in a numerical *and* a geometrical way. Thus, a unit square facilitates via different strategies the computation of the essential probability, that is, the probability of being infected given a positive test result  $P(I|+) =$

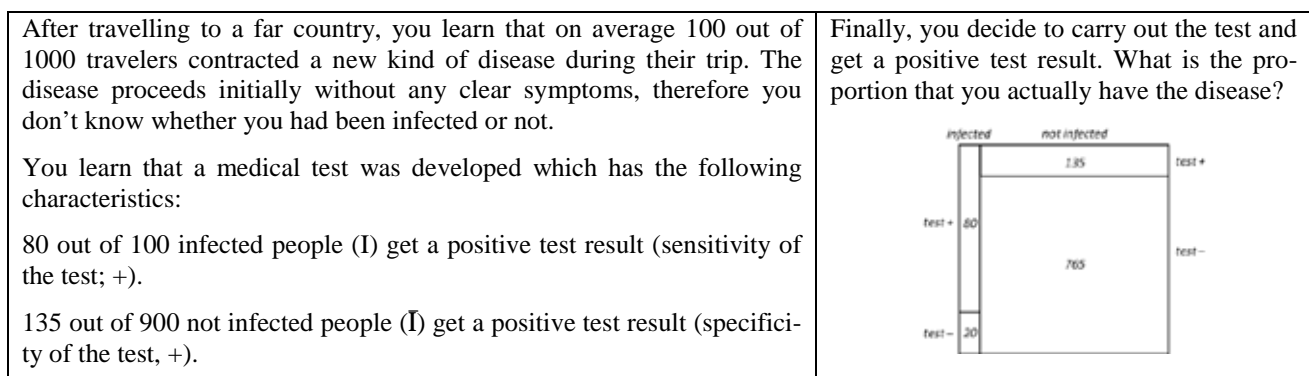

$$\frac{80\% \cdot 10\%}{80\% \cdot 10\% + 15\% \cdot 90\%} \approx 37,2\%.$$

Focusing on facilitating strategies in Bayesian situations in detail is the main goal of this paper: We refer to certain visualization features of a unit square which makes it an effective facilitator for coping with Bayesian situations and for adequately applying Bayes' rule which is a fundamental model for dealing with risk in situations of uncertainty. For this we provide first a brief literature review to discuss the advantages of the unit square in comparison to further visualizations of Bayesian situations. Afterwards we refer to the design and the results of a quasi-experimental training study with 38 students in grade 11 which compares the performance of a treatment group vs. a control group. Our question for this step in an ongoing research project was whether it is possible to improve students' dealing with Bayesian situations by a brief training that is based on representing Bayesian situations by natural frequencies and by a unit square. Implications and conclusions are discussed at the end of the paper.

### The unit square as facilitator of Bayesian situations

Despite the Bayes' rule's relevance for real life situations, psychological and educational research gained evidence that people often fail when applying Bayes' rule (Diaz, Batanero, & Contreras, 2010; Gigerenzer & Hoffrage, 1995; Kahneman, Slovic, & Tversky, 1982). In their meta-analysis McDowell and Jacobs (2017) concluded that only about 5% of participants in various studies were able to solve a problem as exemplarily given in Figure 1 without any facilitating strategy.

A widely accepted strategy to increase people's performance in Bayesian situations is representing the statistical information via natural frequencies instead of using percentages (e.g. Gigerenzer & Hoffrage, 1995). In Figure 2, the Bayesian situation given in Figure 1 is displayed by using natural frequencies. The meta-analysis of McDowell and Jacobs (2017) provides empirical evidence that by using natural frequencies as the only information format people's performance in coping with Bayesian situations increases from about 5% to about 25%.

**Figure 2: Bayesian situation with natural frequencies**

A further facilitating strategy is to provide additional visualizations (e.g. Brase, 2009; McDowell & Jacobs, 2017). However, there are ambiguous research findings about which visualization properties could effectively facilitate dealing with Bayesian situations.

From a theoretical point of view, three properties could be suggested to have a facilitating effect. The first is to use icons as "real, discrete and countable" objects (Cosmides & Tooby, 1996, p. 33). However, from a practical point of view (in terms of time costs) this strategy turns out to be hardly realizable in regular classroom instruction where students have to create visualizations. Further-

more, results of our own research suggest that icons actually have an additional, but small facilitating effect compared to a unit square as shown in Figure 2 (Böcherer-Linder & Eichler, 2019).

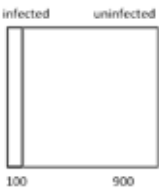

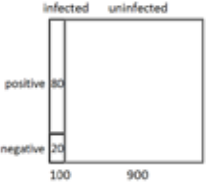

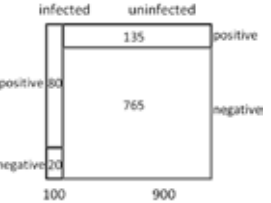

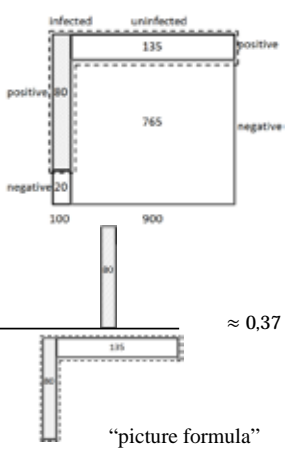

The second facilitating strategy is to make the nested-sets structure transparent which constitutes fundamentally every Bayesian situation (Oldford, 2003). Sloman, Over, Slovak, and Stibel (2003, p. 302) stated that “any manipulation that increases the transparency of the nested-sets relation should increase correct responding”. Actually, our own research revealed empirical facts that the unit square allows exactly for such a manipulation (Böcherer-Linder & Eichler, 2017, 2019). The subsets that have to be identified for successfully solving a task with the Bayes’ formula are directly neighboured in the unit square (cf. Figure 1) and, by this means, they are transparently visualized. In particular, in different experimental studies, we yielded empirical evidence that the unit square makes the nested sets-structure of a Bayesian situation more transparent than the commonly used tree diagram and showed further that the unit square is more effective to facilitate dealing with Bayesian situations (Böcherer-Linder & Eichler, 2017). Actually, compared to only using natural frequencies the additional use of a unit square could further increase people’s performance in coping with Bayesian situations from about 25% (cf. above) to about 65%-70%.

A third facilitating strategy is to use area-proportional representations of statistical information (e.g. Talboy & Schneider, 2017). Going beyond pure numerical information a unit square provides additionally the statistical information by displaying exact graphical proportions of the rectangular sub-plots. When comparing a unit square with a 2x2-table which differs from a unit square regarding the missing area-proportionality we found evidence for the effectiveness of the area-proportionality (Böcherer-Linder & Eichler, 2019). Nevertheless, understanding Bayesian situations is not fully reached by only solving tasks as shown in Figure 1 (Borovcnik, 2012). Moreover, understanding also includes the adequate influence-judging of parameters in these Bayesian situations, that is, the base rate or the conditional probabilities that are called sensitivity and specificity in a medical diagnosis situation. For this purpose, we also investigated the facilitating effect of a unit square compared to a tree diagram by regarding the influence of changing parameter values in Bayesian situations (Böcherer-Linder, Eichler, & Vogel, 2017). In this research, we found a significant supremacy of a unit square compared to a tree diagram. Although we have not yet compared a 2x2-table and a unit square concerning these kinds of changing parameter tasks in Bayesian situations, we hypothesize based on theory (Eichler & Vogel, 2010) that a unit square is of advantage by means of additional visualizing changing proportions.

The research discussed so far is mostly conducted in well controlled studies without a systematic training. However, training should be understood as a fourth strategy which provides facilitating effects additional to the effective strategies mentioned before. However, these very few training studies reported so far were not focused on facilitating properties of visualizations and, they were mostly carried out with university students as participants (e.g. Sedlmeier & Gigerenzer, 2001; Talboy & Schneider, 2017). For this reason, we conducted a training study that addressed learning how to adequately deal with Bayesian situations based on using natural frequencies and, in addition, on using a unit square. Referring to a sample of university students, the results of a pilot study suggest a positive effect of the training with a unit square (Böcherer-Linder, Eichler, & Vogel, 2018). In this paper, we present a training study with students of grade 11. The main question in this study was

whether students' performance in Bayesian situations as well as students' understanding of Bayesian situations in terms of judging the influence of changed parameters could be improved in a brief training based on representing Bayesian situations by natural frequencies and a unit square.

## The training

<b>Step 1: Choice of the sample size</b> For solving the problem, we first consider the question of what the probabilities mentioned in the text imply for a concrete group of travelling people. We choose a sample size of 1000 people. We represent the group of 1000 people by drawing a unit square.		
<b>Step 2: Construction of the frequency representation</b> Since 10% of the travelling people contracted the disease during their trip, 100 out of the 1000 people are expected to be infected. 900 out of the 1000 people are expected to be uninfected. Thus, we divide the unit square in vertical direction for "infected" and "uninfected" at the ratio of 100 to 900. At the bottom of the narrow rectangle we write "100" and at the bottom of the broader rectangle we write "900".		
Since 80% of the infected people get a positive test result, 80 out of the 100 infected people are positively tested. Accordingly, 20 out of the 100 infected people are tested and result negative. Therefore, we subdivide the narrow rectangle horizontally into two parts and write "80" and "20" into the resulting areas.		
Since 15% of the uninfected people get a positive test result, 135 out of 900 uninfected people get a positive result after testing (because 15% of 900 is 135). Accordingly, the other 765 uninfected people get a negative test result. Therefore, we subdivide the broader rectangle horizontally into two parts for "positive" and "negative" and write the numbers into the resulting areas.		
What needs to be found is the probability that a person with a positive test result is actually infected. Thus, we have to calculate which proportion of the people resulting positive is actually infected. For this aim, we surround all positive people with a dashed line in the unit square and emphasize with grey color all of them, that are infected. We read out the following numbers: Number of infected and positive to the test: 80 Number of all positive to the tested: 80+135=215 We calculate: $\frac{\text{infected and positive}}{\text{all positive}} = \frac{80}{80 + 135} \approx 0,37$ This proportion corresponds to the requested probability of 37%.		 <p style="text-align: right;">≈ 0,37</p> <p style="text-align: center;">"picture formula"</p>

**Figure 3: First intervention in the training study ("picture-formula", cf. Eichler & Vogel, 2010)**

Due to an ecological validity, we presented the problems in the probability-text-version (see Figure 1) and trained the students to translate the probabilities into natural frequencies and, secondly, to graphically represent the statistical information in the process of problem solving. The training had

two phases: phase 1 (10 minutes) contained three steps. It was a worked example showing how to solve the problem of Figure 1 with the help of the unit square (Figure 3; translated from German).

Phase 2 (10 minutes) included an exercise that was structurally identical to the worked out example (Figure 2 and Figure 3) but had another context (Trisomy). An oral explanation and a presentation of the correct solution were given. Even though it was possible to draw a unit square true to scale in this case, we only showed a rough drawing of a unit square, since we wanted to enable the participants to work with the visualization as a thinking tool for problem solving which did not necessarily imply a precise drawing.

Finally, we added a brief exercise (5 minutes) on the change of parameters. For this, we only show the instruction referring to the change of the base rate (Figure 4).

<p>3. Change of the base rate</p> <p>The base rate indicates the proportion of an individual having trisomy (5% of the children of women of age 45). An increase of the base rate results in an increase of the area of the thin rectangle on the upper left side of the unit square and, accordingly, a decrease of the area of the rectangle on the upper right side.</p> <p>If the base rate increases to 10%, there would be 90 true-positive people and 90 false-positive people. The change of the base rate changes the proportion as shown below:</p> $\frac{90}{90 + 90} = \frac{90}{180} \approx 50 \%$ <p>Actually, the result shows a considerable change of the probability.</p>	
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

**Figure 4: Part of the training to changed parameters**

## Method

Our sample included 38 students in grade 11, from two classes. By choosing two different classes of students which were not grouped randomly we conducted a quasi-experiment. The class to which we administered the training included 22 students. The class that represented the control group consisted of 16 students.

**Figure 5: Design of the training study**

The design of the quasi-experiment is shown in Figure 5. Since there were not all of the students present in the three phases shown in Figure 5, our analysis is based on 16 students (treatment group) and 13 students (control group).

Both the pre-test and post-test consisted of two Bayesian situations. One of the situations in both tests was the same, the other situation differed to prove whether repeating a task has an effect on performance in Bayesian situations. In the pre-test, one situation included only a performance-task and the second situation included both a performance task and a task in which the influence of

changed parameters was to be estimated. In Figure 6 we show the task that was identical in both tests and include both forms of tasks (translated from German).

There are tests for diagnosing people if they have infectious diseases like measles or scarlet. Concerning such an infectious disease and the corresponding test the following information is given:

The probability of having the infectious disease is 2%. Given there is a patient having the disease, the test yields in 90% of all cases a “positive” result, which means it indicates correctly the infectious disease. Given there is a non-infected patient, the test shows in 5% of all cases also a “positive” result, which means it indicates the infectious disease by mistake.

a) What is the probability of a patient having actually the disease given a “positive” test result?

b) How changes the probability of section a) if the probability of having the disease is higher?

**Figure 6: A test item (translated from German)**

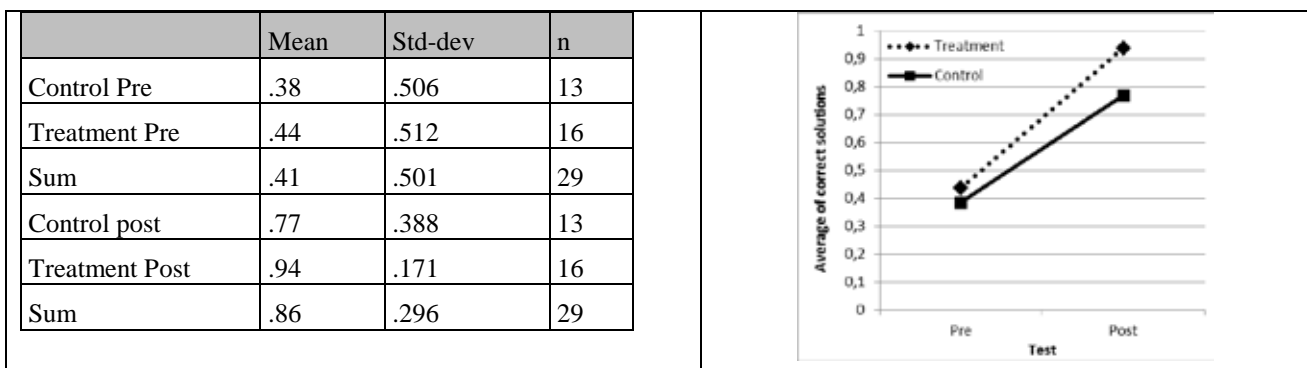

## Results

Regarding the few items the values of Cronbach’s alpha of 0.63 (pre-test) and 0.85 (post-test) appear to be good. Thus, we summarized the scores in each test referring to the performance test-items a).

**Figure 7: Descriptive results of the training concerning item a)**

We applied a mixed ANOVA (within-factor: performance in the pre-test and post-test; between factor: group) to investigate the training effect in the treatment group compared to the control group. According to the robustness of an ANOVA (Schmider, Ziegler, Danay, Beyer and Bühner, 2010), we did not regard non-normality and differences in variances. In a descriptive way, Figure 7 (left) reports the results referring to the pre-test and the post-test. Figure 7 (right) visualizes a clear effect of the treatment referring the means.

**Figure 8: Descriptive results of the training concerning item b)**

As expected, the ANOVA yields a significant effect ( $F=20,733$ ,  $p=0,000$ ) of the treatment with a strong effect ( $\eta_p^2=0,434$ ). Regarding item b) the results were not as expected (Figure 8). Actually, also the control group has an increased average of correct solutions and the differences between the treatment group and the control group are not significant concerning the ANOVA ( $F=0,424$ ,  $p=0,520$ ,  $\eta_p^2=0,015$ ). By contrast, there is a significant main effect for both groups regarding the difference between the pre-test and the post-test ( $F=24,938$ ,  $p=0,000$ ,  $\eta_p^2=0,480$ ).

## Discussion

Regarding the results of the performance tasks it could be stated that a training with the unit square turns out to be helpful for students in school. This finding is in line with the results of our recent study in school investigating the effect of the visualization (cf. Vogel & Böcherer-Linder, 2018). Furthermore, this is particularly emphasized within a practical point of view, a unit square's effective use can be trained within a very short time (in Germany 45 minutes corresponds to one lesson). Regarding the tasks of estimating the effect of changing parameters it should be mentioned that these kinds of tasks were estimated to be more difficult by going beyond the demand of only building a ratio as the Bayes problem's solution. However, most of the students in both groups were able to find the correct solution, even in the control group and, thus, the significant difference between pre- and posttest indicates a learning progress. Particularly the missing difference between the treatment group and the control group could firstly be explained by the high guessing probability of one third, or even one half, if the question "How changes" is interpreted as either increasing or decreasing. Moreover, maybe the students intuitively guessed that the conditional probability would be higher if the base rate increased without analyzing the parameter dependence. However, we expect tasks which necessitate an analysis of the parameter dependency to be trainable as successfully as the performance tasks. This effect is focused on in subsequent studies being conducted currently.

# Learning to ‘deal’: A microgenetic case study of a struggling student’s representational strategies for partitive division

Carla Finesilver

King’s College London, UK; [carla.finesilver@kcl.ac.uk](mailto:carla.finesilver@kcl.ac.uk)

*This paper focuses on the arithmetical understandings and behaviours of one fifteen-year old student with very low attainment in mathematics, as she worked on a sequence of scenario-based partitive division (sharing) tasks with individually-tailored verbal and visuospatial support. The student’s independent and co-created visuospatial representations of arithmetical structures, along with her verbal comments, were analysed qualitatively using a multimodal microgenetic approach. This paper focuses on three particular excerpts which illustrate the fundamentally componential nature of the concept and practice of division, some difficulties that may be experienced when modelling ‘sharing’ tasks, and the pedagogical importance of spatial structuring when a learner is moving between different kinds of representation.*

*Keywords: Visuospatial representation, multiplicative thinking, numeracy, low attainment, special education.*

## Introduction

I encountered Paula during a larger project investigating low-attaining students’ representational strategies for multiplicative structures. Attending a comprehensive school in inner London, she turned fifteen during the study; however, in certain respects her quantitative reasoning more resembled that of a pre-school child. Her particular stage of arithmetical thinking (struggling with the move from additive to multiplicative reasoning) has been of particular interest to researchers, and her reliance on unitary counting-based strategies is a well-known phenomenon. Atypical for Paula’s age, but common in younger learners, was her heavy use of enactive representation with physical media such as cubes. These several factors, along with the slow progress, provided an excellent opportunity for microanalytic case study: to examine this individual’s arithmetical-representational strategies in fine detail, and note even very small changes taking place. Thus, I focused on an arithmetical concept which the participant did not yet comprehend (division), building on an activity in which she was comfortable (counting), within scenario tasks that allowed for multiple representational variations. This paper presents and discusses some brief but illuminative excerpts from my work with her.

## Theoretical background

There is a strong tradition of research into various aspects of early numeracy, such as counting-based arithmetical strategies, taking place in naturalistic teaching/learning environments. Those which focus on children’s own representations of number are often quasi-ethnographic in nature, where (usually very young) children are observed in their mark-making (e.g. Atkinson, 1992) or block-play (e.g. Gura, 1993), and their representations analysed for ‘emergent’ mathematics. Key to this body of work is that it focuses on children’s own, often non-standard, representational strategies; this is in the pedagogical tradition of “de-centring” (Donaldson, 1978), i.e. to shift from an adult perspective and imagine what a scenario, phrase or object might mean to a child. While the details and exact

terminology can vary, in psychological research paradigms some kind of representational progression is also generally assumed, moving from the most intuitive/enactive/concrete models of arithmetical relationships, through iconic/pictorial/drawn forms, to the incorporation of abstract symbols and eventual full formal symbolic notation (e.g. Bruner, 1973). The development of mathematical concepts has also been linked to increasing awareness of pattern, and the ability to make connections between one mathematical representation and another, i.e. to notice similarities and differences, is important for a learner's developing relational thinking. Low attaining students often lack visualisation skills and flexibility, and may indeed find it difficult to replicate and organise representations of groups and patterns (Mulligan, 2011).

Nunes & Bryant (1996), among many others stretching all the way back to Piaget, suggest that to understand multiplication/division represents a significant qualitative change in children's thinking (compared to addition/subtraction) – and so is deserving of particular attention. Regarding the increased complexity, Anghileri (1997) points out that a counting strategy in a multiplication or division task requires three distinct counts: the number in each set, the number of sets, and the total number of items. The second of these – tallying sets rather than units – may be particularly unintuitive for some. Notwithstanding, Carpenter et al.'s (1993) study of kindergarten students (i.e. age 5-6, with <1 year of formal schooling) demonstrated that they could carry out a wider range of division tasks, with greater success, than had formerly been realised – provided the tasks were presented in the form of scenarios which could be directly modelled. Furthermore, they argued that many older students abandon their fundamentally sound problem-solving approaches for the mechanical application of formal arithmetic procedures, and would make fewer errors if they applied some of the intuitive modelling skills of their younger counterparts.

Given this, it is appropriate to combine a subject focus of early division with an analytical focus on informal, nonstandard, and intuitive representational strategies. A previous example is Saundry and Nicol's (2006) investigation of the drawings young children used in division-based tasks, including a 'sharing biscuits' scenario, as used in this study; they describe students manipulating pictures on the page, moving, eliminating, sharing and distributing them, in some cases with patterns of movement resembling the use of physical manipulatives. This is in contrast to much prior research which has analysed visuospatial representations more simply, by organising them into broad categories. However, a third way is possible: considering students' changing representations via an analytical framework of multiple interrelating aspects (Finesilver, 2014).

## Research questions

1. What arithmetical-representational strategies does the student use in division tasks?
2. What do the strategies tell us about their particular weaknesses and capabilities?
3. How do the student's arithmetical-representational strategies change over time and input?

## Methodology

The dataset for this study is taken from a series of four 1:1 problem-solving interviews, each lasting 45 minutes, carried out by the author. While some sessions did include other types of multiplication- and division-based activity (reported elsewhere), a significant proportion of this particular student's time was given over to the 'sharing' tasks described here. It employs microgenetic methods, which

were developed for the study of the transition processes of cognitive development (Siegler & Crowley, 1991). They have been widely used in studies of children's arithmetical strategies and particularly in case studies of individuals with difficulties in mathematics (e.g. Fletcher et al., 1998).

Paula had been described in a past Educational Psychologist's report as having "particularly severe" difficulties with numeracy. This was confirmed through classroom observation by the author, discussion with her mathematics teacher, and a 1:1 qualitative assessment of arithmetical and representational capabilities (see Finesilver, 2014). She demonstrated confident ascending counting and writing of two-digit numbers, and appeared to understand the principles of addition and subtraction well (although made frequent errors in practice). This information was used formatively in devising appropriate in situ tasks and support for developing a basic understanding of division.

In each session, Paula was set a series of partitive divisions expressed via the scenario of a given number of biscuits to be shared between a given number of people. The quantities used were two-digit numbers under 30 that divided exactly by 3, 4 or 5. Numbers were chosen in situ, depending on her arithmetical-representational functioning that day and in previous sessions. Representational media were a particular concern to Paula's teacher, as she was approaching high-stakes national examinations where concrete manipulatives would be unavailable. Thus, scenarios and representation types were chosen that allowed working on first with enactive concrete models, then translation of these visuospatial configurations to graphic form. I gave verbal and visuospatial prompts whenever independent activity came to a halt, up to and including co-creating representations with her.

All sessions were audio recorded, all markings on paper collated, and (when it would not interfere with her work) photographs of concrete representations taken. All markings in purple ink are by the researcher. Each task attempt was considered in terms of the thirteen-aspect analytical framework developed in Finesilver (2014), which covers the type of representation created (*media, mode, resemblance*), the relationships between representation and calculation (*motion, unitariness, spatial structuring, consistency, completeness, enumeration, errors, success*), and teacher-student interactions (*verbal and visuospatial prompts*). Particular attention was paid to any attempts where change in one or more of the aspects was observed; these are considered microgenetic 'snapshots'.

### Data (selected excerpts)

Due to restrictions of space, only a small sample of data may be reproduced in these proceedings; more are included in the accompanying presentation and other publications by the author.

#### Excerpt 1: Difficulties co-ordinating division requirements, Session 1: $15 \div 3$ (Figure 1)

Paula having made no independent attempt at the task "fifteen biscuits shared between three people", I give her a pile of 15 cubes. She first pushes them into two roughly but not exactly equal groups. I restate that **three equal** groups are required, and she distributes them into groups of three. I then draw three *unit containers*, and she pushes three cubes into each. I restate the requirement to share out **all** the cubes, and she adds 1-3 more (unequally) to each circle. I ask if the groups are **equal**, and she counts each group, then adjusts, re-counting, until she can present me with three groups of five. She appears to understand my individual comments, but have difficulty co-ordinating the requirements.

Later in this session, I demonstrate the ‘dealing’ process, emphasising the regular repeating motion. Paula is able to replicate this procedure without error, but does not seem confident that the groups will be equal, and counts each to check.

**Figure 1: Sequence of task attempts; change in *spatial structuring* to introduce unit containers**

### Excerpt 2: Moving from modelling to drawing, Session 2: $15 \div 3$ , $15 \div 5$ (Figure 2)

Paula had been given three drawn circles (as previously) and asked to try to complete the sharing without using cubes. Here she first makes 13 dots in each circle (likely intending 15). I draw new circles, and draw 15 dots above (as a non-concrete analogue for the initial pile of cubes in previous tasks). I demonstrate ‘taking’ dots from the ‘pile’ (by crossing them out) and ‘moving’ them (by redrawing them) into the circles. After watching four dots being dealt out in this way, Paula takes over and continues the pattern of motion, successfully adding dots to the circles in a cyclic sequence (apart from one error in the form of an extra dot, subsequently crossed out). She completes the following task independently and without errors.

**Figure 2: New mode/media, retaining previous *spatial structuring* and *motion***

### Excerpt 3: Confidence in the ‘dealing’ procedure, Session 4: $24 \div 4$

Paula counts out 24 cubes for herself, and deals them cyclically into four circles. However, she pauses in confusion when almost finished. She places her last cube, counts that group and the one next to it, finds them unequal, and twice moves a cube then re-counts (each time finding three groups of six and one group of five) with dissatisfaction. She looks around and finds the last cube (hidden in her sleeve), allowing her to complete the final group. She verbally states “six each” as her solution.

These three ‘snapshot’ excerpts are selected to illustrate particular points for discussion regarding components of division and arithmetical-representational strategies.

## **Discussion**

### **What representational and arithmetical strategies does the student use?**

Paula did not initially have any working representation of her own for use in sharing tasks, and exhibited a ‘helpless’ non-response. While she could read and write number symbols, she could not use them for multiplicative reasoning. However, with a relatively small amount of teacherly input and encouragement, she proved capable of successfully using visuospatial representational strategies to represent equal-groups structures and solve tasks that had previously seemed impossible to her.

Paula’s initial preference was for simple modelling with cubes. However, mixed-media/mixed-mode representations (concrete units in drawn containers) were actually most successful, due to the enhanced spatial structuring of the groups provided by the container forms. At first, she distributed and pushed cubes between groups unsystematically, counting to check for equality, adjusting, and recounting. Later, she adopted the more structured ‘dealing’ procedure.

Paula was willing to move from physical modelling to using fully-drawn representations, with some success. Key to this was keeping both the spatial structuring (i.e. the initial ‘pile’ and container circles) and the dealing motion (repeating hand movement back and forth between the pile and each of the containers in turn) the same as it had been when modelling with cubes, and emphasising this similarity.

### **What do the strategies tell us about their particular weaknesses and capabilities?**

Initially it could be stated with certainty only that Paula knew the division operation required starting with an initial quantity and separating it into a number of smaller quantities (as this was a consistent response in all attempts). This may seem trivial; however, it is not only a necessary component of division, but may be seen as the most fundamental meaning of ‘divide’, prior to any notions of dividends, divisors, quotients, or equality.

Paula made two types of error of particular interest in our sessions on partitive division. On eight occasions she broke the rule that groups must be equal (e.g. Excerpt 1, first attempt), and on seven that the initial number of units must be preserved, i.e. no cubes left over, and no increase through taking extra cubes or drawing extra dots (e.g. Excerpt 1, third attempt). Generally either one or the other of these errors occurred, and sometimes correcting one caused the other to occur. This indicates she experienced a tension in trying to satisfy these apparently-competing demands at the same time.

Paula’s producing of unequal groups implies either that she did not see it as important for groups to contain an equal number, and/or that she did not know a reliable method for distributing them fairly. The latter is indicated, as when reminded, she counted each individual group and took action to even them up. When group sizes were unequal, they only varied by one or two cubes: it is possible that she considered these groups sufficiently equal. For students who struggle significantly with number, it may seem quite reasonable to treat, say, 20 cubes as a continuous rather than a discrete quantity, and thus to perform an approximate rather than an exact division.

Paula's non-preservation of total units implies either that she did not initially see it as important that all of the initial quantity should be distributed, that she believed that including them in the groups already created would conflict with another requirement of the task, and/or that she had simply forgotten about them. The second interpretation seems most likely, as she distributed the remainder when asked, and then re-counted the group sizes to check for equality. There is a small but highly significant difference in Excerpt 3 (compared to previous task attempts): she realises independently that it is impossible to adjust the groups to make them equal, and deduces there is something wrong – I had specified equal groups, and this is impossible unless there is a missing cube.

These observations together suggest that Paula had a three-part conception of division, corresponding to three independent requirements: separation of the initial quantity into groups, that the groups are of equal size, and that all of the initial quantity have been distributed. The priority relationship between the second two requirements was not constant. For most students using a unit-based concrete model, these three stages would be subsumed into one through 'dealing' units cyclically into groups until all of the initial quantity is gone. It is notable that Paula did not initially do this, instead using an unsystematic distribution process. It seems inconceivable that a 15-year-old in mainstream education has never encountered dealing; however, Paula initially did not independently think to use it in these situations. Furthermore, when first trying dealing, she seemed unconvinced of its reliability in delivering 'fair shares'; this implies not initially connecting the structure of the physical dealing action with the numerical structure, visual pattern, or arithmetical operation. The observation that she later stopped checking by counting (when the deal worked out as expected) implies increasing acceptance of it incorporating the structure of, and thus ensuring, equal groups.

Paula's extreme focus on individual countable units, taken with the instances of her sharing into an incorrect number of groups, indicate the possibility (in line with Anghileri, 1997) that she may have difficulty with the very idea of *groups being countable objects*, i.e. with shifting her focus from unit-level to group-level. This interpretation is consistent with both the fact that my drawn containers were helpful to her (through visually reinforcing groups-as-units), and the fact that, despite this, she was somewhat disinclined to draw them independently.

### **How do the student's arithmetical-representational strategies change over time and input?**

Given the level of support required for working with Paula, it is more helpful to consider the overall content of my input and its effect on Paula, rather than individual instances. In summary, I emphasised the three requirements for 'fair sharing', and introduced a practical method for accomplishing this: dealing. I explicitly encouraged visuospatial unitary representation, and introduced an alternative mode (drawing). These were both influential on Paula's ongoing task strategy choices and behaviours.

Although there was a high number of 'teacher-student' interactions, I followed the principle of keeping each teacherly input minimal. Verbal prompts each related to a specific rule that was broken (e.g. unequal sharing) or a single aspect of the task that was misunderstood (e.g. number of groups). In each case, Paula immediately corrected her error (although sometimes making another while doing so). My visuospatial interactions consisted of drawing containers and demonstration or miming of dealing; in each case, Paula was able to take over, complete the representation and use it to obtain an answer to the division task, and then eventually use the same strategy independently. These kinds of

mimicking behaviours may seem trivial to the casual observer, but I argue that for this kind of student it is a significant achievement and important development just to carry out replicatory-structured pattern creation successfully.

While within individual sessions Paula switched from modelling with cubes to drawing, in each subsequent session this temporary confidence had been lost somewhat, and it was necessary to return to the cubes. However, progressively less time was spent in concrete mode, and she also began to draw her own container forms in which to distribute units (examples not included in this paper). It is reasonable to speculate that with further experience, the connections might be strengthened, and the drawn forms regained more quickly and retained for longer.

After I had explicitly demonstrated the dealing process, Paula began increasingly to use this method. While it is true that she required reminding of it in each of the subsequent sessions, she could be observed carrying out the action with increasingly sure and efficient movements. It may be inferred that the repeated success of dealing strengthened her belief in its reliability as a means of fair sharing.

Early on, where Paula had distributed cubes or dots in a disordered way, she often looked at her representation and made adjustments to it via visual approximation, which nevertheless often still resulted in unequal groups. She also presented many incorrect solution representations to me without any attempt to check her work, and simply waited for my response. However, in later sessions, she made attempts to co-ordinate the division requirements herself, for example, checking that all cubes/dots had been distributed and that the resulting groups were equal, addressing these issues if not (e.g. Excerpt 3). Additionally, rather than simply performing a sharing procedure and presenting the representation, she also started to state the group size as her 'answer'.

## **Concluding comments**

A microgenetic level of analysis of this student's arithmetical struggles illuminates certain specific difficulties in conceptualising and carrying out division-based tasks which may be unexpected and go unrecognised in classrooms. It also demonstrates the possibility of improvement even in such severe cases, and has pedagogical implications.

Regarding the concept of division, a three-part deconstruction may be seen: (a) the separation of a quantity into a given number of parts, where (b) those parts are equal, and (c) the original quantity is preserved. Also highlighted is the interplay, and potential for tension, between those requirements, or the overriding of one or the other by partial fragmentary understandings. Where there is difficulty considering more than one 'rule' at a time, what would have been a simple one-stage calculation thus becomes a complex multi-stage process.

Regarding representational modes, the ease with which Paula switched from concrete to graphic representations of numeric relationships is also significant. Translation between representational modes is commonly considered difficult to achieve, particularly for low-attaining students. It was managed here thanks to carefully-designed scenario tasks and representations that maximised and emphasised correspondences and similarities in visuospatial form and structure, and in hand motion.

The nature and degree of Paula's individual difficulties made progress not only extremely slow and effortful, but uneven and unstable; nevertheless, these excerpts indicate changes, however small when

measured against the progress of typically-attaining teenagers. These changes may be considered microprogressions in arithmetical and multiplicative thinking. While it is true that children may sometimes carry out action sequences without understanding their significance, Paula's insecure start but increasingly confident use of dealing – combined with changes in representational mode and accompanying enumeration – indicate a strengthening understanding of the links between the repeated distribution action and the partitioning of quantities into exactly-equal groups. While meaningful symbolic thinking about multiplicative structures may have still been a long way off for Paula, her efforts and achievements in 'learning to deal' deserve appreciation.

# Utilizing dynamic representations to foster functional thinking

Stephan Michael Günster

Julius-Maximilians-University Würzburg, Germany; [stephan.guenster@uni-wuerzburg.de](mailto:stephan.guenster@uni-wuerzburg.de)

*This article proposes a theoretical framework concerned with fostering functional thinking in Grade 8 students in relation to dynamic representations. To explore how functional thinking can be promoted through dynamic representations, tasks were varied systematically for the implementation in the classroom – as evidenced by two exemplar problems presented in this paper. Students' perceptions of engaging with these tasks were ascertained through interviews conducted with Grade 8 students using tablet technology as part of an evaluation of the study. The focus of this evaluation was the effectiveness of the designed tasks for the development of functional thinking and students' skills when dealing with interactive dynamic representations.*

*Keywords: Functional thinking, dynamic representation, variation, tablet.*

## Introduction

The development of the concept of function is an important part of a mathematical education. Working with representations of functions and how to translate between different forms are core skills in this area of learning (Duval, 2006; Höfer, 2008). While there is considerable research concerning the understanding of functions and especially the associated difficulties (e.g. Nitsch, 2015), the increasing availability of digital tools provides the possibility for working with interactive, dynamic and multiple representations. The way students use these representations when developing an understanding of functions has been the focus of substantial research, for example, studies that investigated how students use dynamic representations in connection with different dragging modalities in geometry (Baccaglini-Frank & Mariotti, 2010) or when students explore functional dependence through the use of a dynamic algebra and geometry environment (Lisarelli, 2016). While the benefit of dynamic representations to students is not yet resolved, there is evidence that in certain learning arrangements they are advantageous compared to static representations for the development of functional thinking (Rolfes, 2018) and that computer-simulations are more beneficial than material-based experiments (Scheuring & Roth, 2017).

However, even though interactive, dynamic and multiple digital representations are available, the main goal in mathematics teaching and learning is to develop appropriate mental representations (Weigand, 2014). In this paper, a theoretical framework is proposed as the foundation to design tasks aimed at promoting students' functional thinking through the use of dynamic representations. To this end tasks are designed to support moving from visual to mental representations and foster functional thinking. Insight into this process is provided via the implementation of sample tasks within a Grade 8 classroom. This paper presents the initial findings of this study exemplified through the analysis of two interview protocols.

## Theoretical Framework

This section describes the theoretical framework which was applied to design tasks to foster functional thinking by utilizing interactive dynamic representations.

## Functional Thinking

The teaching and learning of functional thinking have been widely discussed. Usually three characteristic aspects are distinguished (e.g. Doorman, Drijvers, Gravemeijer, Boon, & Reed, 2012; Dubinsky & Harel, 1992; Vollrath, 1989). In the framework utilized in this study, Vollrath's notion is used:

- Assignment aspect: a function creates a relation between two variables. For a given input, an output is calculated. The level of understanding can be determined by how relations are recognized and worked with in different forms of representation.
- Co-variation aspect: a function describes how changes of the independent affect the dependent variable. Typical activities for this aspect are to plan, execute or analyze variations of the independent variable and the resulting covariations.
- Object aspect: a function can be seen as a whole and therefore be dealt with as a mathematical object. This means that attributes can be used to describe a function as a whole (e.g. high points, slope) but can also be derived from it. Furthermore, one can treat functions like mathematical objects in their own right that can be operated on (e.g. add or substitute).

All aspects can be visualized and analyzed if typical representations are seen under a special perspective. However, some representations are more suitable for certain aspects than others. For example, graphs offer the opportunity to display a wide range of pairs of values. This is helpful to view the function as a whole whereas a table only shows a limited number of values. A learner should therefore be able to not only work with but also choose a suitable representation flexibly (Acevedo Nistal, van Dooren, & Verschaffel, 2012).

## The operative principle to develop functional thinking

According to Dubinsky et al. understanding a concept starts with an action as “an action is a repeatable mental or physical manipulation of objects” (Dubinsky & Harel, 1992, p. 85). As actions are repeated and reflected, they may be interiorized as mental processes and later encapsulated into new objects to which then actions can be applied (for details see Arnon et al., 2014, pp. 17–26). Those mental processes are also called operations. Operations can be characterized as reversible, associative and that they can be composed (Piaget, 1967, 47 ff.). However, actions as well as operations cannot be viewed on their own but must be considered as they act on an object. The changes caused to the object by these actions and operations and its properties and relations are to be evaluated. As Wittmann comments “to comprehend objects means to investigate how they were constructed and how they behave when operations are applied on them” (transl. by author from Wittmann, 1985, p. 9). In order to use an investigative approach in the learning process, one should adapt tasks by varying the involved objects, operations or the relations between them to find interesting effects or invariants. Such an approach is referred to as the operative principle (Wittmann, 1985).

The operative principle is useful for developing functional thinking utilizing interactive dynamic representations via digital tools for various reasons. Actions can be performed directly on the given objects, for example, by dragging points or using sliders and the changes can be viewed accordingly. Thereby one can investigate invariances and variations. Relations between different variables can be

studied by varying one variable and examining the changes caused to a dependent one. This can be viewed from all aspects of functional thinking.

To use the operative principle in the classroom, tasks need to be developed which guide the learner to view the problem's different aspects by varying relevant ones. Usually there is a starting condition provided to which operations must be applied to get a target configuration. It seems, therefore, constructive to begin by varying one of those attributes.

In this article we try to answer the following research questions:

1. What is the form of a theoretical framework that describes the relationship between the aspects of functional thinking and the operative principle?
2. How can interactive and dynamic tasks be developed and implemented in order to develop a relationship between aspects of functional thinking and the operative principle?
3. How do students utilize dynamic representations in the context of the developed tasks and how do they reflect and elaborate on their functional thinking?

### The Function-operation-matrix (FOM)

In figure 1 these three aspects of tasks and the three aspects of functional thinking are arranged in a grid – the function-operation-matrix (FOM). To create tasks the problem definition has to first be analyzed regarding which aspect of functional thinking is of interest and its setting (e.g. what is given, what is the target). The FOM is meant to serve as a guide for developing meaningful tasks by selecting cells and varying the problem accordingly.

		Functional thinking		
		Assignment	Co-variation	Object
Variation as proposed by the operative principle	Starting condition			
	Operations			
	Target configuration			

**Figure 1: Function-operation-matrix (FOM) as a guide to create meaningful tasks using dynamic representations for the development of functional thinking**

### Sample tasks

To illustrate this concept two sample sequences of tasks are presented. One typical change of representation which is practiced repeatedly in the beginning of learning about functions is from symbolic formula to a corresponding graph. A coordinate system and a formula are provided, and the learner is required to sketch the graph. One possibility could be to vary the starting condition: Instead of the coordinate system a line is provided and the task is to adjust the coordinate system in such a way that the line represents the given formula (Herget, 2017, p. 9). Using a GeoGebra learning arrangement the coordinate system can be stretched, shrunk, rotated about the origin or shifted as a

whole by dragging the blue points (see figure 2a). Afterwards the result can be checked by comparing the resulting function equation with the given one. The task is described as follows: “A line is given. Adjust the coordinate system in such a way that the line corresponds to the function  $f(x) = 2 \cdot x + 1$ .” This task would be categorized in the FOM within the cell *starting condition – object*, as the learner has to operate with the function as a whole and use its attributes to find the proper configuration. In varying this task further, operations can be restricted, which means moving to the cell *operations – object* (Günster, 2017). For this variation the wording of the task is: “Revisit task 1, with the following restriction. Do not use a) rotation b) shrinking/stretching of the axis.”

A task concerning proportional functions reads as follows: “There is a square ABCD with a side length of 2 cm given. How much does the perimeter of the square change when the side becomes 1 cm longer?” In the FOM, this variation would be located at *starting condition – co-variation* because the change of the dependent variable, the perimeter, under the influence of the starting condition, the length of the side, should be evaluated. As a second subtask one could ask by how much the side must be lengthened to get a perimeter which is 6 cm longer, therefore varying the task according to the cell *target configuration – co-variation*. Subsequently, it can be discussed whether this depends on the initial length of the side of the square or how the problem changes if, rather than a square, a triangle or hexagon is treated. The task then reads as: “For comparison consider an equilateral triangle and regular hexagon. For which figure do you need to change the length of the side the most, to obtain the same change of the perimeter. Explain your answer!” This means extending the task with respect to the cell *target configuration – object*. A dynamic representation is a powerful tool in this case, as the variation of the side can be realized and the relation between the length of the side and the perimeter viewed as a whole by using the trace facility (see figure 2b).

**Figure 2: (a) possible solution ( $y = 2 \cdot x + 1$ ) by shifting the coordinate system and stretching the x-axis (b) studying the relation between the length of the side and the perimeter of regular polygons**

## Methods of the empirical investigation

The interviews presented in the following section were conducted as part of a study at four German Gymnasien (grammar schools) where students are offered the choice of joining a tablet class. Two of the schools made use of iPads, one utilized Android tablets and one used Microsoft Surface devices. In total, five grade 8 classes without and five with tablets were included – a total of  $n = 216$  participants. Teachers were given access to tasks designed according to the FOM described above to use them freely in regular class.

Students were administered a pen-and-paper test at the beginning and at the end of the school year to examine their knowledge regarding functional thinking. Additionally, selected students of different skill levels were interviewed in pairs after half and the full year. Questionnaires evaluated the general usage in school as well as at home through teachers, parents and students. As the study was conducted in the school year 2017/18, only preliminary results are available at this point.

In this paper parts of two interviews are discussed which were run after half a year of working with the tablet in the classroom. The first two students were both female and rated as mathematically capable by the teacher. For the second interview, student 3 was female and student 4 was male while both were estimated to be average students. The students already studied linear functions in class. Both interviews featured first some general questions about the usage of the tablets in class and at home, a few pen-and-paper tasks and, most importantly, two tasks to be solved using GeoGebra for which the screen was recorded using screen capture. The first problem was the one already described above as a sample task to adjust a coordinate system in such a way that a given line corresponds to the function equation  $y = 2 \cdot x - 1$ .

The interviews are analyzed and categorized via qualitative content analysis regarding three guiding questions: how did the students adopt their practiced routines in this scenario? In what way did students use the given dynamic representation? Which aspects of functional thinking did students show? While for the first two questions categories are extracted inductively from the transcripts, the aspects of functional thinking – assignment, covariation and object – are set deductively from the theoretical framework.

## Findings

The presentation of the initial findings is structured according to the three guiding analysis questions.

### Application of routines

First, both student groups adjusted the coordinate system in order to get the correct y-axis intercept. This is in line with their practiced procedure as it is always the first step to draw in the y-axis intercept. For the first group it was possible to just rotate the coordinate system as they rearranged it while testing a number of options, the second one used the shift-option by dragging the origin. This was followed by attempts to try to match the slope.

Again, the students tried to follow their routine implementing the slope by calculating  $\Delta y$  and  $\Delta x$  and thereby finding a second point the line must pass through. They then adjusted the coordinate system accordingly (see figure 3.1). In their first attempt, they made the careless mistake of selecting (1,2) instead of (1,1) since the slope is  $\frac{\Delta y}{\Delta x} = \frac{2}{1}$  but were able to correct it on their own while at the same time explaining their thinking processes. The second group determined the slope by gradually turning and shifting it to make the line pass through to two calculated points. However, they made the common mistake of mixing up  $\Delta y$  and  $\Delta x$  (see figure 3.3) (Nitsch, 2015). Checking their result with the function equation and a little help from the interviewer, the students were able correct the error.

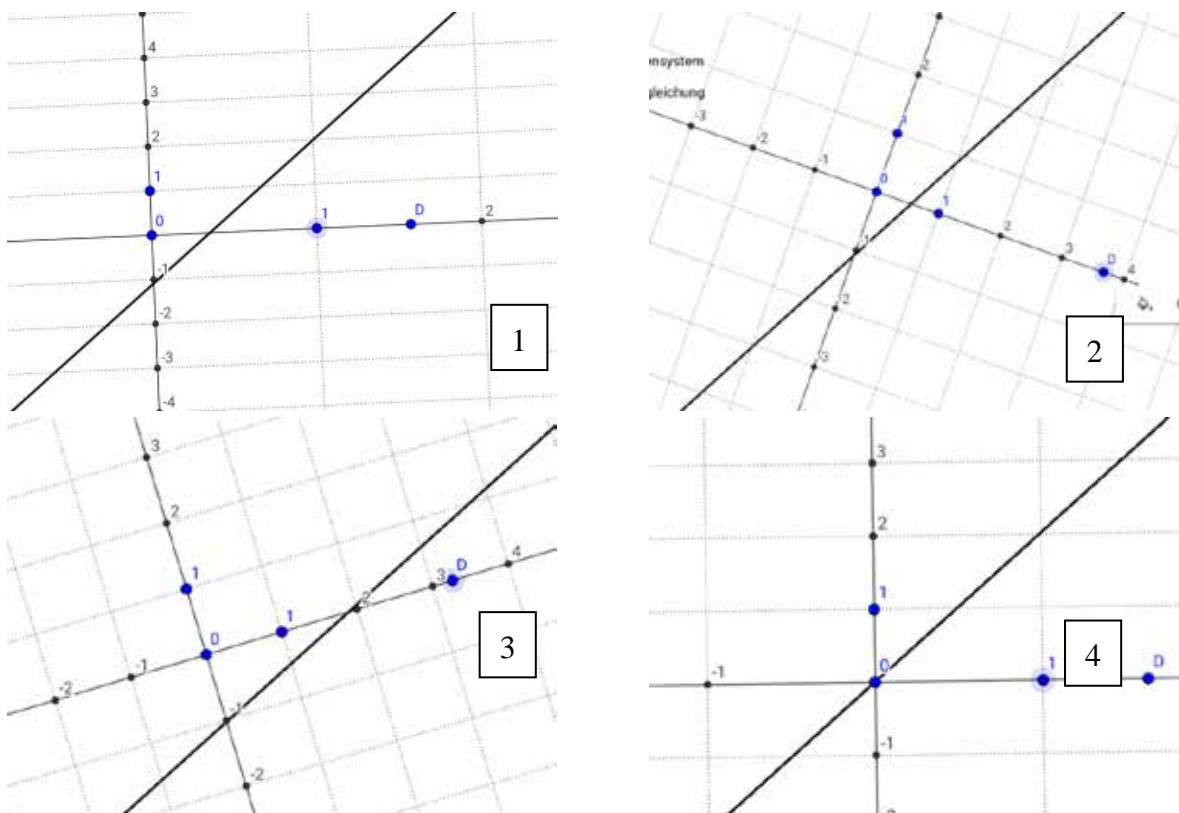

In summary, three possible steps can be identified in students' solution processes: draw in the y-axis intercept; identify  $\Delta y$  and  $\Delta x$  and calculate the slope from the y-axis intercept; or calculate two points and make the line run through those.

### Use of dynamic representation

In implementing these steps using the given dynamic representation, students used similar strategies. For the y-intercept they used whichever tool was available to move the point to the intended position making no difference between them. To make the line run through two calculated points however, they gradually shifted and rotated the coordinate system, e.g.:

Student 2: First, I looked for the y-axis intercept and then I tried to use the rotate turn ... with the slope 2, to pass through this point. And then the y-intercept moved again and again, but then one just has to readjust.

As for implementing  $\Delta y$  and  $\Delta x$  it seemed to the students more appropriate to use the shrink and stretch feature. The second group even adjusted the slope with the line running through the origin and then shifted the coordinate system to match the y-intercept (see figure 3.4.)

**Figure 3: Screenshots taken during the solving process to adapt the coordinate system so that the line corresponds to the function equation  $y = 2 \cdot x - 1$**

### Aspects of functional thinking

The students show only the assignment – through calculating points – or at times the co-variation aspect of functional thinking. For example, when asked about the changes they caused by varying the x-axis, they answer:

Interviewer: What changed, when you were varying the axis?

Student 3: The boxes got larger, when one was at 1 the boxes got like longer.

- Interviewer: When we are talking about linear functions, did the y-axis intercept change? Did the slope change?
- Student 3: No, because it's still 1 to the right and 2 up.
- Interviewer: And regarding this line, which is here...what changes when one varies the x-axis? Does the y-axis intercept change?
- Students are shrinking and stretching the x-axis.*
- Student 3: Mhm. No.
- Interviewer: What does change, though?
- Student 4: Actually, it is only getting more precise.
- Student 3: Only the slope? [...]

The students are able to describe the dynamic representation as they used it, stating that the boxes got larger as well as that it seemed like the coordinate system was getting more precise because of this, since visually it resembles zooming in. However, they have difficulties relating it to the line and the changes which arise through it. They are therefore not able to view the line as a function as a whole.

## Conclusion

This paper describes and illustrates a framework – the function-operation-matrix (FOM) – utilised for the design of tasks used to foster functional thinking via dynamic representations. The FOM combines the operative principle and three aspects of functional thinking. The goal behind this is to develop appropriate tasks for the development of mental representations of functional thinking. Interactive dynamic representations are capitalised upon by visualizing situations and associated mathematical connections and to change these representations through performing actions related to the different aspects of functional thinking.

Two sample tasks demonstrate how the FOM can be used to develop tasks related to different cells within the framework. One can also vary a single problem regarding multiple cells of the FOM. This offers the opportunity to inspect different aspects of the problem and of functional thinking. Thereby, it can also serve as an intuitive way to prepare the focus on the object aspect of functional thinking.

The analysis of the students' solution processes shows that the students had few problems using the given dynamic representations. They adopted their practiced routines for drawing the graph of a linear function according to the available tools. However, they seem to lack the ability to view the changes they made to the representation in respect to the function as a whole – the object aspect of functional thinking. Nevertheless, the task offered a situation in which this aspect could be discussed based on the interactions of the students with the graphical representation. Future research will include additional analysis of other interviews and concerning other tasks in order to confirm the preliminary finds presented in this paper.

# Connecting the everyday with the formal: the role of bar models in developing low attainers' mathematical understanding

Sue Hough, Steve Gough and Yvette Solomon

Manchester Metropolitan University; s.hough@mmu.ac.uk, s.j.gough@mmu.ac.uk,  
y.solomon@mmu.ac.uk

*Use of the bar model has gained momentum in England in recent years through the introduction of Singapore maths. Yet bar models originating from the Dutch approach known as Realistic Mathematics Education (RME), such as the fraction bar, the percentage bar and the double number line, have been available since the late 1990s. In this paper, we discuss the use of the bar in an intervention with low-attaining students in which we employed the RME approach. RME bases understanding in the everyday, where the role of the bar is to sustain modelling across multiple contexts, building on students' informal models. We argue that this context-driven 'bottom up' use of the bar is crucial in supporting progress towards formal mathematics, highlighting important issues to consider in the use of bar modelling, particularly with low attaining students. We suggest a consequent need for caution in use of the Singapore bar as a potential 'top down' model.*

*Keywords: Bar model, realistic mathematics education, singapore bar, low attainers.*

## Background: different versions of the bar model

### The Singapore bar

The success of the Pacific Rim countries in international tests such as PISA (OECD, 2016) has led to the promotion of approaches from Shanghai and Singapore in England, with 'Singapore maths' gaining considerable popularity. Drawing on the work of a number of theorists, but in particular on Bruner's enactive, iconic and symbolic modes of representation (Bruner, 1966), Singapore maths' Concrete, Pictorial, Abstract (CPA) framework focuses on the shift from concrete to abstract via pictorial representations, and features bar modelling as a means of analyzing and solving arithmetic and algebraic word problems.

**Figure 1: Comparison bar model with arithmetic form on the left, algebraic form on the right (from Ng & Lee, pp. 287-8)**

Children in Singapore are taught the method in first or second grade, beginning with the introduction of pictorial representations of quantities using familiar objects such as teddy bears before moving to rectangles in the bar model (Ng & Lee, 2009). Students are taught to recognize a problem type (part-whole, comparison, before-after) and then apply the bar model procedure to find the solution (Ban

Har, 2010). Figure 1 shows the basic comparison bar model. Taken up by the influential National Centre for Excellence in Teaching Mathematics (NCETM) in England, bar modelling ‘is introduced within the context of part/whole relationships... It exposes the relationships within the structure of the mathematics, which are used to find the unknown elements and thus supports the development of algebraic thinking’ (Griffin, nd). Presented in this way, bar modelling focuses on applying a model once the problem structure has been analysed, or as part of the process of its analysis, with the teacher supplying the model and its associated method.

### **The RME use of the bar**

In RME, bar models – including the fraction bar, the percentage bar, the double number line and the ratio table – also take the role of bridging the gap between the learner’s informal understanding of ‘reality’ on the one hand, and the understanding of more formal systems on the other. However, the connection between reality and formal mathematics differs quite fundamentally, in that models are generated from students’ understandings of the context, rather than being offered by the teacher. Mathematical activity emerges from students’ informal models, in contrast to the Singapore use of the bar model which focuses from the outset on the structure of the mathematical problem and the relationships between the numbers involved. This emergent characteristic of RME models means that context plays a crucial role in the process of formalization, supporting extended discussion of models which are then generated as mathematizations of reality rather than being presented as tools for solving particular types of problems<sup>1</sup>.

RME materials expose students to multiple contextual situations which can be represented by a ‘model of’ each particular situation. Designers deliberately choose contexts with potential for developing mathematical thinking; for example, asked to depict how to share a subway sandwich, students may begin by making ‘realistic’ drawings, showing round ends and fillings, but in time will move to a rectangular bar ‘model of’ a sandwich with the ends squared off. Producing a drawing to show how to share the sandwich fairly, marking cuts on the rectangular representation and labelling the pieces with fractions, leads to a bar model picture – a fraction bar. Other contexts such as shading in a rectangular cinema layout to represent the number of seats sold would lead to a percentage bar type of bar model. For some contexts such as marking bottle stops on a race route, it may be more appropriate to draw a line showing distance on one side and bottle stop positions on the other. This is sometimes described as a ‘double number line’ but would still be classed as a type of bar model, where the bar has been flattened to look like a line. Overall, models in RME “should ‘behave’ in a natural, self-evident way. They should fit with the students’ informal strategies – as if they could have been invented by them...” (Van den Heuvel-Panhuizen, 2003, p. 14).

### **Conceptualising progress and the role of the bar model**

How models are used in teaching has implications for the conceptualisation of progress. Whereas the Singapore model is based on Bruner’s enactive-iconic-symbolic framework as a progression heuristic, in RME, progress is indicated when students start to see the similarities between ‘models

---

<sup>1</sup> It is important to note that in RME ‘real’ means imaginable (Van den Heuvel-Panhuizen, 2003, pp. 9-10).

of' situations, and are consequently able to generalise the use of these models and apply them to other problems. At this point they are able to make a shift towards using a bar to represent a situation which is *not* obviously 'bar like', using a bar as a 'model for' solving a problem. Thus progress is defined in terms of formalisation of models (Van den Heuvel-Panhuizen, 2003), and in particular the progression from 'model of' to 'model for' (Streefland, 1985). So, for example, students may begin to see how they can use a bar to represent survey data, and to develop connections between segmented bars, pie charts and fractions, ultimately using a bar to compare and add fractions. This shift is also described as vertical mathematisation (Treffers, 1987), where students recognise the mathematical similarity between different problems and are able to choose an appropriate model to solve a problem. Models, in this view, are far more than given strategies for solving problems; they are central to building the understanding needed to deconstruct a problem. In particular, models in RME depend on a 'bottom-up' process in contrast to a 'top down' approach which offers the model ready-made, to be overlaid onto the problem.

The contrasts between the use of models in RME and the Singapore method raise some questions regarding the current popularity of the Singapore bar – in particular, “what is being modelled, and by who?” The Singapore bar appears to be introduced by the teacher as a ready-made *model for* a mathematical problem rather than being generated by the learner from a context that will support the development of a situated *model of* that has meaning for them, and on which they can build to generate a *model for* which they genuinely own. In this paper, we explore how a group of low-attaining students worked with the bar in an RME-based intervention which aimed to support them to progress beyond poorly learned algorithms towards a deeper understanding of mathematics which is based on their own informal models. Thus, we ask the following research questions:

1. How do students use the bar within an RME context?
2. To what extent do students make progress in terms of moving towards 'model for'?

We consider the implications for the widespread adoption of Singapore bar modelling in the English context of pressure to move quickly towards formal mathematics and algorithmic approaches.

## Methodology

In England, a large percentage (around 30%) of students fail to gain an acceptable pass grade in mathematics in national examinations (GCSE) at the age of 16 each year, and resit success rates are poor (DFE, 2017). Resit courses tend to be short (around 8 months) and focus on revising the same methods which students have already failed to learn and remember, hence the larger study of which this is a part investigated the impact of materials based on RME in four GCSE resit classes across three different sites in the North-West of England, during 2014-15. The research team developed and delivered two short modules focusing on number (12 hours) and algebra (9 hours), employing a quasi-experimental design. For reasons of space, we focus on the number module in this paper. Number teaching materials were designed to draw on contexts that supported students in producing situation-dependant bar-type representations and solutions, thus enabling the natural emergence of the bar as a 'model of'. For example, fair sharing problems required students to share out candy strips, pizzas and ribbon, all of which were chosen for their rectangular and hence bar-like properties. Lessons were delivered by three members of the research team, all experienced RME teachers. They followed the

RME practice of emphasis on discussion of the context, moving from students' informal (and life-like) representations of the context (e.g. buying ribbon, mapping water stops on a fun run, sharing a subway sandwich) to discussion of their various strategies for problem solution, and finally to bar models produced by the students.

One of the questions for this intervention is whether students can recognise the potential of the bar model and associated strategies as '*models for*' tackling problems where use of the bar is not suggested by situation-specific imagery (see Van den Heuvel-Panhuizen, 2003, pp 17-29). All students took a short test prior to and at the end of each module. The number test problems were chosen to reflect a range of topics in proportional reasoning, and covered ratio, proportion, finding a percentage of an amount, finding a fraction of an amount, comparing two rates and a reverse percentage calculation. Each question made reference to a context, but unlike in the teaching materials, the contexts were not suggestive of a bar-like representation. Questions were designed to reflect typical GCSE questions on the target subject matter, but students were additionally asked to explain their answers in order to reveal differences in levels of conceptual understanding.

Seventy-five students participated in the intervention classes and 72 in control classes. In the main study, independent evaluators found small but significant gains for the intervention group on the number post-test ( $F_{1,93}=4.55$ ,  $p=0.035$ , Cohen's  $d = 0.26$ ). They also found a significant correlation between students' improvement from pre- to post-test and the extent to which they used an RME approach (use of the bar or ratio table to solve the problem) ( $r = .258$ ,  $n = 86$ ,  $p = .016$ ) (see Hough et al, 2017, Appendix 8.5). Here, we investigate these findings further through qualitative analysis of the number pre- and post-test scripts in order to identify how students used the bar and its contribution to their learning. Our analysis involved comparing pre-test and post-test solutions by categorising responses given in terms of:

- (1) use of the bar or ratio table versus standard methods/trial and error;
- (2) correct labelling/division of bar parts, and scaling accuracy;
- (3) the bar strategies employed, for instance partitioning/ adding;
- (4) error types: inappropriate halving, incorrect adding, incorrect bar representation; and
- (5) evidence of progress.

## Findings

### The extent to which students could vertically mathematise their use of the bar

In post-test scripts, 73 % of intervention students chose to draw a bar-type model for at least one of the questions. In contrast, methods used in their pre-test scripts referred to operations denoted purely by numbers and symbols. Control group students were highly unlikely to draw a pictorial representation in order to solve a problem. These overall statistics suggest that the intervention led many students to recognise the potential of the bar model as a model *for* tackling a variety of problems, and in that sense to vertically mathematize.

However, it is not enough for students to simply apply the bar model method to the problem. One of the factors which distinguishes RME models is whether the learner perceives the model to be 'emergent' or 'imposed'. Emergent models are described by Gravemeijer and Stephan (2002) as one

of the key design heuristics of RME: models are grounded in reality, they make sense to the learner and even when the model progresses to a more formal version, the learner can always fall back on the original meaning in order to make sense – they are ‘bottom up’ (p. 146). But although the designer may intend engagement with the model to be ‘bottom up’, this does not necessarily guarantee the model will be experienced in this way. Hence, there may be cases where a learner’s experience of working with RME-based models results in a classical ‘top down’ engagement whereby the model is imposed by the teacher in the traditional sense of demonstrating formal procedures. In the next two sections, we look at examples of students using the RME bar model from both a ‘bottom up’ and ‘top down’ perspective.

### The bar model as a ‘bottom up’ sense making strategy / model

For many post-16 GCSE resit students, their experience of learning mathematics involves being shown formal procedures which they can make little sense of, and which they are rarely able to accurately reproduce. The pre-test scripts contained numerous mis-representations of formal procedures, for example writing 17% of £3300 as  $\frac{3300}{17} \times 100$ , calculating  $\frac{5}{8}$  of £600 by replacing  $\frac{5}{8}$  with 0.58, and incorrect additive strategies for two proportionally related quantities. However, analysis of the post-test scripts revealed several examples of sense-making through use of an RME bar model, as in the following three examples.

**Figure 2: Student A pre-test (left) and post-test (right)**

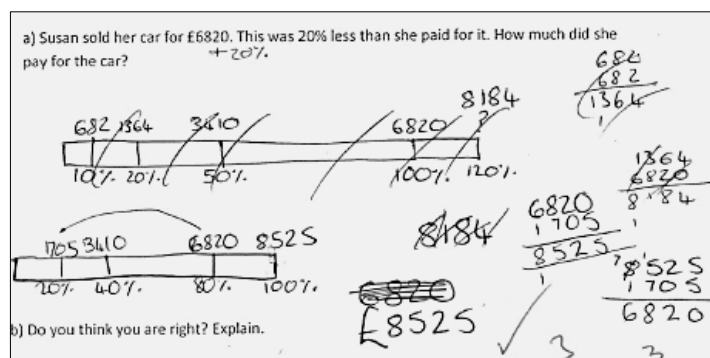

Student A’s pre-test solution (Figure 2, left) may be interpreted as an example of a half-remembered procedure - multiply something by 2 and something by 5. In the post-test (Figure 2, right), in an answer typical of 33% of scripts, she has drawn a bar split into 7 parts and labelled as a continuum from 0 to £140, and she has used shading to distinguish the portions on £140 allocated to Pat and Julie. Here, the student has created a bar model representation which correctly depicts the required sharing processes.

In the next example, Student B demonstrates knowledge of the standard formal procedure used to find a fraction of an amount in her pre-test, but is unable to go any further, commenting that she does not know how to calculate the division  $600 \div 8$  (Figure 3, left). In the post-test, and in common with 20% of scripts, she was able to work out an alternative strategy, targeting the values of  $\frac{4}{8}$ ,  $\frac{2}{8}$ ,  $\frac{1}{8}$  of £600 and combining these to find  $\frac{5}{8}$  (Figure 3, right). Her successful modelling of the problem on a bar enabled her to employ informal approaches to see the relationships between the numbers.

**Figure 3: Student B pre-test (left) and post-test (right)**

The third example concerns a question requiring students to find the original price of a car, when the current price of £6820 is 20% less than the original. Although none of the control students were able to answer this question in either the pre- or the post-test, 18% of intervention students used a bar to model and solve the problem (Figure 4).

**Figure 4: Representing reverse percentage on the bar**

Reverse percentage problems of this type are notoriously difficult for students to access, not least because the standard method involves setting up an equation in one unknown. Representing the information on a bar enables further sense-making in terms of providing opportunities for filling in what else the student knows, and enabling them to build up to the required percentage amount.

### The bar model as yet another ‘top down’ procedure/model

We have seen examples above where students used the bar as a *model for*, enabling them to represent the question and link it to mathematical strategies which they could make sense of and therefore use effectively. However, in the next two examples, we see students able to operate with the bar model, but their subsequent strategies suggest that they are unable to connect the model with meaningful mathematical activity. For example, the student in Figure 5 (left) applied several cycles of halving and combining chunks to fill in as far as the  $\frac{1}{16}$ th way point on his bar, but given that the bar is split into 7 pieces, these calculations served no purpose in finding one part. Some students – around 10% – always marked the half- and quarter- way points of their bars, even when the divisor was an odd amount, suggesting a top down use of the strategy. Figure 5 (right) shows a bar model being used to solve a question which asks how long a photocopier takes to produce 30 copies if it takes 18 seconds

to produce 12 copies. The student has used a bar to model the situation for 24 copies, marking up the bar in one second segments, but has then simply extended the bar by 6 segments to reach 30 copies, omitting to realise that the model shows that one copy takes 1.5 seconds. The error of adding one second for every copy implies that drawing the bar has not provided this student with genuine insight into the underlying structure of this problem. Rather, the bar model has been used as a ‘top down’ model, here, applied without real linkage to the context.

**Figure 5: Top down use of the halving strategy (left) and Using the bar in top-down fashion (right)**

## Discussion

These findings show that the bar has the potential to enable progress. Drawing a bar-type model enabled students to represent problems in helpful ways, allowing some to engage with informal sense-making strategies. The model enabled them to fill in other quantities in order to provide a more complete and detailed representation of the problem. Many students applied an RME method to several post-test questions, suggesting that they were beginning to recognise the unifying potential of the models as a strategy for answering questions across a range of topics in number, and that they were beginning to vertically mathematise and see how to apply their context-specific models to a range of problems.

However, the transition to using a bar model is not unproblematic, and it does not provide an instant solution. Indeed, the issue of inappropriate halving suggests that students can move towards treating the bar as yet another algorithmic method. The intervention was short and as such represented an over-simplification of the RME process, but this served to expose the fragility of these particular students with regard to number sense and their ability to make connections. The complexity of their response to the bar, and the importance of its use for sense-making and not just method raises questions for the Singapore approach to bar-modelling. The significance of this issue is highlighted by Ng and Lee's (2009) analysis of Singapore 5<sup>th</sup>-graders' solutions to a variety of problems, in which high achievers scored well, but mid-level achievers' strategies often showed erroneous use of the model. Incorrect solutions involved the omission or misrepresentation of crucial information, changing unit generators mid-solution, failure to keep the overall goal in mind, or lack of necessary conceptual knowledge (of fractions, for example) - children were using the method algorithmically, failing to monitor what they were doing. Arguing for the importance of discussion in the classroom about different strategies for solution and the development of meta-cognition in problem

representation, Ng and Lee (2009) note that the bar model must be used ‘as a problem-solving heuristic that requires children to reflect on how they would accurately represent the information presented in word problems .... This art of representation has to be taught, but it is then the children’s responsibility how they choose to use this heuristic effectively’ (pp.311-2). Ng and Lee’s warning underlines the potential danger in the Singapore bar’s reliance on formal conventions in terms of which bar model is required to solve a problem and how the bars should be labelled. From an RME perspective, we would ask what are the contextual mediums that enable struggling students to gain access to these conventions. The model offers learners a way to represent algebraic word problems, but how do students lacking number sense negotiate meaning once the bars can no longer be drawn to scale, or when, as Ng and Lee (2009, p. 308) note, they are challenged by the concept of fraction and represent the relationship between rectangles erroneously? We suggest that these considerations need to be taken into account in the adoption of Singapore bar modelling, where students, not the teacher, need to own the model.

# Visualization of fractions – a challenge for pre-service teachers?

Ellen Konstanse Hovik and Camilla Markhus Rodal

Oslo Metropolitan University, Norway; [ellehov@oslomet.no](mailto:ellehov@oslomet.no) and [camilro@oslomet.no](mailto:camilro@oslomet.no)

*Most pre-service teachers (PSTs) are familiar with the algorithm for addition of fractions. The work for teacher education is to help PSTs to "unpack" the algorithm in order to gain breadth and depth in their understanding. In this paper, we investigate which representations PSTs prefer to use when asked to visualize and explain addition of fractions on a national exam in Norway. We discuss in which ways they demonstrate why and how the standard algorithm works. Our analysis shows that the PSTs prefer to illustrate the sum of two fractions using the sub-construct part-whole in a rectangle shaped area model.*

*Keywords: Visualization, explanation, fractions, pre-service teachers.*

## Introduction

There is a widespread agreement that teachers need a certain understanding of mathematics in order to explain not only *how*, but also *why* different approaches work. Therefore, in teacher education by focusing on different methods of representation in the learning of mathematics topics, PSTs will be better able to analyse and understand their pupils' mathematical thinking and thereby be able to provide the best possible support and help in their teaching (Ma, 2010; Lovin, Stevens, Siegfried, Wilkins, & Norton, 2016). Through a national exam, PSTs at all of Norway's teacher education institutions are tested to find out whether they possess such knowledge, for example of fractions.

We will investigate which methods Norwegian PSTs undertaking the national exam, choose to use when asked to illustrate and explain addition of fraction to pupils in school. Our research questions are: Which representations do the PSTs prefer to use? In which ways do they demonstrate why and how the algorithm works?

## Research background and theoretical underpinnings

There is broad agreement that many pupils find the concept of fractions and calculations with fractions problematic. "*Fractions are without doubt the most problematic area in mathematics education*". (Streefland, 1991, p. 6). One reason for this could be the great conceptual leap from whole numbers to fractions (Ni & Zhou, 2005; Lamon, 2012). Another reason may be the introduction of algorithms without understanding (Mack, 1993), or too little variation in forms of representation (Sowder, 1998). A third reason for pupils' difficulties could be the complexity of the concept of fractions.

Fractions can be interpreted in different ways. In conceptual terms, fractions can be seen as both the ratio between two whole numbers and as one number. Behr, Lesh, Post, and Silver (1983) describe five sub-constructs: *part-whole*, *ratio*, *quotient*, *operator* and *measure*. A too narrow focus on only one sub-construct of fractions can lead to inadequate understanding (Behr et al., 1983). Although fractions as a part-whole seems more concrete than, for example, fractions as a measure, this sub-construct has its limitations, particularly when the fraction is greater than one (Mack, 1993).

It is possible to use individual forms of representation or a combination of several. When teachers present fractions to their pupils, it is important that they are aware of the strengths of different representations and how they can work together to reinforce each other. Lesh, Post, and Behr (1987) propose five different forms of representation: *manipulative models*, *static pictures*, *real scripts*, *spoken language* and *written symbols*. These forms of representations apply to all sub-constructs of the fraction concept. A single focus on the sub-construct part-whole can lead teachers to use solely representations such as rectangles, circle sectors or other variants of area models. From naming fractions as parts of areas to identifying fractions as points on the number line is a significant turning point for pupils. They have to understand that, on the number line, the whole is defined as the interval from 0 to 1 (Ball, 2017). Freudenthal (1973) describes the number line as “the most valuable tool (...) it can be an excellent means of visualizing the four main arithmetical operations”.

How teachers choose to teach can vary greatly from teacher to teacher. Ma (2010) states that it is important for teachers to have what she describes as a “*profound understanding of fundamental mathematics* (PUFM)”. A teacher with PUFM can present different and varied approaches to a solution, in addition to seeing the advantages and disadvantages of the approaches and is able to offer different explanations to the pupils, focusing on basic concepts and principles of mathematics, and demonstrating horizontal knowledge. A teacher with such qualities shows understanding and sees connections in mathematics in a thorough manner, which can result in greater understanding both in breadth and in depth for the pupils.

In the article “*Toward a theory of proficiency in teaching mathematics*”, Schoenfeld and Kilpatrick (2008) present a provisional framework for proficiency in the profession, where “*Knowing school mathematics in depth and breadth*” is the first category. Breadth refers to teachers being able to provide multiple ways of conceptualising relevant subject matter knowledge, knowing varied forms of representation, understanding key aspects of the different topics and seeing connections with other topics at the same level. Depth refers to knowledge about the basis for and further development of the curriculum in the subject and knowledge of how mathematical ideas are conceptually developed.

## Method

We have collected our material from 114 PSTs’ answers on the national exam in fractions in spring 2017. The exam is compulsory and is held by all institutions during the semester in which the primary and lower secondary teacher education programmes have fractions on their course plan. The exam consists of 20 tasks, we have focused on one of the tasks.

The exam question we have analysed: *Draw an illustration with an explanation that can be used in primary and lower secondary schools to show the solution to the problem  $\frac{3}{5} + \frac{1}{2}$ .*

It is important that the examiners grade the papers as similarly as possible. For this reason, a team of examiners from different institutions was established. They made grading guidelines pointing out which answers should give two, one or zero points:

To be awarded two points, the candidate must include an illustration with a good explanation either by using fractions or by converting to decimal numbers and arrive at the correct solution. If the answer is greater than 1, it is most appropriate to use a length/number line

model, but other models for fractions can also be used. To be awarded one point, the candidate must find the correct solution to the problem but provide an illustration or explanation with shortcomings. Answers that only include algorithmic calculations are awarded zero points. (Our translation) (NOKUT, 2017).

Additionally, all answers were graded by two examiners chosen by the Norwegian Agency for Quality Assurance in Education (NOKUT).

We have analysed 114 answers, which constitutes approximately 10% of all the answers in the exam. The answers are anonymised with respect to both the PSTs identity and what institution they are affiliated to. This was done before the answers were coded. The 114 answers are therefore randomly selected and can be said to represent primary and lower secondary PSTs in Norway.

We coded the answers in two rounds (shown in Table 1 and 2). The codes were entered in SPSS together with the points awarded by the examiners and analysed. We were both involved in grading the submissions in the national exam. Experience from this work, combined with the grading guidelines and Lesh et al.'s (1987) five different forms of representation formed the basis for our initial codes (Table 1). In the first round of coding, we used three different codes for the models: *Area model rectangle*, *area model sector* and *number line*. The code “*good explanations of transition to a common denominator*” is used for a written text that explains the transition to the common denominator by combining the static picture of the models with the calculation. The initial coding revealed a need for a more detailed coding of the methods of explanation, particularly the use of illustrations, language and how they worked together. In the second round of coding, we therefore reviewed all answers that had been awarded one or two points (Table 2).

## Results and analysis

We started the analysis by looking at all the 114 answers. Of these, 65 candidates were awarded two points by the sensor team from NOKUT, 34 were awarded one point and 15 got zero points. The answers that were awarded zero points contained purely algorithmic calculations or had arrived at the wrong answer and were for that reason left out for the rest of the analysis, leaving us with 99 answers. In the first phase of coding, we focused on different illustration methods and solution strategies. Using the codes given in Table 1 we wanted to see how the different models/forms of representation were distributed. In Table 1, we distinguish between those who were awarded two and those awarded one point by the examiners chosen by NOKUT. We wanted to see if there were any evident differences.

Strategies, models and representations used	Two points (65)	One point (34)
Changing to common denominator	51 (79%)	29 (85%)
Changing to decimal numbers	1	0
Number line	2	1
Area model rectangle	58 (89%)	27 (79%)
Area model sector	4	4
Draws one tenth as part of the whole	44 (68%)	10 (29%)
Good explanation of transition to a common denominator	36 (55%)	4 (12%)

**Table 1: Coding results – first round**

Table 1 shows that some of the main differences between those awarded two points and those awarded one point are whether they have included a good explanation of how to find the common denominator and whether they illustrate one tenth as part-whole. This indicates that the PSTs rewarded two points show a depth and breadth in their understanding of this particular task (Schoenfeld & Kilpatrick, 2008). The form of representation preferred by most of the PSTs, regardless of the points they received, is the rectangle. Very few PSTs choose to use sectors and even fewer use a number line.

As many as 51 of the 65 answers that were awarded two points, have been coded with a good explanation of how to find the common denominator. 25 of the 51 answers are coded for both a good explanation of how to find the common denominator and the conversion to the common denominator. This shows that many PSTs find the common denominator without linking it to a good contextual or visual explanation of the conversion itself. Nearly all the answers (33 of 36) that were coded for a good explanation of how to find the common denominator use a rectangle to illustrate this. This could indicate that this way of illustrating the problem is regarded as a suitable way of explaining the need for a common denominator. Rectangles are easy to divide into equally sized congruent parts that can then be added together.

Amongst the PSTs awarded one point, 85% find the common denominator. This could be due to the fact that PSTs who use a visual explanation of the addition without proceeding through the calculation of the common denominator are awarded two points (for an example of such an answer, see Figure 4). The exam text does not require them to find the common denominator. Here as well, we see that the four PSTs (Table 1) who have been coded for a good explanation of how to find the common denominator have used a rectangle. One explanation for them, nonetheless only being awarded one point, could be that they do not draw the proper fraction part of the mixed number in the correct way. Instead, they choose to draw a separate part without linking it to the whole.

During the first round of coding (shown in Table 1), we saw that many PSTs use illustrations to show the calculations they have made, rather than the other way around. For example, some use illustrations to show the need to divide the rectangles into equal parts to be able to perform the addition. After analysing the answers based on which strategies and models/forms of representation are used, we saw a need to further examine whether the PSTs based their answer on an arithmetic calculation and how they choose to illustrate the algorithm. During the second round of analysis, we therefore looked more closely at the connections in the explanations, whether algorithms are generated or only presented and what role the illustrations and textual explanations play. By algorithm, we mean the following calculation method:

$$\frac{3}{5} + \frac{1}{2} = \frac{3 \cdot 2}{5 \cdot 2} + \frac{1 \cdot 5}{2 \cdot 5} = \frac{6}{10} + \frac{5}{10} = \frac{11}{10}$$

Codes	Explanation of the codes	Number of respondents
A1	Illustrates the whole calculation	20
A2	Illustrates the common denominator and the answer	19
A3	Illustrates only the answer	3
A4	Good written explanation of the calculation	17
A5	Illustrates the calculation, not the answer	3
A6	Illustrates the task and the answer	10

A7	Illustrates only the task	4
B	Generates the algorithm	7
C	Good visual and written explanation. Without arithmetic calculation	19
C2	No good explanation, no arithmetic calculation	19

**Table 2: Coding results – second round**

Table 2 shows that there is variation in the methods of explanation among the 99 answers, where we see that different variants of code A are the most common. These PSTs have calculated the common denominator by using the algorithm and have illustrated the whole or some of the steps of the algorithm. Figure 1 shows an example where all the steps are illustrated. This PST has first shown detailed arithmetic calculations and repeated them under the rectangles. The PST has also included a good written explanation. This is an example of the three different representations working together. According to Ma (2010), different approaches such as arithmetic, illustration and a good explanation of how to solve the problem are important. The drawings and text underline and confirm the calculation without deriving the calculation method.

Text: What I have done is to draw big 'boxes' of equal size divided into  $\frac{3}{5}$  and  $\frac{1}{2}$ . To solve this, we must first find the common denominator and I have therefore drawn up two boxes and divided them into 10 sections, as this is the common denominator of both fractions. We then shade the number of sections that are in the nominator and add these to find out that the answer will be  $1\frac{1}{10}$ .

**Figure 1: Answer paper coded A1**

In the second round of analysis, we saw that some PSTs illustrated the calculation and answer, but not the problem, before expanding the fractions. Figure 2 shows an answer where the 'last part' of the algorithm is illustrated. There is no visual generation of the algorithm itself, it does however give a good illustration of the answer. The PST manages to convey that it is more than a whole. The problem with choosing an area model in the illustration of a task where the answer is an improper fraction, is to illustrate it in a way that makes it easy for the pupils to see that it is  $1\frac{1}{10}$ , and that the tenths are clearly shown in the illustration. This PST has also used a real-life context in the written explanation, as described by Lesh, Post and Behr (1987).

Text: Ola has  $\frac{6}{10}$  of a bar of chocolate. He gets  $\frac{5}{10}$  of a bar of chocolate from Kari. He is then left with  $\frac{11}{10}$ , which is a whole bar of chocolate plus  $\frac{1}{10}$ .

**Figure 2: Illustration showing the common denominator and solution, coded A2**

As shown in Table 1, most PSTs choose to use rectangles in their illustrations. We find some interesting differences in those answers who drew rectangles divided into equal sized smaller rectangles. As shown in Table 2, different steps of the calculation are illustrated. During our work on the analysis, we also saw examples of lack of clarity in relation to equivalent fractions. An example is shown in Figure 3, two rectangles, described as fifths and halves, are divided into 10 parts. Ma (2010) emphasises that it is important to work thoroughly on connections with breadth and depth. For pupils, it is difficult to see this connection if they do not know that  $6/10$  is equivalent to  $3/5$ . Then the illustration in Figure 3 will be hard to understand.

**Figure 3: Example of tenths being referred to as fifths and halves**

The task in this national exam does not specifically ask for the algorithm and we used the codes C and C2 for the answers without the algorithm (C or C2 depending on how good the explanation/illustration is). Figure 4 shows an answer where the PST illustrates and explains well without showing the algorithm arithmetically (Code C). The answer, together with the explanation, demonstrates a breadth and depth of understanding, highlighting how the PST can vary the forms of representation used, and use them to complement each other. Both Ma (2010) and Schoenfeld and Kilpatrick (2008) describe these as important elements in showing good understanding.

Text: First, I draw a rectangle, then I divide it into 10 equal parts and shade  $\frac{3}{5}$  of them, which is 6 of the parts. Then I draw a similar rectangle, with just as many and equally large parts and shade  $\frac{1}{2}$  of these, i.e. 5 parts. When I add the shaded parts, I find that I get a full rectangle where all 10 parts are shaded and a rectangle with the same amount of parts of equal size, where only one is shaded. The answer will then be  $1\frac{1}{10}$

**Figure 4: Good explanation of the steps of the calculation, coded C**

Very few students choose to interpret the task in such a way that there is a need to generate the algorithm, for example using an inductive approach where the need for the algorithm ‘makes itself known’. Such an approach has been coded B. This code has been difficult to use since most students start their written response by showing the algorithmic calculation.

## Concluding remarks

These analyses show that PSTs in Norwegian teacher education programmes prefer to illustrate the sum of two fractions using rectangles and the sub-construct part-whole. This finding is in conflict with what the grading guidelines suggest as most natural, namely using a length/number line model. The PSTs prefer to use an arithmetical representation and a written text in addition to the illustration.

Most of them starts with the arithmetical calculation before they explain the steps further with the other two representations.

The fact that so few PSTs chose other forms of representation than the area model rectangle could be because the PSTs as a group have not developed the qualities that Ma (2010) describes as important for becoming a teacher with PUFM, namely the ability to vary approaches to solving a problem. It could well be the case that the PSTs are familiar with the different sub-constructs of fractions, but that many of them regard the area-model rectangle as the best illustration for explaining addition of fractions with different denominators to pupils. The rectangle model is easier to divide efficiently than for example the area model sector. We see that many PSTs point out that they divide the rectangles into equal parts (Figure 1 and Figure 4). As seen in Figures 1 – 4 the examination paper delivered from NOKUT to all PSTs during the exam has grid lines. This might also have led some of the PSTs to the use rectangles. Although most PSTs use the rectangle as an illustration, the analysis shows great differences in how this is done. Some of them illustrate all the steps, from the calculation to the answer, while others only illustrate how they find the common denominator or only illustrate the task (Table 2).

There were also major variations in the ways the PSTs show how and why the algorithm works, not only between PSTs awarded one or two points for this particular task in the national exam, but also within the group that received two points. In teacher education, the PSTs encounter concepts such as forms of representation and solution strategies, and they work on examples where they combine these in order to help pupils understand fractions. If you calculate the common denominator and then illustrate this calculation with a rectangle, it will be possible to see that they work together because the illustration underpins the calculation and provides a visual expression of the calculation.

Because of the way in which this particular task is worded, it could be understood to mean that the illustration should generate the algorithm (Code B), and that the need for a common denominator can be apparent from an illustration. This approach could entail an interpretation of the illustration as a tool for helping pupils discover the need of equal parts before the algorithm is presented. Very few PSTs interpreted the task in this way. This suggests that they currently lack the mathematical understanding that breadth and depth proficiency in school mathematics entails (Schoenfeld & Kilpatrick, 2008). At the same time, some of those who start to show the calculation of the answer have good illustrations and good explanations (Code A4, Table 2) and are close to generating an algorithm. Many of the answers contain strategies and representations that can serve as support for pupils who are working on the addition of fractions with different denominators, which is after all promising for the teachers of the future. On the other hand, maybe the reason that so many PSTs respond in a similar way to this task is that they see it as an algorithm for “illustration with an explanation”.

Our material is collected from a written school exam, which has its limitations when it comes to identifying breadth and depth in the PSTs knowledge. Among other things various forms of representation like the oral explanation, and the gesticulation and dialogue that are part of a teaching situation are lost. It is also important to emphasise that the PSTs in our study are halfway through a learning process and that they still have several years to go before they are qualified teachers.

## Leveraging difference to promote students' conceptions of graphs as representing relationships between quantities

Heather Lynn Johnson, [Evan McClintock](mailto:evan.mcclintock@ucdenver.edu), and Amber Gardner

University of Colorado Denver, School of Education and Human Development, Colorado, USA;  
[heather.johnson@ucdenver.edu](mailto:heather.johnson@ucdenver.edu), [evan.mcclintock@ucdenver.edu](mailto:evan.mcclintock@ucdenver.edu), [amber.gardner@ucdenver.edu](mailto:amber.gardner@ucdenver.edu)

*By creating different Cartesian graphs to represent the same relationship between quantities, students can expand their conceptions of what graphs represent. Interweaving Marton's variation theory and Thompson's theory of quantitative reasoning, we designed digital task sequences to promote students' conceptions of graphs as representing relationships between quantities. In the tasks, which link animations and dynamic graphs, students created different graphs to represent the same relationship between quantities. We report results of a qualitative study (n=13) investigating secondary students' interactions with the digital tasks in an individual interview setting. We found that the digital tasks were viable for promoting students' creation of graphs to represent relationships between quantities. Our findings have implications for task design. Namely, students should have opportunities to create different graphs to represent the same relationship between quantities.*

*Keywords: Graphs, Computer Simulation, Instructional Design, Learning Theories, Secondary school mathematics*

The term *representation* can have many meanings (e.g., Kaput, 1998). We use representation as both a noun and a verb. Employing the term representation as a noun, a student can conceive of a graph as a representation of a relationship between quantities. Employing the term representation as a verb, a student can engage in representation by creating a Cartesian graph to represent a relationship between quantities. Interweaving Thompson's theory of quantitative reasoning (Thompson, 1993; 2002) and Marton's variation theory (Kullberg, Kempe, and Marton, 2017; Marton, 2015), we designed digital task sequences linking dynamic animations and graphs to engender secondary students' creation of Cartesian graphs to represent relationships between quantities. In this study, using individual clinical interviews, we investigated what secondary students (n=13) intended to represent when interacting with digital tasks linking Cartesian graphs and dynamic animations.

### Theoretical and conceptual framing

#### Representation and intention

We distinguish a representation from an inscription, the latter of which refers to some observable artefact (e.g., Kaput, 1998). From our perspective, an inscription can only be a representation if that inscription represents something for an individual or group. When we claim that a student is "representing," we interpret that the student did something more than just creating some observable artefact (e.g., a graph). We mean that the student intended to represent some "thing" with that graph, and that we have evidence to support our claim.

We aim to study what students *intend* to represent when working on digital tasks linking Cartesian graphs and dynamic animations. In any task setting, there are tensions between the intentions of the task designers/researchers and the intentions of the students engaging with the tasks (Johnson, Coles,

& Clarke, 2017). Theoretically, we acknowledge that we cannot know the intentions of others. We can only infer those intentions based on observable evidence. Furthermore, we do not assume that students will share a stated task aim with that of the designer/researcher. For example, we intended to provide students multiple opportunities to create different Cartesian graphs to represent the same relationship between quantities, and we did not assume that students interacting with the tasks would share our intentions.

### **Interweaving Marton's variation theory and Thompson's theory of quantitative reasoning**

To frame our study, we interweave two theories: Thompson's theory of quantitative reasoning (Thompson, 1993; 2002) and Marton's variation theory (Kullberg et al., 2017; Marton, 2015). In his theory of quantitative reasoning, Thompson explains students' mathematical thinking in terms of students' conceptions of attributes. Thompson (1993) posited that quantities were something different from units of measure. Rather, quantities depend on students' conceptions. If a student can conceive of the possibility of measuring some attribute, then that attribute is a quantity for the student. For example, a student may view an animation of a "Cannon Man," who is shot vertically into the air, then comes back down to the ground. In this situation, there are many different attributes. Cannon Man's total distance traveled—both up and down—would be a quantity for that student only if she can conceive of the possibility of measuring Cannon Man's total distance.

Difference, rather than sameness, forms the essence of variation theory (e.g., Kullberg et al., 2017; Marton, 2015). With variation theory, Marton and colleagues explain how designers can develop instructional sequences to promote students' discernment of critical aspects of objects of learning. Kullberg et al. (2017, p. 560) link discernment and variation, core components of variation theory, positing "Discernment cannot happen without the learner having experienced variation." Furthermore, the type of variation matters. If a designer intends for students to discern critical aspects of an object of learning, students should have opportunities to experience variation (difference) in those critical aspects (Marton, 2015).

In designing our study, we intended to provide opportunities for students to conceive of a graph as representing a relationship between quantities. Drawing on Marton's variation theory, we argue that students' conceptions of what is possible for Cartesian graphs to represent is inseparable from their experiences with different Cartesian graphs. Drawing on Thompson's theory of quantitative reasoning, we argue that designers' choices of attributes can impact students' opportunities to conceive of Cartesian graphs as representing relationships between quantities.

### **Students' conceptions of what Cartesian graphs can represent**

It is useful for students to have opportunities to conceive of graphs as representing relationships between quantities (e.g., Bell & Janvier, 1981; Johnson & McClintock, 2018; Kerslake, 1977; Leinhardt, Zaslavsky, & Stein, 1990; Moore, Silverman, Paoletti, & LaForest, 2014; Thompson, 2002). Yet, researchers have documented secondary students' challenges with creating and interpreting Cartesian graphs (Bell & Janvier, 1981; Johnson & McClintock, 2018; Kerslake, 1977; Leinhardt, Zaslavsky, & Stein, 1990). We identify three key challenges. First, students may interpret graphs as needing to share characteristics with a physical object, such as a hill (Bell & Janvier, 1981; Leinhardt et al., 1990). Second, students may interpret graphs as sharing physical characteristics with

the physical path of an object, such as a person's walk from one location to another (Bell & Janvier, 1981; Kerslake, 1977). Third, students may interpret graphs as representing a single varying quantity, rather than as a relationship between quantities (Johnson & McClintock, 2018).

To engender opportunities for students to interpret graphs as relationships between quantities, designers can incorporate variation in individual attributes within a single graph and variation across different graphs incorporating the same attributes. Thompson (2002) argued that students could use their fingers as tools, sliding them along each axis of a graph, to represent change in individual attributes. In a study investigating prospective secondary teachers' reasoning, Moore et al. (2014) incorporated different graphs representing the same attributes on different axes. When making choices about the kinds of variation to incorporate within and across our digital task sequences, we drew inspiration from the work of Thompson and Moore.

### The digital task sequences

We report on two digital task sequences: The Cannon Man and the Toy Car. In each digital task sequence, students engaged in five main tasks, shown in Table 1. We drew on Thompson's theory of quantitative reasoning and Marton's variation theory to design and sequence the tasks in each situation. First, students had opportunities to discern and conceive of measuring attributes (Tasks V, A1). Second, students had opportunities to represent change in individual attributes (Task A2). Third, students had opportunities to represent attributes changing together (Task G1). In Task G2, we introduced a difference, against a background of invariance—a different Cartesian graph, with the same attributes represented on different axes. Across the digital task sequences, the Cannon Man and Toy Car situations served as different backgrounds.

Task	Description
V	<b>View video animation.</b> Students viewed a video animation of a situation depicting an object in motion, identified attributes in the situation, and discussed how they might measure those attributes.
A1	<b>Identify task attributes.</b> Johnson stated attributes on which that task would focus. If students had not already identified those attributes, they then discussed how they might measure the task attributes.
A2	<b>Represent individual attributes.</b> Students dragged dynamic segments along the axes of a Cartesian plane to represent change in individual attributes. Then, students viewed a computer-generated video of the dynamic segments changing together.
G1	<b>Represent attributes changing together.</b> Students sketched a single Cartesian graph relating both attributes. Students discussed how their graphs showed (or did not show) both attributes at the same time. Then, students viewed a computer-generated graph.
G2	<b>Re-represent attributes in a new Cartesian plane.</b> In a new Cartesian plane, with the same attributes represented on different axes, students re-represented individual attributes, then attributes changing together (Repeat tasks A2, G1).

**Table 1: Descriptions of tasks in the Cannon Man and Toy Car digital task sequences**

## Methods

### Setting/participants

We implemented the digital task sequences with 13 high school students in a high performing suburban high school in the metropolitan area of a large US city. Five students were in ninth grade (~15 years), and currently enrolled in an Algebra I course. Eight students were in eleventh grade (~17 years), and currently enrolled in an Algebra II course. At the school, 52% of students identified as students of color, and 36% of students qualified for free or reduced lunch (an indicator of low socioeconomic status).

We conducted the study over a 4 week time period near the end of the school year. Students volunteered to participate in the study. Johnson conducted a series of three clinical interviews with individual students (39 interviews). Interviews occurred once or twice per week, with at least one day between interviews. Students who participated in all three interviews received a graphing calculator, which they could use for exams and classwork at their school. We conjecture that students who participated in the study were motivated, in part, by the opportunity to receive a graphing calculator.

### Research methods: Clinical interviews, exploratory teaching

During the clinical interviews, Johnson engaged in exploratory teaching (Steffe & Thompson, 2000) to investigate the viability of the digital tasks for promoting students' conceptions of graphs as representing relationships between quantities. In the interview design, Johnson included questions to gather evidence of what students were intending to represent when sketching a graph. These questions included: "What you are trying to graph?"; "Can (How does) your graph show both \_\_\_ and \_\_\_ (the task attributes)?" ; "Look at a point on your graph, can (how does) this point give you information about \_\_\_ and \_\_\_ (the task attributes)?"

The first interview, which served as a preassessment, involved a Ferris wheel situation. In the Ferris wheel situation, students engaged in tasks V, A1, and G1 in the digital task sequence (See Table 1). The second and third interviews, which incorporated the digital task sequences described in this paper, involved a Cannon Man and a Toy Car situation, respectively. In all interviews, students worked on a digital tablet (an iPad).

### Ongoing and retrospective data analysis

All interviews were video recorded. During each interview, either McClintock or Gardner wrote field notes. To promote consistency, we used a field note template, which broke down each interview into sub tasks, to write field notes for each student in each interview. Field notes included evidence of students' conceptions of task attributes as possible to measure and capable of varying, as well as evidence of students' intentions to use a graph to represent a relationship between quantities.

We focused retrospective analysis on students' responses to the Cartesian graphing tasks (Tasks G1 and G2, see Table 1). Across the set of three interviews, students had opportunities to sketch five Cartesian graphs. Johnson and McClintock viewed video of each student's work on each of the Cartesian graphing tasks. In the first pass, we described three aspects of students' work: Sketches of (or attempts to sketch) a viable graph; Explanations of their graph (or attempt) in terms of both attributes; Gestures related to their graphs. In the second pass, we made inferences about students'

representing. We used different codes to characterize students' representing. Table 2 provides descriptions of each code. In the third pass, we examined students' shifts in representing across the Cartesian graphing tasks in each interview, building from observable evidence to develop explanations to account for students' shifts.

Code	Description of code
Relationships between quantities	Students sketched (or attempted to sketch) a single graph. Students described or showed how a single graph could represent a relationship between two quantities.
Individual quantities	Students sketched two separate graphs. Students described each graph in terms of only one quantity (e.g., the "height" graph).
Motion of objects	Students sketched a graph that showed the motion of an object in the situation (e.g., a toy car moving along a path). Students described the graph in terms of motion.
Iconic/Familiar objects	Student sketched a graph that looked like an iconic object or familiar graph. Students described the graph in terms of its physical characteristics.

**Table 2: Descriptions of codes characterizing students' representing**

Viewing video alphabetically by students' pseudonyms, we completed the first and second passes for each Cartesian graph task in the Ferris wheel and Cannon Man situations. Next, we analyzed the Toy Car situation, which resulted in refinements to our codes. In particular, we expanded the code for relationships between quantities to include attempts to represent quantities not explicitly represented (e.g., time). In each pass, we first coded individually, then vetted codes as a team.

Although some students demonstrated evidence of more than one form of representing within a task, we elected to use a single code for students' representing within that task. When we coded a form of representing for a task, a student may have shifted to engaging in that form of representing after an "aha" moment or engaged in that form of representing throughout their work on the task. If a student demonstrated partial evidence of one form of representing, but engaged more consistently in another form of representing, we weighed the evidence, then coded the form of representing that we interpreted to best characterize the students' reasoning in that task.

## Results

We found that the digital task sequences were viable for promoting students' creation of Cartesian graphs to represent relationships between quantities. Table 3 shows the numbers of students engaging in each type of representing across the Ferris Wheel, Cannon Man, and Toy Car graphing tasks. In the Ferris Wheel preassessment graphing task (Ferris Wheel G1, see Table 3), four students (two ninth grade; two eleventh grade) created graphs to represent relationships between quantities. All four of these students continued to represent relationships between quantities in the Cannon Man and Toy Car graphing tasks (Cannon Man G1 and G2, Toy Car G1 and G2, see Table 3). We share results from the nine students who, in the Ferris wheel preassessment graphing task (Ferris Wheel G1), demonstrated forms of representing other than relationships between quantities. By the end of the Cannon Man and Toy Car task sequences, four of these nine students shifted to representing relationships between quantities (Harun, Aisha, David, and Amanda). Five of these nine students

(Kara, Gemma, Carmen, Keshia, and Eliza) continued to represent (or shifted to representing) the motion of objects.

Code	Ferris Wheel G1	Cannon Man G1	Cannon Man G2	Toy Car G1	Toy Car G2
Relationships between quantities	4	6	9	7	8
Individual quantities	2	2	2	1	0
Motion of Objects	4	5	2	5	5
Iconic objects /familiar graphs	3	0	0	0	0

**Table 3: Students engaging in each type of representing across tasks**

### **Shifts to representing relationships between quantities**

The two students (Harun, eleventh grade; Aisha, ninth grade) who represented individual quantities on the Ferris Wheel preassessment graphing task (Ferris Wheel G1) represented relationships between quantities by the end of the interview sequence. Harun shifted to representing relationships between quantities on the first Cannon Man graphing task (Cannon Man G1). Across the Cannon Man and Toy Car task sequences, Aisha continued to represent individual quantities for the first graphing tasks (Cannon Man G1, Toy Car G1). It was only on the second graphing task in each sequence (Cannon Man G2, Toy Car G2), that Aisha shifted to representing relationships between quantities.

The three students who represented iconic objects/ familiar graphs on the Ferris Wheel preassessment graphing task (Ferris Wheel G1) were in eleventh grade. Two of those students, David and Amanda, shifted to representing relationships between quantities in the Cannon Man task sequence. Amanda shifted in the first graphing task (Cannon Man G1), relating directions of change in Cannon Man's height and distance. In contrast, in the first graphing task (Cannon Man G1), David represented the path of Cannon Man. It was not until the second graphing task (Cannon Man G2) that David worked to represent relationships between Cannon Man's height and distance. Notably, David was the only student who shifted from representing motion of objects to representing relationships between quantities.

Two of the four students (Kara, eleventh grade; Gemma, ninth grade) who represented motion of objects on the Ferris Wheel preassessment graphing task (Ferris Wheel G1) demonstrated partial evidence of representing relationships between quantities on the Cannon Man graphing tasks (Cannon Man G1, G2). In the second Cannon Man graphing task (Cannon Man G2), both Kara and Gemma explained how their graphs represented Cannon Man's height and distance. Yet, in both Toy Car graphing tasks (Toy Car G1, G2), they attempted to represent the physical path of the toy car.

### **Shifts to other forms of representing**

Two of the four students (Carmen, eleventh grade; Keshia, ninth grade) who represented motion of objects on the Ferris Wheel preassessment graphing task (Ferris Wheel G1) shifted to representing change in individual attributes on at least one of the Cannon Man graphing tasks. In the second

Cannon Man graphing task (Cannon Man G2), both Carmen and Keshia attempted to represent change in Cannon Man's height and distance. Yet, in both Toy Car graphing tasks (Toy Car G1, G2), they attempted to represent the physical path of the toy car. Furthermore, one of the students who represented iconic objects/ familiar graphs (Eliza, eleventh grade) shifted to representing the motion of objects in the first Cannon Man graphing task (Cannon Man G1). Once shifting to representing the physical path of Cannon Man, Eliza continued to represent motion of objects in the rest of the tasks.

## Discussion

We aimed to leverage difference to promote students' conceptions of graphs as representing relationships between quantities. By interweaving Marton's variation theory and Thompson's theory of quantitative reasoning, we worked to achieve our aim. Drawing on Marton's variation theory, we incorporated difference within and across task sequences. Within each task sequence, students had opportunities to create different graphs to represent the same relationship between quantities. Across task sequences, we incorporated different backgrounds (Cannon Man/Toy Car), as well as different kinds of graphs (linear/nonlinear). Thompson's theory of quantitative reasoning informed our choices about the kinds of differences that might engender students' quantitative reasoning. Because Cartesian graphs represent relationships between quantities, students had opportunities to vary each quantity represented in a graph. Furthermore, we argue that variation within a graph is insufficient to foster students' conceptions of a graph as some "thing" capable of representing a relationship between quantities. Drawing inspiration in part from the tasks reported in Moore et al. (2014), we incorporated different graphs representing the same relationship between quantities.

We posit that our descriptions of codes indicate increasing levels of sophistication in students' representing with Cartesian graphs; however, we do not claim that each of these levels is a necessary step in a progression of reasoning. When representing iconic objects/familiar graphs or the literal path of an object in motion, students are representing physical phenomena in a situation. When representing quantities, or relationships between quantities, students are mathematizing a situation in terms of attributes they can conceive of as possible to measure. We argue that engendering students' shifts from representing iconic objects/familiar graphs or motion of objects to representing individual quantities and relationships between quantities is important for expanding students' conceptions of what graphs can represent.

Students' conceptions of the direction and nature of the motion of objects in a situation can impact their opportunities for representing relationships between quantities. The Toy Car situation proved useful for investigating the stability of students' representing relationships between quantities, in part because the graphs did not share physical characteristics with the literal path of the toy car (e.g., a graph moving up and down as did the Cannon Man). To promote students' creation of Cartesian graphs to represent relationships between quantities, task designers should incorporate graphs that do not share physical characteristics with motion of the objects in task situations.

## Acknowledgement

The development of the digital task sequences was supported by a US National Science Foundation Grant (DUE-1709903). This study was supported by a Faculty Development Grant from the

University of Colorado Denver. Opinions, findings, and conclusions are those of the authors. We thank Dan Meyer for his support of the development of the digital task sequences in Desmos.

## Introduction

Noble, Nemirovsky, Wright, and Tierney (2001) provide multiple references regarding the “strong support in the mathematics education community for the view that students should encounter mathematical concepts in multiple mathematical environments” (Noble et al., 2001, p. 85) and be able to connect these. This poster explores, via a case study, some of the related challenges for the restricted setting of using diagrammatic or graphical representations for arithmetic and algebraic problems. It uses a framing of ‘lived-in spaces’ (Nemirovsky, Tierney, & Wright, 1998) and the underlying research question is, “how can we support the use of diagrammatic or graphical representations becoming a ‘lived-in space’ for users?”

The case study is structured around a particular problem, set out as follows. There are three circular cardboard discs. A number is written on the top of each disc: (6), (7), (8). There is also a number (not necessarily the same) written on the reverse side of each disc. Throwing the discs in the air, and then adding the numbers on the faces, I have produced the following eight totals: 15, 16, 17, 18, 20, 21, 22, 23. Can you work out what numbers are written on the reverse side of each disc? (Association of Teachers of Mathematics (ATM), 1977).

In at least two instances, one – a professional development workshop with a group of 40 secondary mathematics teachers in England, and two – an online discussion group of mathematics educators, none of the initial shared approaches used a graphical representation of the problem, even when unknown variables were denoted by  $x$ ,  $y$  and  $z$ , and could have suggested 3-D Cartesian space. This is striking as a graphical analysis of the problem can help bring to the fore much of the underlying structure. To clarify this, in our case study, two mathematicians, one who had solved the problem graphically and one who had solved it non-graphically, worked on it together for an hour. This was captured and analysed using multimodal microanalysis as by Nemirovsky and Smith (2013).

## Theoretical Background

Those working on the above problem had access to graphical representations but what seemed absent is the creation of a *graphical space* (Nemirovsky et al., 1998) – a ‘common place’ where symbols and their referents are made accessible and sensible. Nemirovsky et al. (1998) develop three themes: *tool perspectives*, *fusion*, and *graphical spaces* to analyze students’ use of a computer-based motion detector in the context of graphing. These three themes are not dependent on the technological nature of the tool and, we propose, apply equally to our setting, with graphical representation being the tool. Indeed, as Nemirovsky et al. (1998) observe, “Tool perspectives look at development of graphical space through simultaneously exploring the qualities of the tool and relation between actions and symbols. Fusion is about the blending of action and symbol in discourse within the graphical space”

(Nemirovsky et al., 1998, p. 124). The growing familiarisation with a graphical space as it is populated with experiences and actions, which make it a space for purposeful and creative activity, is encapsulated by the notion of lived-in space. Noble et al. (2001) propose that “the mathematics that students learn from working in a given environment emerges from their process of making that environment into a lived-in space for themselves” (Noble et al., 2001, p. 86). Our work aims to draw out how the use of graphical representations can become a lived-in space.

## Methodology and results

This case study uses a conversation between two mathematicians to investigate what actions and experiences contribute to fluid and effective approaches to solve the problem and how this can enable the fostering of a related lived-in space. Audio and video data were captured and analysed using constructs from the above referenced papers. The findings have two aspects: (i) an analysis of graphical and non-graphical solutions of the problem and (ii) observations on how the relevant lived-in space can be fostered, and related conclusions. We briefly outline the graphical approach:

1. The chosen number on a disc is independent of the other discs so choices can be modelled in 3-D space, one dimension for each disc. A choice of numbers, e.g., (6,7,8) gives a point in this space.
2. Flipping a disc results in a fixed addition or subtraction – representable by a translation vector.
3. It follows that there are eight choices of 3-tuples and these correspond to vertices of a cuboid.
4. The resulting constraints on the possible sums enable all possible solutions to be determined.

In relation to lived-in spaces, moving to-and-fro between different representations, translating expressions that are clear or articulable in one realm to the other, considering their affordances and constraints, and reflecting on these, provides opportunities for learners to make the graphical space a more familiar lived-in space. This also enables learners to experience and exercise graphical representation in ways which move it from being a representational tool to a more expressive tool.

# Capturing ‘time’: characteristics of students’ written discourse on dynagraphs

Giulia Lisarelli<sup>1</sup>, Samuele Antonini<sup>2</sup> and Anna Baccaglini-Frank<sup>1</sup>

<sup>1</sup>Università di Pisa, Italy; giulia.lisarelli@dm.unipi.it, [anna.baccaglinifrank@unipi.it](mailto:anna.baccaglinifrank@unipi.it)

<sup>2</sup>Università di Pavia, Italy; [samuele.antonini@unipv.it](mailto:samuele.antonini@unipv.it)

*We study high school students’ written discourse about an experience in a dynamic interactive digital environment in which functions were represented in one dimension, as dynagraphs. In a dynagraph of a real function one variable can be acted upon while the other varies as a consequence of the movement induced on the independent variable. Students were asked to write about their experience with the dynagraphs, and their written productions were collected and analyzed using a classification, that emerged a posteriori, in “snapshots, live-photos and scenes”. This classification is presented as a tool of analysis that allows to put discourse about dynagraphs in relation with discourse about functions. Examples of excerpts analyzed through this tool are given.*

*Keywords: Covariation, dynagraph, dynamism, function, time.*

## Functions, covariation, graphs, and dynagraphs

Functions and their graphs have always had a leading role in mathematical practice, including school practices. Being able to interpret the Cartesian graph of a function and to construct a graph starting from the function’s properties are essential processes in mathematical thinking. However, these processes include an understanding of the meaning of *variable* and of the *relation between variations* of the variables, that is *covariation*; and several kinds of difficulties that students encounter when grappling with these ideas are widely reported in the literature (e.g.: Tall, 1992, 2009; Kaput, 1992; Monk & Nemirovsky, 1994; Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Thompson & Carlson, 2017).

A Cartesian graph is defined as the set of points  $(x, f(x))$  with real coordinates on the Cartesian plane, where  $x$  belongs to the domain of the function and  $f(x)$  is its image; these constitute a curve incorporating the functional relation between the two variables. Students encounter various difficulties when dealing with graphs, one being in recognizing that each point on the graph is a coordinated presentation of two pieces of information (Colacicco, Lisarelli & Antonini, 2017). This leads them to consider the curve to be the function itself and to identify a point on the curve only as its  $f(x)$  value. Both the asymmetric relation between the variables and their covariation are lost.

In this paper we focus on the use of a particular technological artifact to represent functions, realized through a dynamic interactive environment (DIE). Many research studies support the use of technology in the teaching of functions (Healy & Sinclair, 2007; Falcade, Laborde & Mariotti, 2007). Here we are interested in representing functions through DynaGraphs (Goldenberg, Lewis & O’Keefe, 1992), dynamic representations in which the domain variable is dynamically draggable on a line and it is presented separately from its image. Both the  $x$ - and  $y$ -axes are horizontal; originally, they were referred to as “the  $x$  Line” and “the  $f(x)$  Line”. DynaGraphs cannot be constructed without using a DIE, where objects can be moved on the screen.

The independence of the  $x$  variable is realized by the possibility of freely dragging a point, bound to a line (the  $x$  Line), and the resulting movement visually mediates the variation of the point within a specific domain. Whereas the dependence of the  $f(x)$  variable is realized by an indirect motion: the dragging of the independent variable along its axis causes the motion of a point, bound to another line (the  $f(x)$  Line), that cannot be directly dragged. The use of dragging can visually mediate the discourse on functional dependency, since it can help students interpret the exploration in terms of logical dependency between two different types of motion: direct and indirect motion.

**Figure 1: Screenshot of a dynagraph used in this study**

The authors, together with Nathalie Sinclair, built on the original idea of DynaGraphs to realize functions as in Figure 1, within the dynamic geometry software Sketchpad (a similar design was adopted also in Lisarelli, 2018) which will be called *dynagraphs* (no capitals, to distinguish them for the original ones) in this paper. Many properties of a function can be recognized in a dynagraph. For example, looking at the movements of the two variables that either follow the same direction or move in opposite directions, an expert can recognize when a function is increasing – if both variables have the same direction of movement – or when it is decreasing – if the variables move in opposite directions. The movement and the identification of invariants are central in the exploration of dynagraphs, since the DIE enables students to deal with the dependence relation in terms of possible or impossible movements; we are interested in how this dynamic and temporal experience can be narrated on a static sheet of paper – a process that is frequent in mathematics.

Many researchers have described the relations between movement, time and mathematics, in particular in calculus. Tall (2009) describes calculus as the mathematical field that begins with the desire to quantify how things change, the function, the rate at which they change, the derivative, and the way in which they accumulate, the integral. So, this field is fundamentally dynamic: even the calculation of static quantities, such as areas or volumes, involves dynamic processes of adding up a large number of very tiny elements. At a certain historical moment, a transformation took place and calculus turned into rigorous definitions, developing into the formal theory of mathematical analysis which is used today by textbooks and by many teachers. This transformation led to the teaching of calculus based on the definition of limits, which satisfies mathematicians' logical needs, but it proves to be rather complicated for students (Tall, 1992). However, even if formal mathematical discourse aims at eliminating time and dynamism, this does not imply that mathematicians engage in purely a-temporal modes of thinking. Indeed, they seem to frequently communicate in ways that suggest they think of mathematical objects in motion (Sinclair & Gol Tabaghi, 2010).

### **Theoretical background and research focus**

For this study we make use of discourse analysis; in particular, we adopt the commognitive theoretical perspective (Sfard, 2008). According to Sfard, communication and cognition are two manifestations

of a same phenomenon and mathematics can be considered as a special type of discourse, or communication. Mathematical learning is the process by which students become able to communicate about mathematical objects, that, unlike others, are purely discursive objects that can have different *realizations* (p. 165). Moreover, mathematical discourse, as a particular kind of discourse, involves a frequent use of *visual mediators*, visible objects realizing the object of the discourse (p. 133).

In this study, we use dynagraphs as particular realizations of the mathematical object ‘function’ within a DIE, in order to allow students to experience the dependency between two covarying quantities in terms of motion. This approach brings temporality into play. We intend to study how students deal with the temporal dimension that characterizes their experience in the DIE, when they are asked to describe it through a written explanation. Moreover, we are interested in the mathematical aspects expressed in these written explanations, especially in how variation of variables and covariation – the relation between variations – are conveyed.

The research question that led the design and the development of this study is the following:

What are characteristics of students’ written discourse on dynagraphs related to their management of the movement and time experienced during the exploration that can be put in relation with discourse about functions (as mathematical objects)?

## Methodology

We designed 7 dynagraphs of functions to be explored. The markers realizing the two variables had no labels, because we wanted to allow students to decide which words or symbols to use. We consider this to be an important process related to distinguishing the two variables and the asymmetric relation between them. The two points 0 and 1 were marked on the lines with ticks in order to provide the unit segment and to highlight that the lines visually realize two copies of the real numbers.

Students belonging to four different 10<sup>th</sup> grade classes of Canadian high schools worked in pairs on as many dynagraphs as they had time for during one lesson (60 minutes). Their task was to “explore the dynagraphs on the iPad and write down their observations about them” on the whiteboard and/or on paper. We collected these written productions. This task was designed to “force” the students to describe in writing an experience which was completely time-and-motion-immersed.

### Tools of analysis: snapshots, live-photos, and scenes

From analyses of the high school students’ written productions we reached a characterization that was later refined through further rounds of analysis of the excerpts. Coherently with our research interest in gaining insight into how movement (the variation of position in time) enters students’ written discourse we introduced a first possible characterization of written accounts of the experiences in the DIE, using a terminology that refers to images in the context of photos and videos. In Table 1 we define the main types of accounts and describe characteristics of the discourse it characterizes, both in the case in which the discourse is about the dynagraph (which may or may not be related to the notion of function for the students) and when it is about the function realized through the dynagraph.

Type of account of the DIE experience		Discourse about dynagraph	Discourse about function
snapshot	<u>snapshot</u> : photo at a certain position showing one or more properties	provides an instantaneous shot in which movement is stopped at a certain position	pointwise properties
	<u>snapshot-album</u> : set of snapshots, each showing something in particular	expresses properties in selected positions; these constitute a finite discrete set; each property is shown in one snapshot	pointwise properties at a particular set of points
	<u>snapshot-cluster</u> : set of snapshots showing relationships between them	one or more properties are described through a comparison of snapshots of the dynagraph; the focus is on the relationships between snapshots; it may be in a sequence coherent with the order on the line or not.	properties that refer to variation and/or to invariants in specific intervals identified by analyzing and comparing different points
live-photo	<u>live-photo</u> : animated photo showing what happens a bit before and a bit after a certain instant.	one or more properties that depend on the nearby positions are described at a certain position; certain positions of the dynagraph are shown close to a specific position	local properties of functions, at a specific point and the variations in any neighborhood of the point.
scene	<u>scene</u> : video showing movement over a period of time; it can be realized through snapshots, or live-photos, in an album or cluster.	description of one or more properties of the movement over an arc of time, in an interval of real numbers, or in the space covered by the point moving along the line; it includes various positions. The intervals can be limited or unlimited; the scene can be described statically or dynamically	properties of functions that are global, general, or present in a whole interval

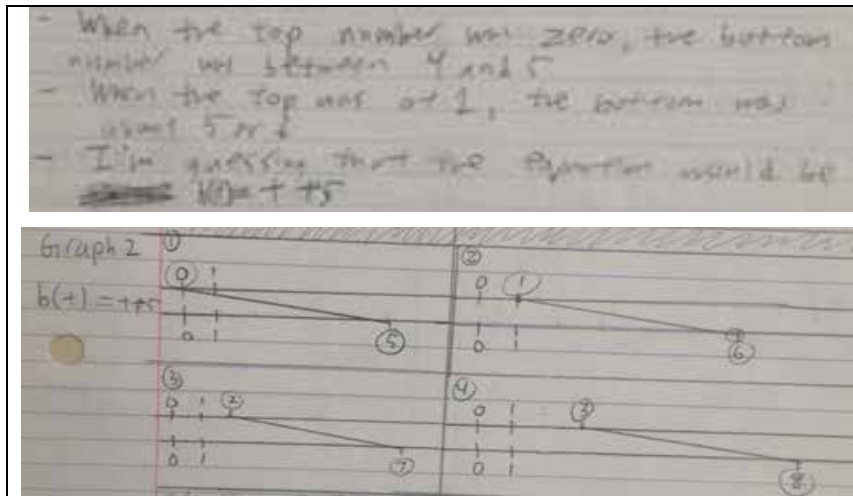

**Table 1: Characterization of students' written discourse**

Table 1 shows the main types of accounts (snapshot, live-photo and scene) and their further characterization with respect to ways in which more than one could be used (as albums or clusters) in the excerpts of written discourse that we will now analyze.

We observe that live-photos may also be found in albums and in clusters. A live-photo album is set of live-photos, each showing something in particular; it expresses properties in selected positions, which constitute a finite discrete set; each property is shown in one live-photo. From a mathematical point of view, these correspond to local properties in neighborhoods of a particular set of points. A live-photo cluster is a set of live-photos showing relationships between them.

### Analysis of students' written products

This section contains examples of analyses of students' written products using the characterization.

**Excerpt 1: Scene of snapshots depicted through written words and diagrams****Figure 1a,b: Scene of snapshots**

“When the top number was zero, the bottom number was between 4 and 5. When the top was at 1, the bottom was about 5 or 6. I’m guessing that the equation would be  $b(t)=t+5$ .”

Excerpt 1 contains discourse about the dynagraph of the function  $f(x) = x+5$ ; Figure 2a and 2b depict a scene through snapshots presented using written text and visual mediators. The first property in Figure 2a is described through a snapshot taken ‘when the top number was zero’. The first drawing in Figure 2b presents this specific instance. The second property is described analogously as a snapshot taken “when the top number was at 1”; the second drawing in Figure 2b presents this specific instance. The third property in the scene is described through the algebraic formula “ $b(t) = t+5$ ”.

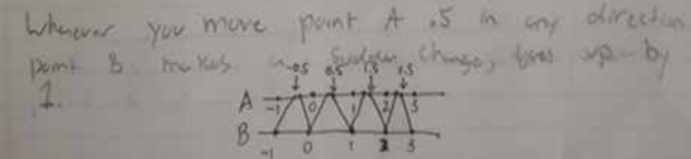

**Excerpt 2: Live-photo depicted through two snapshots showing ‘initial’ and ‘final’ states****Figure 2: Live-photo**

“There’s a limited distance between points A & B. After point A is dragged a certain fixed distance, the red line jumps another 1 point.”

The dynagraph in excerpt 2 realizes the nearest integer function. The students describe the jumping of the red line as A is dragged across the midpoint of the interval  $[0,1]$ . This part of their discourse appears to be a live-photo depicted through two visual mediators that are particular snapshots showing an ‘initial’ and a ‘final’ state of the dynagraph as A moves in a neighborhood of 0.5.

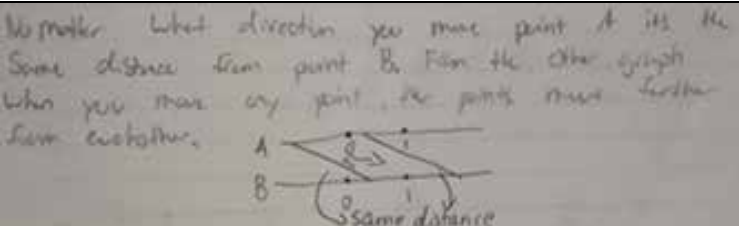

**Excerpt 3: Album of live-photos**

 <p><b>Figure 3: Album of live-photos</b></p>	<p>“Whenever you move point A .5 in any direction point B makes a sudden change, goes up by 1.”</p>
--------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------

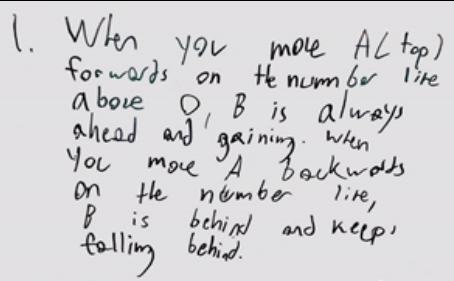

The dynagraph in excerpt 3 realizes the nearest integer function. The students produce a single visual drawing realizing the dynagraph’s interval  $[-1,3]$  on both axes (Figure 4), and describe its behavior written in words. Each live photo shows A near the midpoint of a unit interval. We see these as live-photos because each ‘sudden change’ is shown by a position of the segment AB immediately before and immediately after the transition of A across the midpoints (the ones realized are -0.5, 0.5, 1.5, 2.5) of the unit intervals.

**Excerpt 4: Scene depicted through a cluster of snapshots**

 <p><b>Figure 4: Scene</b></p>	<p>“No matter what direction you move point A it’s the same distance from point B. From the other graph when you move any point the points move further from each other.”</p>
------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The dynagraph discussed in Figure 5 realizes the function  $f(x)=x+5$ . The students who author the discourse in excerpt 4 emphasize the invariance of the distance of A from B, conveyed through the words “no matter what direction” and through the visual mediation of two congruent parallel segments in the drawing with in between a double-headed arrow and two arrows pointing to the words “same distance”. The written text and the visual mediators appear to be a cluster of snapshots depicting the invariant property identified.

**Excerpt 5: Scene album depicting two properties of a dynagraph**

 <p><b>Figure 5: Scene album</b></p>	<p>“ When you move A (top) forward on the number line above 0, B is always ahead and gaining. When you move A backwards on the number line, B is behind and keeps falling behind.”</p>
-------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

In excerpt 5 (Figure 6) the students use only written words to outline the behavior of dynagraph of  $f(x)=2x$ . They consider a whole interval of time (and space): this is suggested by their use of the adverb “always”, and by the fact that they make several references to possible movements and to the reciprocal position of the two variables (“forwards”, “ahead”, “backwards”, “behind”). Moreover, the

students start with the present tense of the verb “to be” (“B is always ahead [...] B is behind”), which gives their statements the form of an absolute observable truth, but then they add details on the quality of movement, passing to the “-ing form” of other verbs, indicating spatial dynamic features (“always [...] gaining”, “keeps falling behind”). This could suggest that the students see the movement as not ending even when it cannot be seen anymore within a large interval.

## Conclusions

The analytical tool we have introduced to describe written accounts of the DIE experience allows to characterize different ways used by students to realize movement and time experienced during the exploration of dynagraphs, and puts them in relation with mathematical discourse about functions. In particular, it highlights how the choice of the time interval being described, that can be identified in students’ discourse by looking at the verb tenses, adverbs and at their use of visual mediators to realize movement, corresponds from a mathematical point of view to different properties of the functions realized through the dynagraph. The classification has value at the cognitive, didactical and epistemological levels. From a cognitive point of view, the tool is important because the classification proposed was identified *a posteriori*, through empirical analysis of the data collected, and it seems to be a powerful tool for analyzing all the data collected. Epistemologically, the types of accounts can be put in relation with different mathematical properties of functions in formal mathematical discourse, as shown in Table 1.

Thinking about properties that are pointwise, local or global, the discourse – even that of experts – that can emerge about these may have characteristics such as those we have found in students’ discourses, focusing on “instants” that capture the behavior of isolated points, systems of points, sequences, neighborhoods of points, points as limits, intervals... Moreover, experts’ discourse can capture properties at certain points, variations and invariants. For example, a description of what happens in a neighborhood of a point can be conveyed through a live-photo, while the behavior at infinity requires a scene, since a neighborhood of infinity can be seen as a scene “from a certain point on”, that is, as a live-photo at infinity.

From a didactical point of view the classification is important, assuming that we value promoting various forms of students’ discourse, and therefore students’ flexibility in constructing such discourse. The teacher can interpret students’ discourse from a mathematical point of view, seeing it as a ‘mirrored image’ (with some possible distortions) of experts’ discourse about pointwise properties, local or global properties, variations, and invariants. Doing this, the teacher can then promote these forms of discourse through appropriate tasks (e.g., by using the behavior of dynagraphs in certain positions, intervals, etc.), knowing what to expect and how to gradually foster the transition to more formal mathematical discourse. One particularly fruitful type of discourse seems to be that involving transitions from pointwise to local properties, and thus discourse involving live-photos. However, this needs to be studied in future research currently under development.

## Acknowledgments

We graciously thank Nathalie Sinclair for her support in the realization of the activities described in this paper, and for all the fruitful conversations she has engaged in with us. This study has been partially supported by GNSAGA of INdAM.

*This paper investigates the types of representations used by high-achieving eleven-year-old pupils in their argumentation in the process of mathematical problem solving. The literature review addresses pedagogical and psychological aspects of knowing representations and using them in the process of problem solving. In our empirical study we examine a sample of 109 eleven-year-old pupils who took part in the final round of a national mathematical competition in Serbia. A total of 656 problem solutions was analyzed. The results show that these pupils used and often combined inventive iconic and conventional numerical/symbolical representations in their argumentation. We discuss pupils' choice of representations which lead to correct solutions and adjusted representations corresponding to the type of problem (algebraic or logical-combinatorial). The aim of the paper is to draw attention to the importance of studying representational approaches pupils take when solving problems.*

**Keywords:** Representations, problem solving, argumentation, solution representation.

### Introduction

There has been rising interest among mathematics educators in the usefulness of representations in the process of learning and problem solving. Competent use of representations in problem solving appears to be a significant indicator of level of mathematics literacy (De Lange, 2003). Then, it is a plausible assumption that investigations on how high-achieving pupils use representations in problem solving could lead to the development of strategies for choosing adequate representations in problem solving process.

Some of the principal objectives of mathematics education are to enable pupils to be good problem solvers (Schoenfeld, 1992). Solving problems in various ways on one hand and “decoding, encoding, translating, distinguishing between, and interpreting different forms of representations of mathematical objects and situation” on the other hand are recognized as some of the key competences needed for mathematical literacy as it is defined by national curriculums worldwide (De Lange, 2003, p.77). Representations, as tools for presenting problems, are considered to be means for understanding. It is also advocated that using multiple representations in problems may contribute to higher achievement (Cai, 2013). Role of representations in problem solving is recognized as important issue (Janvier, 1987; Cuoaco & Curcio, 2003; Shoenfeld, 1992). Two important issues are 1) which representations pupils invent when solving non-routine tasks and 2) which representations more often assure successful argumentation.

### Theoretical background

In numerous conceptualizations of mathematical competences and mathematical thinking, ability to use representations (symbolic, numerical, visual, or verbal expressions) is identified as important parameter of mathematical abilities. Tchoshanov (2002) discusses types of representations on the

concrete to abstract continuum as they reflect different modes of representation: concrete (real object, physical model, manipulative), pictorial (photograph, picture, drawing, sketch, graph), abstract (sign, symbol, written, verbal language). Matteson (2007) identified five categories of mathematical representations in problem solving: numerical, iconic, verbal, symbolic, and dual. Numerical representation focuses on specific numerical values in a variety of formats, such as decimal, fraction, percentage, or a numerical list (such as a list of numbers appearing as outcomes of probability). According to Matteson, iconic representations encompass different visual representations, from pictorial, (realistic) models, horizontal charts, vertical charts to graphs and coordinates graphs. Pictorial representations are pictures of real-world objects such as toys, dice, etc. As we slightly depart from Matteson's classification, we will consider iconic representation as distinct from pictorial (which closely resembles real world objects). For example, an apple may be "iconically" represented as a dot. Verbal representations require application of written (or spoken) language to express understanding, to describe, analyze, explain, or reflect upon numerical, algebraic, or graphic representation (which does not include brief phrases such as directions for solving the problem). Symbolic representations involve symbolic notation and include usage of variables and formulas such as: equation, expression, algebraic equation, algebraic expression, and formula (Matteson, 2007). Yet pupils may not use only one representation in problem solving. Under the term "dual representation" Matteson considers dealing with two categories of representations in problem solving (e.g. numerical and verbal). Matteson claims that "problems' (solutions) incorporating multiple representations generally result in more incorrect solutions" (Matteson, 2007, p. 60).

Some researchers pointed out that visual representations play an important role in supporting reflection and as a tool of communicating mathematical ideas (Arcavi, 2003; Gagatsis et. al, 2010; Sfard, 1991). The main functions of visual representation are to illustrate symbolic representation and to resolve conflict between intuition and symbolic solution. Successfully arriving at solutions to mathematical problems utilizes a combination of problem representation skills and symbol manipulation skills (Brenner et al., 1997). The first mentioned function involves skills which "include constructing and using mathematical representations in words, graphs, tables, and equations" (ibid). Lesh and colleagues argue that besides the significance of each representational system, attention should be directed toward translation among representational systems as well as to transformation within them (Lesh et al, 1987). They point their research shows that the act of representing tends to be "plural, unstable and evolving". Along the line, Duval discusses changes of register of representation in terms of cognitive operations: 1) transformations within the same register, like for example in case of algebraic operations or numerical computation, 2) translation of representation into different register, which is more cognitively challenging (Duval, 1999, 2003).

Several researchers attended to multiple representations in problem solving (Lowrie, 2001; Hegarty and Kozhevnikov, 1999; Matteson, 2007). Lowrie (2001), in a study of the relationship between different forms of problem representation and pupils' performance in problem solving, has found that high-achieving middle school pupils tend to use nonvisual methods when solving problems. He pointed out that most studies examining representational preferences along a visual-nonvisual continuum have considered preference alone and did not attend to effectiveness of method (ibid). Lowrie found that those "pupils' who were able to use visual representations regularly and in an

efficient manner, were able to solve mathematics problems in a more effective manner than pupils' who were more inclined to use nonvisual aids on a regular basis" (Lowrie, 2001, p. 360).

Stylianou and Silver (2004) examined differences in using representations between mathematicians and undergraduate students (as novices). They found that experts construct visual representations more frequently and use qualitatively better way to understand problem situation. School teachers are traditionally inclined to rely on symbolic, analytical representations. Consequently, pupils tend to do the same. The role of different types of representation in problem solving, particularly the effects of the usage of multiple representations is not fully explored.

## Methodology

We investigated types of representations used by high-achieving eleven-year-old pupils in solving problems. The main research questions were: 1. what representations pupils most frequently use when solving problems; 2. what representations are associated with correct solutions; and 3. how many representations used at the same time in argumentation are most often associated correct argumentation. Our questions were proposed based on previous research from Matteson, Lowrie, and Brenner and colleagues.

The data was collected in the final round of a national mathematics competition "Mislisa", similar to "Kangaroo without borders". In this competition, mathematics relevant for solving problems is not strictly limited to the national curriculum. Successful problem solving in this competition requires critical thinking and applying knowledge in non-standardized situations. The problems range from the simplest computation problems, to algebraic, logical, and combinatorial problems most often set in realistic context. The competition promotes the value of mathematics literacy in pupils.

The study sample consists of 109 pupils who qualified for the finals of the competition by achieving the maximum score in the preliminary round of competition. We examined problem solutions from all finalists. The subset of 8 problems in which competitors were explicitly asked to provide explanation was analyzed in our study. Descriptive statistics was done for those eight problems.

Solutions for two of the problems are analyzed qualitatively in greater details. Our preliminary analysis of all solutions, resulted in selection of *The Bottle problem* and *The Castle problem* as exemplars for the points we make. They are the following:

*The Bottle problem* There is three times more milk in the first bottle than in the second one. If 3l of milk is added in the first bottle, and 5l of milk in the second, than there would be two times more milk in the first bottle than in the second one. How many litres of milk has been in the bottles at the beginning? Explain your answer.

*The Castle problem* A Castle has 6 towers. Each tower has a room. Each room has one door. Each door has a lock. All rooms are locked and keys are mixed up. What is the maximum number of trials a guard needs to check, in order to open the doors?

In the Bottle problem, finding way(s) to represent relationships between amount of milk in the first and the second bottles is the key for finding the solution. Problems similar to this are commonly solved in schools with the strategy of forming an algebraic expression (symbolic representation). But there are alternative strategies for solving this problem such as 1) the "method of segments" which

relies on expressing relationships between quantities on line segments (iconic representation) or 2) the “method of trials” (involving number representation) or 3) simply explaining the solution in words (verbal representation) or 4) some other creative approach.

The Castle problem is logical-combinatorial. The maximum number of trials in the first cycle to get to the door that can be unlocked is obviously equal to the number of rooms. In the following cycle of trials, one door is already unlocked so five doors remained to be checked in. There is no one “school” strategy for solving this problem.

## Results and Discussion

Here we present descriptive analysis of pupils’ solutions. A total of 656 problem solutions are taken as units of analyses. Out of them, 355 items were solutions to algebraic problems and 301 items solutions to logical-combinatorial problems.

Table 1 shows that choice of representations for algebraic problems did not match representations used in combinatorial problems. Since pupils often used more than one representation, the percentages in each column do not add to 100.

Type of representation	Algebraic problems	Logical-combinatorial problems
Numerical	31,9%	57,8%
Iconic	22%	20,8%
Verbal	21,8%	61,2%
Symbolical	45,9%	8,3%

**Table 1: Percentages of problem solutions with particular type of representation**

In accordance to Duval’s claim, pupils tended to use non-visual representations. To explain algebraic problem solutions, pupils most frequently used symbolical representation. It is not surprising since traditionally solving algebraic problems in a way other than writing down equivalent equations is undervalued in classrooms. In contrast, the logical-combinatorial problem solutions pupils primarily relayed on verbal and numerical representations. Particularly, verbal representations were often used for argumentation in solving logical combinatorial tasks, rarely for algebraic problems.

We examined whether there is an association between number of used representations (1, 2 or 3) and correctness of solution (False/Partially correct/Correct). The percentages are presented in the Table 2. Percentage of correct solutions including more representation, were bigger than of correct solutions with smaller number of representations used. We performed the  $\chi^2$  test of independence for variables Number of used representations (1, 2 or 3) and Correctness of solution (False/Partially correct/Correct) on problems. There is a significant relationship between “number of used representations (1,2,3)” and “Correctness of solution (false, partially correct, correct)”. ( $\chi^2=67,478$ ,  $df=4$ ,  $N=656$ ,  $p<0,001$ ). Cramers’s V coefficient of 0,227,  $p<0,001$  suggests moderate correlations. Thus, successful problem solvers constructed significantly more representations than unsuccessful problem solvers. Our finding confirm Lesh’s observation about plural and evolving nature of the act

of representing. The finding does not reinforce Matteson's statement that "multiple representations result in more incorrect solutions" (Matteson, 2007)

Number of representations	False solution	Partially correct solution	Correct solution
1	35,4%	23,7%	40,9%
2	20,7%	10,4%	68,9%
3	4,5%	9,1%	86,4%
Total	27,3%	17,2%	55,5%

**Table 2: Percentages of number of used representations according to correctness of solution**

Iconic representations are considered to be more intuitively comprehensible and closer to reality than symbolic representations which involve abstraction and generalization in mathematics domain (Liu, 2012). Yet sufficient experience with such representations is a prerequisite for their' appreciation. The high-achieving pupils in our study had a tendency to use symbolic representations in algebraic problems. Almost half of the solutions involved using of symbolic representation in those problems. The test of independence showed that there is significant association between correctness of problem solution and use of symbolic representation ( $\chi^2=62,417$ ,  $df=2$ ,  $p<0,001$ ). The strength of relationship is medium (Cramer's  $V=0,419$ ,  $p<0,001$ ).

Many pupils obviously assumed that they were expected to use pictures when explaining their solutions. But often pictures were neither sufficient nor effective aid in argumentation. Some pupils combined pictorial with numerical representation (e.g. counting up number of attempts in the Castle problem). The others combined pictorial with symbolic and verbal representations by creating number sentences and written explanations of steps.

### Prototypical representations in pupil's solutions

Pupils created diverse representations for their argumentation. In the Castle problem a significant number of pupils used numerical representation. Yet, others supported argumentation with pictorial representation in combination with other representations. Figure 1 shows an example of argumentation based on dual representation (pictorial and numerical).

**Figure 1: Dual representation - pictorial and numerical (left)**

**Figure 2: Dual representation - number line and algebraic expressions (right)**

When using iconic representation, most commonly the pupils relied on number line and the method of segments. This method is commonly taught in Serbian schools. Figure 2 illustrates an example of argumentation based on number line representation in solving the Bottle problem. In her problem

solution, Ana used the method of segments (number line representation) to show the relationship between elements in the initial state and the final state (so this pupil represented how the situation changed by drawing two pairs of number line segments). Ana switched from the number line representation to symbolic ones as she wrote a chain of equivalent equations.

An example of the solution of the Castle problem, solely based on iconic representation is presented in Figure 3. Marko put a key for his iconic presented argumentation on the right, where “x” meant unsuccessful attempt, “✓”, successful attempt, and “-“ that the door cannot be opened.

**Figure 3: Iconic representation**

Figure 4 shows Sara’s solution, assessed to be a creative argumentation involving Roman and Arabic numerals in solving the Castle problem. The solution consisted of five equalities. Sara counted the cycle of attempts by Roman numerals. She used Arabic numerals to show number of attempts in the particular cycle. Formally, without (absent) supplementary explanation the record was not mathematically correct as it stated e.g.  $I = 6$  and  $V = 1$ . Sara used different numeration to distinguish between number of attempts and number of trials in the cycle, overlooking meaning of the equality sign. Her solution was assessed to be too sketchy and although the answer was correct, she did not earn points for argumentation.

Pupils often combined different representations in solving problems. In those cases they usually started with pictorial representation, than they turned to verbal or symbolic representation. Using pictorial representation, enabled them to provide simpler explanation. An effective presentation of thought process with no verbal explanation is presented in Figure 1.

**Figure 4: Combined numerical representations (left)**

**Figure 5: Multiple representations - pictorial, verbal and numerical (right)**

In Figure 5 is Luka’s solution of The Castle problem with multiple representations. He initially used pictorial and numerical representations along with verbal explanation and finalized the solution with numerical calculation. The realistic picture of doors itself hardly helped in solving the problem. Nevertheless Luka used it as a tool in argumentation. He probably meant to indicate with that picture

that all 6 doors were checked with one key. The other cycles of tries were not visually presented in Luka's solution. But his verbal explanation presented on the right side of the picture was accurate. Luka wrote: "Since there were 6 keys and 6 doors, with the first key there could be no more than five failed attempts, in the next step 4, than 3, and so on, in each successive step 1 less".

## Conclusion

Successful problem solvers construct significantly more representations than unsuccessful problem solvers. Our results do not endorse previous arguments that multiple representations are associated with more incorrect solutions. Using combined representations often results in correct solution. Typically, pupil's argumentation starts with pictures, than turns to verbal or symbolic representation. Using pictures frequently enables pupils to provide sound explanation.

We found that talented pupils had a tendency to use symbolic representations. Pupils' choice of representation could be a consequence of limited experience in using different representations in the past. Ultimately teachers need to help pupils to develop flexibility in using different representations and ability to combine representations (or move in argumentation from one to another one).

In particular, future research should test whether pupils should be encouraged to provide argumentation by 1) combining numerical and verbal representations in the case of logical combinatorial problems and 2) numerical pictorial and iconic representations in the case of algebraic problems. More generally, we need to focus on developing methods for improving pupils' abilities to visualize and verbalize thought process and to be flexible in combining representations in the process of problem solving.

# Geometric prediction: proposing a theoretical construct to analyze students' thinking in geometrical problem-solving

Elisa Miragliotta

University of Modena and Reggio Emilia, Department of Physics, Computer Science and Mathematics, Modena, Italy; [elisa.miragliotta@unimore.it](mailto:elisa.miragliotta@unimore.it)

*We consider geometric prediction (GP) as a mental process through which a figure is manipulated, and its change imagined, while certain properties are maintained invariant. In this paper, we explain our interest in this process and how we define it. Furthermore, we describe a tool for analyzing students' productions. In particular, we present brief analyses of students' interviews while they are solving a geometric open problem explicitly designed to elicit processes of GP. Finally, we summarize some preliminary results about the features of this construct. These results are part of a doctoral project aimed at gaining insight into the process of GP.*

*Keywords: Spatial reasoning, visualization, intuition, figural concepts.*

## Introduction

It is well known that spatial reasoning and visualization are topics of interest for mathematics educators (e.g. Duval, 1995; Presmeg, 2006) to the extent that Cuoco, Goldenberg and Mark (1996) have proposed to organize curriculum around *mathematical habits of mind*, which include visualization and tinkering. These are described as being at the heart of mathematical research and, therefore, crucial for helping students learn to think like mathematicians. These habits are particularly involved in geometrical problem-solving. Indeed, when solvers approach a geometrical task they can interact with visual or mental images in several ways. Cognitive Psychology explains this interaction by the intervention of several *visuo-spatial abilities* such as *imagery generation ability* and *imagery manipulation ability* (Cornoldi & Vecchi, 2004).

In a previous study (Miragliotta & Baccaglini-Frank, 2017) we tried to analyze students' solution processes when solving a geometrical task, but found shortcomings in using the visuo-spatial abilities for at least two reasons: much effort goes into establishing which abilities are used during each analyzed process, and interpretation plays a large role and is not consistent across researchers; none of the abilities explicitly deal with the Theory of Euclidean Geometry within which figures and their properties are defined, when the reasoning is carried out in this context. This is because as mathematicians we know that, when we solve a geometrical task, we can imagine consequences of (mental) transformations on a geometrical object which are consistent with theoretical constraints, given or induced by a particular construction. Indeed, mathematical objects have a particular nature, the investigation of which usually requires theoretical elements which refer to a domain different from the one of perception. In line with Neisser (1989), we consider perceiving and thinking as different cognitive activities. *Perception* "is immediate, effortless, and veridical" in one word "direct"; *thinking* is "indirect", because it "may not depend on the immediate environment at all, it is often anything but effortless or immediate, and frequently goes astray" (Neisser, 1989, p. 11).

In the specific domain of 2D Euclidean Geometry, in order to cope with the difficulties listed above, we defined a new theoretical construct called *geometric prediction (GP)*. Although at the moment, we are working towards a finer operative definition, it seems to be an interesting construct to use in

order to shed light onto problem solving processes in geometry. Furthermore we expect it to be trainable, that is to ameliorate through appropriate educational practices. The aim of our research is to gain insight into the process of GP. So we set out to observe and analyze what happens during the resolution of particular open problems, focusing on instances of *geometric prediction* in solvers' discourse, gestures, drawings, and dragging modalities used in a second phase of the resolution of the given problem in a Dynamic Geometry Environment (DGE). Because of what we present in this paper, in which the role of the DGE is marginal, and since the space limited, we will not discuss this second phase. In this paper, we present the construct of GP and describe a tool used for analyzing its emerging features in students' data that are collected in task-based interviews.

## Theoretical framework

In the specific domain of Mathematics Education, under the umbrella of *spatial reasoning* literature collects a large set of definitions, which share the reference to the activity of imagining objects and interact with them through mental transformations (rotation, stretch, reflection, etc.). Among these definitions, we have considered *spatial reasoning* as defined by the Spatial Reasoning Study Group: “the ability to recognize and (mentally) manipulate the spatial properties of objects and the spatial relations among objects” (Bruce et al., 2017, p. 146). We considered *visualization*, according to Presmeg's (2006) description, as “taken to include processes of constructing and transforming both visual mental imagery and all of the inscriptions of a spatial nature that may be implicated in doing mathematics” (p. 206). Here visualization is considered to be explicitly linked to mathematical activity, and it could involve mental images.

## Geometric prediction

Previous research on visualization informs us that when solvers face a geometrical task, they can interact with mental images; they can imagine the consequence of (mental) manipulation of the geometrical figure. Moreover, it seems that in this process the theoretical elements play an important role. With “theoretical elements” we mean those related to the Theory of Euclidean Geometry (TEG). The process of *geometric prediction* is “a mental process through which a figure is manipulated, and its change imagined, while certain properties are maintained invariant” (Mariotti & Baccaglini-Frank, 2018, p. 157).

Products of GP may or may not be coherent with theoretical constraints. Indeed, in order to take into account all theoretical constraints, the solver must *theoretically control* the figure, that is “mentally impose on a figure theoretical elements that are coherent in the Theory of Euclidean Geometry” (Mariotti & Baccaglini-Frank, 2018, p. 156).

## Fischbein's Theory of Figural Concepts and Intuitive knowledge

In order to explain the nature of geometrical objects, we refer to the *Theory of Figural Concepts* (Fischbein, 1993), according to which they have a dual nature. Geometrical objects are completely described and controlled by an axiomatic system of definition and theorems, but at the same time they maintain certain figural aspects of images. Fischbein (1993) thinks of a *figural concept* as a complex mental entity (different from pure concepts and pure images) “which simultaneously possesses both conceptual and figural properties” (p. 144), realizing a fusion between the conceptual and the figural components.

A construct which seems to be involved in GP is *intuition* (Fischbein, 1987). It is a kind of cognition, characterized by self-evidence and immediacy, different from perception, and implying an extrapolation of information beyond that directly accessible. Intuitions can have an anticipatory role. Indeed, anticipatory is a kind of intuition, which belongs explicitly to problem-solving activity; it provides a global view of a solution, which precedes the analytical one.

## Research questions and methodology

The data we present are part of a doctoral research project on GP for which 6 geometrical problems were designed and proposed to 37 Italian high school students (ages 14-18), undergraduates, graduate and Ph.D. students in mathematics (ages 19-33), during the months of February and April 2018. The problems were designed to elicit processes of GP and they were used within task-based interviews (Goldin, 2000). We decided to use a semi-structured type of interview: the first question is always the same; then there is a sequence of questions defined a priori and a set of stimuli in order to elicit students' comments.

Consistently with our purposes, we designed a particular kind of open problems (Arsac, Germain, Mante, 1998; Silver, 1995), *prediction open problems*, in which the solver is asked to describe possible alternative arrangements of a geometric configuration (imagined, given by a drawing and/or by a step-by-step construction) maintaining given properties. Predictions could be asked for explicitly or not.

Although all data have not yet been thoroughly analyzed, we use some of the data to present a preliminary report on the following questions: (a) How can we characterize GP processes (in the case of the prediction open problems given)? (b) In solving a prediction open problem, what kind of gestures, words and drawings are performed by solvers? What do these allow us to infer about the GP processes?

In the following section we report on an example of the task used during interviews.

### The “locus of P” problem

The task used in this study is composed of two parts. The first one is:

Read and perform the following step-by-step construction: fix two points  $A$  and  $B$ ; connect them with a segment  $AB$ ; choose a point  $P$  on the plane; connect  $A$  and  $P$  with a segment  $AP$ ; construct  $M$  as the midpoint of  $AP$ ; construct the segment  $MB$  and name its length  $d$ .  $A$  and  $B$  are fixed, and the length of  $MB$  has to always be  $d$ .

Then the interviewer asks: “What can you say about the point  $P$ ?”

**Figure 1: Instance of figure obtained by step-by-step construction**

The step-by-step construction could be accomplished with paper and pencil (obtaining a construction like the one in Figure 1). Once the solver had proposed a solution or stated that s/he was not able to

find one, part two of the task was given: the interviewer opened a dynamic geometry sketch and she asked the solver to move  $P$  in the figure, consistently with her/his prediction, or else to explore the figure to help reach a solution. As highlighted before, in this paper we will not focus on this second phase.

### Construction of a new tool for data analyses

In our data analyses, we have been highlighting instances of GP by spotting and analyzing students' gestures, drawings and discourse. In particular, we are trying to identify elements which belong to the students' conceptual component and their figural component of the geometrical objects in focus. In order to analyze solvers' GPs, we collect these elements in a sort of "funnel" (Figure 2) which shows a product of GP in gestural and/or discursive form.

**Figure 2: Elements collected in the funnel and its product**

The tool, as shown in Table 1 and sketched out in Figure 2, is composed of 3 columns. In the first and in the third there are, respectively, *theoretical elements* and *figural elements*, referred by solvers in gestural or discursive way or inferred by us (in square brackets). These two constructs are defined and identified according to Fischbein's (1993) distinction between conceptual and figural components of geometrical objects. In the center column, we used two different colors to highlight which element of the two columns is expressed by the solver at a specific moment. Indeed, the vertical order of boxes follows the chronological sequence in which solvers made elements explicit. Furthermore, we added an "X" when the element is mathematically incorrect or incoherent with respect to the given geometrical construction. At the end of the funnel, there is the product of the GP. Each funnel represents the sequence of the observable steps of a new GP.

As an example, here we show the construction of the funnel referred to an excerpt of Student A's interview. She is solving the "locus of  $P$ " problem. This excerpt begins right after the interviewer asked the first question.

Student A: The point  $P$ ...meanwhile **is part...of the straight line** in which...on which there is also... $AM$  and is **outside the triangle  $AMB$** .

Student A: In this case – but I think it is a particular case – **perpendicular** to...not the point  $P$ ! It is **a straight line** on which there is the point  $P$  that is **perpendicular to  $MB$** , but it is a particular case, I think!

Interviewer: Ok. Make a prediction. Do you think that the point  $P$  can have other positions?

Student A: If I draw again...if **the length of  $MB$  must always be  $d$** , it could be **like a mirror**, so it could take the place...the same position, only **on the other side of the segment**.

In this excerpt, we recognize some figural elements (and underlined them), like segment  $AM$  and triangle  $AMB$ . We use bold type to highlight the identifiable theoretical elements, like perpendicularity and (line) symmetry. We recognize a product of a GP in the last student's statement:  $P$  takes a symmetric position with respect to  $AB$ . The GP is both discursive and gestural (the student shows the expected position of  $P$  using a pen (Figure 3a)). Then, she undertakes another GP, strictly connected with the figural elements observed before. Indeed, she claims:

Student: Yes, it [point  $P$ ] moves along the segment  $M$ ...along the **half-line  $MP$**  and then etcetera, etcetera... along the half-line that would continue, because it does not interfere with the **triangle**.

Figure 3: Gestures performed by (a) Student A (b) Student C (c) Student D

We collected all elements in two funnels, as shown in Table 1 (see Student A). The blue arrow highlights how the product of the second GP (named GP2) is directly connected with and derives from the product of the first GP (named GP1).

## Preliminary findings

### Funnels as a tool to gain insight into solvers' processes of GP

At the moment we have analyzed 15 interviews during which the “locus of  $P$ ” problem was proposed. Here we show only four examples of funnels (Table 1): Student A is a 9th grade student (15 years old); Student B is a 13th grade student (18 years old); Student C is an undergraduate student and Student D had just completed a master's degree in mathematics. The chosen funnels summarize some of the solvers' common behaviors during the resolution of the first part of the task and highlight how this tool can be used to gain insight into the process of GP.

The first funnel (Student A) represents an example of a mathematically incorrect GP during which the student focuses on particular figural elements of the given configuration. Indeed, Student A explicitly mentioned the triangle  $ABM$  and then the segment  $MP$ . Our analyses reveal that in all cases in which the triangle is mentioned (5 interviewees), the solvers seem to have considered the configuration as made up of two completely independent figural elements: a triangle and a segment. This hypothesis is consistent with the solvers' stated predictions about the behavior of the configuration and it is confirmed by instances of surprise observed during the subsequent exploration in a DGE. The relation between figural elements induces Student A to speak of moving  $P$  along a half-line, maintaining  $MB$  not only constant in length, but also in the same position. Possibly, it is the lack of theoretical control that induces the solver to infer the necessity of maintaining invariant so many properties. In this case, the invariance of the length is maintained by the invariance of the whole

and coherent (with the TEG) theoretical elements. Moreover, she does not mention triangles, but she focuses only on segments and points. This seems to allow her to refine the first product of her first GP and, finally, to reach the last one (point  $M$  on a circle).

Student D's processes of GP highlight another emergent feature of GPs: often they are accompanied by intuitions. In particular, we observe a kind of intuition which appears during a solution process and that expresses an immediate and global view of a solution: *anticipatory intuition*. The occurrence of this kind of intuition could explain what happens in short chains of GP, like the one performed by Student B. His funnel shows a chain of GP in which most rows contain theoretical elements and no other elements could be recognized between the two products of GP: GP1 and GP2. This could be explained by his resorting to intuitive knowledge.

## Conclusion

The analyses of students' videos and transcripts reveal that GP is a process involving an interplay between perception and reasoning processes. Indeed, GP seems strictly related to figural components. In the case of the problem analyzed, it seems that students who see the configuration as a triangle and an independent segment do not reach a mathematically correct (or coherent with the TEG) product of GP. The notion seems to be in line with Duval's (1995) findings related to perceptual apprehensions of a geometric configuration and dimensional change. Nevertheless, GP also involves theoretical elements which belong to the TEG, and it has a strong relation with the idea of students' theoretical control over a figure. Indeed, theoretical control that is coherent with the TEG should lead to correct predictions (see Student C and D). Moreover, GP is related to conceptual components to the extent that in the case of Student B the discursive element "the length of  $MB$  must always be constant" fostered recollection of the definition of circle, leading to immediate recognition of the locus of  $M$ . So, it seems that theoretical elements play an important role in the immediacy and correctness of GPs. Student B reveals how for an "expert" solver GP can become an immediate and automatic process. This finding is promising for the trainability of GP through appropriate educational practices.

Furthermore, we notice that often GP is coupled with *anticipatory intuition* (see Student B and Student D). Nevertheless, the two constructs are not identifiable. Indeed, in other cases (see Student C) correct products of GPs are produced without any recognizable intuitive knowledge.

In conclusion, processes of GP seem to be observable through the solver's productions; funnels are useful tools for shedding light onto this process, but they must be accompanied by qualitative analyses of transcripts for gaining deeper insight into the GP. Moreover, GP seems to be an interesting construct in order to shed light onto problem solving processes in geometry.

We believe that this kind of research can provide new insights into students' difficulties in learning geometry. Moreover, awareness of prediction processes could be very helpful for teachers. Outcomes of GPs seem to be windows onto students' mental images and processes generating them. Such knowledge could help in guiding mathematical teaching and learning, because teachers could know which properties students are imposing on a given configuration by asking them to make explicit their GPs. If students are imposing on a figure too many or incorrect properties, the teacher can intervene appropriately. Moreover, geometrical activities to strengthen students' theoretical control by fostering awareness of their conceived invariants can be designed.

# Fibre mathematics: exploring topological forms through material practices

Kate O'Brien and Elizabeth de Freitas

Manchester Metropolitan University, Manchester, UK; [katherine.obrien@mmu.ac.uk](mailto:katherine.obrien@mmu.ac.uk),

[l.de-freitas@mmu.ac.uk](mailto:l.de-freitas@mmu.ac.uk)

*Through its focus on “fibre mathematics,” this paper contributes to discussions of how mathematical representations entail complex mixtures of matter and form. Drawing on inclusive materialism (de Freitas & Sinclair, 2014) as a way of rethinking the material labour of mathematics, we analyze data collected in a two-week weaving workshop, focusing on how participants worked with the mathematical concepts of dimension and connectivity in problems that were at once topological and material. Focusing on one student’s work, “Akari’s Problem,” we explore how the loom operates as a rich experimental field for the (re)creation of mathematical concepts. This paper takes up issues associated with mathematical representations by focusing on the haptic, visual, and material way that mathematical forms come to life through making processes.*

*Keywords: Textile art, dimension, topology, materiality.*

## Introduction

The term *fibre mathematics* refers to the mathematical activity entailed in textile arts. Studies of fibre mathematics have been pursued within ethnomathematics – for instance, research on the weaving practices in the Bedouin culture of the Negev desert (Katsap & Silverman, 2016) and Quechua speaking communities in Peru and Bolivia (Ascher & Ascher, 1981; Urton & Llanos, 1997). These studies point to how these practices are not (only) representations of Western mathematical concepts, but entail innovative ways of *doing* mathematics through various maker processes. The challenge is then to study material practices of various kinds, no matter their location, for how they *engender* distinctive mathematical concepts. We argue that different modalities and representations entail distinctive meaning, precisely because they involve different materialities. Our shared earthbound status means that humans are likely to work with similar mathematical concepts and materials across the planet, although these will be bound up with the particular corporeal habits valued in different localities. Our approach thus questions theories of representation which treat the concept-matter relationship as one which assumes *concept as form-shaper* and *matter as passive form-taker*.

Our research indicates that students learning textile arts are often also learning complex mathematical concepts and exploring challenging mathematical problems. We show how one student’s work (“Akari’s problem”) entailed creative interventions that were both technical (associated with the loom and other materials) and mathematical (associated with formal and aesthetic goals). Through analysis of video footage and interview data, we show how problem solving in such cases involves the loom as an “open machine” with a distinctive “technicity” – two terms defined by the philosopher of technology, Gilbert Simondon (1958/2017). We explore how a technical “hack” of a traditional craft tool opened up new conceptual space, allowing research participants to invent new fibrous forms and explore complex geometric shapes that broke with classically Euclidean representations of space.

The research questions we explore in this paper are: (1) How do problems in the textile arts offer opportunities to explore rich mathematical thinking? (2) How does weaving as a material practice entail the mathematical concepts of dimension and connectivity? (3) In studying maker processes as mathematical, does representation best describe the relationship between concept and materiality?

## Theoretical Framework

Simondon (1958/2017) defines the “technicity” of a technical object as that which concerns its fundamental structure rather than its use. Attending to technicity is a way of better understanding the mode of being of the technical object, across various situations. This requires a genetic history of the technical object (in this case the loom), so that we can compare different manifestations and identify key elements of its structure. We do this to better understand how technology and mathematical practices are linked, and how material media are essential in mathematics, be they writing surfaces, touch screens, or paper and pencil. The work of Simondon offers us new materialist ways of thinking about how mathematics is made and performed outside of mainstream mathematical representations.

This philosophical framing of our approach sets the stage for a study of mathematical practices in contemporary textile arts. Following Simondon, who advocates for historical and philosophical studies of technology, we see technology as more than a tool that enhances human interests, more than a device for representing concepts conceived in the mind. Our relationship with technics is more complicated and we benefit from considering more nuanced ways of understanding the force of the technical object in our cultural practices (including mathematics). Writing just at dawn of cybernetics and the “information age,” Simondon argues we must examine our technologies to understand how our concepts are implicated in them, not as representations, but in a more direct assemblage.

We consider mathematical behavior as an ontogenerative practice (a making practice) that brings new concepts into the world, and in so doing reshapes the world. Learning mathematics becomes “an indeterminate act of assembling various kinds of agencies rather than a trajectory that ends in the acquiring of fixed objects of knowledge” (de Freitas & Sinclair, 2014, p. 52). This implies an understanding that mathematics takes no definite or final form, but rather it continually (re)emerges within the material practices of the workshop or the classroom. Our non-dualist approach argues that representations of mathematical ideas cannot be isolated from the phenomenon to which they are wedded. In particular, this paper focuses on technological interventions/actions that enable new formal and aesthetic choices that mobilize new conceptions of dimension and connectivity.

Weaving is performed with an ancient but ever-changing technology, called a loom. The loom creates a problem space for exploring pattern, texture, dimensionality, connectivity and number. The loom is both an “open machine” and an “associated milieu” for the technical-aesthetic activity of weaving (Simondon, 1958/2017). As an open machine, the loom itself can be undone and remade, maintaining its structural integrity while allowing for inventive alterations that enable students to build complex topological shapes. Indeed, weaving of all kinds, be it planar cloth or a three-dimensional objects, operates through the relationship between the discrete and the continuous, using thread, yarn or other continuous matter to create patterns that often achieve their aesthetic impact through discretization of and contrast between *individuated* units of color or texture. Many weaving practices operate through this pixelated effect, with links to the history of computing and digital image making (Plant, 1995;

Bachmann, 1998). Given this aesthetic aspect, and the pivotal role of the relationship between discrete and continuous magnitude in fueling mathematical invention (de Freitas, 2017), we consider weaving an excellent case study for examining the material labour of mathematics, and for rethinking the role of representation in mathematical behaviour. This perspective supplements research that has explored the aesthetic aspect of mathematics (Coles & Sinclair, 2019), the sensory capacity of the body (de Freitas, 2016), and the more-than-human and ontological nature of mathematics (Gutiérrez, 2017).

## Methods and Data

Research data was generated through participant observation and informal interviews conducted in the weaving studio of a craft school in the eastern United States, during a two-week weaving workshop called: “Weaving Origami and Other Dimensional Possibilities.” Twelve students (including the first author), motivated by personal interest in the proposed course, applied and were accepted into the class by the craft school selection committee. Most of the twelve participants – who spent at least eight hours/day weaving during the workshop – had more than five years of weaving experience. Data consisted of field observation writing and sketching, video recording during studio sessions, and interviews of nine participants. Cameras were both fixed (to walls and looms) and worn on persons, to obtain diverse perspectives on the material and ritual practices entailed in weaving. Interviews focused on artifacts and instruments from the studio, and questions targeted participants’ manner of describing the various problems they encountered during the two-week course.

The workshop focused on a distinctive challenge – how to weave “dimensional” cloth. The workshop’s title, “Weaving Origami,” describes a specific technique developed by the workshop instructor, Sue Taylor, which involves weaving short bands of cloth that jut out from the classically two-dimensional woven plane. These bands can fold into various origami forms (Figure 1). The technique for generating these three-dimensional bands derives from a common weaving trick used to repair broken warp strings. The instructor showed students how to use the free weights employed in this technique to alter how the loom distributes tension. Students began by directly imitating the instructor’s work. After two days, many in the classroom quickly moved to innovate on this thinking.

In this paper, we describe the work of one participant (Akari), by looking at the way that “Akari’s Problem” involved complex topological forms and became a gathering point for workshop participants. To illustrate, we discuss two woven objects Akari produced during the workshop (Figures 2 & 3). These woven forms offer a snapshot of a generative material-mathematical challenge. In our analysis, we draw on video from a chest-mounted GoPro video camera Akari wore while she worked on her first weaving and a loom-side interview with Akari, as she made her second sample.

**Figure 1: Susie Taylor      Figure 2: Akari's first sample      Figure 3: Akari's second sample**

## Discussion

Dimension is a hugely important mathematical concept on which our ideas about measurement and space depend. Mathematicians in different specialized fields define dimension in many different ways (Pearse, 2003). The concept, however, proved problematic in the late 19<sup>th</sup> century, when various mathematicians (Cantor, Peano, Brouwer) paradoxically demonstrated how to map the interval to the plane (Pearse, 2003). New theories of dimensionality emerged in the 20<sup>th</sup> century from Lebesgue, Hausdorff, and others, alongside the study of fractals and fractional dimensions. Plugging into our intuitions of space as it crisscrosses mathematical domains, the concept of dimension is multiple. Freudenthal (1983) suggests we consider dimension within three frameworks: Euclidean (an integer property of objects and spaces), Analytic (determined by the number of variables needed to describe an object), and Topological (pertaining to freedom of movement and boundary relationships).

Panorkou and Pratt (2016) contend that mathematics classrooms rarely address dimension directly. Skordoulis, Vitsas, Dafermos, and Koleza (2009) argue that a Euclidean notion of dimension is typically assumed and sometimes in conflict with an Analytic framework. Most mathematics students will not interrogate the concept of dimension, despite its incredibly opaque and open-ended nature. In the workshop, however, dimension was an incredibly common buzzword. Participants struggling to invent dimensional cloth on the loom engaged with the concept directly. Moreover, they each had distinctive aesthetic problems to solve, which allowed for an open and diverse group inquiry.

Due to the technical requirements of the loom and soft pliable nature of cloth, the working of woven form into three dimensions already involves the kind of contortions conceptualized mathematically by topology. Topology is a field of mathematics that investigates how objects remain unchanged after stretching, bending and twisting. It is often referred to as “rubber sheet geometry” (O’Shea, 2007) because objects studied by topologists can be pulled and stretched without changing their topological properties. Topology lends itself to the study of non-rigid forms, as in the case of weaving. Although weaving requires the heavy use of counting and anticipatory calculation in planning projects, the production of cloth is an essentially connective process in which lines of fibre fuse according to a systematic relationship to produce planar cloth. Weaving techniques developed to double the

capacities of the human arm span further enhance the complex connective possibilities of the loom. These techniques allow one to interconnect several layers of cloth in a manner limited only by the scope of the loom itself and the amount of time a weaver wishes to commit to her project.

To explore how fibre mathematics and topological concepts of dimension can be productively entangled, we begin by articulating Akari's original problem and analyzing her two weavings from a topological perspective. After experimenting at length with paper models, Akari planned a complex folded weave involving five parallel bands of cloth that emerge a ground cloth (Figure 4). Akari hoped to fold and twist these bands to reveal and conceal the colorful underside of each band. Because, in weaving, color forms through interlacing warp and weft, Akari planned a complex structure in which she would weave a cylindrical form made up of two intersecting planes (Figure 5, where these planes are colored pink and purple). This would allow two distinctive colors to alternate in prominence, depending on the pattern of folding. Looking to analyze the weaving topologically, we began by imagining the weaving as made up of a ground cloth with five pinched tori. (The pinched torus (Figure 6a) is called a pseudomanifold because there is a singularity at the pinch, creating an obstacle that cannot be traversed continuously. Pseudomanifolds are, however, still orientable.) However, further examination of the weaving revealed that there was not a singular pinch but rather a *crease* at the end of each tube (Figure 6b). Akari's cloth had five protrusions, which were neither manifold nor pseudomanifold, but something else altogether (Figure 6c).

**Figure 4: Paper models of the cloth**

**Figure 5: A diagram of Akari's layers**

These moments of creasing, where the weaving branches to form five bands, make this artifact complex in both the making and the mathematics. The creases represent a fundamental break in the object's basic Euclidean texture. If we select one such crease, and zoom in far enough, to see what is going on, we find four planar cloths all intersecting in the line (Figure 6d). If we keep zooming in, further and further, in search of the basic Euclidean plane, we will never be able to find it. No matter how close we get, every point on that line will belong to neighborhoods in four planes, breaking Euclidean rules, and making the crease singularity quite problematic. Akari's problem, in other words, involved making a mathematical form with yarn that exceeded conventional Euclidean geometry, and indeed exceeded conventional rules of behavior for manifolds and pseudomanifolds. Although ostensibly her weaving is made of two-dimensional surfaces, topologically it cannot be modelled as a two-dimensional manifold. This is because the cloth is not "locally Euclidean" precisely at these creases. Hacking the loom allowed Akari to break with the planar grid in regulated but inventive ways. At these intersections, no matter how closely you stretch and examine the material, Akari's cloth will never behave like a flat two dimensional plane.

**Figure 6: a) Pinched torus, b) Akari's tube, c) Rendering Akari's cloth, d) Four planes of cloth**

Akari came to know the properties of this shape not through this mathematical vocabulary or instruction but through an elaborate pattern of passes, which she developed to construct each of the five tubes. She noted in her interview how difficult this was: “My head was like wait! Wait! Wait!” Watching her activity on video, we see that Akari taps into a rhythm measured out by gestures made with and towards the loom. To keep her place in a 22-step progression of movements, she neatly organizes her threads to mark out visually her place in the pattern.

Despite her best efforts to plan her work, the materiality of Akari's concept broke away from the representation she had generated in her paper model. About 20cm into her project, Akari discovered that her double-layered tubes of cloth are structurally too dense to fold according to her plans. Video footage from the chest-mounted GoPro shows Akari pausing to examine her work. Sensing this break, six workshop participants gather around to observe and comment on her work. In the video footage, Akari shares her thinking aloud, while manipulating the cloth. A key conversation ensues about how to best explore the new freedoms opened up by the technological transformations that all participants have performed on their looms. At a climactic moment, three participants point to the loom's new tensioning system and exclaim in chorus “Cause they're weighted! They're weighted separately!” They point out that the new distribution of tension, now controlled by water bottles swinging off the back of the loom, works as a third dimensional coordinate in Akari's cloth. This marks a collective realization about the dimensional possibilities opened up by the redistribution of tension on the loom. Analysis of this episode reveals how the coupling of tension with dimension was not simply the *representing* of an immaterial concept (dimension) in a material form (a thread under tension), but was instead a matter of delving deeper into the potentiality of mathematical concepts as they inhere and mutate within matter.

## Concluding Comments

This paper builds on previous work on topological thinking in mathematics education, and the challenges of representing (or enlivening) complex manifolds in material form (de Freitas & McCarthy, 2014; Strohecker, 1991). It seeks to contribute to a growing body of literature on the role of technology in developing mathematical aspects of spatial sense (de Freitas, 2017; Ferrara & Mammana, 2014; Panorkou & Pratt, 2016) and it offers new possibilities for exploring mathematics in informal learning settings (Nemirovsky, Kelton, & Rhodhamel, 2013), pointing to the importance of aesthetically structured activities in mathematics teaching and learning (Coles & Sinclair, 2019).

Our study shows how maker and craft practices are an important site for innovative and unconventional representations of mathematical concepts. Although the usual question posed to those studying informal mathematics is “where is the mathematics?,” we suggest that mathematics is found in the material practices embodied by the weavers. These weavers are not mathematicians (and they might be the first to admit that!) and although there was no *direct* instruction as to how to use topological concepts to build the dimensional cloth, the problem space created an opportunity for doing mathematics through *direct* engagement with technical objects (the loom, the threads, etc.). These problem spaces are engendered by the loom, *but the solutions paths are not scripted* by the loom, especially in this case, where the loom is an *open machine* and literally modified by individual participants (hacked with weighting) as they each explored their own problem space, driven by their aesthetic goal. The loom thus operates as a kind of generative problematics. The various goals of the weavers entailed different mathematical relationships, which had to be mobilized in order to create the desired patterns and asymmetries. The specific technicity of the loom has particular structural features that create opportunities to work with particular mathematical concepts.

When educators speak of mathematical representations, they typically point to an object or diagram or symbol as that which stands in for (or refers to) an immaterial mathematical concept. Does it make sense to speak of Akari’s cloth as a *representation* of a mathematical concept? Our case study shows how a weaving problem can engender a very complex mathematical form, indeed a form so complex it might be deemed the sort of “monster” that Lakatos wrote about when he discussed the intellectual labour of mathematical invention. Mathematical monsters are initially barred, but then you realize you want to play with them, and the rules need to change so that you can. Akari’s cloth is the result of a weaving process that played with the conventional tension of the loom, in order to dive into the indeterminacy of the concept of dimension. Once we attend more carefully to the way material media play a big role in mathematical labour, and perhaps rethink the nature of representation in terms of making processes, the question “where is the mathematics?” becomes even more interesting. Of course, one needs to attend to the differences between the material labour of a mathematician working with chalk or software and the material labour of a weaver at the loom. Our claim is that more attention to these material media will open up our understanding of mathematics in all its diversity, demonstrating how representation is entangled in making processes.

# Prospective mathematics teachers' extrapolative reasoning about misleading bar graphs

Samet Okumus and Ercan Dede

Recep Tayyip Erdogan University, Turkey; [samet.okumus@erdogan.edu.tr](mailto:samet.okumus@erdogan.edu.tr),  
[ercan.dede@erdogan.edu.tr](mailto:ercan.dede@erdogan.edu.tr)

*This study investigates prospective mathematics teachers' (PSTs) reasoning about magnitudes in misleading bar graphs. We report results from three student teachers who worked in a group. They made sense of vertically-oriented bar graphs whose vertical axis was not equi-spaced or y-axis did not start with zero. We analyze PSTs' extrapolative reasoning that refers to the ways they identified implicit relationships in graphs. The results demonstrated that PSTs modified or re-produced the bar graphs to overcome the misleading information, and re-labeled the numerical values of the categorical variables. They focused on arithmetic calculations and used them as a checking tool when they modified the bar graphs. They changed the location of the zero baseline and tended to keep the lengths of the bars invariant.*

*Keywords: Prospective mathematics teachers, misleading bar graphs, magnitude, extrapolation.*

## Introduction

Huff (1993) emphasizes that we are often exposed to misleading statistics in daily life. Scaling is one of the most common types of misleading statistics. In most cases, large increments of data display could compress the graph vertically. However, if the increments get smaller, the vertical graph could seem curved or the graph could have zigzags (Huff, 1993). It is also common to put a break in the scale on the vertical axis. This change places the different intervals for the axes to represent the variables, which shows different relationships between the variables other than they actually have. Graphs that incorporate a third dimension are most often confusing for the graph reader, particularly when comparing two or more values. In this sense, the height of neighboring bars affects the accuracy of measuring one value (Huff, 1993).

When students learn to recognize misleading statistics, they develop a new understanding of presenting data. Even in classroom environments and in textbooks, it is possible to encounter misleading or incorrect examples. In particular, statistical studies may be misleading and “at the heart of the matter lurks a black box, the fuzzy and multifaceted ‘context’ or ‘personal factors’ or ‘subjective meaning’, which cast doubt on both simple counts and causal explanations” (Wolf, 2007, p.26).

Bar graphs represent categorical data with rectangular bars that signify measured values. Also, bar graphs show frequency or proportion of categorical data. They highlight relative magnitudes and allow for encoding absolute values of discrete data (Friel, Curcio, & Bright, 2001; Curcio, 2010). Friel, O'Connor, and Mamer (2006) emphasize that “a bar's height is not the value of an individual case but rather the number (frequency) of cases all have that value” (p.125). Although

previous research studies have highlighted students' difficulties reading bar graphs (see Shah & Hoeffner, 2002), there is little research that indicates how students reason about magnitudes in bar graphs with a misleading representation. The purpose of this study is to investigate prospective mathematics teachers' reasoning about magnitudes in bar graphs when they modify or re-produce the graphs to overcome the misleading information. The research question of this study is: "In what ways do prospective mathematics teachers reason about the magnitudes in misleading bar graphs while they go beyond the data?"

### **Theoretical framework: Graph comprehension**

Friel et al. (2001) describe *graph comprehension* as "graph readers' abilities to derive meaning from graphs created by others or themselves" (p.132). The researchers identified three important components of graph comprehension. According to the first component, the graph reader "must understand the conventions of the graph design" (p.152) to be able to obtain information from the graph. For example, "a bar graph highlights relative magnitudes, which are considered analog information; numerical values can be approximated only through scale interpolation" (p.140). In this sense, the graph reader should be able to read the *specifiers* and *labels* on bar graphs. Specifiers are visual representations that signify the data values (e.g., bars on bar graphs) or marks that indicate relationships between the data values on a graph (e.g., the box in a box plot that signifies the interquartile range). Curcio (2010) refers to the level of graph comprehension that "requires a literal reading of the graph" as *reading the data*. The *background* information (coloring, grid, etc.) may help the reader identify the specifiers in the graph (Friel et al., 2001). Also, Friel et al. (2001) refer to the axes, scales, grids and reference markings as the *framework* of a graph.

The second component of graph comprehension emphasizes manipulating "the information read from a graph" (Friel et al., 2001, p.152). Manipulation of the obtained information from specifiers in a graph requires making comparisons (e.g., quantities) and calculations (e.g., addition, division) to combine and integrate the data – that is also known as *interpolation*. For example, one may compare the relative heights or lengths on a vertically- or horizontally-oriented bar graph, and find the proportional relationship between the values of individual specifiers. Curcio (2010) associates this level of graph comprehension with *reading between the data*.

The third component of graph comprehension emphasizes processing the information in the graph taking into consideration the context of the data "to generalize, predict or identify trends" (Friel et al., 2001, p.152) – that is also known as *extrapolation*. In extrapolative reasoning, students read *beyond the data* and find patterns or relations that go beyond values already displayed or known. As Curcio (2010) highlights, "whereas reading between the data might require that the reader make an inference that is based on the data presented in the graph, reading beyond the data requires that the inference be made on the basis of information in the reader's

head, not in the graph” (p.9). Extrapolative reasoning ability may require modifying or re-producing a graph to present and demonstrate new information that is not found in the graph.

## Methods

The participants of this research study were selected from a group of prospective middle school mathematics teachers who were enrolled in a methods course about teaching mathematics with technology. The class met two hours per week and the first author was the instructor. The participants were in their third year of the program. One week prior to the study, prospective mathematics teachers (PSTs) learned about making graphs (e.g., bar graphs, histograms, etc.) in Microsoft Excel and GeoGebra. However, the instructions for making graphs aimed to develop PSTs’ technological knowledge. The data were collected from nine PSTs (four female, five male) outside the regular class hours. The PSTs were not taught how to make misleading graphs in the computer programs. The participants worked in groups of three. For this study, we report on results from one of the groups. The group members were Nese, Sevgi, and Umut (all names are pseudonyms). Nese and Sevgi are female, and Umut is male.

The participants solved three tasks, and worksheets guided them to investigate vertically-oriented bar graphs. The PSTs were not informed that the graphical displays were misleading. Also, the worksheet questions did not ask the participants to modify or re-produce the bar graphs. For each task, they were given a color-printed worksheet with four additional black and white copies. After the completion of the three tasks, a whole-class discussion was generated. In the first worksheet, the vertical axis of the bar graph was not equi-spaced (see Figure 2a). The graph with some data labels indicated the amount of money a child was given by his family members. The PSTs used the horizontal lines on the graph to identify the missing data labels on the y-axis. We asked them to find the relative ratios of money of the child’s family members (e.g., the ratio of money with grandfather and uncle). In the second worksheet, the 2015 PISA scores of three countries (USA: 470, Croatia: 464 and Greece: 454) were represented with a bar graph whose y-axis did not start with zero (see Figure 3). In this task, The PSTs most often reasoned about counter examples. For example, they were asked how they would respond to a child who claimed that the score of Croatia was 6 times of the score of Greece. The third worksheet asked the participants to compare the number of singles a music recording studio sold using the information from a bar graph that incorporated a third dimension. However, in this study, results from the third task were not reported.

While the participants were solving the tasks, the first author monitored them. Also, he became involved in group discussions, gave prompts, and asked follow-up questions. A video camera for each group was placed at a fixed view. Also, the second author videotaped the interactions among the PSTs while the instructor was monitoring their progress. The PSTs’ gestures were captured from the video recordings. After the study, the researchers constructed verbatim transcripts coordinated with gestures and written responses of the participants.

In this study, we did not focus on the PSTs' literal reading of the graphs. Rather, we were interested in identifying moments when the PSTs made sense of information that was not provided directly in the graphs. The participants' reasoning about the graphs to obtain information was categorized into two: interpolative and extrapolative. On the one hand, the PSTs' use of specifiers (e.g., horizontal lines on the graphs) to find an unknown value, comparison/manipulation of information in the graphs and arithmetic calculations were identified as their interpolative reasoning. On the other hand, we categorized the PSTs' strategies for rescuing the graphs from misleading information as their explorative reasoning, in particular when they modified or re-produced the graphs. We focused on in what ways they took into consideration the magnitudes of the bar graphs and estimated a value following a pattern in their new data displays. For example, we identified whether they preserved the lengths of the bars when they modified the graphs. The central focus of the results was on the PSTs' extrapolative reasoning in the process in which they rescued the graphs from misleading information. We also analyzed the PSTs' interpolation process to show how they laid the foundations for their explorative reasoning. In other words, the interpolation process was helpful in identifying how they linked their modified/re-produced graphs with their interpolative reasoning to indicate the true relationships between the categorical variables.

## Results

In the first task, the graph indicated the amount of money a child was given by his family members. The PSTs found the missing specifiers on the y-axis counting the lines between two known numeral values using them as reference markings using their interpolative reasoning. Then, they focused on the arithmetic calculations as asked in the worksheet. When they were asked if they could identify the relationships between the categorical variables without making any calculations, they considered the magnitudes of the bars. The researcher's prompt encouraged them to modify the graph. For example, Sevgi measured the length of the grandfather's bar placing her thumb and index fingers on the bottom and top of it as shown in Figure 1a. Then, she kept the same distance between her fingers and made a part-to-part comparison between the lengths of bars of uncle and grandfather (Figure 1b). Finally, she figured out that the length of the grandfather was two and a half times of the uncle's. However, in their earlier arithmetic calculation, they found the ratio of money with grandfather and uncle was 3.

(a)

(b)

(c)

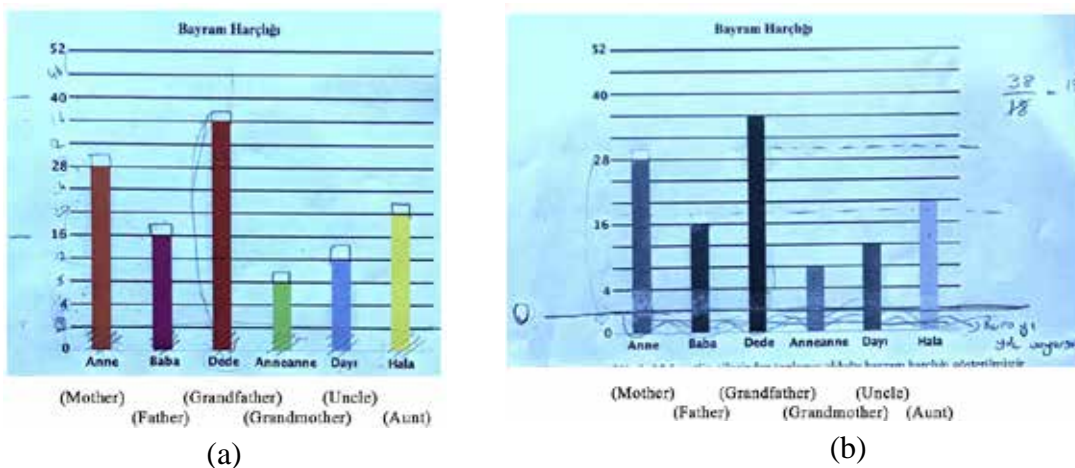

**Figure 1:** (a) Sevgi takes the length of the bar of the uncle as a reference, (b) She makes a part-to-part comparison between the lengths of the bars of the uncle and the grandfather, (c) She notices

**the length of the grandfather is two and a half times of the uncle's**

Then, using explorative reasoning, they modified the bar graph to be able to use the lengths of the bars and to check whether the ratios between the categorical variables were consistent with their calculations.

The PSTs equalized the scale of the axis and increased the numeral values of the y-axis by 2. However, this modification gave rise to changing the amount of money given by the family members. For example, the numeral value of the mother changed from 28 to 16. Then, they cut off the bars from the value of 2, and added the cut-outs onto the corresponding bars as shown in Figure 2a. This strategy allowed them to make the intervals increasing by 4. They located the cut-outs onto each bar by adding 2, and preserved the lengths of the bars. Then, they referred to the intervals between the horizontal lines as units and counted them (Figure 2a). Umut said: “Then, if we look at the amount of the money the grandfather and father gave: 1-2-3-4-5-8-9 [pauses]. Isn't it one half [means 9.5]? If we count the father's: 1-2-3-4 and a half. 9.5 and 4.5.” Using interpolative reasoning, the PSTs noticed that the re-labeled specifiers (increments) did not match with their arithmetic calculations. The strategy of adding cut-outs onto the corresponding bars did not satisfy the participants. They investigated new strategies to overcome the misleading information.

**Figure 2: (a) PSTs cut off the bars from the value of 2 and added the cut-out bars onto the corresponding ones, (b) They quit adding the cut-out bars onto the corresponding bars**

Nese noticed that if they canceled out the cut-outs (Figure 2b) and counted the intervals between the horizontal lines, the ratios between the categorical variables were the same as those in their earlier calculations. Nese's strategy made the graph equi-spaced and allowed them to count the intervals between the horizontal lines. Then, the PSTs compared the magnitudes of the grandmother and the aunt in their new strategy. For example, in their earlier calculation, they found the ratio of money with aunt and grandmother as 2.5 ( $20/8$ ), and Nese used this information to support her claim. The below excerpt indicates Nese's approach to the problem.

- Nese: For example, let's do not think of that portion [the cut-out] as if it was not there. Let's write zero here and when we count the intervals [between the horizontal lines], we find the same ratios.
- Umut: Let's check aunt's and grandmother's. Let me check the aunt's.
- Nese: 5 is for the aunt, and 2 for the grandmother.
- Umut: 2.5 [the ratio]. Exactly [the same].
- Sevgi: Yes. Give me a high five!

In the second task, the participants most often talked about a child's claim that the PISA score of Croatia was six times of the score of Greece. The PSTs read the specifiers and concluded that the claim of the child in the problem context was false. However, Sevgi emphasized that, in the first task, they changed the location of the zero baseline and used the intervals between the horizontal lines. She suggested re-labeling the zero baseline, as it was 452 in the original. In other words, she considered the relative magnitude 452, and subtracted it from the numerical values of the bars. Accordingly, she revised the numeral values of the countries as shown in Figure 3 (USA: 18, Croatia: 12, Greece: 2). Nese and Umut did not agree with Sevgi, and they convinced her by saying:

- Umut: We can compare proportionally as they have equal intervals [in the first task], can't we? But, the student [child] is misled here because the graph [y-axis] does not start with zero. It [the child's claim] would count right if this [Figure 3] started with zero...
- Sevgi: We removed [the cut-outs] here in this bar graph [refers to the first task]. We removed the same values from all. We can think of it "6" [the ratio of scores with Croatia and Greece] when we take away the same numeral values from all.
- Umut: Since it asks for the total score, I think we should not take them away. Especially, we will consider it 470 (for USA) and they [the scores] cannot be reduced.

**Figure 3: Sevgi re-labels the numeral values of the countries**

The PSTs made a decision to start the graph at zero, in order to be able to show the true relationships between the scores of the countries. They extended the magnitudes of the bars to

the zero baseline (Figure 4a). When the instructor became involved in the group discussion, Umut made a gesture as shown in Figure 4b to demonstrate that they extended the zero baseline. He said:

Umut: To able to show the actual magnitudes. The graph shows the score of Greece with an increment of 2, but it actually earned a high score, 452. Namely, there is not much difference [in magnitudes] between 452 and 470. It shows only the upper section [of the bar graph] with an increment of 2. It looks like it [the graph] conceals the actual graph in the background. So, we wanted to make it clear that it [the ratio of scores with Croatia and Greece] is not 6. Eventually, the child numerically sees that 464 is not six times of 454.

**Figure 4: (a) PSTs extend the magnitudes of the bars to the zero baseline, (b) Umut makes a gesture that signifies the extension of the bars**

## Concluding remarks and implications

The results of this research suggest that the PSTs focused on performing arithmetic calculations in their early reasoning about the task without considering the graphical displays were misleading. They performed arithmetic calculations to find the proportional relationships between the variables. When the instructor gave a prompt about finding the relationships without making any arithmetic calculations, the PSTs stressed the misleading information. They identified the proportional relationships taking into consideration the lengths of the magnitudes of the bars, and figured out that the relative ratios did not match with their earlier arithmetic calculations. Then, they became more interested in modifying or re-producing the graphs to show the true relationships between the variables. They used their calculations as a checking tool when they modified or re-produced the bar graphs, and re-labeled the numeral values of the variables to overcome the misleading information. The PSTs modified the zero baseline to make the y-axis equi-spaced, cut off the bars from specifiers, and added the cut-outs onto the corresponding bars. They tended to preserve the lengths of the bars invariant when they modified the location of the zero baseline. After they checked their arithmetic calculations, the PSTs noticed that the relationships between the categorical variables were not consistent with their calculations. In this sense, their arithmetical calculations (interpolative reasoning) laid the foundations for their explorative reasoning.

We observed differences in graph comprehension abilities of the participants. For example, Sevgi focused on the magnitudes of the bar graphs when she made an inference. On the other hand, Nese and Umut took into account the arithmetic calculations as a checking tool. As Friel et al. (2001) state, graph comprehension requires spatial judgments or modifications in specifiers and labels in graphs. Future research may indicate how individual differences may affect graph comprehension of students when they make sense of misleading graphs.

One of the limitations of our study was that the PSTs reasoned about vertically-oriented bar graphs. However, the affordances of vertically- and horizontally-oriented bar graphs differ (Shah & Hoeffner, 2002). For example, “horizontally oriented bars may be better for other dimensions for which the horizontal dimension is more meaningful, such as in depicting data about the distance traveled (p.51)”. Researchers may investigate how students’ making sense of misleading graphs differs in vertically- and horizontally-oriented bar graphs.

It is important to examine not only the axes of bar graphs and check whether they are starting with zero (when graphing positive values) but also if the axes are equi-spaced. If the y-axis is not equi-spaced or does not start with zero, the graph may cause misleading information for the reader. However, a bar graph with a zero baseline may also give rise to missing the relevant information of data. For example, suppose we measure the body temperature of a person with fever in Fahrenheit for a day, at intervals of an hour. If we show the body temperature of the person using a zero baseline in a line graph, it may indicate almost a straight line and conceal the jumps between the neighboring hours. In this sense, the context of the data matters.

*Keywords: Graphic representations, drawings, visualisation, word problems, geometry.*

## Introduction and theoretical background

The use of drawings when working with geometry word problems will emerge naturally in students; however, the strategic use of representations to solve the problem does not. The contribution of visualisation to mathematics education, and especially in geometry, is undeniable; however, it is worth noting that to make effective use of this tool in the solution of word problems, the student will need specific prior knowledge and certain cognitive skills (Schnotz, 2002). Mathematics relies heavily on visualisation because it deals with abstract objects (Arcavi, 2003), the possibility to "see" the mathematical objects and express numerical information through graphical representations helps students understand concepts and solve problems (Edens & Potter, 2007).

Although the drawings with pictorial characteristics do not seem to be related to performance in mathematical modelling and the correct solution, they can serve as a preliminary step to more schematic representations (Rellensmann, Schukajlow, & Leopold, 2016). This sequential process from pictorial to schematic drawings contributes mainly to the understanding of the situation and the task, which has shown to be particularly useful for students who have more difficulty making the transition between the real world and the mathematical world.

## Method

Research question: What is the role of the drawing that students do when they solve a problem of geometry in which they are asked to find the area of a figure that is not presented explicitly but results from the relationship of the elements?

Participants: 20 students of the 9th grade from a public school in Mexico (12 girls and 8 boys) with an average age of 14 years.

## Procedure

For the research, a worksheet was developed including one area problem: *A dog is tied to a chain that allows a maximum range of 2 metres, attached to a ring that moves in a bar in the shape of a right angle whose sides measure 2 metres and 4 metres. What is the area of the region that the dog can cover?*

The worksheet was applied in a single session with all the participants without any previous intervention. This study only considered the analysis of the drawings made by the students on the worksheet to solve the problem.

In the analysis of the representations, two processes were carried out: a classification process and a qualitative analysis of the drawings. Three levels of classification of the drawings were made considering (1) level of abstraction, (2) relationship with the statement of the problem and (3) the explicit inclusion of information in the drawing that is mathematically relevant to solve the problem. The qualitative analysis consisted of a finer revision of the characteristics of the representations considering the students' proposed figure; the information included; the proportionality of the presented elements; and the transitions between pictorial, schematic, operations and result domains.

## Results

None of the participants was able to draw the expected figure or reach the correct result. Most of the students showed some difficulties, inadequately representing the proportions of the objects in the situation and paying excessive attention to mathematically irrelevant details, such as flowers, clouds and the dog's house.

The analysis of the drawings showed how the students carry out the transition between the real domain posed by the problem and the mathematical domain. Some students make a gradual transition, while others move directly from the representation of the situation to mathematical operations. Given the above, we can classify the transitions into three groups: (1) pictorial to pictorial with data, (2) pictorial to schematic, and (3) pictorial to numerical.

## Conclusion

Although the use of drawings in solving geometry problems emerges naturally in students, effective use of graphic representations must be worked on through activities in the classroom. If the drawing activity is kept away from mathematics classes, it is very likely that the students may assign a purely decorative function to the drawings. The representations generated by the students can be a handy tool for observing their reasoning in such a way that allows us to understand better what they know and how they know it.

# Exploring Strategies Used to Solve a Non-Routine Problem by Chilean Students; an Example of “Sharing Chocolates”

Farzaneh Saadati and Mayra Cerda

*Keywords: Mathematical thinking, problem solving, representation strategy.*

## Introduction

In Chile, mathematical problem solving has been incorporated in the school curriculum. However, it has been shown that problem solving activities are practically absent in the classrooms (Felmer & Perdomo-Díaz, 2016). Furthermore, despite an emphasis on problem solving in the new curriculum for grades 1-8 (MINEDUC, 2012), teachers appear reluctant or unable to incorporate rich problem solving practices in their classrooms. Cai and Nei (2007) suggested that students' performance in problem solving is affected by the cultural context, teachers' beliefs and their practices. In another study, we found a mismatch between Chilean mathematics teachers' beliefs and practices (Saadati, Cerda, Giaconi, Reyes, & Felmer, 2018). Teachers have sort of reformed beliefs about problem solving, however in classrooms, problem solving is predominantly seen as a set of concrete techniques, and teachers focus on the repeated practice of procedures. These conditions and circumstances can obviously have an impact on students' problem-solving ability and on their mathematical thinking. In this study, we are going to explore Chilean students' representation strategies to solve the problem on sharing chocolates:

*3 boys share 2 bars of chocolate equally and 8 girls share 6 bars of chocolate equally. Who gets more chocolate, the boys or the girls? Explain or show how you found your answer.*

This problem is a process-constrained problem categorized as a non-routine problem for Chilean elementary students since they are not familiar with this type of problem. To solve this problem, they might fail to consider all of the information presented in the problem, or “compute first and think later” (Hegarty, Mayer, & Monk, 1995). Students' representation might be directed towards using division because of the presence of the term “share” and the numbers. It can be represented as  $\frac{3}{2}$  or  $\frac{2}{3}$ . We refer to this form of representation as *direct-translation*. The students could also try to construct a representation of the situation being described in the problem (Hegarty et al., 1995). The representation constructed based on this approach is usually a more meaningful and concrete way that involves the construction of a mental model. We call it a *meaning-making* representation strategy which can become a basis for construction of a solution plan. In this study, we explore the dominant and most accurate representation strategies and the rate of success among students.

## Methodology and Results

The students were asked to solve three problems presented by Cai (2000). Here we discuss the problem “sharing chocolates”. Participants were 143 students from several public schools; 72 girls, and 71 boys, included 52 sixth graders, 52 seventh graders, and 39 eighth graders.

There were 74 students who had a plan to solve the problem by following the three-step process. In contrast, 52 students did not devise any plan to solve the problem. These students skipped the first

two steps and tried to answer only the third part of the problem which was the sense-making question. The rest of the students (17) did not try to solve the problem and left it blank. The results revealed that 46 out of 74 (32% of students who followed the three-step process) were able to finish it, and 28 students stopped before reaching the third part or sense-making question. Among the students who followed the process, 17 students out of 74 showed a direct-translation representation – correctly or incorrectly – to solve the problem. The rest of the students used a meaning-making strategy. By using the meaning-making strategy, 45 students pictorially represented their solution (drawing only or mixed with a verbal explanation), the other 12 students just verbally explained their solutions. Finally, only 9 students could solve the problem completely without any mistakes; 3 students used a direct-translation and 6 got the answer by using the meaning-making representation strategy.

## Discussion

The results of the Chilean grade 6<sup>th</sup> to 8<sup>th</sup> students revealed that using the meaning-making representation was more prevalent among them. The students' performance was comparable with U.S. students in a similar study done by Cai (2000). However, there was a large rate of failures among these students and just a few of them (about 6%) could solve the problem successfully. We believe, the mismatch between teachers' beliefs and practice can explain the gap between their tendency of using meaning-making strategies and their failure. The teachers' reformed beliefs may lead them to put more value on meaning-making representation strategies, while their traditional teaching approach explain their students' lack of skills and inexperience with non-routine problems. In fact, the failure highlights the necessity of a shift of instruction towards more student-centered practices in order to give students more space to develop their mathematical thinking while working with those non-routine problems. Therefore, we suggest changing school practices and organizing effective and related teachers' professional development programs.

*A theoretical discussion of possible connections between some non-conventional external representations (i.e., textual tasks of a particular format) and their corresponding internal representations (i.e., perceptions of these tasks by mathematics learners) is presented in this paper. Our goal is to analyze the interplay between external and internal representations in relation to non-conventional textual tasks of "who-is-right?" format. Such tasks involve a relatively long textual story introducing a situation that can be interpreted in (at least) two contradictory ways, which are explicitly given. The solvers of the task are required deciding which interpretation is correct and support their decision by an argument that would convince their peers. The presented theoretical analysis in terms of representations can serve as a tool for teachers and teacher educators in designing tasks specifically tailored to their students' needs.*

*Keywords: Experientially real representations, socially shared representation, task design, controversy.*

## Introduction

Ways in which mathematical ideas are represented are fundamental for how people learn and use these ideas (Heinze, Star, & Verschaffel, 2009). Goldin and Kaput (1996) refer to *representation* as a configuration of some kind that corresponds to, or is referentially associated with, or symbolizes something else. According to the National Council of Teachers in Mathematics (NCTM, 2000), *representation* refers "to the act of capturing a mathematical concept or relationship in some form and to the form itself" (p. 4). In other words, representations refer to both processes and products of learning and doing mathematics.

Goldin and Kaput (1996) differentiate between internal and external representations. Internal representations allude to possible mental configurations of individuals. As such, they cannot be observed directly. Rather, they can be inferred based on theoretical analysis, and when appropriate – based on behavioral clues, like gestures, speech and acts. In contrast, external representations allude to physically embodied, observable configurations such as texts, graphs, pictures, or mathematical symbols. These are in principle accessible to observation.

The theoretical discussion of possible connections between some non-conventional external representations (i.e., textual tasks of a particular format) and their corresponding internal representations (i.e., perceptions of these tasks by mathematics learners) in this paper corresponds with the Call for Papers of CERME11 TWG24 in the following way. We concern with creation, interpretation and reflection on external representations in learners' minds, with the purpose of depicting and communicating information, thinking about and developing mathematical ideas, and advancing understandings. Hence, we address the following question posed in the Call: "How can non-conventional representational activity contribute to mathematical thinking?" Specifically, our

goal in this paper is to analyze the interplay between external and internal representations in relation to non-conventional textual tasks of "who-is-right?" format.

In the sections below, we present a "who-is-right?" task format, followed by analysis of examples in the contexts of algebra and geometry, with particular focus on conjectured internal representations. The conjectures, though theoretical, are supported by our experiences of enacting the presented tasks with various audiences. The concluding discussion is related to aspects of designing tasks of "who-is-right?" format, specifically to taking some conventional mathematical tasks and turning them into un-conventional ones.

### **The "who-is-right?" task format**

An external representation of "who-is-right?" format (henceforth, WIR task) involves a relatively long textual story introducing a situation that can be interpreted in (at least) two contradictory ways. Rather than asking students to interpret the situation, the contradictory interpretations are explicitly given in the voices of two or more virtual characters. As a rule, each interpretation involves argument based on attention to some aspects of the story; otherwise, the argument supporting the interpretation must be revealed by actual solvers of the task. The actual solvers of the task are required deciding which interpretation is correct and support their decision by a convincing argument.

Such tasks have several representational characteristics. First, the textually presented situation alludes to experientially real world of the potential solvers of the task (Gravemeijer & Doorman, 1999). That is, the situation is rooted in solvers' perception of experientially real, everyday-life phenomena. Second, the task is presented in everyday language, which might be ambiguous once referring to mathematical objects or mathematical objects in disguise. Third, the task does not require solving a textbook-like mathematical problem, at least not explicitly. Instead, two contradictory claims about the situation are presented. The learners are asked to take a stance and defend it. In order to be able to do so, the learners need to build two internal representations of the situation by taking into account each of two contradictory claims. This activity has the potential to advance their ability to overcome the limitations of the experientially real (but subjective) representations, towards building a shared representation based on mathematically valid argument that can convince the other learners when non-mathematical argument fails to do so. Fourth, the mathematically valid answer to the question "who is right?" may be not only of the "one of the characters is right" format but also of non-conventional formats such as "both are right", or "both are wrong", or "it depends". Such options potentially add an element of surprise to the task. Fifth, WIR tasks can be sequenced so that dealing with the next task requires not only a comparison between two interpretations of the given situation but also comparison of a new situation with the previous one.

Several WIR tasks have been used in previous studies as research instruments. For example, researchers (Buchbinder, 2010; Buchbinder & Zaslavsky, 2013; Healy & Hoyles, 2000) have used such tasks for revealing the student conceptions of proof and examples. In particular, Buchbinder and Zaslavsky (2013) designed a WIR task based on a claim "For every natural  $n$ ,  $n^2 + n + 17$  is a prime number" plus two responses to this claim by virtual student-characters. The first student-character argued that the claim is correct because she checked its validity for the first 10 integers, and the second student-character claimed that the statement is false because  $n^2 + n + 17$  is not prime for

$n = 16$ . Then 12 high-school students were exposed to the task and asked to determine who was right and explain why. All students exhibited indicators of understanding that for a universal statement to be true it has to hold for all cases. At the same time, some of these students remained convinced that a statement can be 'proven' through examination of several confirming examples.

Another WIR task was used in a teaching experiment conducted by Koichu (2012) with a group of pre-service teachers. The teachers were exposed to two pictures: a picture of the famous Penrose triangle and a picture representing a sculpture of the Penrose triangle taken from an angle that created an impression that the Penrose triangle can be made as a real 3D object. The students were required deciding whether the Penrose triangle indeed could be a 3D object or prove otherwise. This study resulted in a description of a particular set of instructional conditions in which mathematical defining and proving could be intellectually necessitated for the students.

In spite of the fact that in both tasks one of the included responses was intuitively more appealing than the other one, the tasks proved themselves as triggers for evoking uncertainty in their solvers, as well as useful tools for revealing the students' (mis)conceptions and reasoning. These tasks stimulated our interest in further developing WIR representational activities as research and teaching tools that would correspond to curriculum-determined mathematical topics. In the next section, we present two WIR activities, one in algebra and another in geometry, and discuss their common features as well as subtle differences inherited in their design.

## Examples and analysis

The WIR tasks presented in this section are designed for the use with middle-school students. The forthcoming discussion of internal representations associated with these tasks is based on our experience of enacting and discussing the tasks with two groups of in-service teachers.

### Example 1: Subtle matters related to percentages

Figure 1 presents the first task in the sequence of three tasks.

Towards the end of the summer holidays, suitcases are sold with a 30% discount. The final price of a suitcase includes VAT of 17%.	
In calculation of the price, one can first take into account the discount and then calculate VAT or otherwise. It appears that a buyer and a tax collector have different opinions on this matter.	
<b>Advice from Buyer:</b> I think that one needs first to calculate the price including VAT and then the discounted price. In this way, the discount would apply to a greater number and the final price would be lower.	<b>Advice from Tax Collector:</b> I think that one needs first to calculate the discounted price and then to add VAT. In this way, the sum of VAT would not be influenced by the discount and the final price would be higher.
<ol style="list-style-type: none"> <li>1. What do you think?</li> <li>2. How would you convince a peer who disagrees with you?</li> <li>3. How can we decide who is right?</li> </ol>	

**Figure 1: The first task (discount and tax)**

We now outline a conjectured scenario of dealing with this task. The student reads the story and decides who is right (a buyer or a tax collector) based on the mainly emotionally loaded process of taking the perspective of a buyer or of an authority. It was our intention to make the buyer's and the tax collector's responses more or less equally plausible for the solver. The process of the task comprehending requires the students to create competing internal representations of the situation, but at the individual level, one of two internal representation eventually prevails, and the student convinces herself that "a buyer is right" or "a tax collector is right". At the collective level, the class splits (always worked in our teaching), so that each student can see that his or her opinion is not the only possible one. At this stage, many students cannot think of an argument in support of the opposite opinion, so the split is perceived as a surprise. When asked by the teacher to convince the opponents, the students attempt to explicate their internal representation and produce explanations in everyday language often accompanied by gestures. Then, the students are surprised even more when they find out that these explanations are incomprehensible or perceived as too vague for their counterparts in order to be convincing. A collectively shared need to find a way of getting to the common ground arises. At this stage, an option to employ mathematical apparatus emerges, usually as a spontaneous suggestion of one of the participants. This is probably because of the general context: after all, the discussion occurs at a mathematics lesson. Some meta-level questions arise with the help of the teacher. For example, what argument can be convincing? How can the buyer's or the tax collector's argument be expressed mathematically?

Next, the teacher suggests the students to attempt to mathematize the situation, in the hope to construct a shared (external) representation that would be convincing for all. The students begin using mathematical language, first in order to test the correctness of their initial claims; then in order to assess their claims as well their opponents' claims. In this process, the classroom map of agency changes, and the teacher does not act as a source of knowledge about the correct solution but as a facilitator of establishing the new discursive rules (Sfard, 2002), and as a mediator of the discussion. In this way, the teacher stops being an authority whose role is to approve or disapprove the student solutions, but becomes an authority who can support or disregard (for example, by re-voicing) types of arguments produced by the students. This situation promotes the individual student argumentative talk based on gradually established rules (Hershkowitz, Tabach, Rasmussen, & Dreyfus, 2014).

Eventually, the surprising to many students resolution of the given situation – the buyer method and the tax collector method lead to the same final price – may ease the emotional tension in class. This would be a good moment to present the next task of the sequence (Figure 2).

Presenting this task second, one cannot but compare it with the first task. In this context, the individual may create an internal representation of the task by attending to the following parallels: decreasing the length of one side is the counterpart of the discount, and increasing the length of the other side is the counterpart of the VAT. This may overshadow for the students an important difference between the external representations of the tasks. It is now not about the multiplication operations performed sequentially, where the second operation is applied on the result of the first operation, hence the final answer does not depend on the order. In the second task, each of two multiplication operations is applied to the same initial number, and then the results of these two operations are multiplied to find the area of a new shape, hence the final result may change.

The area of any square equals to the area of a rectangle built from that square by increasing one side by 10% and decreasing the perpendicular side by 10%. Is it so?	
<b>Michael:</b> Yes.  The square sides are of equal length. Therefore, adding 10% and cutting 10% of the side lengths imply that what you add and what you cut is the same.	<b>Josef:</b> No.  If the side length is 10 cm, the area is $100 \text{ cm}^2$ . The rectangle will have 9 and 11 as side lengths, and the area will be $99 \text{ cm}^2$ .
1. What do you think? 2. How would you convince your peer who disagrees with you? 3. How can we decide who is right?	

**Figure 2: The second task (changing the area)**

In this case, using the same 10% change for the adjusted sides of the square may add to the internal representation that leads to the (wrong) conclusion that "nothing changes". For these reasons, reading Josef's explanation may serve as an eye-opener, in line with the counterexample for  $n = 16$  in the task from the Buchbinder and Zaslavsky's (2013) study, as presented above. The calculations of Josef are easy to follow and validate. Hence, we expect that the discussion of the WIR question would rather be quick, and that the discussion of the question "how are the first and the second tasks different?" would be longer. Then, the discussion might develop, again, with the help of the teacher, in an epistemological direction. Namely, the class may discuss what can be concluded from just one counterexample and what argument can be made about whether the Josef example more convincing.

Our suggested sequence does not stop here. The third task is ready to be presented (Figure 3).

The perimeter of any squares equals to the perimeter of a rectangle built from that square by increasing one side by 10% and decreasing the perpendicular side by 10%. Is this correct?	
<b>Ron:</b> No.  We just solve this problem and saw that it would not be the same.	<b>Gal:</b> Yes.  Two sides became larger and two become smaller. The additions and cut-outs are of the same size; hence, the perimeter will not change.
1. What do you think? 2. How would you convince your peer who disagrees with you? 3. How can we decide who is right?	

**Figure 3: The third task (changing the perimeter)**

Reading the third tasks may immediately raise a déjà-vu feeling of we have already solved this one, and, indeed, Ron's claim gives room for this feeling. Yet, reading Gal's argument may lead the learners to re-consideration of Ron's stance. We believe that for this task to be the third in the sequence, middle school students may turn to the search for (external) mathematical representations of the situation quicker than in the previous two tasks. And once more, a surprise would await them

(after all, Gal is right!), which may evoke a hot discussion of how this task is different from the previous one. From our experience, elaboration on the differences between the external representations of all three tasks in tacit association with students' internal representations, which gradually emerge in the classroom discourse, is a non-trivial endeavor. This was true even for the in-service mathematics teachers, who were exposed to the sequence, and even for those of them who were familiar with a variation of the first task. All the teachers acknowledged the plausibility of the above scenarios and expressed the wish to use the sequence with their students.

### Example 2: Dynamic loci of points

A task presented in Figure 4 follows the WIR format, but it differs from the previous example in (at least) three important aspects: (1) it concerns geometry; (2) it requires reconstruction of two different arguments rather than comprehending the given arguments, hence the questions to the solvers are not as in Example 1; (3) the answer to the task is of "it depends" format.

Einat and Sarah like touring and exploring. One day they found an old wooden box containing a note, written, apparently, by pirates. The note said: "There is no choice, we retreat. The treasure is too heavy and we are forced to hide it. The treasure is in 200 steps from a segment connecting the tallest eucalyptus tree and the tallest maple tree of this area, and in 300 steps from the midpoint of this segment."	
Einat and Sarah found the eucalyptus and maple trees, but then argue what to do next.	
<b>Einat:</b> There is no chance to find the treasure. It just does not exist.	<b>Sarah:</b> Let's try. With small effort, we have a chance to find the treasure.
<ol style="list-style-type: none"> <li>1. What might be the Sarah argument?</li> <li>2. What might be the Einat argument?</li> <li>3. Unver which conditions could Einat or Sarah be right?</li> </ol>	

**Figure 4: The treasure task**

With no exception, the solvers begin from drawing a sketch (external representation), as the one presented in Figure 5.

**Figure 5: A sketch for treasure task (E stands for the eucalyptus, M stands for the maple)**

At first glance, the sketch supports Sarah's opinion, because the stadium-like shape (represents the locus of points at the distance of 200 steps from segment  $EM$ ) and the circle (represents the locus of points at the distance of 300 steps from the middle of  $EM$ ) intersect in exactly four points. Therefore, according to the sketch, the treasure must be located in one of these points, and checking only four points is a feasible task. Of note is that creating the above sketch has been proven as difficult for the solvers. With in-service teachers, the most interesting discussions revolved around two questions: "How can the distance between a point and a segment be defined?" and "What is the locus of points?"

The most challenging part of the task is to re-construct the argument that may underlie the Einat's opinion. The tentative (but supported by practice) scenario of doing the task relies on the following assumption: Any external representation of the task situation by means of a drawing relies on an internal representation that includes an assumption about the length of line segment  $EM$ . Most of the learners intuitively assume that it is longer than 200 steps, as in Figure 5. However, if  $EM = 200$ , the locus of points described in the situation would consist of exactly two points. Furthermore, if  $EM$  is less than 200 steps, the locus becomes an empty set, and in this case Einat is right. Since the story does not include information about the length of  $EM$ , but only the information that Einat and Sarah found the trees, each of them can be right. Hence, the answer to the task is "it depends".

The readers are invited to explore the situation by means of a dynamic GeoGebra applet at <https://www.geogebra.org/m/n5mRrtMf> (consider varying the position of point B at the applet).

Of note is that whether or not a dynamic external representation of the task by means of GeoGebra is used, dealing with the task requires the learner to create a dynamic internal representation of the situation. This is an additional point of difference: in Example 2, the dynamic representation might be continuous, and dealing with the change in Example 1 might require creation of a discrete series of static representations.

## Discussion

On the face of it, turning "conventional" tasks into WIR tasks is simple. Instead of concluding a textual description of a situation by an open-ended question (e.g., "would the price change?" or "make a map and denote the treasure"), an additional layer of two contradictory arguments by virtual characters is added. Yet, we seek arguments that can be perceived by the learners as plausible, so that the class would split between favoring one argument over the other. Hence, designing worthy WIR tasks is not as simple as it may seem.

As mentioned in the introduction, any analysis in terms of internal representation cannot be conclusive just because these are not directly accessible. Accordingly, we do not assume that the above-presented scenarios are realistic or that we can realistically describe what is going in the minds of the solvers. Yet, the value of our analysis is in that it can serve as a design heuristic for teachers and teacher educators, like in thought experimentation, when designing WIR tasks.

Our hypothetical analysis of the interplay between internal and external representations was mostly at the level of an individual solver, and thus is in line with the claim made by Rittle-Johnson and Star (2011): "comparison is a fundamental part of human cognition and a powerful learning mechanism" (p. 221). In addition, we approached the interplay between the individual and the social in

implementation of the WIR tasks. In sum, we have argued that a WIR task can present students opportunities to engage with classroom-level argumentative talk based on an emerging need to resolve conflicting opinions expressed by individuals, and hence to be a step towards constructing some socially shared internal representations of the task.

*In this paper we analyze the practice of a grade 3 teacher. We focus our analysis on teacher-pupils interaction in the classroom, aiming to understand how she strives to promote her pupils' use of representations. Data were collected through video recording of lessons and were analyzed in the introduction of a task, during pupils' autonomous work, and in a whole class discussion. The results show that the teacher's actions change according to her pupils' activity and difficulties and also vary depending on the moment of the classroom work. To promote her pupils' use of representations, the teacher adapts the type of questioning and her actions to the difficulties of her pupils.*

**Keywords:** Representations, elementary school teachers, teacher's practice, questioning.

## Introduction

Pupils' understanding of representations constitutes a fundamental basis for their mathematics learning, making it very important to know the way teachers deal with representations in their practice (Stylianou, 2010). A representation may be defined as a mental or physical construct that stands for a concept and enables to relate it to other concepts (Goldin, 2008). The fact that mathematical representations are related to each other in different ways creates difficulties for pupils' understanding and learning of representations (Goldin, 2008). Tripathi (2008) indicates that, in order to facilitate pupils' understanding of a given concept, teachers must use different kinds of representation. Some researchers, like Acevedo Nistal, Doreen, Clarebout and Verchaffel (2009), suggest that, as a starting point for learning symbolic representations, teachers must encourage pupils to create their own informal representations. In this study we aim to understand how an elementary school teacher explores a task with her pupils in the classroom, with special attention to the way she strives to promote the use of representations.

## Teachers' practice, representations and questioning

An important aspect of teaching practice is the way teachers explore tasks in the classroom (Ponte & Chapman, 2006). Pupils' activity on a task is determined by the actions of teachers, the role that teachers assume, how they introduce the task, the questions that they ask, and the way how they lead whole class discussions (Swan, 2007). Ponte (2005) indicates that the classroom work on a task may involve three main moments: (i) introduction of the task which may involve negotiations of meaning (Bishop & Goffree, 1986), (ii) pupils' autonomous work, (individually, in pairs or groups), and (iii) whole class discussion.

Representations play an important role in mathematics. Their understanding is a complex process because a representation may have different meanings and in turn, a meaning may have several representations (Goldin, 2008). For example, the representation "5" may mean the 5<sup>th</sup> floor, 5 pm, or 5 as a quantity and, in turn the meaning of 5 as a quantity, can be represented as "|||||", "5" or "V".

For that matter, Duval (2006) indicates that, to understand the features of a mathematical object, we need to be able to make changes within a representation (treatment) or to change a representation in another representation (conversion).

To support pupils' learning of concepts, procedures and problem solving processes, the teacher may introduce new representations, linking them to pupils' previous knowledge (Stylianou, 2010). As Bishop and Goffree (1986) indicate, teachers must facilitate the interpretation of representations and encourage the establishment of connections among representations.

As pupils work on a task, the teacher's actions can be analyzed regarding how they promote the understanding of representations (Table 1). We defined four categories for pupils' activity that are related to teachers' actions: (i) support the pupils' design or selection of a representation; (ii) promote the use of a given representation; (iii) promote the transformation of a given representation; and (iv) promote pupils' reflection about representations. In table 1 we assume that there is a mutual influence between pupil's activity and teachers' actions. This way, pupils' activity can affect teachers' actions and teachers' actions promote pupils' activity. This framework about teacher actions is a specification of the general framework indicated in Ponte and Quaresma (2016).

<b>Pupils' activity regarding representations</b>	<b>Teachers' actions</b>
<b>Choosing/ Designing</b>	Promoting the free choice of a representation
	Challenging to choose a different representation
	Guiding about an adequate representation
	Providing explicit suggestions or examples
<b>Using</b>	Challenging to use a representation
	Asking to interpret a representation
	Guiding about the use or interpretation of a representation
	Informing pupils about how to interpret or how to use a representation (In)validating a representation chosen by pupils
<b>Transforming</b>	Challenging to establish treatments, conversions and connections
	Guiding to establish connections
	Guiding to identify possible treatments and conversions
	Inform about treatments and conversions
<b>Reflecting</b>	Challenging to systematizations
	Leading to systematizations
	Informing about systematizations

**Table 1: Teachers' actions in different moments of the pupils' activity**

Each teacher communicates in a different way with his/her pupils and how and when they do it. To Purdum et al. (2015), pupils' knowledge is influenced by teachers' questioning. Mason (2000)

indicates three different aims in teachers' questioning: (i) focusing, that is when the teacher question pupils through a funneling effect in order to focus them in a certain aspect; (ii) testing, in which the teacher analyses pupils' comprehension, and how they articulate ideas and establish connections and (iii) inquiring, in which the teacher questions pupils to understand what they are thinking. Regarding questioning, Blosser (1975) identifies four main categories or question types: (i) managerial, to give operating instructions; (ii) rhetorical, used to emphasize an idea; (iii) closed, with a limited number of possible answers (iv) open, with a large variety of possible answers, a type of questions used to promote a class discussion or pupils' interactions. In this way, we considered three different types of questions, with some subtypes (Table 2).

Type	Subtype	Examples
Focusing	Rhetorical	We saw this already, didn't we?
	Processual	Could you open your books on page 58?
		What if we look back into the task?
	Orienting	What if you sum it all?
Confirmation	Closed	How many will we have if you add 10?
Inquiring	Open	Do you agree with your colleagues' answer? Why?

**Table 2: Different types of teachers' questions**

## Research methodology

This paper is a part of a wider research about teachers' practices regarding mathematical representations. The participant of this study is a grade 3 teacher, Sónia, from a school cluster in the surroundings of Lisbon (where she has been for the last 10 years) and her 20 pupils (teacher and pupils' names are pseudonyms) who have been together since grade 1. During the research, Sónia was a member of a team of four teachers with whom she worked regularly, preparing and analyzing their teaching. The group indicated that the pupils were used to solve problems similar to the one reported on this paper, however, they chose this task taking into account their perception that it could be solved using a diversity of representations. Although the main research includes the analysis of pre and post classroom sessions, in this paper we only present and analyze teacher-pupils interactions during the classroom work, showing how Sónia promotes pupils' use of representation as they work on the following task: "In a theatre play performed by grade 3 pupils, João, Pedro and Ulisses wanted to be the King. On the other hand, Ana, Inês and Estrela wanted to play the Queen. How many pairs King/Queen may be formed?". Data was gathered by video recording during class observations and through collecting pupils' written work. It was analyzed through content analysis in the moments of introduction of the task, pupils' autonomous work and whole class discussion. Teacher's actions were categorized according to teachers' actions indicated in Table 1 and to teachers' questioning presented in Table 2.

## Sónia's Class

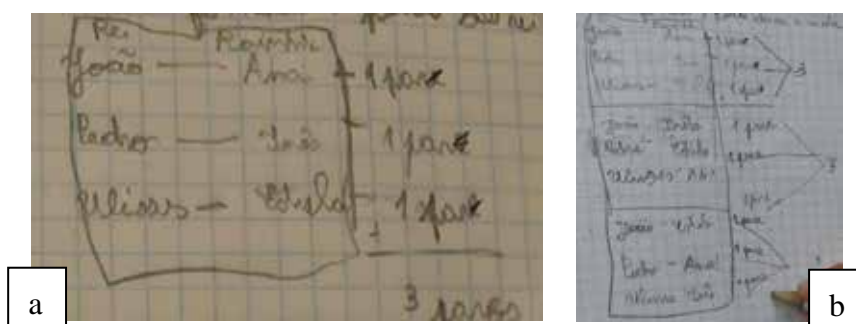

### Introduction of the task

To introduce the task, Sónia starts reading the statement of the problem and asks a pupil to go on reading it. Then, she guides pupils about the interpretation of the task (she focuses on number of boys and girls and the awareness that a problem may have more than one answer) and questions pupils through confirming questions about the conditions of the problem. At a certain point, a negotiation of meaning took place, since the pupils did not know what a “pair” was. Sónia challenges them to interpret this meaning through inquiring questioning (“Can I have two pairs and a half?”, “What is a pair?”), but the pupils remain silent. Then she decides to question them through confirmation questions (“How many persons do I have in a pair?”), getting the interpretation from a pupil as “A group of two!”

### Pupils' autonomous work

The pupils work autonomously for ten minutes, but Sónia notices that some of them struggle to understand what to do and she decides to discuss their difficulties collectively. She questions the pupils with confirming questions in order to guide them about the interpretation the statement of the problem (“Who can be the King and Queen?”, “Only a boy can be the King”, “Who are they?”). She suggests a specific representation to help the pupils to interpret the statement of the problem, by using an active representation, referring to the pupils' reality as if they were, at the time, involved in the school theatre play (“Imagine that . . . I am going to pick the King and Queen!... These three girls would raise their arms . . . And these three boys wanted to be the King... And now... Which are the possibilities?”). At the end of the discussion she challenges the pupils to use an adequate representation through inquiring questioning (“Let us discover!?”).

A pupil, Angelo, says that it is possible to get three different pairs (Figure 1a). Sónia challenges him to interpret his representation through inquiring questioning (“Can you explain me what this is...?”). The pupil says that he made a “table” picking the boys and girls randomly. Sónia guides him about the use of his representation through inquiring questioning (“Why João does not like Inês or Estrela? Is he angry with them?”). As Angelo does not understand that his answer is incomplete, Sónia changes her actions again and informs Angelo that he did not consider that each boy could be paired with three different girls (“How many are the possibilities? It does not say: ‘Tell me three [possibilities]...’”). When the pupil acknowledges that he has an incomplete answer she lets him continue working. Later Sónia comes back to see his work (figure 1b) and she challenges him to interpret the chosen representation through inquiring questioning (“What are you doing?”, “What are you repeating here?”). Angelo then explains why he considers nine pairs as he describes his representation (“If the first [group] is made... It has three [pairs]! Other [group]... It has one pair, another pair, another pair... They are three [groups]! (pointing to the third group) One pair, another pair, another pair... Three [more pairs]!”).

**Figure 1 (a and b): Angelo's representations before and after Sónia actions**

Later, another pupil, Joaquim, begins to complain loudly, because he feels that he is spending too much time on his representation (he drew every Queen and King in detail). Assuming he had to draw, Joaquim questions Sónia. Noticing that more pupils are using similar representations, she decides to guide pupils with confirming questioning (“Did anyone told you: Spend a lot of time on drawings!? Or to draw all the Kings and Queens?”). Another pupil, Fernando answers (“No! Why [should we draw]?! They have names!”) and fulfils the aim of Sónia. Then, she reinforces the pupils’ free choice of a proper representation (“If you think that you are taking too much time... Don’t do it...”). A few moments later, she returns to see his work) (figure 2).

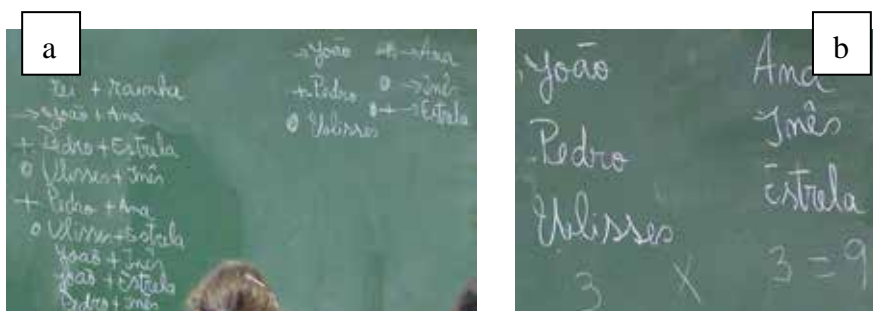

**Figure 2: Joaquim's representation**

Sónia challenges Joaquim to interpret his representation using inquiring questioning (“What are you doing?”) and he responds correctly (“I made the first group! Then I draw a line and divided the first group from the second! João, Inês. Pedro, Ana. Ulisses, Inês... And João, Estrela. Pedro, Estrela. Ulisses and Ana! And there are no more [pairs]!”). At a certain point most of pupils had solved or tried to solve the task and Sónia decides to begin the whole class discussion.

### Whole class discussion

During the pupils’ autonomous work Sónia noticed that many of them had trouble in choosing a proper representation and in identifying the number of possible pairs. She decides to begin the whole class discussion by inviting Luís to present his solution (he has an incomplete answer). She asks him to interpret his representation using confirming questions (“Why did you not consider João and Estrela?”). Based on the representation of Luís she suggests another representation – a scheme with circles, arrows and crosses (Figure 3a), and the pupils acknowledge that it was an incomplete answer (Luís: “Ah! He can [also be paired] with Ana!”).

### Figure 3 (a and b): Sónia's representations

During the remaining of the discussion, Sónia actions vary greatly. Sometimes she challenges pupils to systematize through inquiring questioning (“Why have not you done that?”, “Are there more possibilities?”) but when they do not respond, she leads the pupils to establish connections and to identify conversions and she informs the class about systematizations.

This task had a follow up question “During the rehearsals, Inês decided that she wanted to drop out of the play. How many pairs are now possible?” During the moment of autonomous work, only the fastest pupils got to solve this question. However, faced with the class difficulties in the whole class discussion, Sónia decides to solve it in whole class and she challenges the pupils:

Sónia: How many pairs are there right now? (some pupils answer “six” loudly) Why?

Laura: Because João can be [a pair with] Ana and Estrela. . . Pedro can be with Ana and Estrela . . . And Ulisses can make [a pair] with Ana and Estrela... It's six!!

Sónia: So Laura says that João can be a pair with Ana or Inês (she writes the names on the board and she connects João with Ana and Estrela as she speaks)... So... Two possibilities for João (she writes the number “two” on the left of the first representation)... Pedro can be a pair with Ana and Estrela... [He has as well] two possibilities and Ulisses with Ana and Estrela (she continues both representations as she speaks) (figure 4)! So... All together (she transforms the “two” into a vertical calculus)...

Pupils: Six!!!! (the teacher writes “six” below the vertical column of 2s)

**Figure 4: Teacher’s diagram and symbolic representations**

As Sónia challenges her pupils to interpret the question, Laura explains easily to the class how she thought. Sónia transforms Laura's explanation into a written representation (figure 4), in order to lead her pupils to establish connections between representations. Afterwards, Sónia leads them to make connections between all representations (figures 2a, 2b and 3). She ends the discussion by suggesting the multiplication sign ("If we have... Three boys [she writes "3" below the boys' names] and three girls ([she writes "3" below the girls' names]... I have (she puts the  $\times$  sign writing  $3 \times 3$ )... Nine! Nine possibilities!").

## Conclusion

During the introduction of the task, most of Sónia's actions were focused in promoting pupils' understanding of the statement of the problem, by guiding them through confirming questions (Who? How? How many?). As several pupils had trouble with the meaning of the word "pair", Sónia handled this problem leading a negotiation of meaning, challenging the class through inquiring and guiding questioning. In that way, Sónia's actions begun by addressing the understanding of the statement of the problem, so that pupils could think about how to solve it and figure out what type of representation is more adequate.

During the moment of autonomous work, Sónia led the pupils to write their answers and representations and to justify them. She made the pupils to convert their mental representations into written ones. While interacting with the pupils, Sónia used challenging actions through inquiry questions ("Explain me that...", "I am not understanding..."). When this did not work, she changed her actions and questioned pupils with confirming questions, leading them to explain their representation. Usually, she seemed to re-evaluate her pupils' activity and shifted between actions in order to take them to use adequate representations. At the beginning of pupils autonomous' work, Sónia promoted pupils' free choice of representations and did not influence her pupils' work. Later, while pupils were using and transforming their representations, she did not suggest alternatives nor guided them to find conversions or treatments, even when they were struggling. In that way, her actions (i) enabled the emergence of a large variety of representations to be considered during the whole class discussion, (ii) supported the establishment of connections; and (iii) promoted pupils' reflective activity about their own representations.

In the whole class discussion, most actions of Sónia were informing about new representations and informing and guiding the pupils to figure out the connections and transformations that they could do. Due to her pupils' difficulties during their autonomous work, she felt compelled to systematize all the information and to act with more guiding actions. As in McClain (2000), the pupils' representations had less relevance. In fact, Sónia used pupils' representations as a starting point for discussion, and then she introduced her own representations. At the end of the discussion, she suggested the sum and multiplication signs as adequate representations and connected them to her first representation (that she made from a pupil's explanation). However, since there was no further discussion, it is unclear what understanding pupils made of that.

In summary, during the three phases of the work, Sónia's actions tended to change according to her pupils' answers and difficulties. At the introduction of the task, Sónia considered necessary to support the conversion of the statement of the problem into a different representation. Although pupils knew the multiplication sign, this did not mean that they knew how it can be used to model situations as in this problem (Acevedo Nistal et al., 2009). In that way, at the end of the discussion, the teacher felt the need to guide her pupils about the use and interpretation of the multiplication sign. Only in future classes, one may know if this led the pupils to understand the use of symbolic representation in this kind of situations. In this study, we see that Sónia changed her actions according to pupils' activity in order to promote their use of representations. When pupils had an organized strategy and an adequate but incomplete representation, she questioned them, so they could review their strategies

and representation and find out how they could finish the task. When pupils had a disorganized strategy and an adequate but incomplete representation she tried to help them to understand why the representation was incomplete, focusing in the need of using a more organized strategy. And when the pupils had an inadequate representation she questioned them, guiding the pupils to choose a different representation and strategy.

*The explaining of mathematical terms is part of both learning and teaching mathematics. In this study, explanations, in the forms of a video in sign language, a video and an audio recording in spoken language (all on the subject of quadrilaterals), are compared. Therewith, the explanation process is understood as semiotic mediation, as proposed by Hasan (2002, 2005). The question regarding which role the modality plays in transitioning from specific geometric forms to general statements of the geometric forms is also pursued.*

*Keywords: Semiotic mediation, sign language, spoken language, use of representations.*

## Introduction

The explaining of mathematical terms is part of both learning and teaching mathematics. With this, the process of explanation can be understood as semiotic mediation (Hasan, 2002, 2005), which refers to a “mediation by means of the modality of language” (Hasan, 2002, p. 112) This study focuses on the modality of language, or to be more specific, on the differences in explanations in sign language and in spoken language. For the subject matter of the ‘House of Quadrilaterals’ (a hierarchic structure of different quadrilaterals; see figure 1), three medially different explanations were developed along the lines of the same subject analysis: one video and one audio product, both in German spoken language, along with one video in Austrian Sign Language (ÖGS<sup>1</sup>). Thus, this study focuses on the question: What roles do modalities of spoken and sign language play in transitioning from specific geometric forms to general statements of the geometric forms?

## Semiotic mediation of a geometrical concept

Hasan (2002, 2005) considers ‘semiotic mediation’ as a process, in which a mediator mediates something to a mediatee, the addressee. Though, the details of the mediation, regarding modality and where it took place, can differ (cf. Hasan, 2005). For the process of mediation, Hasan (2002, p. 115) distinguishes between acting by doing and acting by saying, which she defines as *material action* and *verbal action*, respectively. In the context of this paper, for example, material action includes writing down or pointing at mathematical inscriptions on blackboard or on pinboard (see Figure 2). Both forms of action can take place independently, though possibly in the same place or even simultaneously. In the last case, Hasan differentiates between *ancillary verbal action*, where “verbal action is assisting in the conduct of the ongoing material activity” (p. 116) and *constitutive verbal action*, where the verbal action is not “running in parallel” (p. 116) with the material action, but is pivotal for the topic of a discussion. Hasan primarily considers daily conversations, wherein a

---

<sup>1</sup> ÖGS stands for “Österreichische Gebärdensprache“.

physical action is commented on and, after a *shift* from ancillary to constitutive verbal action, the discussion then distanced from the physical level to then focus on topics, which go beyond the physical level. Hasan considers this shift to be of importance because, after such a change, an additional invisible mediation can take place in which habits of mind can be communicated.

Mathematical inscriptions (on paper, on the chalkboard, etc.) and experimentation with these is a fundamental part of mathematical activity (cf. Dörfler, 2016), which is principally of material nature. With the help of inscriptions, one can not only provide for concrete propositions, but can also generalize these. This is especially visible in geometry when, for example, quadrilaterals are compared and general propositions are made. Dörfler (1991) describes this as an “empirical generalization”, though the “basic process is to find a common quality or property among several or many objects or situations (mostly from sense perceptions) and to notice and record these qualities as being common and general to these objects or situations” (p. 65). For example, the figurative forms of geometric inscriptions can be compared and then generalizations can be made. For instance: ‘Every square is a rectangle, but not every rectangle is a square.’

How can an explanation, which leads to a generalization, differ with different language modalities such as sign language and spoken languages? Sign languages are natural languages, just like spoken languages. Though, these are visual, in contrast to auditory spoken languages. The consequence of this is that different visual levels can be processed simultaneously (cf. Grote & Linz, 2003). Particularly, signs utilize space in a distinct manner: Often times, in narratives, a “singular aspect” is focused on and located in the sign space. This point of focus is referred back to throughout the narration (cf. Grote, 2016, p. 144). One example is the description of a picture: In spoken language, a picture is typically described in a linear fashion, for example, from left to right. Contrasting to this, in sign language, a central object is described and all other objects are then related to it.

A further central characteristic of sign language is the iconicity and indexicality of many signs, especially in terms of mathematical signs (cp. Krause, 2017; Wille, submitted). An icon, understood in the sense of Peirce, represents relations (cp. Hoffmann, 2007, p. 3; Peirce EP II 13). Mathematical signs rather frequently picture either the apparent relational structure of mathematical inscriptions or are similar to operations with the inscriptions. This is not limited to geometric forms only (cp. Wille, submitted), even if such are the focus of this study. To provide for an example, in Austrian Sign Language (ÖGS), the sign RECTANGLE<sup>2</sup> is communicated by tracing the geometrical form of a rectangle with the fingers. The sign ROTATION, on the other hand, resembles the actual operation of rotating a geometric form (cf. Schreiber & Wille, submitted). This principally means that mathematical ÖGS signs often look like concrete inscriptions. Although signs are used symbolically, just as often as words in spoken languages, this “does not imply that the iconic dimension of a linguistic sign becomes completely blended out or deleted” (Grote & Linz, 2003, p. 35). In the following, the question regarding how the transition from specific forms to general propositions can take place in sign language is compared to spoken language.

---

<sup>2</sup> In this study, ÖGS signs are written in gloss with capital letters as is common in sign language literature. (cf. Skant et al., 2002).

### Three different explanations regarding quadrilaterals

Three medially different explanations on how a square is related to other quadrilaterals were developed on the basis of the same subject analysis at the universities of Giessen and Klagenfurt:

For the video in spoken language, based on the subject analysis, a script was prepared with different scenes, containing the action of the students, the spoken text and material to use in the video (see the example below). This script was critically discussed with the students and optimized. In the video, reproductions of the geometrical figures were successively pinned to the board. These figures were discussed and relationships between the figures were identified and explained.

For the audio recordings, the script dialogue was developed so that a pair of both male and female speakers reciprocally demonstrated the relationships between the quadrilaterals, which, in this case, are not presented in the form of a picture.

The realization into Austrian Sign Language (ÖGS) took place in cooperation with a deaf colleague from the center for sign language and hearing-impaired communication of University Klagenfurt. For this, a script in German written language served as the basis for a discussion in sign language, concerning how this text could be properly realized. This was then transferred to a teleprompter, in gloss, which was signed with slight variation in the video. Geometrical forms were also attached to a bulletin board. For the spoken language realizations, in the forms of both audio and video, scripts also served as the foundation. Though, these scripts were not changed, due to the fact that there was only a shift from “writtenness” to “orality” (see Schreiber, 2013, p. 1598).

These videos and the audio do not have the purpose of replacing lessons, but were rather developed with the intention of comparing various modalities of the mathematical explanation. For this reason, the influence of such explanations on students is not being focused upon.

### Analysis of videos in sign language from the standpoint of Hasan’s theoretical perspective

In contrast to mathematical terminology in spoken language, mathematical signs feature an inherent form of materiality. In ÖGS, forms such as the square, rectangle and rhombus are traced with the fingers. The sign ROTATION not only depicts that something is being rotated, but one can also see the type of object. Furthermore, for the sign PARALLELOGRAM, a right-angled parallelogram is transformed into a non-right-angled parallelogram (see Figure 1). This means that in ÖGS, the difference between material action and verbal action is not as distinguishable as in German spoken language.

**Figure 1: The ÖGS signs SQUARE, RECTANGLE, PARALLELOGRAM and ROTATION**

Which shifts from ancillary to constitutive verbal action are thus discernable in the ÖGS video? At first, the ÖGS video will be compared to the corresponding script. In the next section, a comparison to the spoken language video and audio follows.

When comparing the script text for the ÖGS video with the actual transcript for the ÖGS video in gloss, it can be seen that in the ÖGS video, ancillary verbal action increases and, simultaneously, constitutive verbal action decreases. The following section demonstrates this noticeably.

The following text is an excerpt of the script of line 42 to 47:

#### **Script Text in German**

42 Also: Dieses Rechteck ist kein Quadrat.  
 43 Es besitzt nicht alle Eigenschaften, die das Quadrat hat.  
 44 Aber wie sieht es andersherum aus?  
 45 Ist ein Quadrat ein Rechteck? – Ja!  
 46 Jedes Quadrat ist ein Rechteck. Es ist ein besonderes Rechteck.  
 47 Es besitzt alle Eigenschaften eines Rechtecks.

#### **English Translation**

So, this rectangle is not a square.  
 It does not possess all the properties of the square.  
 But, what about the other way around?  
 Is a square a rectangle? – Yes!  
 Each square is a rectangle. It is a specific rectangle.  
 It has all the properties of a rectangle.

The corresponding transcript (in gloss) for the ÖGS videos is the following:

#### **Transcript for the ÖGS videos in gloss**

42 IX RECHTECK NICHT INHALT QUADRAT  
 43 NICHT ALLE EIGENSCHAFT  
 44 IX QUADRAT INHALT JA RECHTECK  
 45 AUFPASSEN QUADRAT IX BESONDERS INHALT ALLE EIGENSCHAFT DA DA DA  
 46 ABER RECHTECK NICHT IMMER QUADRAT  
 47 BEISPIEL IX RECHTECK INHALT KEIN QUADRAT

#### **Translation in English**

This rectangle is not a square because it does not have all the properties.  
 This square is indeed a rectangle.  
 It should be noted that this square is a specific one (a special rectangle), since all properties are fulfilled.  
 But a rectangle is not always a square.  
 For example, this rectangle is not a square.

In the section above, there is a shift to constitutive verbal action. First, in lines 42 and 43, it states: “So, this rectangle is not a square. It does not possess all the properties of the square.” This refers to the specific rectangle, which is attached to the bulletin board in the background and was used to speak about reflections, rotations, parallel sides and right angles. After this, at line 44, there is a transfer to constitutive verbal action, since all squares are now being talked about in a general way: “But, what about the other way around? Is a square a rectangle? – Yes!” Instead of speaking about “this square”, it is now called “a square”. Thus, the verbal action changes from speaking about the concrete forms to then speaking about forms of one type in general.

In contrast to this, the verbal action in the corresponding part of the ÖGS video is, with the exception of line 5, ancillary. The ÖGS sign IX is an indexical sign, with which the pointer finger signs. It can be translated with “this”. It is noticeable that only in line 46 there is constitutive verbal action. This means that only one shift from ancillary to constitutive verbal action is between lines 46 and 47. The

expression “a rectangle is not always a square” can be described in no other manner than generally. All other sentences concretely reference the rectangle on the bulletin board.

A second thing is noticeable in this section, when comparing the ÖGS video with the script text: In the script, a concrete rectangle is at first discussed and then the discussion moves to only generally talk about squares. In contrast to this, “IX RECHTECK” (this rectangle) seems to act as an anchor in the ÖGS video. This occurs at both the beginning and the end and acts as the central point to which the rest then references. Such concurs with the observations, noted above, stating that sign language narratives often place something singular in the focus of attention, which is then referenced back to. In this section it’s “this rectangle”. In the context of the whole ÖGS video, however, “IX QUADRAT” (this square) takes on this role.

For example, such can be seen in the following excerpt (line 63 to 65), concerning the relationship between the rhombus and the square. In the script, solely constitutive verbal action can be observed:

### Script Text in German

- 63 Ist eine Raute ein Quadrat? – Nein! Sie besitzt nicht alle Eigenschaften des Quadrats.  
 64 Ist ein Quadrat eine Raute? – Ja! Jedes Quadrat ist eine besondere Raute.  
 65 Alle Eigenschaften der Raute sind erfüllt.

### English Translation

- Is a rhombus a square? - No! It doesn't possess all the properties of a square.  
 Is a square a rhombus? - Yes! Each square is a special rhombus.  
 All properties of a rhombus are fulfilled.

Whereas one can observe the following in the ÖGS video segment:

### Transcript for the ÖGS videos in gloss

- 63 IX RAUTE INHALT QUADRAT? NEIN  
 64 ABER AUFPASSEN IX QUADRAT INHALT RAUTE? JA  
 65 WARUM? IX ALLE EIGENSCHAFT RAUTE DA DA DA  
 a IX QUADRAT BESONDERS RAUTE

### Translation in English

- Is this rhombus a square? No!  
 But watch out! Is this square a rhombus? Yes.  
 Why is that so? All properties – are fulfilled – those discussed earlier  
 This square is a special rhombus.

The script’s linear-constructed text in the ÖGS video is once again changed. In the last part, “IX QUADRAT” (this square) is referred to multiple times.

In addition, it seems as if this is all ancillary verbal action. Nevertheless, there is something here, which cannot be equally expressed in spoken language. The ÖGS sign “IX” in line 64, is signed toward the bulletin board (see Figure 2, left-hand side). Here, a reference is being made to the concrete square. Though, later in line  $a^3$ , “IX” is signed to the front, toward the audience (see Figure 2, right-hand side). This can be understood as an intermediate step for generalization, respectively as an intermediate shift between ancillary and constitutive verbal action. In this case the second phrase “IX QUADRAT” (this square) in line  $a$  not only refers to the concrete square, but also to the square as a paradigmatic example, which stands for the general case.

<sup>3</sup> This line in the transcript does not correspond to a line in the script. Therefore, this additional line is marked with “a”.

Figure 2: The ÖGS sign “IX” in line 64 (left-hand side) and line *a* (right-hand side)

### In comparison: ancillary and constitutive verbal action of spoken language in video and audio

Due to a lack of space for this study, both the spoken language video and the audio recording can only be briefly outlined, in order to substantiate the indications. More detailed examples can be found in Schreiber & Wille (submitted).

The explanations in the video, in spoken language, are categorized as verbal action, while the material action takes place through either pointing at the constituting properties of the forms, drawing in properties or by drawing in arrows to indicate relationships between the quadrilaterals. For example, this is apparent in the excerpt of the script, example *a*:

Scene	Action	Spoken Text	Depiction
2	The person points to the angles and the sides.	It's directly noticeable that there are four equally long sides. The sides are in a certain position in respect to each other. Adjacent sides build a right angle and opposite sides are parallel.	

In this video, concrete forms are referred to in the sense of ancillary verbal action (see example *a*). Forms are recurrently referred to in a general sense, utilizing constitutive verbal action to illustrate general relationships, like in example *b*:

Scene	Action	Spoken Text	Depiction
4	The camera zooms out so that all figures are visible.  The person draws an arrow between the square and rhombus.	It's also noticeable that this rhombus has properties similar to the square. Both have four equally long sides but different angles and, because of this, different symmetries. We are drawing an arrow from the square to this rhombus. The square is a special form of the rhombus, actually a rhombus, which has four right angles.	

Initially, the concrete rhombus is referred to, which is located on the bulletin board. It is directly compared to “the square”, though this does not necessarily refer to the concrete square, which is

located on the board. “The square is a specific kind of rhombus” is already formulated in a general sense, which is emphasized by referring to the properties, a “rhombus, which has four right angles”.

In the audio, exclusively general cases are described. One can only speak of forms in general, due to the absence of the visual mode of presentation. Thus, constitutive verbal action is utilized throughout this special setting. Such can be seen with student 1’s initially posed question and student 2’s corresponding answer:

s1 Honestly, what is actually so special about a square? It’s really just a very basic quadrilateral.

s2 The square combines the properties of all the other quadrilateral.

No specific square is being referred to, even though *the* square is noted. In particular, this square can readily be compared to all quadrilaterals. Such is also the case at a later point, when student 2 compares the general rhombus with the general square and when student 1 explains the general rhombus more in-depth:

s2: That’s right. For the rhombus, the difference to a square is that the four angles mustn’t be right angles, right?

s1: Yes, the angles don’t have to be right angles for the rhombus.

The utilization of material action is omitted and, in the here-discussed example, ancillary verbal action is not present.

## Conclusion

A comparison of the three medially different explanations shows that the prevalence of ancillary to constitutive verbal actions differ. In the ÖGS video, concrete forms are recurrently referred to. As previously discussed, when the ÖGS sign “IX” (this) is signed toward the front, this can be interpreted as a reference to a paradigmatic example.

Hasan (2002) explains that, in terms of constitutive verbal action, habits of mind can be mediated. She calls this invisible mediation. A typical mathematical “habit”, in the sense of empirical generalization, is that of considering concrete mathematical forms, equations, structures, etc., to reach generalizations. It can be observed that the modality of a visual language changes an explanation, in relation to spoken language.

## Acknowledgment

We wish to thank Christian Hausch from the center for sign language and hearing-impaired communication of University Klagenfurt, Austria, for his cooperation during the production of the videos in Austrian Sign Language.

# Characterizing fraction addition competence of preservice teachers using Rasch analysis

Marius Lie Winger, Julie Gausen, Eivind Kaspersen and Trygve Solstad

Norwegian University of Science and Technology, Norway; [marius.l.winger@ntnu.no](mailto:marius.l.winger@ntnu.no),

*Keywords: Fraction addition, competence, representations, Rasch analysis.*

## Research topic and theoretical framework

Norwegian preservice teachers (PSTs) produce lower scores on tests of prerequisite mathematical knowledge than other student groups, and fractions is a particularly difficult topic (Bjerke et al., 2013; Ånestad et al., 2014). The low mathematical competence in turn poses a hindrance to acquiring didactical competence from courses in mathematics education.

Several theoretical frameworks for mathematical competence emphasize the role of representations and transformations between representations (e.g. Niss & Højgaard, 2011). If the target and source representation are the same, this transformation is called a *treatment*, whereas it is called a *conversion* if they are different (Duval, 2006). For example, a calculation in the symbolic representation is a treatment of the mathematical object, while graphing a function from a table is a conversion. Conversions between representations have been suggested to be a common source of incomprehension for students, where the direction of the conversion could substantially affect the perceived difficulty of a mathematical problem (Duval, 2006). As a step towards understanding and strengthening PSTs' competence with mathematical representations, we ask:

What characterizes PSTs' competence in representations of fraction addition as they enter mathematics education, and how does their competence develop through teacher training?

In this poster, we report on the development of a Rasch measurement scale for answering these questions, and present quantitative and qualitative results from a group of PSTs at the beginning of their teacher training. By using Rasch analysis we will obtain an invariant measurement scale ensuring that the results can be compared confidently over a time period. Furthermore, this approach provides insight into the dimensionality of competence in representations of fraction addition.

## Method

A Rasch instrument including 18 items on fraction addition was developed. The items concerned the transformation between symbolic and two kinds of diagrammatic (area and number line) representations of fraction addition. Data was collected from a group of 98 first-year PSTs who had not yet had instruction in fractions in their mathematics education courses. The group therefore reflects a wide range of experiences with fraction representations from classrooms across the country. The student answers were analysed qualitatively and scored according to pre-defined criteria developed in a pilot study.

## Result and discussion

First-year PSTs were highly competent at solving fraction addition problems in the symbolic representation register. At the same time, there was large variability in the PSTs' competence in converting addition problems between the symbolic and diagrammatic representation registers, where conversion from symbolic to diagrammatic form was the most challenging.

Principal Component Analysis (PCA) of the instrument indicated two potential dimensions, or *contrasts*, in the data. The first contrast separated items according to which diagrammatic representation was involved (linear vs area model). The second contrast separated the items according to the direction of conversion between symbolic and diagrammatic representations, which could be considered a subdimension of the instrument. This can be interpreted as saying that competence in representation of fraction addition should be measured using more than one variable.

We conclude that competence in fraction addition was a multidimensional construct for the group of first-year PSTs. The PSTs' high level of competence in the fraction addition procedures did not necessarily transfer to representing fraction addition in a diagrammatic model, and producing diagrammatic representations was more difficult than interpreting diagrammatic representations, likely reflecting a difference in experience with the different kinds of conversion. These quantitative results were reflected in the qualitative analysis. The coding and scoring process showed that although many of the students that performed well on the area model tasks tended to apply part-whole interpretations to the number line. These results lend support to the theory that different aspects of competence in a single concept can be developed independently (Usiskin, 2015).

The present study provides a foundation for investigating whether different representation registers of fraction addition, and transformations between these, become increasingly associated towards a coherent concept as PSTs progress through the teacher education program.

*Keywords: Inclusive mathematics, special education, teacher education, special needs in mathematics education, differentiation, diversity.*

### **Introduction**

For CERME11, a new TWG about inclusive mathematics education has been established, with its first meeting at CERME11. This group was created due to an arising need for a forum to discuss issues of inclusion in the light of special needs in mathematics (SEM) in educational research. This branch of research has been developed in relation to general educational research about special educational needs (SEN) over the last decades, and has come to include not only disability and psychological issues, but also social, cultural and educational issues (Magne, 2006) Hence, the notion of SEM covers different epistemological fields as well as touching upon issues of normality (Skovsmose, 2019).

The scope and focus of TWG25 is hence SEM and inclusion, in the intersection of mathematics education research and special education research. Since this scope is broad, the TWG-papers compromised grades 1-12, teacher professionalization and teacher education programs, types of inclusive settings in mathematics, concepts and models for instruction and subject matter didactics, special educational needs and child characteristics, and content related decisions for inclusive mathematics education.

During CERME11 there were 17 participants in TWG 25 from 10 countries – colleagues from Europe, and also from Canada and Hong Kong. 10 papers and 2 posters were presented during the week, and the thematic schedule was oriented towards the topics of the submitted papers and posters (presenting authors below). The first session was spent on a discussion about the aims and objectives of this new TWG and an exchange of overarching issues of the situation of SEM in the different represented countries. In the following TWG-sessions, two or three papers were presented each time, under an overarching theme. The themes were: (1) *Development of materials, tools, learning arrangements, settings, etc.* (2) *Research on classroom situations, out-of school situations* (3) *Research on teacher education (pre-service and in-service).*

The themes were discussed in the initial session in order to include all participants.

*(1) Development of materials, tools, learning arrangements, settings, etc.*

This theme includes discussions of how to develop tools to identify students in SEM, but also how to promote their learning, including the research aims: for example, seeking to know the place of mathematics education in dyscalculia research, how to reconcile approaches to reach a better understanding of the disorder and provide professional development activities for both, pre-service and in-service teachers, regarding the multicultural education and presenting all attributes of a designed learning software.

*Florence Peteers:* Diagnosis tools of dyscalculia – contribution of didactics of mathematics to numerical cognition

*Janka Medová:* Designing Mathematical Computer Games for Migrant Students

*(2) Research on classroom situations, out-of school situations*

This theme includes discussions of inclusion in relation to SEM students, mathematics classrooms and out-of school situations, where the focus lied in the challenges and possibilities in mathematics education. Examples of research questions within this theme are: How are inclusion and disability constructed in the discourses of teaching staff and pupils in mainstream mathematics classrooms? (paper Stylianidou & Nardi) How do SEM-students perceive their participation in terms of learning and teaching in an inclusive mathematics classroom to have optimal opportunities to learn? (paper Roos).

*Helena Roos:* I just don't like math, or I think it is interesting, but difficult ... Mathematics classroom setting influencing inclusion

*Laurie Bergeron & Audrey Perreault:* Strategies that promote the mathematical activity of students with language disorders: an analysis of language interactions

*Kinga Szűcs:* Do hearing-impaired students learn mathematics in a different way than their hearing peers? Challenges and possibilities of cognitive enrichment in inclusive mathematics classrooms – a review

*Angeliki Stylianidou:* Mathematical discourses of a teacher and a visually impaired student on number sequences: Divergence, convergence or both?

*(3) Research on teacher education (pre-service and in-service)*

This theme includes discussions of inclusive education and SEM in relation to teacher education and teachers' views. How are teacher education programmes related to inclusion and what are adequate strategies for teachers to develop inclusive mathematical settings. Examples of research questions within this theme are: How should didactical courses in teacher education be designed to address the topic 'inclusive mathematics'? (paper Scherer). What challenges do

mathematics teachers experience when teaching students with mathematics learning difficulties in an inclusive classroom and what potential measure do they use? (paper Hamukwaya) What is the effect of improving the knowledge of braille display and Text-To-Speech synthesizer support of mathematics teachers on braille reader's achievement in mathematics? (paper Van Leendert)

*Petra Scherer:* The potential of substantial learning environments for inclusive mathematics – student teachers' explorations with special needs students

*Laura Korten:* An in-service training to support teachers of different professions in the implementation of 'inclusive education' in the mathematics classroom

*Chun-ip Fung & Dichen Wang:* Teaching mathematics to students with intellectual disability: What support do teachers need?

*Sarah Buró & Susanne Prediger:* Low entrance or reaching the goals? Mathematics teachers' categories for differentiating with open-ended tasks in inclusive classrooms

*Annemiek van Leendert:* Supporting braille readers in reading and comprehending mathematical expressions and equations

*Shemunyenge Taleiko Hamukwaya:* K-12 Namibian Teachers' Views on Learning Difficulties in Mathematics: Some reflections on teachers' perceptions

## **Introductory discussion – overarching issues of the situation of SEM**

The world is changing very fast and so are the demands on teachers. School classrooms are growing increasingly heterogeneous – with respect to language, culture and abilities. This requires differentiation with regards to learning goals, instruction strategies and individual tasks, to accommodate the classroom to enhance every students learning (Bishop, Tan, & Barkatsas, 2015).

Internationally, a trend is visible towards inclusion, a comprehensive school for all, where students with very different levels of abilities and different skills are educated together (Bishop et al., 2015). Some European countries have a very long tradition of inclusion, while in other countries it is relatively new, since students with more marked disabilities used to be educated in special schools. The change in the system generated a passionate discussion on the advantages and disadvantages that inclusive education brings, which reflects the negative attitudes that teachers might have towards inclusion (e.g. De Boer, Pijl, & Minnaert, 2011).

Inclusive education brings many challenges to schools. Often it is connected to a lot of administrative load in many countries. For example, some school systems and governments require detailed and individualized progress reports and education plans to include every student, and this has to be done in so-called multi-professional teams for which they might not be prepared (see Ritter, Wehner, Lohaus, & Krämer, 2018). All this applies to mathematics education, too. A mathematics teacher is expected to cope with the demands within the inclusive classroom, to plan lessons where all students will receive appropriate support and challenge. At the same time, they

often have to deal with more administration, and often with more rules and monitoring from the management or government. This could even lead to teachers feeling stressed and opposing the whole idea of inclusive education. Although large differences between countries exist, the problems are recognized to a smaller or larger extent in all countries. The work in TWG25 showed that there are ways that can help pre-service and in-service teachers and teacher educators to support these processes. If teachers are better trained for teaching in a heterogeneous classroom and have adequate tools, methods and techniques to make it work, they will be much more motivated and willing to support the system.

During almost all sessions in TWG25, one big question was circling, namely how do we understand inclusion in mathematics? Is it static? Is it depending on national and cultural settings? How do the teachers, the learners and/or the researchers describe and understand it? Do they understand it the same, or differently? Is the way, inclusion is understood affected by the perception of students *in* need, or *with* need? Is it dependent on the perception of the student? These questions are immersed and reflected (implicitly or explicitly) in the overarching themes that emerged from the discussions of TWG25, and described below.

## **Overarching issues of TWG25**

Research in the field of inclusive mathematics covers a wide range. This can be seen in the directions taken in research covering disability, psychological, pedagogical and didactical issues. It can also be seen in how research covers aspects on either societal level or classroom level working with notions such as equity and diversity (Roos, 2019; Kollosche, Marcone, Knigge, Godoy Penteado, & Skovsmose, 2019), and several trends in mathematics instruction were presented in the papers of TWG25. All papers focus on some aspects of mathematics teaching and learning in relation to SEM and deserve due attention. During the TWG-sessions based on the paper presentations, the following points were discussed, especially how they are linked with each other.

### **Inclusive system or special schools?**

As stated in the introductory part, there are countries where special schools have a relatively long tradition (e.g. more than 100 years in the Netherlands) (Evans, 2004). Their clear advantage is that the staff has a specialized knowledge to work with and help special needs children. The number of students in classes is relatively low and thus the teacher has the time to individualize work. These schools have been criticized in the past by the EU for their exclusive nature, and many countries extended or built up inclusive systems according to the realization of the UN conventions (see UN, 2006). Inclusive education means each child has the right to be educated in the local school. However, in some countries, there is still a debate whether this is for the benefit of the student.

### **Teacher education in relation to SEM**

Depending on the tradition of inclusive education, SEM is taken into consideration to a greater or lesser degree in the mathematics classroom. In countries with a longer tradition the system has more experience and mathematics teachers are more experienced to take SEM into consideration in their teaching.

Without any doubt the education must adapt to the situation and much more attention has to be paid to special needs in mathematics – taking children with mental or physical disabilities, students in great access to mathematics or second language learners into account. These different directions are discussed in the TWG-papers by *van Leendert et al.*, *Hamukwaya*, *Stylianidou & Nardi*, *Roos*, *Szücs* and *Bergeron & Perreault*. Also teacher education needs to prepare fresh graduates to know possible methods, techniques, and activities that will enable them to differentiate and individualize lessons. Teachers must have the theoretical background knowledge about different disabilities, in addition to practical examples of how to manage the classroom, what activities to use are essential. With all these special competences, the different forms of knowledge, subject specific knowledge included, is essential (cf. Shulman, 1986). Teacher education should reflect the findings of current research on work with special needs children as this is a fast developing area. This is discussed in the TWG-papers by *Scherer*, *Korten et al.* and *Fung & Wang*.

### **Change of teaching and learning strategies?**

Does SEM imply using new teaching and learning strategies? Taking an inclusive standpoint in the classroom asks for differentiation and individualization of work and take the individual student as a point of departure as discussed in the TWG-paper by *Roos*. Then the teacher's role is changing to the role of a facilitator, to the role of the person who plans the lesson and activities and then monitors students' work and helps wherever is needed. One of the ways of allowing inclusive classes to learn is to focus on how tasks can be designed and used to differentiate between students of different levels, like the paper by *Buró & Prediger* shows. Teachers are not always aware what kind of adjustments are needed for the different levels amongst their students.

Another point of discussion is whether constructivist approaches could help as all students build their own knowledge in a way that is suitable for their needs. However, there is no clear empirical evidence that this is the best way to teach students in SEM as the research result might be contradictory (e.g. Chodura, Kuhn, & Holling, 2015; Scherer, 1997).

### **How can mathematics teachers be motivated to work with SEM?**

The issue of motivating teachers to work with SEM is essential. Inclusive education is reality and teachers must be ready to face it. If they are well motivated, they are more likely to cope with the situation well. This, and how to work with teachers and different methods to use is discussed in the TWG-papers by *Scherer*, *Fung & Wang* and *Korten et al.*

One way to motivate teachers is to equip them with such tools that they will feel confident enough when facing a heterogeneous classroom with students with very diverse educational needs. Having diverse teaching methods and techniques that enable differentiation and motivation will help. Also having experience with managing a classroom where an assistant is present will help and will give the teacher the needed self-confidence. Not everyone is happy with having a “critical” eye in all lessons.

Another way to increase teachers' motivation is providing them enough opportunities to improve their knowledge and skills in the area. Pre-service teacher programs must pay enough attention to

the issue, and high quality in-service teacher training programs should be available. If possible they should be designed and run by a number of specialists from different areas (special pedagogues, psychologists, but especially experienced teachers of a particular subject).

Once methodology and techniques of work with special needs students become more widespread and results will be tangible, motivation of teachers will become easier.

### **Who is in SEM?**

The large heterogeneity of the students with special needs in mathematics was discussed in TWG25, ranging from low IQ to gifted, from specific learning disabilities like dyscalculia (discussed in the TWG-paper by *Peteers & Ouvrier-Bufferet*) to behavioral and developmental disorders, including students with different cultural backgrounds (as discussed in the TWG-paper by *Medová et al.*). Also teachers' views on special needs as presented in the TWG-paper by *Hamukwaya* was discussed. The question arose why we use the term special, and what is perceived as 'normal' (see Skovsmose, 2019). Wouldn't it be better to talk about heterogeneity and take the individual differences as norm?

### **Conclusion and further directions of TWG25**

Reflecting back on the arguments made in the papers of TWG25 and on the discussions, there are, as prior discussed, diverse issues concerning inclusion in mathematics education and challenges for students with special needs in mathematics. In the TWG-papers about development of materials, tools, learning arrangements and settings, arguments are made for both developing sustainable ways of identifying dyscalculia in mathematics education (paper *Peteers & Ouvrier-Bufferet*) and developing learning software for both, pre-service and in-service teachers (paper *Medová et al.*).

In the TWG-papers about research on classroom situations and out-of school situations the focus was on challenges and possibilities in the classroom from different perspectives. Strategies promoting mathematical activities in relation to students with language disorders were discussed: Too often teachers tend to reduce learning opportunities within mathematical tasks by focusing on their cognitive characteristics and behavior, although the reported research shows that if a teacher offers space for dialogue with students and questions them in order to trigger their mathematical activity it becomes a powerful driver of student activities in a classroom context where the teacher offers a space where all voices are legitimized (paper *Bergeron & Perreault*). Another issue in relation to how to work in classroom was how a classroom setting influences inclusion in mathematics, and the importance to consider how to plan the classroom to include everybody (paper *Roos*). In relation to work in the classroom, mathematical discourses of a teacher and a visually impaired student were investigated highlighting the interaction teacher – student (paper *Stylianidou & Nardi*). Also a review highlighting the learning of hearing-impaired students and the challenges and possibilities of cognitive enrichment (paper *Szücs*) was discussed within this theme.

In the TWG-papers about research on teacher education the focus was on how teachers view inclusion and SEM, and how teacher education can work to help teachers work inclusively. The

potential of substantial learning environments (Wittmann, 2001) for inclusive mathematics in relation to student teachers' explorations with special needs students were reflected upon with the conclusion of the importance to include such type of explorations and reflections of inclusion in the teacher education (paper Scherer). In relation to this, it was discussed how in-service training can support teachers of different professions in the implementation of 'inclusive education' in the mathematics classroom (paper Korten et al.). Support to teachers was also discussed in relation to teaching mathematics to students with severe intellectual disability (paper Fung & Wang), with the conclusion that it is mathematics that must be in the centre of attention when discussing SEM, something that may sound too trivial to consider, yet often too easy to overlook. The development, testing, and refinement of didactical action plans involves studying various phenomena and their corresponding mathematical meanings, which can only be done from within mathematics. Support to students by supporting teachers in relation to braille readers in reading and comprehending mathematical expressions and equations through specific instructions was problematised (paper van Leendert et al.). When looking into mathematics teachers in relation to inclusion and SEM the way teachers categorise for differentiating in inclusive classrooms were highlighted, problematising low entrance (paper Buró & Prediger). Also teachers' perceptions in relation to learning difficulties in mathematics was problematised (paper Hamukwaya).

The major question, still left to be answered, is how we understand inclusion in mathematics, and how we can have a common ground in research despite the diversity of research directions and cultural and national differences. Still, it is interesting to see that even if there are very diverse issues concerning inclusion in mathematics education, there are similarities too. This can be seen in the themes of the TWG-papers. Hence, there seem to be opportunities to build a common ground regarding inclusive mathematics teaching and challenges for students with special needs. enrichment in inclusive mathematics classrooms.

Looking forward to CERME12 the community got a challenge to build further on the work at CERME11 and build a common ground to address issues within the scope of TWG25.

*This article outlines the methods of a teacher of mathematics who works with a class of students with language disorders related to autism. By adopting the theoretical framework of the Dual Approach (ergonomics and didactics) and Maturanian epistemology, we show how an analysis of language interactions allows for a better understanding of teaching practices and their influence on the mathematical activity of students. We explore the nature of the language interactions, both verbal and non-verbal, within a specific learning project, when it comes to reinvesting, in a non-explicit way, basic mathematical objects. Our analysis highlights the richness of a practice in which the teacher proposes different types of help to trigger the mathematical activity of her students.*

*Keywords: Language interactions, mathematical activity, teaching practice, language difficulties.*

### Problematic

In Quebec, approximately 15 000 students have an autism spectrum disorder. In general, these students present difficulties related to language, communication and social interaction with their peers (MSSS, 2017). Moreover, since language interactions are an integral part of the teaching practice, finding ways to carry out a project represents a significant challenge in the context of a special class for students with autism (Odier-Guedj & Gombert, 2014). For the teaching of mathematics, this phenomenon is particularly problematic given the difference in the meaning of words in everyday language and those used in mathematical language. Although the Ministry of Education prescribes guidelines encouraging teachers in Quebec to adapt their practice according to their students' characteristics (MELS, 1999), operational means are not proposed. Thus, teachers are required to determine and implement their own means of adaptation. In this context, research in psychology of ergonomics and didactics (Robert & Rogalski, 2002) has led us to question the way that teachers adapt their practice in order to meet the specific needs of their students, and to inquire whether these adaptations and this help contributes to the mathematical activity of their students.

This paper focuses on the richness of the language interactions and the types of help offered by a teacher to trigger the mathematical activity of her students. In this article, we present a part of our analysis of the practices of a teacher within the context of a project requiring students with autism spectrum disorder to build a birdhouse to reinvest basic mathematical notions. We begin by outlining our epistemological stance, our conceptions of language and mathematical activity, as well as the types of help offered by the teacher to trigger the students' activity. After highlighting our framework for the analysis of teaching practices, we reveal an overview of our results.

## **Epistemological foundation and theoretical context**

### **What is mathematical activity**

Mathematical activity accounts for the process of appropriation and reasoning required to answer or mathematize a given problem or situation (e.g. Freudenthal, 2012; Proulx, 2015). Within the framework of our research, mathematical activity exists as a process of “coordinations of coordinations of doings” (Maturana & Verden-Zöller, 2008). In this process, teacher and student actions take place within an ethical space where their legitimacy is mutually recognized. Their immediate actions and their respective historical and cultural experiences (Radford, 2010) are interrelated to their representation of mathematics and shared by and through different forms of language (Barrera-Curin, Bergeron, & Perreault, in press). According to Maturana and Verden-Zöller (2008), interactions emerge within and through language as a way of coexisting in the coordination of coordinations of actions. Language, in all its forms, becomes a fundamental element to consider when studying interactions within an educational context.

### **Language and the specificity of teaching practices**

Many recent studies in the fields of didactics of mathematics and mathematical education have focused on the link between language interactions, language and mathematics (e.g. Bulf, Mithalal, & Mathé, 2015; Morgan, 2013; Moschkovich, 2010; Sfard, 2008). Within the framework of our research (Barrera-Curin, Bulf, & Venant, 2016), the language of mathematical activity is considered as a dialogical and situated activity involving not only language with its written and verbal codes, but also the diversity of its manifestations. The appropriation of mathematical objects, “does not necessarily result in the same consequences for all persons, because it is a historical, situated and individual process” (Bauersfeld, 1995). As Bauersfeld (1995) raises it: “only across social interaction and permanent negotiations of meaning can “consensual domains” emerge” (p. 275).

In order to study language interactions where students’ language difficulties are added to the already existing constraints influencing teaching practices, it is necessary to observe these practices in a localized way. In studies that articulate didactic, psychological and ergonomic concepts (Robert & Rogalski, 2002; Roditi, 2013) the teacher’s task is viewed as the management of a diverse, dynamic and complex environment where interventions focus on knowledge acquisition and on students, while considering that students progress according to their participation and interactions in the classroom. The mediating and cognitive components of a teacher’s practice are central to the didactical organization of the mathematical tasks proposed by the teacher and adapted through interactions with the students. Thus, a teacher’s practice includes the targeted mathematical content, the choice of tasks and their organization, the types of help offered, classroom management, the language forms chosen by the teacher, and the different forms of student work. As we enrich the dual approach with Maturana and Varela’s framework as seen below in Figure 1, the teacher’s activity is viewed as a process of adaptation resulting from the coordination of the coordinations of actions between a teacher, their students and the environment.

**Figure 1: Modeling teaching activity (Barrera-Curin, Bergeron, & Perreault, 2018)**

The teaching activity can be grasped by analysing beyond the immediate observation of interactions in the classroom: institutional constraints, historical background, action logics of the teacher and personal beliefs, didactical implication and interaction in context. Therefore, analysing this activity must take into account different components of the action *in situ*. To identify those components, the Dual Approach (Robert & Rogalski, 2002) propose the observables concept, which take place within the language interactions between the students and their teacher. The observable categories consist in types of helps, task enrollment attempts and interaction surrounding mathematical objects (Barrera-Curin et al., in press). Procedural helps act directly on the initial task by dividing it in a series of simpler ones. Constructive helps focuses on questioning the student in order to serve his knowledge construction. Compensatory helps aim to compensate a disorder of the student that could slow down or prevent his mathematical activity.

In the present work, we focus on the articulation of these types of help with the mathematical tasks proposed to the students in order to observe in which ways mathematical actions are brought forth. In other words, we study how different types of help within language interactions carried on by the teacher trigger the mathematical activity of the students in the context of a specialized class.

### **Analyzing the articulation of language and mathematics**

Five teaching sessions were observed and videotaped with focus on language and interactions surrounding mathematical objects. Interviews were conducted with the teacher before and after each observations and focused on the teacher's choices (before) and her explanations about the progress of the session (after). In this paper, we focus on the first session and the corresponding interviews.

First, we analyzed the interviews to conduct a didactical analysis of the mathematical tasks and objects (Robert & Rogalski, 2002) planned for the session as well as the teacher's chosen form of teaching (action logics and constraints). Secondly, we identified episodes in the first session according to the richness of language and social situated interactions surrounding a mathematical object. Those episodes were then described according to the observable categories (types of help). Finally, we analyzed how those interactions trigger the mathematical activity of the students.

## Hélène's Project

Hélène teaches in a class for students with autism spectrum disorder designed to prepare them with skills for the workforce. The students are between 16 and 20 years of age and their mathematical knowledge varies from sixth grade of primary school to the second year of high school.

### The project to build a birdhouse

The teacher's focus was for students to reinvest geometrical concepts through a project of constructing birdhouses. Project based teaching of mathematics is not the usual approach within the context of special education. In special needs classes, teachers seek to respond to institutional expectations by conventional methods, in particular the evidence based model. In this case, Hélène plans to focus her sessions on dialogue and on the problematization of her students' questions. She proposes to her students to design their own birdhouse. During the session, she brings sheets of white paper and milk cartons. She wants each student to make a 2D model of their birdhouse using a set of 3D objects. She anticipates that the students would use these objects as points of reference for measuring the faces of the birdhouse. She plans 4 sessions to allow time for students to: design the paper plan, reproduce the plan with drawing software, perform laser cutting, and assemble a wooden birdhouse. To carry out this project, students must understand the relationship between the faces of the solid (incidence relations) and anticipate the operationalization of the solid as it passes from 2D to 3D. In this paper, we focus on the first session, particularly on some interactions that has led Hélène to add an unexpected session in order to work on the incidence relations.

### Creating conditions that trigger language interactions: help that becomes constructive

During her interactions with students, Hélène realized that she had not anticipated certain difficulties related to the 2D modeling of a 3D object. In fact, during the first session, she noticed that several students had designed a plan that did not include incidence relations. Up until that point, her questioning of students regarding the feasibility of their respective plans had not led to adjustments desired. Therefore, printing on wood without anticipating results was not possible. She decided to add a session in which students would cut out the development of their solid in paper form, build it and modify it as needed. At the end of the first session, the teacher decided to involve her students in a process of reflection regarding their final product. In the following excerpt, the questions raised by Hélène help to build her students' knowledge collectively as they are focusing on the students and the task at hand (constructive help).

Hélène: If we ever cut it in the wood and it doesn't work? What happens (pointing the plan), once cut, it will make a birdhouse?

Student 1: We'll make a simulation.

Hélène: We'll make a simulation with what?

Student 2: With the computer?

Hélène: We will have to ask the technician, but what if we don't have a computer, a bit like what we did with Phil and his roof?

Student 1: We make the sketch and we will cut out?

By analyzing language interactions, we notice that the teacher allows her students to reflect on a real issue related to the construction of the birdhouses. She does not present herself to the students as having the solution to their problem, but instead, she offers them a space to reflect where the end product of the task remains their responsibility, because “at any stage the child is an informant child as the teacher is an informed expert” (Bauersfeld, 1995, p. 278). When the teacher speaks, she considers the student’s proposal repeating the words that they used, while guiding them by reframing her questioning towards the more precise elaboration of a solution. In doing so, she creates an ethical space where her students’ legitimacy is recognized and where classmates listen to each other. Hélène’s place in the interaction remains central, but the context of the project and the way that she engages her students by raising questions promotes the expression of their ideas and encourages their participation in the collective reflection. Through a superficial analysis of this session, we could attribute to Hélène the status of a teacher who puts into place compensatory and procedural helps, but a more in-depth analysis of language interactions reveals that the help is constructive because of the importance given to dialogue as well as the activity it triggered.

Another moment during the first session reveals students seeking to validate their product by their teacher before continuing their work. But the teacher does not respond by answering or refusing her students' request. Instead, she questions them. This management of the process is particularly important in terms of its mediating and cognitive components (Figure 2) because the task remains the responsibility of the students while H  l  ne presents herself as a trigger of their mathematical activity. At that particular moment in the session, the mathematical task at hand required identifying the appropriate measurements in order to optimize the production of the pieces of the birdhouse.

- Student 3: So far, my floor is done.
- Hélène: Yes, what's missing after the floor ... we said?
- Student 3: Ummm... The sides!
- Hélène: What measurements are they going to have? [...]
- Student 3: Ummm, the height of my side ... Wait! If that ..., if we counted 25 cm, that's it?
- Hélène: Hum, hum. (she agrees)
- Student 3: Maybe 25 too?
- Hélène: 25 ... how much is your floor?
- Student 3: Ummm ... 20 cm!
- Hélène: So ... does it ... have to be wider or more narrow than your floor... your side? Your wall is going to go like this. (She takes a pint of milk to show it to the student on his sheet.) Here I will ... We'll go up like this. You want the wall to come to where?
- Student 3: Maybe equal?
- Hélène: Equal? So how much would it be?
- Student 3: Uh 20 ...?

- Hélène: 20. With a height of how much?
- Student 3: ... ummm ...
- Hélène: There will be the floor like that 20, and... a height of?
- Student 3: 25. (hesitates a little)
- Hélène: So, two walls of?
- Student 3: 25 cm! [...]
- Hélène: And with a width of?
- Student 3: ... 20 ...
- Hélène: Two times 20 by 25. (She mimes two times the width and then the height.)
- Student 3: Wait, kind of like... 20 here, 25, 20? (He shows the sides with his hands.)

The teacher addresses the student's questions, but procedural help is suggested by the new questions that she raises - she helps the student to organize the steps for developing his plan without giving him the answers. The student, in turn, adapts in a flow of interactions by trying to answer her questions. When he experiences difficulty formulating his answers, the teacher proposes compensatory help, in this case, modeling the incidence relation between the floor and the wall with the help of material. At the language level, the teacher models the measurements with the help of gestures that the student will repeat afterwards in order to appropriate them (Figure 2).

**Figure 2: Teacher and student's gestures to model and appropriate measurement**

However, the help that the teacher puts into place does not change the mathematical objectives of the task. She triggers mathematical activity by putting in place different types of help (procedural and compensatory) in the form of questions that promote explanations from the student. Therefore, Hélène's help becomes constructive regarding the mathematical activity of this student.

## Discussion

To sum up, the proposed approach for making meaning of teaching practices allows us to reveal the influence of language interactions in a classroom where a teacher offers space for dialogue with students and questions them in order to trigger their mathematical activity. Through the preceding examples, we have the opportunity to see in a new light how different types of help, that may modify the task or the mathematical object, can become a powerful drivers of student activity in a classroom context when the teacher offers a space where all voices are legitimized. The Dual Approach combined with the Maturanian foundation allows us to investigate the teachers practice at a macrostructural level as well as microstructural. Those two dimensions help us understand some

reasons for the action of the teacher but also to analyze how those action logics (in reference to the teacher beliefs about his practice and his students) and institutional constraints come to act. If H  l  ne can promote language interactions that enable students to socially build their knowledge, it's because, among others, few institutional constraints represent obstacles in terms of planning the delivery of her courses and her choices in terms of content and form of teaching. This teacher shares with researchers that she appreciates that a rigid educational program is not imposed on her. This greater professional freedom allows H  l  ne to consider broader possibilities for the mathematical activity of her students by seeking to maximize the usage of the tasks proposed and to be in sync with her conception of teaching. According to our analysis, H  l  ne prioritizes open and authentic questioning that encourages her students to engage in a process of reflection regarding the tasks at hand. Thus, it is both the supple institutional framework and the teacher's conception of the importance of student dialogue that promote the emergence of the language interactions observed.

As a final reflection, we want to underscore that the interactions we witnessed in this classroom diverge from the usual expectations for the behavior of students on the autism spectrum. Hence, we hypothesize that the importance that H  l  ne places on the collective dimension of her classroom promotes the emergence of language interactions, which may not be possible in a special class with a more prescriptive environment. Those results lead us to reconsider dominant teaching practices in Qu  bec and to place in the foreground the richness of mathematical reflections possible among all students, even those with a language disorder, when the classroom environment encourages authentic language interactions. What we witnessed in this class of students with language disorders related to autism, in terms of interactions around a mathematical object, is not so different of what we can observe in an “ordinary class”. Unfortunately, H  l  ne’s case is an isolated one. What we observed in other “special classes” within this research is merely comparable. In fact, other teachers tend to reduce learning opportunities within mathematical tasks (see Buro & Prediger, 2019, in this volume) by focusing on their cognitive characteristics and behavior. Thus, our analysis leads us to question the learning environment provided for students with language disorder. Therefore, we must reconsider the teachers’ formation in an institution that promotes differentiated instruction and the impact of this instruction model on the inclusion of students with a language disorder.

# Low entrance or reaching the goals? Mathematics teachers' categories for differentiating with open-ended tasks in inclusive classrooms

Sarah Buró and Susanne Prediger

TU Dortmund University, Germany

sarah.buro@tu-dortmund.de & prediger@math.uni-dortmund.de

*Open-ended inquiry tasks are considered a powerful approach for addressing the diversity of inclusive mathematics classrooms due to their potential for natural differentiation. However, this potential can only unfold when the teachers know how to work with the tasks. This article investigates teachers' personal categories for differentiating with an open-ended task, especially with respect to providing support for students with special needs. In a qualitative case study, a category-eliciting activity was conducted within a professional development session. Data gathering comprised 14 secondary mathematics teachers' and special needs teachers' video-taped group discussions and written answers, which were analyzed qualitatively. The results show that most teachers' ideas for support provided for the students with mathematical learning disabilities only addressed the low entrance, but not the core learning goals and the required basic conceptual knowledge.*

*Keywords: Inclusive education, natural differentiation, professional development, teacher knowledge.*

Most German secondary schools only recently shifted to an inclusive system, so many secondary mathematics teachers and special needs teachers currently learn how to differentiate in inclusive mathematics classrooms. As effective PD programs need to take into account teachers' typical starting points, we investigate teachers' perspectives to deal with various differentiated teaching approaches, here specifically with respect to differentiating with open-ended inquiry tasks (Scherer, Beswick, DeBlois, Healy, & Moser Opitz, 2016).

The paper starts with presenting the teaching approach of open-ended tasks and its potential for natural differentiation (Scherer & Krauthausen, 2010). The necessary teacher expertise for differentiating with open-ended tasks is conceptualized in the framework of Bromme (1992). The qualitative case study based on this conceptual framework uses category-eliciting activities for pursuing the following research question in the empirical part of the paper:

*Which categories and self-reported practices do teachers activate for differentiating in inclusive mathematics classrooms with an open-ended task? And how can this be supported by facilitation?*

## Background on classroom level:

### Open-ended inquiry tasks for natural differentiation

Inclusive mathematics classrooms call for differentiated instruction with joint whole-class experiences and specific support for students with special needs (Lawrence-Brown, 2004; Tomlinson et al., 2003). One of the teaching approaches which have proven useful (Scherer et al., 2016), applies rich open-ended inquiry tasks with the potential of so-called *natural differentiation*:

Open-ended tasks with a low entrance and high ceiling provide the potential for natural differentiation if they allow for multiple representations, diverse solution pathways and different cognitive activities along the trajectory of discoveries (Scherer & Krauthausen, 2010).

One example for such an open-ended task for Grade 5 is printed in Figure 1. It aims at discovering the multiplicative structure of the volume of cuboids, and has a wide differentiating potential (see Figure 2). The task has a *low entrance* as all students succeed in finding at least one cuboid. The task's *core goal* is to discover that counting in rows and layers leads to a multiplicative structure of the volume. The *high ceiling* for students with strong mathematical potentials covers the combinatorial challenge to find all cuboids, usually by considering the multiplicative decomposition of 24 in three factors.

### Open-ended task: Build many cuboids

Here, you have 24 wooden cubes. Which cuboids can you build with them? Document all cuboids which you have found. How many do you find?

Possible differentiating prompts:

- Do you find one cuboid?
- Do you find many cuboids?
- Do you find all cuboids?
- How can you be sure that you have found all?

All possible cuboids:

$1 \times 1 \times 24$ ,  $1 \times 2 \times 12$ ,  $1 \times 3 \times 8$ ,  $1 \times 4 \times 6$ ,  $2 \times 3 \times 4$ ,  $2 \times 2 \times 6$ .

Figure 1: Open-ended task for discovering the multiplicative structure of volumes (Prediger, 2009)

### Diverse ways of using material and structures

- longer or shorter use of hands-on material
- later or earlier discovery of structures
- more or less systematic search for all cuboids
- more or less strive for justifying completeness

### Possible steps in the trajectory of discoveries

- Step 1 Build with the cubes and count separately
- Step 2 Build with the cubes and count rows and / or layers and sum up these partial results
- Step 3a Build with the cubes, multiply for areas in each layer and add layers (partly use multiplicative structure)
- (OR Step 3b Build the cuboid, decompose it in layers and discover their multiplicative structure)
- Step 4 Build only parts and mentally imagine the rest and / or partly use multiplicative structures
- Step 5 Mentally imagine the cuboid and use multiplicative structures for rows and layers
- Step 6 Purely use multiplicative structures for rows and layers

### Multiple representations for the documentation

### Necessary basic mathematical concepts

- entry level: definition of cuboid as shape with rectangular faces
- access to goal: mental model of multiplication as counting in groups

Figure 2: Differentiating potential of the open-ended cuboid task as empirically identified by Prediger (2009)

## Teacher expertise for differentiating with open-ended tasks

The degree to which rich and differentiating tasks are really productive for inclusive mathematics classrooms depends on the teacher's expertise for really ensuring responsiveness, not only in a reactive way (i.e. ad hoc repairing occurring obstacles), but also proactively in preparing specific support for students in need for it (Tomlinson et al., 2003). Especially, low expectations have often been problematized (Büscher, submitted) as research shows that students with mathematical learning disabilities can reach more than often expected if responsive, proactive support is provided (Peltenburg, 2012). That is why the teachers must be prepared for these challenges. In order to base professional development offers on teachers' starting points, the study presented in this paper aims at capturing the teachers' current categories for differentiating with open-ended tasks.

Personal categories are a crucial part of Bromme's (1992) conceptualization of teacher expertise. He defines teacher expertise as the teacher's capability to cope with complex situations in subject matter classrooms, comprising (a) the teacher's practices by which they cope with situational demands (the so-called jobs), (b) the orientations, e.g. the (content-specific or content-independent) attitudes guiding the prioritization and interpretation of the jobs and (c) the categories which implicitly or explicitly guide their perception and practices (see Prediger, 2019 for a more general discussion of this conceptualization). Especially, Bromme suggests a powerful "heuristic to search for the 'natural' categories in expert knowledge" (Bromme, 1992, p. 88, translated by the authors) by analyzing the situational demands with respect to the relevant practices and their underlying implicit categories.

Based on the large literature on differentiating in inclusive mathematics classrooms (Tomlinson et al., 2003; Lawrence-Brown, 2004; Scherer et al., 2016), we identified three sub-jobs for the larger job of differentiating with open-ended tasks:

- (1) analyzing tasks with respect to students' potentially diverse solution pathways and approaches
- (2) identifying differentiating potential in a task and possible obstacles for reaching the core goals
- (3) providing support for students with specific needs for reaching the core goals.

Job 1 is a preliminary job for Job 2 and 3, which is necessary in order to unpack the mathematical structure and the possible steps on the trajectory of discovery (see Figure 2). The differentiating potential identified in Job 2 can refer to these steps and the multiple ways or representations, but also to possible obstacles, mainly those lying in required basis concepts. The later is crucial for proactively providing support in Job 3, especially for students with specific needs (in our case, students with mathematical learning disabilities, with or without the official status of having special needs).

Taking into account that effective differentiation is always knowledge-centered (Tomlinson et al., 2003), the teachers should have a focus on the six steps of the trajectory of the discovery as well as on the required basic knowledge in understanding the underlying mathematical concepts (as Scherer et al., 2016 emphasize). In the concrete task, this concerns the concept definition of cuboid and, even more importantly, the mental model of multiplication as counting in groups which is required for the transition of counting separately (Step 1) to counting in rows or layers by multiplication (Step 2-4). Providing support for students with specific needs should not only guarantee the low entrance of the task, but also the possibility of reaching the core goal, here the multiplicative structure of the volume. At the same time, the high ceiling (finding all cuboids with 24 cubes) provides challenges for the students with strong mathematical potentials.

## Methods of the qualitative study for investigating teachers' starting points

Given that teachers' expertise is often implicit in their practices, the research question (Which categories and self-reported practices do teachers activate for differentiating in inclusive mathematics classrooms with an open-ended task? And how can this be supported by facilitation?) was pursued in a qualitative study based on a category-eliciting activity.

### Methods for data gathering by a category-eliciting activity on three jobs

**Sample.** The sample consisted of 14 secondary math teachers who participated in their first session of a volunteer professional development series on inclusive mathematics classrooms. They had between 2 and 20 years of experiences in math teaching. 8 of them held a teacher degree as mathematics teachers (PCK<sup>+</sup>SNK<sup>-</sup>, i.e. with a formal qualification in pedagogical content knowledge in mathematics education, abbreviated PCK<sup>+</sup>, but no formal qualification in special needs knowledge on specific needs of students with learning disabilities, abbreviated SNK<sup>-</sup>), 1 of them was special needs teacher without a degree in mathematics education (PCK<sup>-</sup>SNK<sup>+</sup>), and 5 of them were special needs teachers with a degree in mathematics education (PCK<sup>+</sup>SNK<sup>+</sup>).

**Category-eliciting activity.** For eliciting teachers' personal categories and self-reported practices for differentiating with the open-ended task, the teachers' activity in Figure 3 was structured according to the jobs introduced in the next section. The teachers were asked to write down their ideas and discuss them in small groups during the PD session. The group discussions were video-taped and partly transcribed.

#### Students' task: Build many cuboids

Here, you have 24 wooden cubes. Which cuboids can you build with them? Document which one you have found. How many do you find?

#### Questions for teachers:

- (1) Which solution pathways and approaches would you expect from your students for this task?
- (2) Which potential for differentiation does the task provide?
- (3) How would you support students with mathematical learning disabilities?

Figure 3: Category-eliciting activity for three jobs

### Methods for qualitative data analysis

The qualitative data analysis was based on deductive-inductive procedures (Mayring, 2015), starting from the prospective analysis of differential potential and possible obstacles (see Figure 2), but open for teachers' further personal categories. The articulated personal categories were inductively subsumed under the most relevant categories (results listed in Table 2). The elicited categories along the three jobs were compared between the three subsamples PCK<sup>+</sup>SNK<sup>+</sup>, PCK<sup>+</sup>SNK<sup>-</sup>, PCK<sup>-</sup>SNK<sup>+</sup>.

The video data was analyzed qualitatively with respect to the inductively developed categories and their emergence in the discussions. The video data was of specific importance for determining not only what teachers miss, but also how the facilitator could activate inert knowledge after a while.

## Insights into teachers' practices and categories for differentiating

### Main focus on low entrance in Step 1 instead of learning goals and basic concepts

Table 1 shows exemplary answers written by three teachers, together with the category assigned to the answers in the data analysis. Table 2 embeds these three cases into the complete group of 14 teachers (if only 13 teacher occur, one has not answered this part).

	Melanie (PCK <sup>+</sup> SNK <sup>+</sup> )	Dieter (PCK <sup>-</sup> SNK <sup>+</sup> )	Hayat (PCK <sup>+</sup> SNK <sup>-</sup> )
<b>Job 1: Analyzing the task</b>	<ul style="list-style-type: none"> <li>Some kids just start → trial &amp; error</li> <li>some find pattern and use them (de-composition of 24 in multiplication tasks with 3 factors)</li> </ul> → Step 1; Step 2-6 in one line	<ul style="list-style-type: none"> <li>one self-confident student (most probably with no special needs) overtakes the task</li> <li>attitude to work [...]</li> <li>trial</li> </ul> → affective/social factors, low expectations, implicit Step 1	<ul style="list-style-type: none"> <li>Students find cuboids with same volume and same lengths</li> <li>Students find cuboids with different lengths and same volume</li> <li>Just start and build</li> </ul> → Step 1; systematic or trial & error
<b>Job 2: Unfolding differential potential</b>	<ul style="list-style-type: none"> <li>Some kinds only find one cuboid by trial and error; others find many / all cuboids by mathematical thinking; commutativity (different cuboids by shifting factors)</li> </ul> → natural differentiation along the steps and diverse ways <ul style="list-style-type: none"> <li>different modes of documentation</li> </ul> → natural differentiation regarding documentation & high ceiling	<ul style="list-style-type: none"> <li>Preset the layers</li> <li>make writing task more precise</li> </ul> → no natural differentiation but reduce complexity	<ul style="list-style-type: none"> <li>Students find some cuboids or only one</li> <li>Students find pattern</li> </ul> → natural differentiation along the steps
<b>Job 3: Planning specific support</b>	<ul style="list-style-type: none"> <li>For some students: no support</li> <li>for students with physical disorders: larger cubes</li> <li>support for articulation</li> </ul> → support for documentation surface level (material) no basic concepts addressed	<ul style="list-style-type: none"> <li>Less cubes</li> <li>present basic face? → kills fun</li> </ul> → reduce complexity; no basic concepts addressed	<ul style="list-style-type: none"> <li>Working in pairs</li> </ul> → surface level (grouping); no basic concepts addressed

Table 1: Examples of teachers' written answers and the assigned categories

In **Job 1** (Analyzing the task), Dieter and Hayat only focused on Step 1 of the trajectory of discovery (see Figure 2), only Melanie also considered further steps (even if condensed in one line without unpacking the necessary steps). Within the group of all teachers (see Table 2), Melanie was an exception, whereas many teachers (6 of 13 teachers) only focused on Step 1 of students' trajectory, but not how to reach the core goal of the task, discovering the multiplicative structure of the volume. Other categories teachers activated in Job 1 concerned social and affective factors, many of the teachers expressed low expectations like Dieter and two of them even expect that students get no possibility to build a cuboid.

In **Job 2**, it is interesting to see that Dieter (and with him three other teachers) could not identify the potential for natural differentiation and immediately started to provide specific support for weaker students. Those who identified potential for natural differentiation like Melanie and Hayat focused on the steps (7 of 13), the students' diverse ways of using material and structures (2 of 13), or on multiple representations for documentation (2 of 13). Teachers with PCK<sup>+</sup>SNK<sup>+</sup> could identify more potential for natural differentiation than the teachers with PCK<sup>+</sup>SNK<sup>-</sup>. The teacher with PCK<sup>-</sup>SNK<sup>+</sup> found none. The required basic concepts (cuboid, multiplying as counting in groups) were only addressed by one teacher in Job 2. With respect to **Job 3**, most teachers have some resources for planning support for students with mathematical disabilities, this is shown by the fact that only three teachers planned their support exclusively on surface levels of grouping strategies or taking larger wooden cubes.

However, as a consequence of the strong focus on Step 1 in Job 1, the planned support in **Job 3** mainly focused on Step 1/2 again. That means, 2 of 5 teachers with PCK<sup>+</sup>SNK<sup>+</sup> and 4 of 8 with PCK<sup>+</sup>SNK<sup>-</sup> only provide support for guaranteeing the low entrance. By this focus, they miss the core

goal of the task, which was discovering the multiplicative structure of the volume. As a consequence of the limited view on the necessary basic concepts, only three teachers with PCK<sup>+</sup>SNK<sup>+</sup>, provided support for overcoming limitations in the basic concepts, and none of PCK<sup>+</sup>SNK<sup>-</sup> did. Among the three who took care of basic concepts, two made sure that the definition of cuboid as shape with rectangular faces is accessible also for students with mathematical learning disabilities, and only one single teacher's support addressed the potentially missing mental model for multiplication as counting in groups.

	Subsample PCK <sup>+</sup> SNK <sup>+</sup> (n=5)	Subsample PCK <sup>+</sup> SNK <sup>+</sup> (n=1)	Subsample PCK <sup>+</sup> SNK <sup>-</sup> (n=8)
<b>Job 1: Elicited categories for analyzing the task</b>

**Table 2: Quantitative overview on elicited categories**

### Shifting teachers' categories by prompts to further steps

In order to avoid a deficit-oriented inventorization of teachers' perspectives, it is crucial to consider how the teachers' activation of categories can be supported by facilitation in the PD session.

When the facilitator collected teachers' ideas of the aspects of natural differentiation and for supporting students with mathematical learning disabilities after the first group discussions in the PD session, she became aware of the exclusiveness of teachers' focus to the first steps of the trajectory. After acknowledging all teachers' efforts for guaranteeing low entrance for everybody and collecting the diverse aspects of potential for natural differentiation, she shifted the focus to the central learning goal, emphasizing the multiplicative structures of counting in rows and layers for determining the volume. She sent the teachers back into their group discussions with the following prompt which started an interesting process of eliciting further categories:

143 Facilitator	What do we do know [ <i>means for the students with learning disabilities</i> ] that they can really...? So what kind of support can we give so that they can learn - not only what to calculate, but also understand why to use multiplication?	How to come to Step 2-5?
-----------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------

144 Melanie	The levels while layering, there are the layers [ <i>shows the layers with her hands</i> ]	Step 2
...		
149 Melanie	And then coloring, well anyway, really draw the picture as three-dimensional and mark the layers and reflect, how many cubes are in one layer	Step 2+3a
150 Hayat	I mean, when you have worked adequately, then they know this, this with lying the dot plates [ <i>she refers to rectangular arrays such as printed here</i> ]	Basic concept multiplication
151 Carmen	I was just gonna say, the point system and with it, you can take the cuboids of one layer.	Step 3a
152 Hayat	Yeah.	
153 Carmen	And then the point system behind, then they will get it, length times width.	Step 4, High expectation
154 Hayat	Exactly, I have first..#	
155 Carmen	#That is then, the remediation of the rectangle [...]	basic concept
157 Christiane	Yes.	
158 Carmen	Area, isn't it [...]	
160 Melanie	And then the rectangle.	Step 4
161 Carmen	And then the multiplication [...] You have the dot frames and the rectangle – that is what I would remediate here, and then there are the layers, though. [...]	basic concept
- 165	And then, if you color that, you are, easy peasy, in multiplication.	Step 4
...		
169 Christiane	You mean, decomposing it, actually, after it, decompose into the same forms.	Step 3b
...		
173 Melanie	But then, of course, you are still in the hands-on, and you have to anyway, ehm.	Step 5
174 Carmen	Or you come into the multiplication. [...]	relevance of
-177	IF you have remediated it thoroughly, before.	basic concept

The analysis of the transcript with respect to the implicitly or explicitly addressed categories from Table 2 shows that after the facilitator-initiated shift of attention from the low entrance to reaching the core goal, the group discussion at the observed table quickly turns to carefully thinking through all steps of the trajectory of discovering multiplicative structures (as marked next to the transcript). During this reflection, the teachers also identify the most important basic concept, the mental model of multiplication in the rectangular array (addressed by the teachers with different idiosyncratic terms – the dot plates, the point system, etc. – but exactly that meaning).

It is only now that the teachers discover an important form of differentiating with the open-ended task: When planning how to provide support for students with mathematical disabilities, the basic concepts required for reaching the learning goals of the task must be identified and possibilities for integrated remediations of these basic concepts have to be searched. In addition, teachers can express higher expectations.

## Discussion and outlook

Although the sample of 14 teachers is much too small to take the quantitative comparisons of teachers' different backgrounds as statistically representative, these first insights into an ongoing project can already point to teachers' resources and blind spots for differentiating with open-ended tasks:

- Open-ended tasks can only *unfold their potential of natural differentiation* if teachers can unpack this potential. In our sample, 9 teachers started to unpack it, which is a good starting point.
- Their focus is mainly on the start of the trajectory of discovery, and as a consequence, the provided support for students with mathematical learning disability is concentrated on the first steps, but not on the steps towards reaching the learning goal. As a consequence, also the *support is not yet concentrated on the core goals*.

- The observation that only three teachers provide *support for overcoming obstacles posed by potentially missing basic conceptual knowledge* is a very strong concern as students cannot reach the learning goals without getting access to the basic mathematical concepts.
- Within the PD session, the facilitator succeeded to shift the participants' focus from the low entrance to possible *supports for reaching the core goals*, so with adequate prompts, the teachers can activate categories in their PCK that help them. These include especially the basic concepts.
- Further questions: Which other blind spots for differentiation can be identified and how can they be processed?

## Acknowledgment

The paper has grown within the research in the German National Center for Mathematics Teacher Education (DZLM, funded by the Deutsche Telekom Foundation). The research is organized in the PD research project MATILDA, funded by the German Ministry of Education (grant no. 01NV1704 to S. Prediger & J. Kuhl). We thank our project partners for the collaboration, especially Christian Büscher for the coordination.

*Abstract: Mathematics teachers in Hong Kong find they have no confidence in designing effective instructional plans for students with intellectual disability (ID). Based on our four-year experience of dealing with mathematics teaching problems faced by teachers of students with ID, we claim that an understanding of mathematics knowledge structure is the pre-condition of generating hypothetical learning trajectories. To illustrate this point, a study on developing a progressive learning framework for teaching mental objects to students with moderate or severe ID is presented here.*

*Keywords: Design science, intellectual disability, mathematics teaching, teacher professional development.*

## Introduction

Over the last four years, we have been engaged in a professional development programme for supporting mathematics teachers of students with intellectual disability (ID). ID is a disability characterized by significant limitation in intellectual functioning and daily adaptive behaviors (AAIDD, 2010). Students with ID face serious obstacles in abstract thinking, reasoning, comprehension, and communication (Taylor, Richard, & Brady, 2005), which greatly influence their learning performance in mathematics. The cognitive limitation suggests that the mathematics learning trajectory for students with ID cannot possibly be the same as those for students with normal intelligence.

In the local community where we are working, the government provides teachers with a total of 250 hours of training for support students with special educational needs (SEN), including students with ID (Education Bureau, 2018). The majority of time is spent on developing teachers' skills and strategies in supporting students learning and instilling teachers' knowledge in handling students' cognition, behavioral, emotional, sensory, communication, and physical needs. Subject content (such as mathematics or science) is rarely covered. It seems that policymakers regard the enhancement of teachers' knowledge for teaching mathematics to students with SEN as just adding generic pedagogical knowledge to whatever mathematics specific preparation teachers have already acquired in previous training.

Similarly, in the research community, the importance of mathematical knowledge for teaching SEN students has not received much attention. Allsopp and Haley (2015) conducted a synthesis of research and found that, during 2004 to 2014, only 16 studies included the criteria of teacher education, mathematics, and students with learning disabilities. On the topic of intervention studies for ID students' mathematics education, only 16 papers were found to have been published between 1989 to 1998 (Butler, Miller, Lee, & Pierce, 2001), and 7 papers were found to have been published between 1999 to 2010 (Hord & Bouck, 2012). After a glance of the very limited literature on mathematics

education for students with SEN, it is easy to discover that studies on intervention based on a mathematics-specific perspective are rare.

The pedagogical content knowledge (cf. Shulman, 1986) for teaching mathematics to SEN students is an under-addressed area. Is mathematics for teaching SEN students the same, in both content and form, as mathematics for teaching students without SEN? Or how different are the two? To what extent do generic knowledge and skills about SEN students' learning enable teachers to carry out mathematics teaching that is effective to SEN students? We attempt to discuss these questions based on our experience with teacher development in recent years.

The paper describes data from a study in which we collaborate with school teachers to develop an instructional framework for students with moderate (IQ from 35 to 50) or severe ID (IQ below 35). We use this study to illustrate teachers of students with moderate and severe ID need support for designing appropriate mathematical experiences for their students, a point that is overlooked by most teacher training programmes of special education.

Fourteen teachers from five special schools in Hong Kong participated in this study, six of whom teach students with moderate ID, and eight teach students with severe ID. Qualitative data are collected, approved by participating schools, teachers, and students' parents, including written notes of the meetings, video recording of teaching experiments, and audio recording of interviews with three teachers who took part in the teaching experiment.

### **Generating a hypothetical learning trajectory**

In each of the participating schools, teachers have been trying hard to find ways to expand their students' possibilities in mathematics learning. When teachers were asked about their difficulties in teaching, the following comment, made by Teacher 1, was common among the teachers:

When I prepare to teach a piece of mathematics content, I think that I learned that content by this way, but for children with ID, how do they learn?

It shows that teachers understand that the learning trajectories of ID students are different from what they experienced themselves in schools during their years as students, but they have no experience of what it is like to learn mathematics with the limitation that their students have. Given all this, teachers usually are left alone to make up the details of their teaching – extrapolating from whatever mathematics textbooks or other learning resources might offer. However, most of the available materials are designed for students without ID, and teachers would easily find themselves being left in the unknown area of teaching.

In what follows, we outline general steps by which we help teachers to arrive at a hypothetical learning trajectory for students with ID. The procedure resembles the French approach of didactical engineering (Artigue, 1994), in which a serious analysis of the teaching contents and constraints at epistemological, cognitive, and didactical levels constitutes an essential component.

### Step 1

We listen to the teachers talk about the teaching problem they are confronted with and have an observation about the target student groups, during which, we try to answer the following questions as far as we can:

- What is the teaching problem?
- What is the goal that the target students need to achieve?
- Is there any constraint that need to be considered?

The answers to these questions provide us with a general picture of our mission.

### Step 2

Before we start designing a hypothetical learning trajectory of a topic, we carry out an epistemological analysis of the content structure, which aims to portray a longitudinal picture of knowledge acquisition. During the process, we try to reconstruct a path of knowledge development that on the one hand links up well with prior learning experiences, and on the other hand, contributes to effective subsequent learning. The structures identified in this stage underpin a skeleton of the hypothetical learning trajectory, which ensures the resulting trajectory will be mathematically sound.

### Step 3

The skeleton of the hypothetical learning trajectory provides teachers with a direction for generating an instructional plan. In the third step, we need to work with teachers to insert various intermediate stages, with attention paid to characteristics of students, classroom constraints, curriculum constraints etc. With teachers' input, we begin with a thought experiment (cf. Freudenthal, 1991), imagining how the teaching-learning processes will proceed and spotting out the gaps in the proposed learning trajectory that will impede students' knowledge construction.

### Step 4

Lastly, teachers, with some help from the researchers perhaps, fill in the fine details to arrive at a detailed instructional action plan for their own students. Afterwards, it will be field-tested and open to amendment based on implementation evidence.

### **An illustrative example: developing a framework to teach mental objects to students with moderate or severe ID**

The learning of mathematics involves creating mental objects (Freudenthal, 1991). Number, length, angle, circle, square, weight, straight line, ... are mental objects commonly encountered in mathematics lessons. They, being intuitively clear among children with normal IQ, are often found to be very difficult for students with moderate or severe ID. Unfortunately, these difficulties are usually unknown to their teachers who were once children with normal IQ in their younger days.

When teachers try to communicate the meaning of mental objects, how can they convey those messages to students with ID? And, how can they check if students indeed acquire what their teachers intend to communicate? The situation becomes worse for students with specific language impairment. When verbal communication fails, is there any possibility of conveying abstract mental objects to

students? In short, how can we draw students' attention to mental objects without relying on language? This is the situation we were confronted with in Step 1 after discussions with teachers. The main teaching problem is how to convey the meaning of a mathematical concept (which is, in essence, a mental object) to students with moderate or severe ID? As these students often do not have satisfactory verbal communication skills, teaching is constrained to using a minimal amount of verbal communication. The goal to achieve is that students can identify the mental object from among others in a multiple-choice question.

In Step 2, we proceeded to analyze the knowledge structure concerned. Indeed, a mathematical term sometimes refers to a relation, as in the case of 'being less', an operation, as in the case of 'subtract', or a class of objects, as in the case of 'straight line'. For example, in Figure 5, we will say "This is a straight line" when we point to each of the three different straight lines. In essence, the term 'straight line' refers to the class of figures in which no two of them are indeed identical. Teaching involves conveying a class of objects that shares certain properties without ever going explicitly into those properties in detail. When language is not the vehicle of communication, we are left with the scenario that students can only 'sense' the meaning through examining a large number of examples and non-examples. This understanding forms the basis of the Pick the Odd One (POO) framework.

POO is a framework for designing a series of multiple-choice activities under which a student could progressively develop a sense of a mental object without relying too much on verbal communication. Although the teacher is free to employ any verbal explanation during its execution, the main thrust that drives students to the target mental object comes from the teacher's confirmation of the correctness of a student's choice, which may well be done using body language or facial expression.

In Step 3, we had to portray various intermediate stages of the POO. These stages should encompass sufficient variation across examples and non-examples of the mental object to be conveyed. To begin with, there should be a key concept, or a focus mental object, that will appear in the series of multiple-choice activities. Going through the series of multiple-choice activities, the student will systematically visualize or experience these variations. Each multiple-choice item includes a total of four or five choices, with at least one choice corresponding to the focus mental object, and at least one choice corresponding to the other. The student should indicate (by pointing or other means) the odd one out. Through systematically varying these choices, the student's attention is drawn to the focus mental object. Timely feedback from the teacher serves to shape how the mental object is developed, and hence is an indispensable component of the activities.

There are four stages of the POO. In Stage 1, each item consists of exactly one choice corresponding to the focus mental object (straight line in this case), while the remaining are identical choices in identical orientation (Figure 1). In Stage 2, each item consists of exactly one choice not corresponding to the focus mental object, while the remaining are identical choices corresponding to the focus mental object, in identical orientation (Figure 2). Variations of the forms of the mental object and the otherwise across items should strive for comprehensive coverage as far as possible (see Figure 3 and Figure 4). In Stage 3, each item consists of exactly one choice not corresponding to the focus mental object, while the remaining choices correspond to the focus mental object in different forms (Figure 5). Up to this point, the student should have seen or experienced a large number of examples and non-

examples of the focus mental object. The teacher could now reveal relevant terminology in written or oral form. In Stage 4, no specific restriction is imposed on the choices and the student is required to pick out the unique choice corresponding to the focus mental object by its name (Figure 6). In other words, the student tackles multiple-choice questions commonly found in regular mathematics class only at Stage 4. All the previous activities are designed to fill the gap before the student is capable of handling this.

**Figure 1: POO stage 1**

**Figure 2: POO stage 2**

**Figure 3: Variations of stage 1**

**Figure 4 Variations of stage 2**

**Figure 5: POO stage 3**

**Figure 6: POO stage 4**

In principle, this framework can be applied to teach a variety of mathematical mental objects or informal notions such as straight line, circle, emptiness, being long, inner part, being heavy, many, etc.

In Step 4, teachers proceed to design the details of the series of multiple-choice activities. Pilot tests carried out by teachers indicated that there should be a preparatory stage (see Figure 7 and 8) to confirm that the student is capable of matching object or picture at hand with a group of identical objects or pictures not necessarily in the same orientation.

**Figure 7: Exactly identical objects**

**Figure 8: Identical objects in different orientations**

After inserting the preparatory stage, the second round of teaching experiments was conducted. The progress in moderate schools was very obvious, in which most students could correctly choose the unique straight line among the four choices after two weeks' training, and some of them could classify straight lines and curves (in the form of physical objects and printed figures) in the third week. Teaching experiments were also conducted with four students (S1, S2, S3, and S4) with severe ID who have little ability of communication. One of the students, S4, is with autism spectrum disorder, and he always exhibits restricted and repetitive behaviours. The learning pace of the students was slow, but progress was still observable as shown in Table 1.

Student	1st video recorded lesson	2nd video recorded lesson (after 6 weeks)
S1	Able to choose the straight line from four choices (POO Stage 4)	Able to classify straight line and curves
S2	Cannot choose the straight line from four choices (POO Stage 1)	Can choose the curve from four choices (POO Stage 2)
S3	Cannot classify the straight line and curves	Able to classify straight line and curves
S4	Cannot give teacher an identical object	Able to put two identical objects into a group

**Table 1: Severe ID students' learning performance in two video recorded lessons**

Students' learning progress was also observed by the interviewed teachers. They all agreed that the framework helped their students learning mental objects. Teacher 1 who applied the framework to teaching her students with moderate ID the mental object 'being less', told us:

For example, I would like to teach them the concept of 'being less'. During the activity, 'being less' will be the different one among the choices. If you directly point to the group with less objects and tell the student "this is being less" [without drawing their attention to the difference in amount], they will mistakenly name the objects they see 'being less'. Actually, they do not get what you mean, and they haven't even compared them [the quantity]. However, in this framework, they need to identify the difference first and then, we teach them the difference is 'being less'. Before we applied this framework in teaching, our students' performance of 'being less' was not stable, but through the framework, I pointed to the difference and told them it is 'being less', they soon have a grasp of the concept.

Teacher 1 found the framework provided a way for teachers to communicate with moderate ID students. She had never thought that POO could be an effective starting point to learn a mental object.

Teacher 2, who was in her second year of teaching students with severe ID, found that POO not only assisted her students' learning but also enhanced her professional competence in teaching students with severe ID.

Interviewer: What changes have you had after participating in this teaching experiment?

Teacher 2: Before this teaching experiment, I didn't know what content I should teach [to students with severe ID]. Now, when I teach mathematics, I have something to follow. I can make a reference to the framework. There are many levels and steps, so I can evaluate what level a student has achieved and know what learning activities should be assigned to the child in the next level. This makes lesson planning easier because the framework enables me to plan my teaching for each individual student.

Interviewer: What changes do your students exhibit?

Teacher 2: One student could pick the odd one only when it differs from the others significantly, now she is able to do it with even a small difference. I found that when they are familiar with the learning activity, they can make progress much faster. It is good for them to learn different topics under one progressive learning framework. Before this teaching experiment, I included a variety of learning activities in my class because I believed it would make a fruitful lesson. However, from the perspective of students with severe ID, this is not the case. They cannot handle a frequent switch of contents and learning methods, and consequently make little progress.

Interviewer: Did your students perform up to your expectation?

Teacher 2: More than half of the students performed better than I expected.

Interviewer: What was your expectation before?

Teacher 2: Before? I didn't expect much. I just gave them some manipulatives related to mathematics and hoped they could explore by themselves. I was satisfied if they could touch and play with them. But now, I expect more. I hope they can make some mathematical sense out of the activity instead of just playing.

Teacher 3, who has more than twenty years of experience in teaching moderate ID students, also mentioned:

We have learned more about mathematics. This is because that part of mathematics falls onto the blind spot of our knowledge. We were not able to see them because we skipped them quickly when we learned. As our starting point [of learning] was not that low, it is natural that we missed all the steps that our students need to have. Therefore, we would not think of these steps in our teaching. Fortunately, the learning trajectory developed explicitly lists those steps out, reminding us of what we missed in our teaching.

## Concluding remarks

Our experience with the framework POO reveals the following observation that deserves serious attention. Teachers need support on creating a knowledge structure for understanding and planning for students' progress. Such a structure should enable teachers to divide teaching into small steps that can possibly engage students with moderate or severe ID. This is especially important when teachers cannot possibly draw on their own previous learning experience where those intermediate learning stages were virtually absent. To produce such a knowledge structure and subsequent action plan constitutes the design science of mathematics education (Wittmann, 1995, 2001). It involves studying various phenomena and their corresponding mathematical meanings, which can only be done from within mathematics (Freudenthal, 1983). Judging from students' performance and teachers' feedback, this approach is seen to have a positive impact on improving the quality of learning of ID students. It re-confirms the importance of mathematics in mathematics education (Akinwunmi, Höveler, & Schnell, 2014), something that may sound too trivial to consider, yet often too easy to overlook.

# **K-12 Namibian teachers' beliefs on learning difficulties in mathematics: Reflections on teachers' practice**

Shemunyenge Taleiko Hamukwaya

University of Turku, Finland; shtaha@utu.fi

*This paper explores K-12 Namibian mathematics teachers' beliefs on difficulties associated with learning mathematics in school and examines their perceptions of problems affecting Mathematics Learning Difficulties (MLD). 231 teachers (100 primary and 131 secondary teachers) completed the survey. The findings reveal that teachers frequently frame students' difficulties within a deficit framework seeing students' difficulties as emanating from cognitive disabilities. Teachers' identification of potential causes of MLD is discussed. The paper concludes by considering the pedagogical implications of providing additional support to students with MLD and by providing recommendations for future research on changing teachers' negative perceptions towards students with MLD to optimize students' performance.*

*Keywords: Learning difficulties, teachers' perceptions, mathematics learning difficulties, beliefs.*

## **Introduction**

Many countries across Africa have reported poor mathematics performance among their students (International Mathematics Union Report, 2014). According to the Organization for Economic Co-Operation and Development (OECD), mathematics becomes a stumbling-block for the majority of students (OECD, 2014). In Namibia, like many other countries, mathematics is a compulsory subject in the K-12 curriculum because of its significance and practical value in everyday applications (Tjikuua, 2000). However, in the last three decades, since Namibia's independence in 1990, majority of students perform poorly in mathematics. Literature on mathematics education highlighted numerous factors leading to poor performance including students' difficulties in learning mathematics (e.g. Siyepu, 2013). To better understand students' difficulties in Namibia from the teachers' perspective, this study examines Namibian mathematics teachers' perceptions on Mathematics Learning Difficulties (MLD) and challenges experienced in teaching students with learning difficulties. Preliminary research shows that little is known about Namibian mathematics teachers' perspectives on MLD, rather past studies have focused on learning and teaching of specific content in mathematics, instead of understanding MLD. Therefore, the study's aim is twofold: contribute to the research on mathematics teachers' beliefs and mathematics education in terms of how teachers cater diverse learning needs of students with MLD and suggest potential ways for teachers' intervention starting by changing teachers' beliefs to improve the academic performance of Namibian students.

## **Theoretical background**

Mathematics education researchers describe MLD in different ways. Morgan, Farka and Wu (2009) associate MLD to risks in mathematics proficiency. Karagiannakis, Baccaglioni-Frank and Papadatos (2014) describe MLD as a variety of obstacles that lead to difficulties in processing numbers. While some researchers claim that MLD is the result of sociocultural norms around developing

mathematical skills or comprehending arithmetic relations (Kaufmann & von Aster, 2012, p. 767), other researchers assert MLD is related to cognitive functions (Mazzocco, 2007). All students with MLD work slowly in mathematics (Wang, Du, & Liu, 2009) and perform poor academically (Jitendra et al., 2013). Building on the previous literature, this study considered MLD as any limitations or constraints that are believed have negative effect on students' achievement, and leads to difficulties in learning and poor performance of mathematics.

Several reasons and factors that might cause the learning problems in teaching students with MLD have been identified, including poor foundation in content knowledge, unwillingness to learn, and teachers' incompetency (Siyepu, 2013). The literature also reveals several causes that teachers attribute to mathematical difficulties, which include the lack of student motivation and the medium of instruction (Wang et al., 2009; Siyepu, 2013). Students tend to develop positive attitudes towards mathematics in early grades; however, some lose interest in mathematics as they move to higher grades (Lee, 2009) and experience difficulties in mathematics and perform poorly due to lack of interest in the subject (Tella, 2007).

To address the needs of students with MLD, Torbeyns, Verschaffel, and Ghesquire (2004) suggest that teachers pay special attention to effective teaching techniques at a slower pace, as this will improve student performance. However, such implementation requires understanding teachers' perspectives of MLD which has not been investigated before. Thus, this study explores Namibian teachers' beliefs about the difficulties associated with learning mathematics and how they perceive MLD. The perceptions of teachers are important in the identification of difficulties and factors involved in MLD and ultimately have a significant influence in changing practices (Kasanda, 2015) towards a more inclusive mathematics teaching.

### **Mathematics teachers' beliefs and practice**

Mathematics teachers have a wide set of beliefs regarding mathematics content and the nature of mathematics, but also on effective teaching and learning of mathematics. These beliefs are often based on a teacher's own knowledge base, or his or her own experiences acquired through his or her adapted teaching practice (Maab & Schlöglmann, 2009). This study has adopted the definition of beliefs from Ajzen and Fishbein (1980), who define beliefs as whatever a person regards as true in a certain situation. These beliefs include thoughts, attitudes and principles adopted by individuals through a shared environment. Researchers on mathematics teachers' beliefs agree that beliefs play a critical role in determining how teachers teach and what they do (Thompson, 1992). Research also suggests more studies on beliefs on teaching and learning mathematics as well mathematics itself as a subject (Perry, Tracey, & Howard, 1999, p. 39). Also, Haser and Star (2009) suggest more belief studies are needed in different educational contexts to better understand how teachers deal with different situations. The present paper extends the work of Perry (1970), who explored mathematics teachers' epistemology beliefs – whereby the study will look at beliefs based on the experiences of teaching students with MLD to determine their notion of an inclusive setting. This perspective acknowledges that the personal beliefs of teachers might influence their teaching practice. According to Ernest (1991), a teacher's perspective is an individual belief system about the nature of mathematics. Ernest (1991) further found that mathematics teachers' perspectives, which are regarded

as beliefs or thoughts, influence a teacher's social context of teaching and the level of teacher's thought. Furthermore, educational researchers emphasize that teachers' beliefs and the social context affect the nature of how mathematics is taught or learned (Ernest, 1991). Thus, educational programs need to reshape those beliefs that may hinder effective mathematics teaching (Maasepp & Bobis, 2015). Researchers suggest that teachers' beliefs regarding teaching and learning affect their own practices (Thompson, 1992). It has been found that there is a strong relation between teachers' perspective of teaching and their perspective of students' mathematical knowledge (Sosniak, Ethington, & Varelas, 1991). Ernest (1991) concluded that to change the nature of teaching and learning of mathematics, changes in a teacher's belief structure is needed, while acknowledging that belief change is difficult. On account of this, the present study intends to answer the following questions:

1. What are Namibian mathematics teachers' beliefs about mathematics learning difficulties?
2. What challenges do mathematics teachers experience when teaching students with mathematics learning difficulty in an inclusive classroom and what potential measure do they use?

## **Methodology**

### **Instrument**

A survey with closed (teaching experience, education background) and open-ended questions (Kelley, Clark, Brown, & Sitzia, 2003), was administered, to get the perspectives of mathematics teachers' on MLD by asking the following questions: (i) What do you understand by 'learning difficulties' in mathematics? (ii) What challenges do you experience in teaching students with learning difficulties in mathematics? (iii) How do you deal with such challenges? The instrument also collected information on teachers' views about challenging topics to students as well as their estimation on difficulty among mathematics students as they move from primary to secondary level which are not reported in this paper because of limited space. The design process followed the recommendation of Zhanga and Zhou (2016) about the design of the questionnaire, that it should allow participants flexibility to provide rich data. The survey was designed by the author and revised by two experienced researchers in the field in terms of wording as well as its content for validity.

### **Participants and procedure**

A total of 231 primary and secondary (100 and 131 respectively) teachers voluntarily completed the survey. Participants' teaching experience ranged from one to twenty years, and their educational backgrounds varied. Only five of the participants did not have the minimum teaching requirements, a diploma as per Namibian teaching requirements, and the majority taught at rural public schools.

The survey was given to teachers during an annual Namibian mathematics teachers' congress in 2017 where 232 teachers teaching at both primary and secondary phases participated. This congress is a venue where mathematics teachers across the country come together to share their experience and challenges encountered in teaching mathematics. This was a better platform for the author to obtain representatives from all fourteen educational regions to contribute to the study. Permission to conduct the survey was obtained from the conference coordinator. Teachers were briefed about the research objective and they were informed that their participation was anonymous and confidential. Teachers

were told to base their answers to what they experienced. Completion of the survey was done at the same time, about 30 minutes. One hundred and six teachers opted to submit the survey through Google Drive while one hundred and twenty-five placed the surveys in a drop box that was allotted for this purpose at a conference venue.

### **Data analysis**

Responses to closed-ended questions were for comment on participants' background information. A qualitative approach was most appropriate to understand and interpret the data of the study, which were the respondents' answers to the open-ended questions. Data were analyzed using a thematic analysis (Ritchie & Lewis, 2003) based on the research questions mentioned earlier. According to Braun and Clarke (2006), descriptive themes enhance meaningful insights of data with deeper understanding. Every individual statement was considered for data analysis and all related features of the data were coded after data familiarization. Key words used in coding include "disabilities", "unable", "less ability", "lack of interest", and "struggling". Categories were identified and refined to make descriptions of the data understandable. The coding process generated three themes. Some of the descriptions are illustrated as direct quotes to support claims and to have a coherent conclusion.

### **Findings and discussions**

The findings reveal that teachers have a wide range of beliefs. In general, the study reveals that teachers' beliefs illustrate that they are unaware of the causes of MLD. Three themes emerge from this study: Difficulties as the result of learning competency, students' low interest in mathematics, and insufficient mathematics learning foundation. However, this paper will only address competency in learning and students' low interest in mathematics.

#### **Difficulties as a results of learning competency**

The most interesting and emergent finding is related to teachers' perceptions on students' ability to learn mathematics. Data analysis showed that Namibian teachers are pessimistic about the ability of students to learn mathematics. They believed that students are unable to perform, they cannot learn in certain settings, or that students' potential to learn mathematics is limited. These teachers' perceptions revealed that Namibian teachers tend to associate MLD to a student's cognitive ability. These beliefs are shared by Mazzocco (2007) in her study as she described that student's ability to learn mathematics is cognitive-based, focused on what students cannot do, instead of what they can do or know. This belief is illustrated by the data, which identifies common key words in the data set, such as: "unable", "inability", "lack", "slower", "struggle", "not achieve", "cannot do", "not able", "poorly", "obstacles", or "hardly catch up". The analysis indicates Namibian teachers consider students to have learning difficulties if they cannot acquire certain skills or have difficulties meeting the learning objectives. Similar findings were addressed by Wang et al. (2009), where teachers stated that students with MLD develop a poor sense of numbers, they have low competency in learning mathematics and need individual support. Moreover, the data report that students with MLD are hardly able to catch-up as they exhibit disabilities when trying to meet the required skills and are unable to function at base level. One teacher reported that, "students struggle[d] to use acquired mathematics skills." While another teacher who based his/her remarks on student arithmetic skills

stated that, “learners demonstrate slow or inaccurate recall of basic arithmetic facts”. Teachers’ beliefs about MLD are illustrated below:

These are challenges that learners face in the classroom setting which contribute [...] to poor performance and misunderstanding of mathematics [...]. Remedial is needed.

I consider a learner to have learning difficulties if they cannot acquire certain skills or have difficulties meeting the learning objectives.

As illustrated in the above quotations, teachers’ perceptions indicate that MLD are regarded as problems that hinder a students’ learning process, they negatively affect students’ academic performance, and consequently cause students to perform poorly in mathematics. Teachers further disagree on the performance levels of students in relation to the competency to be achieved at a certain stage or level. Teachers believe students with MLD cannot master the skills one is expected to attain at a certain level or in a certain learning area. Hence, one teacher mentioned additional learning support for students with MLD:

... [If a] learner is unable to master 40% of the competencies a learner will need special attention apart from [the] normal allocated time for the period. So, such a learner will be given some extra classes for improvement.

Further, majority of teachers reported that by offering a variety of teaching methods, students with MLD could improve their performance in mathematics. Teachers’ seem to believe that not only students with MLD experience difficulty, but even the gifted ones, too. They believe that every individual has some specific learning difficulties, as reported in the previous studies (Eisenberg, 2002). Further, the identification of learning support strategies was helpful in improving student performance across the board. This indicates that learning support can be explored to remedy challenges facing students with MLD as stated below:

With learning difficulties, I do understand that not only the slow learners experience learning difficulties, but the gifted learners can also experience learning difficulties [and ...] compulsory teaching/support can remedy the situation.

Another teacher who stressed the use of learning support materials reported that she used array of teaching methods, including the use of, “concrete materials, remedial teaching and learning support, games [...], opportunities to work together and practical examples.” These examples would require a demonstration of the correction between those techniques/methods and higher student performance. Moreover, a handful of participants believed that regular learning activities and those that accommodate all student abilities might improve overall student performance.

### **Students’ low interest in mathematics**

Additionally, the survey results indicate that teachers believe learning difficulties are associated with a student’s low interest in the subject. Mathematics education literature stresses that the promotion of students’ interest enables greater student success (Hulleman & Harackiewicz, 2009). The data analysis reveal that MLD is often identified to be the cause when students are “not academically good” in mathematics, as a results of “low enthusiasm” in the subject. Findings indicate that students with MLD “lose interest” in the subject, are considered “not serious,” and “usually [do] not participate

in math class.” However, teachers report that despite learning difficulties, some of these students are willing to learn mathematics, particularly if they receive support, and are given positive reinforcement. These responses are similar to those reported by (Zakaria, Chin, & Daud, 2010) as they found that, individual students’ needs should be supported with effective teaching and learning. As one teacher reported, “these are learners who are willing to learn but they have difficulties in the learning process.” As another teacher stated, students with MLD need positive reinforcement, so for “those who lose interest, [that teacher...] gave them positive feedback.” Similarly, another teacher said, “I used to buy them sweets when they did better in a test and also do remedial teaching in the afternoon.” This shared belief by teachers was summarized by another teacher:

Learners must be encouraged by means of positive feedback, such as ‘very good,’ ‘excellent,’ [or] ‘you are doing well.’ Learners [...] experience success by giving them classwork and by giving them immediate feedback. The more success learners [...] experience, the more they become confident and hence learning will take place.

## **Conclusions and future perspectives**

The survey results show that the personal beliefs of the participants may have a negative influence on their teaching practices related to students with MLD. According to the personal beliefs of the participants, and Karagiannakis et al. (2014), mathematics learning difficulties are seen as obstacles that hinder the learning of mathematics, including learning environments and social contexts. Participants indicated they believe these obstacles result in shortcomings in mathematics comprehension, and result in a student’s inadequate development of a mathematics foundation in certain topics or the subject area as a whole. According to the findings, Namibian teachers also believe that MLD delay the learning process and negatively affect students’ academic performance. Responsive statements from the survey show that some of the negative views teachers had might affect their perceptions of students with learning difficulties, and have the potential influence their teaching process (Kasanda, 2015; Thompson, 1992). Further, the majority of participants frame learning difficulties to intellectual aptitude but they did not connect these beliefs to lack of interest or lack of math knowledge though it is mentioned in the literature (Siyepu, 2013; Tella, 2007). Thus, to improve performance outcomes for students experiencing MLD, there is a need of belief change among mathematics teachers, as suggested by Ernest (1991). However, the question remains: How to change teachers’ negative perceptions towards students with MLD? This could be a direction for future research in order to optimize the current study’s outcomes. Furthermore, problems persist as identified by teachers for students with MLD, as these students not only perform poorly in the classroom, but they present low participation and demonstrate little interest in the subject, among others factors. Yet, the majority of Namibian teachers, participated in this study believe that MLD result from an inadequate mathematics foundation, as stressed by Siyepu (2013). However, this current study shows negative connotations of students with MLD, though they may acquire mathematics skills through extra learning support as highlighted in the findings.

*Keywords: Inclusive mathematics education, teachers’ in-service training, blended learning.*

## **Introduction**

In the German project “GLUE – Gemeinsame LernUmgebungen Entwickeln” (‘developing collaborative learning environments’), an in-service program was developed with the aim to support teachers of different professions (special needs teachers, school teachers) in the implementation of inclusive mathematics education. The program is based on a German website (pikas-mi.dzlm.de), which provides teaching resources and instructional materials for an inclusive mathematics classroom. These materials enhance existing conceptions of mathematics teaching (e.g. Scherer, Beswick, DeBlois, Healy, & Moser Opitz, 2017). In the focus is the development of ‘collaborative learning environments’ for diverse learners to enable every child to participate in mathematical activities, as these are main characteristics of the definition of ‘inclusive education’ in this project.

## **The main features of the in-service program:**

- 1) Self-directed web-based learning is combined with workshop activities (*blended learning*).
- 2) The *workshops* include theoretical inputs as well as practical examples of ‘collaborative learning environments’ for diverse learners in an inclusive mathematics classroom.
- 3) During the workshops participants will adapt, develop, explore and reflect ‘collaborative learning environments’ for their own classes (*transfer from theory to practice*).

Well-founded design elements for in-service trainings for teachers will be taken into account (Barzel & Selter, 2015; Borko, 2004).

## **Research design**

The GLUE-project faces research interests on the *level of design* – with the aim of designing an effective in-service training – and on the *level of research* to evaluate the effectiveness.

All together one-hundred teachers will participate in the study. One half of these participants are special needs teachers, the other half are primary and lower secondary school teachers, to encourage collegial support and reflection between different professions (Bräuning & Nührenbörger, 2010; Wember, 2013). All participants are split in two groups: treatment group and control group.

A *pre-post-follow-up-test design* includes standardized questionnaires (quantitative) and interviews (qualitative) to gain information about the participants' *self-efficacies*, *adaptive mathematical didactical competencies* and their *attitudes* towards inclusive education before and after their participation, to evaluate the effectiveness of the program. Also, the *acceptance* towards the developed in-service program gets surveyed (see exemplary items below).

## First results

Until now, the in-service program of the treatment group and the analyses of first pre- and post-tests have started. The first results indicate some high effect sizes concerning the perceived *self-efficacy* by the target group, as the following questionnaire-items show.

**Exemplary item 1:** *I know instruments for the diagnostically founded support of mathematical competences (e. g. four-phases model).*

**Figure 1: Results of item 1 (paired sample: p-value <0,00; d = 1,500758; effect size high)**

**Exemplary item 2:** *I can adapt instruments for the diagnostically founded support of mathematical competences (e. g. four-phases model) to plan my lessons for the inclusive mathematics classroom.*

**Figure 2: Results of item 2 (paired sample: p-value <0,001; d = 1,001214; effect size high)**

## Designing mathematical computer games for migrant students

Janka Medová, Kristína Bulková and Soňa Čeretková

Constantine the Philosopher University in Nitra, Faculty of Natural Sciences, Department of Mathematics, Nitra, Slovakia; [jmedova@ukf.sk](mailto:jmedova@ukf.sk), [kristina.bulkova@ukf.sk](mailto:kristina.bulkova@ukf.sk), [sceretkova@ukf.sk](mailto:sceretkova@ukf.sk)

*Keywords: Language of instruction, educational games, computer games.*

In recent years a high percentage of students are (first or second generation) immigrants not only due to the open labour market in the European Union. The current affairs regarding immigrants might indicate the future increment of this ratio. Lot of research has been conducted with the aim at influencing the formal education in the language which is not the mother tongue of students (e.g. Meyer, Prediger, César, & Norén, 2016). According to teachers experienced in working with immigrant-students, the materials suitable for students with a limited knowledge of the language of instruction should be based on symbolic and visual features and elements, implicitly using only a restricted amount of text elements (Kijáková, 2018).

Other crucial factors influencing the school performance are the different personal cultures of immigrant-students. The contexts of problems are suitable when they are part of students' everyday life, familiar to the learner, up to date, and do not focus too much on any social issues (Rossouw, Hacker, & de Vries, 2011). Intercultural teaching materials can be beneficial for all students, not only for immigrants. Materials should be built on the culture-related context, respecting the background of every individual student.

The educational computer games have the potential to motivate students to learn mathematics (Papastergiou, 2009), hopefully also under difficult circumstances. Despite of it that there are plenty of electronic materials available for mathematics classrooms, however, there is only a limited amount developed for multicultural learning situations, especially for the specific situation of immigrant-students.

The main aim of this poster is to promote the project **Innovative Mathematics Learning Software for Migrant Students – immiMATH** supported by the Erasmus+ programme and to describe the principles leading the design of the educational software for a specific group of students.

**Principle 1:** Designed software should **minimize the amount of text**.

**Principle 2:** Designed software should **relate to the everyday life** of students.

**Principle 3:** Dividing into levels should allow students to **monitor their progress**.

Two kinds of games were designed (see Table 1): (i) motivational games showing students the role of mathematics in their everyday life; (ii) games for revising the acquired knowledge in the manner decreasing the anxiety and increasing students' self-confidence in solving mathematics tasks. The project team consists of university teachers (mathematics teacher educators), school teachers and software-company experts experienced in designing educational software. The designed software will be evaluated by project partners and piloted in selected schools. Each piece of software will be tested twice. The software will be adjusted according to the first pilot trial that will be carried out with future mathematics teachers with special focus on migrant students. The second version will be piloted by

regular students, including immigrant-students. The second objective of the project is to provide professional development activities for both, pre-service and in-service teachers, regarding the multicultural education and presenting all attributes of the designed learning software.

Software for motivation			Software for practice		
Name	Topic	Grade	Name	Topic	Grade
Trip through Europe	Linear Functions	9 to 10	Journey around the World	Linear Functions	9 to 10
The Algebraic Garden	Algebraic Expressions	8 to 10	Penny Bank	Financial Literacy	4 to 6
Save Europe!	Percentage	8 to 11	Geometria Land	Planimetry	9 to 11
The Math Princess' Tower	Number Sense (Integers)	4 to 5	The Little Architect	Spatial Geometry	4 to 6
Multicultural Logic Train	Logic	4 to 6	Building a city	Functions and Graphs	9 to 11
Deli Shop	Fractions	4 to 8	Birthday Party	Measurements	4 to 6

## **Diagnosis tools of dyscalculia – contribution of didactics of mathematics to numerical cognition**

Florence Peteers<sup>1</sup> and Cécile Ouvrier-Bufferet<sup>2</sup>

<sup>1</sup>Paris Diderot University, France; peteers@math.univ-paris-diderot.fr

<sup>2</sup>Paris-Est Créteil University, France; cecile.ouvrier-bufferet@u-pec.fr

*Research about dyscalculia must still be developed. The dominant perspective focuses on the individual's cognitive characteristics. We seek to know the place of mathematics education in this research and how to reconcile approaches to reach a better understanding of the disorder. We present here a methodology of analysis for tests which are designed to evaluate basic mathematics skills with various theoretical frameworks (cognitive sciences, psychology or didactics). We highlight some biases in tests from numerical cognition thanks to didactic frameworks and open perspectives to build a mathematical difficulties detection tool to facilitate the exchanges between teachers and speech therapists by providing a common inventory of the child's difficulties.*

*Keywords: Dyscalculia, mathematical learning disabilities, tests, numerical cognition.*

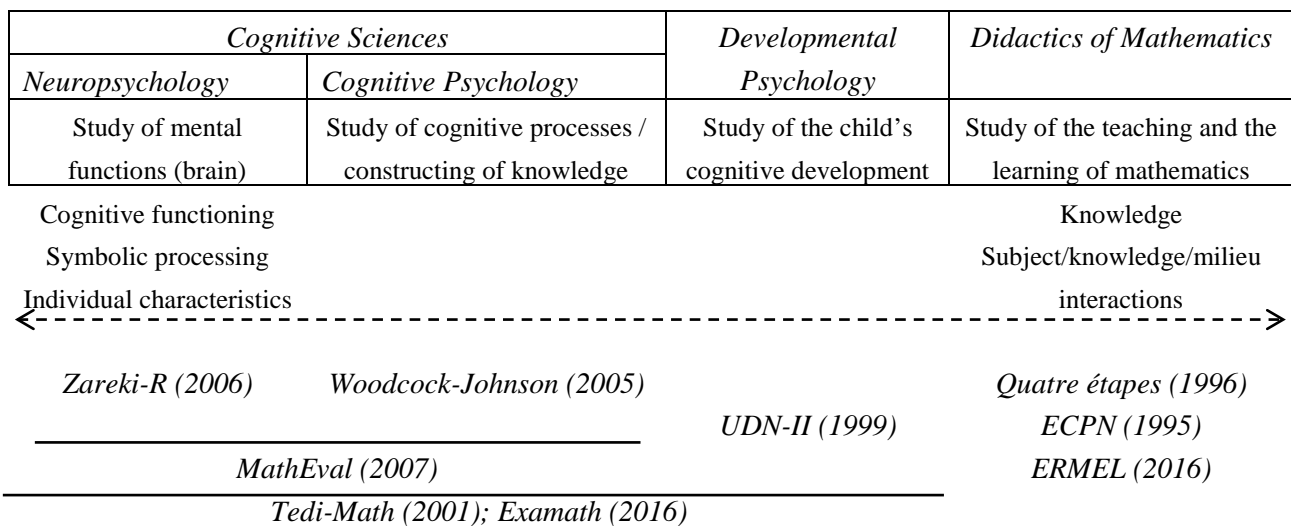

### **Context**

These last decades are clearly marked by an increase of the research and a better understanding of learning disabilities. While some disorders are now well identified and managed (dyslexia for example), others remain more complex and less studied (Lewis & Fisher, 2016). That is the case for the *mathematical learning disabilities* (MLD) which would affect 5 to 8% of students (Geary, 2011). There is currently no consensus about the definition of this trouble (Lewis & Fisher, 2016). MLD are often reduced to difficulties in processing numerical quantities and arithmetic calculation (thus the use of the term of dyscalculia). But an increasing number of studies indicate that MLD are heterogeneous (Fias, Menon, & Szűcs, 2013) and affect several aspects of mathematical skills (Kaufmann & al., 2013). These definition problems make the diagnosis and its methodological validity debatable (Lewis & Fisher, 2016). From the educational point of view, politics are concerned by the difficulties in the learning of mathematics and the processes of “inclusion” (e.g. “Loi pour la Refondation de l'École”, since 2013 in France). We claim that specific studies should be structured and developed in mathematics education regarding MLD in order to improve the identification and the remediation of MLD in an educational context. In particular, that implies a better knowledge of the existing research dealing with MLD. In fact, MLD are studied by different disciplinary fields and each of them develops its own models and hypothesis (Giroux, 2011). We can highlight two distinct approaches: the cognitive sciences approach is centered on the cognitive functioning and individual characteristics (Wilson & Dehaene, 2007), while the mathematics education approach focuses on knowledge specificities as well as the didactic characteristics of learning situations. The difficulties are not only due to an individual's dysfunction: it is also necessary to look for what prevents or stimulates the learning in the interaction between the student, the knowledge and the didactic situations. This compartmentalization of approaches is not without consequences. Indeed, many professionals who surround children with and are not leaning on the same approaches of the disorder: cognitive sciences for the paramedical professionals and

mathematics education for the teachers. The dialogue between these actors is therefore sometimes difficult, especially as medical confidentiality prevents the dissemination of some information. This is particularly problematic in the case of the exchanges between teachers and speech therapists.

## Objectives

Research about MLD are mainly focused on the cognitive approach so we question the place of mathematics education and the way to reconcile the different points of view to a better understanding of MLD. We consider more precisely the reconciliation of approaches through the creation of a mathematical difficulties detection tool that can be used both by teachers and speech therapists. This device should facilitate the exchanges between these two types of professionals by proposing a common inventory of child's difficulties that can be used by each of them (for a diagnosis and for pedagogical adaptations). To develop this tool, we conducted an analysis of existing tests designed to evaluate mathematical basic skills at the end of kindergarten or at the entry to elementary school. To ensure the diversity of the theoretical foundations, we selected diagnostic tests used by medical professionals (for the most part from research in numerical cognition), but also tests used to evaluate the child in school (from mathematics education area). The final selection contains Francophone diagnostic tests (*MathEval*, *Examath*, *ECPN* and *UDN-II*) and school tests (grade 1) (a numerical skills test of basic school program, *ERMEL*, and the device "*Quatre étapes*"). We also selected an Anglophone diagnostic test (*Woodcock-Johnson*) and diagnostic tests translated into several languages used internationally (*Zareki-R* and *Tedi-Math*). Figure 1 points out the main backgrounds of these tests and their distribution into the research areas.

**Figure 1: Analyzed tests in numerical cognition and didactics of mathematics (following the organization of research areas studying mathematical learning difficulties of Giroux (2011, p. 152))**

## Methodology

In order to define our analysis criteria, we made a state of the art about number construction and first number learning in didactics of mathematics and in numerical cognition. Thus, we highlight different number tasks and the variables that can affect the complexity of these tasks or the resolution strategies. These variables constitute our analysis criteria. In mathematics education, Brousseau's Theory of Didactical Situations (1997) allowed us to identify situations giving

meaning to number as well as their didactic variables. Moreover, thanks to Vergnaud's Theory of Conceptual Fields (1996), we could identify criteria for analyzing additive problems. In numerical cognition, we identified characteristics of numerical representations according to the different number processing models (especially the Dehaene's triple code model, 1992, the McCloskey's model, 1985, and the Von Aster's developmental model, 2007). We have also drawn analysis criteria for cognitive functioning of mathematical activities, based on the calculation model of Shrager and Siegler's strategy choice model (1998) or the transcoding's model of Barrouillet, Camos, Perruchet and Seron (2004). Finally, we studied the impact of some underlying cognitive functions like working memory, attentional functions, visuo-spatial abilities or digital gnosis in mathematical activities. Indeed, it has been shown that problems with these cognitive functions are generally associated with low mathematical performance (see Finnane (2006) for example). To articulate our criteria within a functional analysis table, we identified four categories of task based on our state of art (tasks where the number is used to express a quantity or a position, operation resolution tasks, digital code and transcoding tasks and tasks used to evaluate mental representation of numbers). Then we listed the tasks related to these four categories in the tests and used the criteria identified in state of art to analyze them. For this article, we choose to describe the analysis tables and to illustrate them with some examples. The whole analysis is available in Peteers (2018).

### **Tasks where the number is used to express a quantity or a position**

Numbers allow us to express quantities (cardinal aspect) and positions (ordinal aspect). We therefore searched in each test if these two functions were present. For the use of numbers to express quantities, we analyzed in detail the four quantification procedures identified in our states of art (didactics of mathematics and numerical cognition): term-to-term correspondence, counting, estimation and subitizing. Figure 2 summarizes the criteria used to analyze these types of tasks.

For example, the Tedi-Math (Van Nieuwenhoven, Grégoire, & Noël, 2001) does not contain tasks in which numbers are used in their ordinal aspect. For the quantification procedures, only counting is evaluated through different items. Some evaluate the procedure itself (Gelman and Gallistel's principles) and others evaluate the spontaneous use of counting (construction of an equipotent collection to a given one). If we analyze more precisely these tasks, we can notice that the collections used in counting tasks are always composed of non-manipulable objects, which makes the "enumeration"<sup>1</sup> more difficult (Briand quoted by Ouvrier-Buffet, 2013). For the construction of an equipotent collection, the model collection remains accessible, which does not stimulate the use of counting procedures because the term-to-term correspondence remains possible. However, the task will be considered successful only if the child uses counting.

---

<sup>1</sup> Briand (1999) has underscored several preliminary steps in the learning of counting. In the series of actions required for counting, the pupils have to look over all the elements of a finite collection one time and only one. This task characterizes a non-taught knowledge, called by Briand "enumeration". Enumeration is clearly linked to the one-to-one principle (Gelman & Gallistel, 1978). The number word is a tag (and such a tag is a convention) but a tag is not necessarily a number word. Learning "enumeration" is not an explicit part of teaching. The research of Briand (1999) proves the necessity of activities involving "enumeration" in the pre-numerical domain.

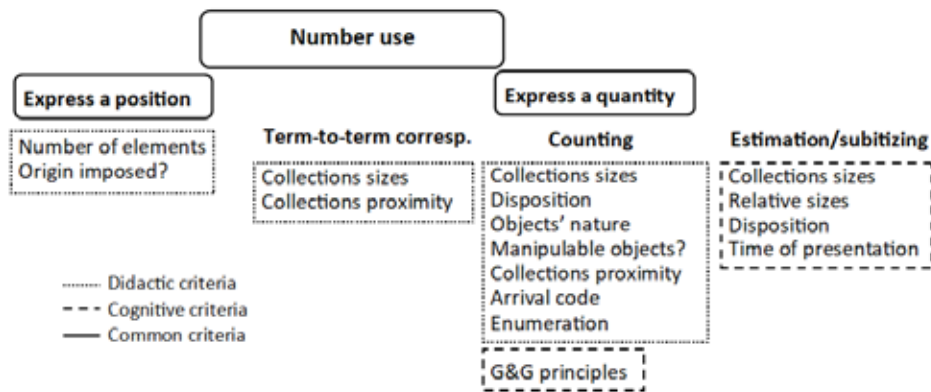

Figure 2: Analysis criteria for tasks regarding number use (quantity or position)

### Tasks used to evaluate mental representation of number

There are different theories in numerical cognition about the nature of representations of numbers magnitude (Noël, 2005). In each test, we therefore looked for the two types of representation (decimal or analogical) evaluated and how these representations are evaluated. We identified three types of tasks that can be used to evaluate analogical representations: analogical comparison tasks, comparison tasks involving oral or arabic code and tasks consisting in positioning numbers on a number line. For the evaluation of decimal representations and the comprehension of our number system, we considered two types of tasks: tasks related to writing numbers and tasks involving material collections. Figure 3 shows the criteria used for the analysis of these types of tasks.

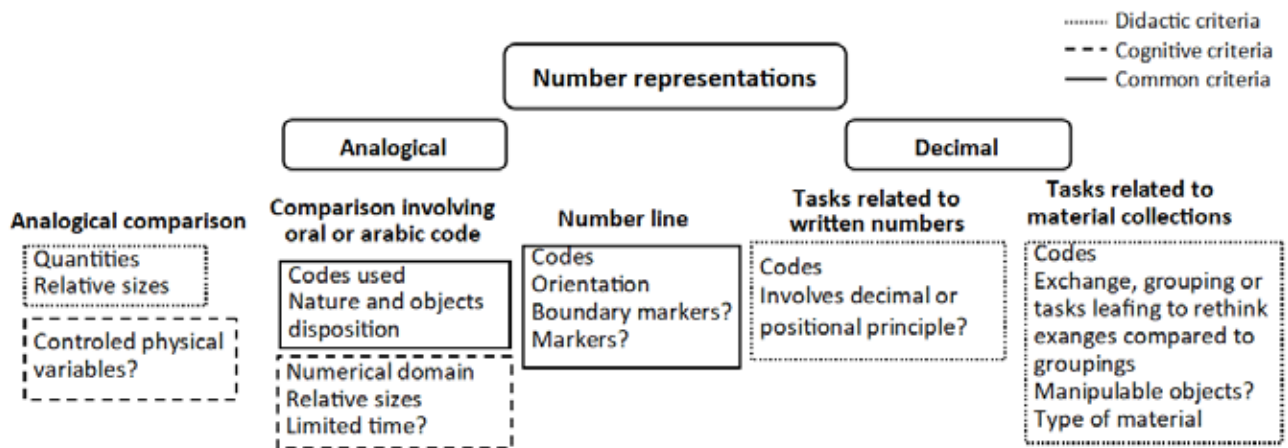

Figure 3: Analysis criteria for number representations tasks

### Digital code and transcoding tasks

We identified in the tests the tasks used to determine the mastery of oral code (extension of the stable and conventional part of the verbal number sequence and its organization). We also made an inventory of other tasks designed to evaluate the mastery of oral code and we did the same for the written code. For the transition from one code to another, we chose the following criteria (Figure 4).

**Figure 4: Analysis criteria for transcoding tasks**

For example, here are two transcoding tasks (Table 1, from oral to arabic code), one from the Zareki-R (Dellatolas & Von Aster, 2006) and the other from the UDN-II (Meljac & Lemmel, 1999).

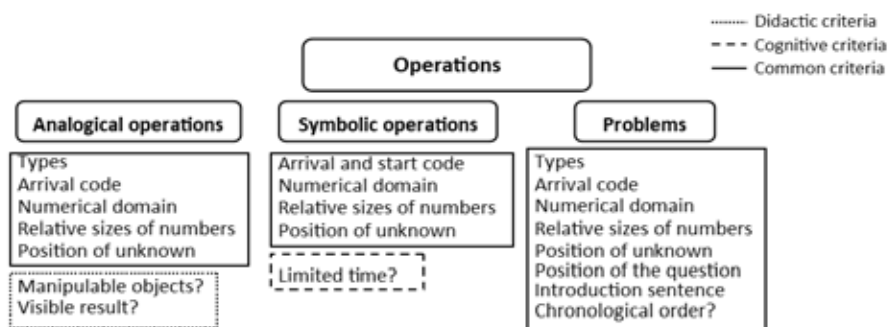

Dictated numbers in Zareki-R	Dictated numbers in UDN-II
14 – 38 – 1200 – 503 – 169 – 4658 – 756 – 689	3 – 5 – 9 – 15 – 18 – 27 – 54 – 76 – 89 – 93 – 138 – 272 – 605 – 1061 – 4396 – 7042 – 10001

**Table 1: Transcoding tasks from the Zareki-R and UDN-II**

We can see that, in both tests, the writing of numbers containing zeros is well evaluated. However, unlike the task proposed in UDN-II, we find in Zareki-R only few complex tens and lexical primitives. The numbers proposed in this test are relatively large and their transcoding strongly solicits working memory. This type of task does not allow us to precisely identify the source of errors. The task proposed in UDN-II makes a more precise characterization of the difficulties.

### Operation resolution tasks

Finally, we identified among the tasks proposed in the tests, three categories of tasks requiring the resolution of an operation: analogical operations involving a material support, symbolic operations involving written or oral code and operations with verbal wording consisting in resolving a problem involving an operation. The criteria used to analyze these types of tasks are summarized in Figure 5.

**Figure 5: Analysis criteria for operation resolution tasks**

## Results

Based on our analysis table, we wrote a descriptive analysis of each test. We present here some general results (see Peteers (2018) for more details). We can note that all the tests are different in terms of the knowledge and skills evaluated. The differences are particularly marked for the numerical cognition tests, which is not surprising since these tests are based on different models. Then, we can notice that some types of tasks are specific to theoretical frameworks. In other words, there are tasks specific to the numerical cognition tests (estimation or subitizing tasks, analogical comparison tasks, ...) and others specific to the didactic tests (tasks in which the number is used to

express a position, tasks in which the child must extract a given number of elements from a collection, ...). We can also find some types of tasks in every test regardless of their theoretical foundation (numerical cognition or mathematics education). This is the case for the counting tasks, the evaluation of the numerical verbal sequence, the transcoding tasks, the analogical operation resolution tasks, ... However, the variables of these tasks change depending on the tests. In counting tasks for example, the number of objects in the collection and their disposition vary in each test. There are also differences depending on the theoretical foundations. In our example of counting, the tasks proposed in the cognition tests focused more on the counting procedure (with statements like “how many elements are there?”). In the didactic tests, the focus is on the types of situations in which the child can use a resolution procedure based on counting. The manipulability of the objects also differs according to the theoretical foundations of the tests considered. The cognition tests propose only counting tasks with non-manipulable objects unlike the didactic tests. From a didactic point of view, two elements can be underlined. We note that some knowledge and skills highlighted in our state of art in mathematics education are not evaluated in any of the tests (in both cognitive or didactic tests). This is the case of “enumeration” for example (Briand quoted by Ouvrier-Buffet, 2013). However, the choice of variables used in the counting tasks in the cognition tests does not always facilitate enumeration. Indeed, the objects used in this type of task are not manipulable (like our example with Tedi-Math), so, the separation between counted and not counted objects must be done mentally. Enumeration difficulties can therefore impact the resolution of counting tasks and are not identified because any task allows the evaluation of this specific skill. We can also notice that the choices of variables used in the tests are not always appropriate. Indeed, if we take again the example of the equipotent collection construction task in the Tedi-Math, the model collection is always accessible during the construction of the equipotent collection which does not stimulate the use of counting because the tasks can be resolved without using the number (using term-to-term correspondence for example).

## **Conclusion and perspectives – towards a detection tool**

We have shown in this article a part of the results of our PhD thesis. We can point out that the mobilized didactic frameworks (Theory of Didactical Situations and Theory of Conceptual Fields) allow us to structure our analysis table, and also bring us another perspective about numerical cognition tests which are not used for school environment. They provide us a framework for critical analysis to highlight some biases of these tests in relation to what is taught and to mathematics education knowledge (non-evaluated elements such as enumeration or questioning of the choices of variables in some tasks). These elements confirm the interest of didactics of mathematics in research about MLD, in particular regarding the diagnosis. We have identified a set of tasks and variables that can be used by the different professionals involved (especially teachers and speech therapists). We now have bases (theoretical tools from didactics of mathematics and numerical cognition frameworks and analysis of the most frequently used tests) to build a mathematical difficulties detection tool (presented in Peteers, 2018). This device uses digital technologies environment but also concrete manipulations for tasks like equipotent collection construction in order to avoid visuo-spatial difficulties for instance. This tool is made of four units (Prerequisites; Cardinal and ordinal aspects; Representations of number; Operations). Each unit is composed by

tasks coming both from numerical cognition and didactics of mathematics. For each task, variables are chosen depending on the age of the pupils (three levels of difficulty are defined) and the well-known learners' difficulties identified in didactics of mathematics. The "Prerequisites" unit deals with: analogical comparison, subitizing and estimation, enumeration, term-to-term correspondence, verbal number sequence. The "Cardinal and ordinal aspects" unit explores the spontaneous use of counting, the Gelman & Gallistel's principles, the counting up process, and the identification of the position of a number (ordinal aspect). The "Representations of number" unit takes into account transcoding tasks, number line and numbers' comparison tasks, and situations requiring decimal positional principle. Finally, the "Operations" unit proposes tasks involving analogical operations, symbolic operations and problems. For each task, we define a coloring code (green, orange, red) to evaluate the success or the failure. A synthesis is then automatically generated for the teacher: it helps her/him build remedial interventions. After such interventions, the teacher can reuse some tasks of the test in order to evaluate the impact of them. In case there are no benefits, the whole synthesis of the test can help teacher to orientate the child to a paramedical professional and inform the speech therapist. We have conducted a first experiment to test our detection tool. Considering the results of this experiment, our tool is currently the subject of a new development (exclusion of some tasks and inclusion of new ones; improvement of the coding process and the synthesis etc.). We still have to normalize it. We will give more details about this device during the conference.

## **Mathematics classroom setting influencing inclusion**

Helena Roos

Linnaeus University, Växjö, Sweden; [Helena.Roos@lnu.se](mailto:Helena.Roos@lnu.se)

*This research reports on a study investigating how three students perceived as being in special educational needs in mathematics (SEM), either as students in access to mathematics or as students in struggle to get access, talk about participation in mathematics education. Discourse analysis is used as a theory and a tool to investigate the students' own stories of learning and teaching in an inclusive mathematics classroom. The results show that students' participation in mathematics education is influenced by how the mathematics education is set up. That is, how the organisation of the mathematics classroom and students being in a small group influence students' participation. The results also show that even though the same issues of the organisation influence the three students, there is a diversity within the issues, calling for a critical question, is the inclusive classroom setting really inclusive in terms of participation and access to mathematics?*

*Keywords: Discourse analysis, inclusion, participation, special educational needs in mathematics.*

### **Introduction**

How to set up mathematics lessons to facilitate participation for every student within an inclusive classroom is not an easy task. Nevertheless, it is a particularly important educational task in order to promote an equitable mathematics education and create opportunities for every student to learn (Moschkovich, 2013; Askew, 2015). The setup of the mathematics classroom, including didactical choices of the mathematics teacher(s), is influenced by many different aspects. For example, Askew (2015) identifies a Western way of teaching mathematics with a one-size-fits-all approach, influencing the setting of the mathematics classroom. Hence, the set-up of the mathematics education is not in full an actual choice of the teacher, but a choice of the school, or even a choice of the society. This implies there are cultural, social, and institutional factors, such as social patterns, strongly impacting mathematics education settings. For example, patterns of advantage and disadvantage (Civil & Planas, 2004). Then, the awareness and the ability of the teacher to know how to act and care in the moment in order to promote learning of every student (Mason & Spence, 1999) becomes even more of importance. This implies, the awareness of factors, external of the actual classroom interaction, influencing the mathematics education, the set up, and enactment of the teaching inside the classroom is of importance to promote participation and learning. So, if defining inclusion in mathematics as processes of participation for every student (Roos, 2015), inclusion is strongly connected to the promotion of equitable mathematics education in terms of how the mathematics education is set up (Moschkovich, 2013). Moreover, since inclusive mathematics classrooms are diverse in terms of students' backgrounds (gender, ethnicity, culture, achievement etc.), the mathematics education needs to provide a diverse education (Roos, 2017). This suggests a diverse setting of the mathematics classroom considering every students' needs. Within the research field of mathematics education, the notion of inclusion is often connected to special educational needs in mathematics (SEM) (Roos, 2019a). Often when discussing SEM, the student in mind is a low

achiever, struggling to get access to mathematics education. However, a high achiever can also be in SEM even though she or he has access to the mathematics education, because she or he might need specific solutions in order to have optimal opportunities to learn. Accordingly, the notion of SEM can work in two directions, one direction towards mathematics difficulties, and one direction towards mathematics facility, showing differences in access to mathematics education. Inclusion in mathematics education for both ends of the SEM-continuum can be provided by the promotion of participation focusing on teaching practices and intervention strategies taking off from learning situations enabling meetings among differences (Scherer, Beswick, DeBlois, Healy, & Moser Opitz, 2016). Hence, setting up teaching promoting participation becomes an important challenge. To take on this challenge, we need to know the meaning(s) of students regarding participation in the inclusive mathematics classroom. Hence, the aim of this paper is to describe SEM-students meaning(s) of inclusion in their talk about learning and teaching in an inclusive mathematics classroom to have the best opportunities to learn.

## **Methodology**

In this section the site and the participants of the study are described, as well as the theoretical and analytical approach and the data analysis.

### **The site and participants**

A lower secondary school in an urban area in Sweden that has set out to implement inclusive work was chosen for this investigation. The inclusive work at the school aims at including all students in the ordinary teaching in every school subject, and integrate the special education into the ordinary teaching. A grade 7 and a grade 8 classroom at the school were observed during one semester. At least one approximately 50 minutes long mathematics lesson each week for each class was observed. After each observation student interviews were carried out. The selection of students for the interviews was made in cooperation with the students, parents and teachers and took ethical and organisational issues into consideration. The mathematics teachers suggested students they perceived as being in some kind of SEM. Thereafter, if the students and parents gave their consent, they were offered to take part in this study. Six students took part in the study. The interviews were conducted when the organisation and students allowed it. The interviews took place in a small room familiar to the students once a week and were based on the observations made the same week. Hence, open questions about situations and content of the mathematics education were asked in a discussion type of manner. This paper focuses on three students: Veronica in grade 7, Ronaldo and Edward in grade 8. Veronica says that “math is pretty hard” and she states “I don’t like math”. The mathematics teachers perceive her as a student who struggles to get access to mathematics. Ronaldo describes himself as a student with learning difficulties “I have difficulties within all subjects, and it’s like concentration and all that.” He also experiences that he forgets stuff “I don’t remember, I have to repeat a lot”. The mathematics teachers perceive him as a student who struggles to get access to mathematics. Both Veronica and Ronaldo have just about a passing grade. Edward describes himself as a person that thinks mathematics is really easy and does not need much help at all. He does not have to make any effort, mathematics works “automatically” for him and he “already knows” most

of what they are doing in math class. The mathematics teachers perceive him as a student with access to mathematics, and he has the highest grade possible in mathematics (grade A<sup>1</sup>).

### **Theoretical and analytical approach**

When investigating students' stories of their own participation in mathematics education, there is a need to identify critical aspects of learning and teaching in the stories. In this research this identification is made by using Discourse Analysis (DA). DA is a helpful tool since the focus of DA is the study beyond text, and because DA has an explanatory power of social contexts. Thus, by analysing the use of language in a certain type of situation we can say something about the social world. When going beyond the text in this particular study, construed discourses of what influences students' participation in mathematics education makes it possible to describe the social world from the students' perspective. In this study, the perspective of Gee (2014a, 2014b) is used, since Gee's focus on DA is descriptive and this study aims at describing students' view of participation in an inclusive mathematics classroom to have optimal opportunities to learn.

Big and small discourses (henceforth Discourse with capital D and discourse with lowercase d) are used by Gee (2014a, 2014b) as theoretical notions in the use of DA. Here Discourse(s) are describing a social and political context and are always embedded in many various social institutions at the same time. For example, a Discourse can be "school mathematics". Discourses are language plus "other stuff" (Gee, 2014a, p. 52), such as actions, interactions, values, beliefs, symbols, objects, tools and places. Small d discourse has a focus on written and spoken language in use, what stretches of languages are visible in the stories we investigate (Gee, 2014a). Stretches of languages is Gee's notion to describe small conversations within the stories. In this study, big and small discourses will be the theoretical perspective. Gee provides a toolkit for analysing different forms of language, both spoken and written. These tools highlight the communication and pose questions to the text to investigate what is beyond the text in terms of Discourses and discourses. In this paper, the toolkit is used as a methodological tool and is exemplified in the section data analysis. Summarising, DA is used both as a theory and an analytical tool and provides a set of theoretical lenses in this study.

### **Data analysis**

In this paper seventeen interviews, five with Veronica, six with Ronaldo and six with Edward and eight classroom observations have been analysed. The observations were used as contextualisation for the interviews as well as for supporting construction of Discourse(s). The analysis of the data was guided by questions asked to the text. These questions were adapted from Gee's (2014b) toolkit, and with their help both small and big discourses could be constructed. That is, the questions were posed to the text and the answers made stretches of language(s) visible, indicating small discourses. When adding analysis of the data from the observations, such as text on the blackboard and events in the classroom, big Discourses could be construed. The analysis opened up for the construction of three Discourses, the Discourse of assessment (described in Roos, 2018), the Discourse of accessibility

---

<sup>1</sup> In the Swedish grading system A is the highest grade, then B, C, D, E and F. E is the lowest acceptable grade and F is the grade you get when you don't pass.

(described in Roos, 2019b) in mathematics education and the Discourse of mathematics classroom setting. In this paper the Discourse of mathematics classroom setting is in focus.

## **The Discourse of mathematics classroom setting**

From the stretches of language identified in the texts from interviews with Ronaldo, Edward and Veronica, three (d)iscourses were construed, indicating a (D)iscourse of mathematics classroom setting influencing the students' participation. The three small discourses are described below.

### **The discourse of classroom organisation**

This discourse is construed by stretches of language where the students highlight how the organisation of the education influences their participation.

A topic visible in the talk of all three of the students was the use of the textbooks. The textbook used in mathematics in both classes has six chapters divided into sections with specific mathematical areas. Each section has four levels, where “level one is easy tasks and level four gives real challenges”. Veronica says “I start at level one or two [in the textbook]. Well, it is easier to start, so that you don't start with something difficult right away, that you don't master. Because it is a little easier. So, I don't make mistakes later on. I usually work by myself”. She mentions the textbook in relation to preparing for tests “Before a test, we have the mixed tasks that sum up what we have done in the whole chapter.” Also how to write in her notebook “well, it's like these small squares in it, so I usually try to write in them, so it doesn't get too big so you have space”. Even Ronaldo mentions the notebook, and it seems like he struggles with the writing of the tasks “well it gets, if I write it often gets bloody smudgy, it gets so bloody messy [in the notebook]”. Edward mentions the textbook as the one deciding the severity “It is the book that chooses what level you want”. He also talks about the levels in the book. “I skip it [skip the first out of four levels in each chapter of the text book], it is too easy (laughing). To have a soft start in the specific area [he starts with level two]”. For Edward the textbook also guides him in solving tasks, this is visible when he says that “I look in the key first, or I test first, then I look in the key and then I can see how it should be”. Even Edward talks about the notebook in terms of what he doesn't write “when I just calculate ordinary in my book, in the textbook, then it's mostly mental calculations”. [...] “It is more convenient not to write everything down”. In the observation notes it is visible that teaching by the textbook, where the students sit and work separately or in pairs, is the most common way the mathematics education is organised in both classes. Ronaldo talks about the textbook in terms of sections he feels secure or insecure of as well as levels in the textbook: “Well, I start, I think that number one has become easier now [level one in the textbook], because it feels like I have become better at math now, so I sort of starting with number two.

Another topic regarding organisation influencing the students' participation being visible in the talk of all three students was to talk, discuss and work with peers in the classroom. Veronica talks about this as a hinder in her participation “Well, I have always been like afraid of that if I raise the hand, I am wrong and everybody thinks like.. that you are.. like... [...] I get unsure of myself, if I am right or wrong, and don't dare...” She also feels insecure when having discussions with peers in the classroom “Well, I have trouble with explaining... I don't know why. I don't know what to say, so they (the peers) get it. Ronaldo sees discussions both as a hinder and as a help for his participation. When he talks about discussion, he says that he can discuss “in groups, but not as much in the whole

class. Or I can, but I don't want to." He says that the reason is that he is uncomfortable, but in a group situation he perceives it as a help "I like to cooperate. It is fun to be with others, like Edward or Leo, because they are really good at math and they can explain really well. So you get it more". Though, it depends on whom he cooperates with, "I feel comfortable with everybody in the group sort of ... well some I can trust, or I know better than others. So it depends on whom you have in the group". Also for Edward it's an issue of with whom to discuss. "It's not super easy... because often I have come a lot further, so I have to explain to them ... it never happens that I discuss ... I mean with somebody else, that we discuss like that.. [...] It depends on whom I sit next to". When Edward gets the question if there is somebody in the class that he feels that can challenge him, he says that there are two, but he does not sit next to them, but he would like to "I think I would get more out of it".

Going through<sup>2</sup> was yet another topic all of the three students discussed. Veronica reflected on when she thinks she learns the best by saying "I think it is when it is going through and when I work by myself actually". Describing what's good with going through, she says that "I don't really know (laughs), it's just nice when he [the teacher] stands there and talks, shows and explains". Ronaldo talks about going through in relation to him forgetting and implies that others think he should have more going through by saying: "I was supposed to have an extra going through like this, it is just as well, so that I don't forget that, too". He refers to going through in a negative way "it is so bloody much of going through now. It is so boring, you can't stand listening" and he says that "going through does not matter that much I think". Although, he thinks that "sometimes it [going through] can be good, but well, if you are entering a new area, you are supposed to work with, it's good to have a going through. But then, like we have now, a going through each lesson, about the same thing. It is ... well I do know it's just to repeat and all that, but it is so damn hard". This implies going through is a challenge for Ronaldo's participation. Edward says that he listens and learns from going through, but not always. He thinks they have a lot of going through, but that they aren't always good, and when they interfere with his previous way of solving, it gets messy. "I think it gets messy when you have to mix in a lot of stuff to think, because I have my own way of thinking, so it only gets messy to mix in something else". He also thinks the tasks in the going through are basic "it is not really that advanced up on the blackboard, but, well, it's enough that I get the basics, then I can work from there" implying he would like more challenges, and that he is left alone to work further. Edward mentions that he liked the going through of a substitute teacher "I thought it was good when we had that secondary teacher, then I learned a lot in the going through. [...] I learned a lot, because it was kind of on another level. It feels like it was a much higher level than the regular teachers".

Yet another topic talked about by all the students was teaching approaches. Veronica talks about the need of hearing stuff, "it is good to listen [to the teacher], like I always learn a little more when we have going through". She likes it when the teachers "talk". She also states that when she is working by herself, she learns the best. Also, she likes problem solving, because "you can choose what you

---

<sup>2</sup> In Swedish mathematics education, it is common for the lesson to start or end with a "going-through" (in Swedish, *genomgång*). Andrews and Nosrati (2018) point out three instances of what can be considered "going-through": when the teachers inform the students of what to work with, when presenting new models, and when demonstrating solutions to problems the students find difficult.

want to use, and, like which way you [can] think. [...] It is really fun!” Ronaldo on the other hand talks about problem solving as something he “despises more than anything” as he finds it hard to “connect the text to the task, it is too much”. When asked how the mathematics education could be more fun for him, he says that he doesn’t know and “I just don’t like math, or I think it’s interesting, but difficult”. When he elaborates on teaching approaches he likes, he says “[...] you should have more math games or something”. In another interview he elaborates on how he learns best and says “not just sit down and work, but like be more active also, you might do some math outdoors, or like do math games or something, not just sit down with the text book all the time, it gets so bloody trite, or like really boring in the end. So, vary things”. Here, Ronaldo indicates that he would like variations of ways of working to enhance his participation. This is emphasized in another interview when Ronaldo contrasts variations with working in the textbook. “It is a bloody lot of [work in the textbook] ... you could play more math games or stuff like that”. Even Edward highlights this contrast when he states “when you are doing more practical stuff, then it is fun, instead of having the nose in the textbook all the time.” “Instead of keeping turning pages, drawing lines and writing the number of the task and all that, these things takes such a long time”, he would like “those whiteboards in front of you, and sit and sketch and experiment. Because then it’s much faster. I want to spend the time on the math”. Hence, Edward thinks that the work with the textbook and notebook hinders him from spending time on math, consequently it hinders him from participation.

### **The discourse of being in a small group outside the classroom**

This discourse focuses students’ talk about being outside the classroom in a small group. This is mostly mentioned by the students struggling to get access in mathematics, Ronaldo and Veronica. Both Veronica and Ronaldo address feelings when they talk about being in a small group sometimes.

When Veronica was asked if she has been outside the classroom during lessons, she answers “Yes, god yes!” and laughs. Veronica often talks about being in a small group outside the classroom and often says that it “feels good”, and that she feels secure in the small group. The reason why she feels good is that “you get help right away and doesn’t have to sit and wait (for help) so long” and “it is an extra time, so if you didn’t get it when Oliver [the ordinary mathematics teacher] did the going through, you get it [the going through] once more”, “It’s like you get an extra occasion. If you don’t get it the first time, you can get one more time”. Also she says that she feels good because “It’s less people, it like just three or four persons”. Ronaldo says that “I dare to say stuff to, it feels like I am developing more” and “when you are in smaller groups, you dare to say more”, when he talks about being outside the classroom. He contrasts it with the way it was before and says that “it has become a lot better now, we have started to be outside [the classroom] in small group, which we didn’t do before, and it is much better now. I concentrate better and it is peaceful and quiet”. This implies he needs a place where he can feel secure and a place where it is calm to be able to concentrate. Also, he connects being in a small group to the level of security in relation to the mathematical content “But if I feel in between [of being sure or unsure], or a bit insecure like don’t really know, then I go [to the small group]”. Even Edward talks about the small group, but in a different way. When he gets the question if he is in the small group sometimes, he laughs and says “No, but she [the special teacher] takes the ones who wants to go through the basics, she usually takes [them] with her and does some going through and stuff like that. [...] I don’t think I would get something out of it, I don’t.” Here

Edward talks about “them”, as the ones who want to go through the basics” and he does not include himself in that group. The observation notes show that on several occasions the special teacher brings a few students with her out into a small room beside the classroom. Often it is Ronaldo and Veronica.

## Discussion

The Discourse of mathematics classroom setting pinpoints critical issues for the three students’ participation in the mathematics education in terms of the organisation and being in a small group. It seems like the Western way of teaching with a one-size-fits-all mathematics education (Askew, 2015) influences the setting of the mathematics classroom, which is visible in the students’ description of the use of the textbook, the mathematical discussions and the going through. This certainly “turns diversity into a problem” (Askew, 2015, p. 129), since there seem to be contradictions in the students’ stories, even though they talk about the same issue, it’s not in the same way. For instance, Veronica thinks she learns best when listening at going through, but Ronaldo seems mostly frustrated, and Edward thinks they are too basic. Also, when Ronaldo talks about going through in relation to him forgetting, he is placing the struggle getting access to mathematics within himself, creating frustration. Hence, how to realize going through in the classroom is a critical issue. The “problem with diversity” is also seen in the way the students describe discussions. Veronica feels insecure and does not know how to explain her thinking to her peers. Ronaldo on one hand feels the same as Veronica, insecurity when it comes to whole class discussions, but on the other hand he really likes discussions with peers, mostly because they can explain well to him. Hence, it is not him discussing, but using the peers, for instance Edward, as tutors. Edward recognises this, that he has “to explain to them”, and he feels that most often he does not get any challenges in the discussions. In this study, textbooks and the work the students do in the notebooks, seem to govern the mathematics education, and is an important factor for participation. This can be seen in the way the students describe how the different levels in the textbook affect their participation, and how they are supposed to write in the notebooks. Thus, it is not just the decisions of the teachers influencing the setting, but also the textbook and the mathematical norms that are established, play a crucial role. This makes the textbook, how it is organized and how it provides access to knowledge, as well as how to write in the notebook important factors to consider, which is also seen internationally (Fan, Zhu, & Miao, 2013). Is being in a small group outside the classroom including or excluding the students? Both students struggling to get access talk about the small group as a secure space and the classroom as an insecure space. Edward on the other hand laughs and does not think he would gain anything from the small group. Veronica answers “Yes, god yes!” and laughs when she is asked if she has gone out of the classroom sometimes. The laughter can be an indication of roles taken by the students as either students in access or in struggle to get access, and the roles seem to influence the students’ participation. This is indicated by the fact that the struggling students feel insecure in the classroom situation. This is in line with the finding of Civil and Planas (2004), that participation is influenced by organizational structures. Consequently, the result in this study calls for a critical question: Is the inclusive classroom really inclusive for the students in terms of participation and access to mathematics?

# **The potential of substantial learning environments for inclusive mathematics – student teachers’ explorations with special needs students**

Petra Scherer

University of Duisburg-Essen, Faculty of Mathematics, Germany; [petra.scherer@uni-due.de](mailto:petra.scherer@uni-due.de)

*Although in Germany there exists a long research tradition concerning common instruction and inclusive education, more research is needed concerning the subject-matter specific programs for inclusive teacher education. The paper reports on the project ProViel (‘Professionalisierung für Vielfalt’ – ‘professionalisation for diversity’). Within the project inclusion is pursued as a common objective for all subjects and disciplines. In addition, sub-projects concentrate on selected subjects as ‘Mathematics Inclusive’. For this sub-project concepts and modules for teacher education will be developed, tried out and reflected with respect to inclusive mathematics. The paper presents the mathematics project’s aims and objectives, followed by data concerning the concrete course ‘Learning Mathematics with Substantial Learning Environments (SLEs)’ and primary teacher students’ practical experiences and reflections.*

*Keywords: Pre-service teacher education, special needs students, inclusive education, substantial learning environments, field studies.*

## **Introduction**

In Germany students with special needs either visit special schools for handicapped children or regular schools in inclusive settings (cf. Klemm, 2015). According to the realization of the UN conventions (see UN, 2006), the proportion of students with special needs in inclusive settings has increased continuously over the years. In Germany, for the school year 2013/14 about 50 % of the students with special needs on the primary level visited regular schools (Klemm, 2015). But actually a decrease or stagnations can be observed in some states (Klemm, 2018). Inclusive settings show extremely heterogeneous groups in classrooms, so that a high degree of differentiation is needed.

Teacher education programs preparing for an inclusive school system are in the state of development at the moment, and corresponding research is done. As an important field for research the subject-matter specific preparation of teachers has been pointed out (see Heinrich, Urban, & Werning, 2013). The paper presents first results of a study that aims at implementing substantial mathematics for all.

## **The project ‘Mathematics Inclusive’ within the project ProViel**

The project ProViel ‘Professionalisierung für Vielfalt’ (‘Professionalisation for Diversity’; <https://www.uni-due.de/proviel/>) at the University of Duisburg-Essen is funded by the Federal Ministry of Education within the frame of a program for teacher education (1<sup>st</sup> phase: 2016–2019; 2<sup>nd</sup> phase: 2019–2023). Numerous university departments are involved to ensure the development of a coherent conceptual program for teacher education. One field of action is ‘Diversity & Inclusion’,

and numerous sub-projects might cover the wide facets and dimensions in this field (cf. Bishop, Tan, & Barkatsas, 2015; Good & Brophy, 2008).

Following a design based research approach, the sub-project ‘Mathematics Inclusive’ aims at implementing subject-specific concepts and modules for inclusive mathematics education. The central research questions are the following:

- (1) How should didactical courses in teacher education be designed to address the topic ‘inclusive mathematics’? (firstly, for the primary BA-/MA-program, later on for the secondary BA-/MA-program)
- (2) What are student teachers’ prerequisites concerning inclusive mathematics?  
2a) experiences with mathematics instruction      2b) existing attitudes and beliefs
- (3) Which changes of student teachers’ attitudes and beliefs and competence developments can be identified after they had completed a course that addresses inclusive mathematics?
- (4) Which modifications for the didactical courses arise from experiences and results of the empirical testing (based on research question 1 to 3)?

Research questions 2 and 3 will be answered on the basis of quantitative as well as qualitative data, whereas the questions 1 and 4 concentrate on qualitative data and methods.

### **Concept and objectives of the course ‘Learning Mathematics with SLEs’**

The developmental work to answer research question 1 firstly concentrates on the course ‘Learning Mathematics with Substantial Learning Environments (SLEs)’ (3<sup>rd</sup> year, BA-program for primary mathematics). The didactical concept of working with SLEs, and by this realizing a natural differentiation is in line with a constructivist understanding of teaching and learning, and has been proved to be suitable for heterogeneous learning groups in primary mathematics (cf. Hirt & Wälti, 2008; Krauthausen & Scherer, 2013; Scherer & Krauthausen, 2010). These projects also focused on the realization in in-service courses whereas the current paper concentrates on pre-service teacher education, especially with regard to inclusive mathematics.

The design process started in 2016, and the first course has been running during the winter semester 2016/17, followed by the second and third one during the winter semester 2017/18 and 2018/19.

Competencies the student teachers should develop within this course, as formulated in the BA-curriculum for primary, are the following:

- The student teachers are able to design a mathematical learning environment on the basis of mathematical und didactical foundation according to a particular focal point.
- The student teachers are able to carry out and analyze an interview with primary students including subject-specific perspectives (according to a particular focal point).

The course concept is as follows: The course contains a weekly 90-minute lecture combined with a weekly 90-minute seminar. The lecture should be attended by the whole cohort of student teachers, and it covers the theoretical background of SLEs and the concept of natural differentiation in contrast to more traditional concepts of differentiation.

SLEs can be defined by the following four constituting demands (Wittmann, 2001; Krauthausen & Scherer, 2013; Scherer & Krauthausen, 2010): (1) They represent central objectives, contents and principles of teaching mathematics at a certain level. (2) They are related to significant mathematical contents, processes and procedures beyond this level, and so they are a rich source of mathematical activities. (3) They are flexible and easily adaptable to special conditions of a classroom. (4) They integrate mathematical, psychological and pedagogical aspects of teaching mathematics, and so they form a rich field for empirical research.

In addition, the constituent characteristics of the concept of natural differentiation are: All students get the same learning offer, and this offer must be holistic, and may not fall below a specific extent of complexity and mathematical substance. Holistic contexts in that sense by nature contain various levels of demands which must not be determined in advance. In addition to the level the students decide to work on, they can freely make their own decisions concerning the ways of solution, use of manipulatives and facilities, kinds of notation, etc. The postulate of social learning from and with each other is fulfilled in a natural way as well (cf. Wittmann, 2001; Krauthausen & Scherer, 2013; Scherer & Krauthausen, 2010).

During the lecture not only the theoretical background is given, but also examples for planning and designing concrete learning arrangements as well the analyses of concrete interview or classroom situations for various SLEs and various mathematical contents, for example taken from former studies (see Scherer & Krauthausen, 2010).

For the corresponding seminars, the cohort is distributed in groups of about 15 student teachers. The seminars are related to different focal points like *differentiation*, *difficulties in language* or *inclusive mathematics*. The latter one is part of the sub-project 'Mathematics Inclusive'. During the whole semester, in the seminars the student teachers have to work in small groups up to four persons. They have to design and carry out clinical interviews with pupils from primary school working on selected SLEs. For the seminar focusing on 'inclusive mathematics' each student teacher has to interview two or more children with and without special needs. The student teachers should offer one and the same substantial learning environment and tasks to the different pupils and videotape the interviews. Within their small group as well as in the seminar group they have to analyze and reflect on the interviews in general, the concrete learning processes and pupils' existing competences as well as existing difficulties.

The course should enable student teachers to design common learning situations and learning within a common topic and mathematical content. The course concept cannot cover all dimensions of effective instruction but focuses on the dimensions *teacher*, *students* and *teaching approaches* (cf. Hattie, 2009).

### **Questionnaire and interviews with student teachers**

*Pre-post questionnaire:* To answer research questions 2 and 3 a standardized questionnaire was used in a pre-post-design. The initial questionnaire contains items concerning experiences as well attitudes and beliefs with respect to inclusion and inclusive mathematics (cf. Meyer, 2011). The latter ones are also included in the post-test. The relevance of beliefs and attitudes can be assumed (cf. Sullivan,

Clarke, & Clarke, 2013, p. 18 f.), and with the pre-post-design one of the questions will be, if and how student teachers' attitudes and beliefs changed after completing the course.

*Retrospective self-assessment:* Moreover, to answer research question 3 for the post-test six items for a retrospective self-assessment for the development of individual competencies were added (cf. Nimon, Zigarmi, & Allen, 2011), and the student teachers had to rate their competencies before the course and at the end of the course. These items were designed according to the curriculum objectives focusing on substantial learning environments, clinical interviews and analyses of students' thinking and learning processes (see section 2.1). The student teachers had to rate their competencies for these three aspects on the one hand in general, on the other hand concerning the relevance for inclusive mathematics. For example, the two statements referring to clinical interviews were (see section 3):

General: *I know the relevance of clinical interviews for mathematics teaching.*

Relevance for inclusive mathematics: *The use of clinical interviews seems relevant to me to support special needs students in inclusive classrooms.*

*Additional interviews:* For deeper analyses, additional interviews with selected student teachers were carried out. The interviews comprised selected items of the questionnaire (attitudes and beliefs), and asked for more detailed explanations of the student teachers' experiences before the course. Moreover, the interview focused on the concrete experiences the student teachers had made during the course (example: *In what way could you gain experiences for inclusive mathematics?*) as well as perspectives for their future teaching (example: *In what way can you imagine to use your insights for your future teaching of mathematics?*).

## Results

In the following section exemplary results will be reported. Firstly, student teachers' pre-experiences with inclusive mathematics (data from pre-test), and secondly, the retrospective self-assessment for the development of individual competencies with respect to substantial learning environments (data from post-test and selected interviews).

*Pre-experiences:* For detailed results concerning student teachers' individual pre-experiences with inclusive mathematics (research question 2a; open item: *Which experiences have you made so far with inclusion in mathematics instruction?*) see Scherer (2019). For the here reported course, the following results are relevant: Although the participating student teachers had completed in their BA-program at least one or two practical phases at school of about 5 weeks in total before, it showed that only about 50 % of the student teachers have made school-related-experiences whereas the others had no experiences or made experiences out of school or in other fields. The school-related-experiences cover a wide spectrum of aspects: Apart from organizational or personal requirements of inclusive settings, the statements could be specific for mathematics education or be more general.

One could identify *main categories for mathematics* that are of great importance for the course concept 'Learning Mathematics with SLEs', namely *differentiated learning offers* and forms of *inner or outer differentiation*. The student teachers' school-related-experiences most frequently could be assigned to these categories. Looking in more detail at the category *differentiated learning offers* one could identify a wide range of aspects: offering more time, more/less number of tasks, different

worksheets or tasks on different levels of difficulty, different textbooks or mathematical topics, additional materials and manipulatives, additional help, learning step-by-step, more repetitions.

Although a questionnaire does not allow in-depth analyses of the underlying concepts of teaching and learning or of the underlying concept of differentiation, one might assume that the classroom situations the student teachers have experienced did not follow the concept of a natural differentiation and the children did not work on common subjects, problems and tasks, as the student teachers rarely report situations that pupils work on common topics or SLEs. Some of the student teachers' statements might lead to the conclusion that the teaching and learning setting more or less represents an exclusive setting with separate learning situations than inclusive education (see also Scherer, Beswick, DeBlois, Healy, & Moser Opitz, 2016, p. 640 ff.). In contrast, the course 'Learning Mathematics with SLEs' focuses on common learning situations for *all* students, enabling individual as well as cooperative learning situations, for example by realizing the concept of a natural differentiation (cf. Krauthausen & Scherer, 2013; Scherer & Krauthausen, 2010; section 2.1).

*Retrospective self-assessment:* So one interesting question would be how the student teachers rate the development of their competencies concerning SLEs, especially the relevance for inclusive mathematics (research question 3). On a Likert scale from 1 to 6 (1 = not at all true; 6 = extremely true) the student teachers had to rate the following statements referring to SLEs:

General: *I know the characteristics of substantial learning environments for mathematics teaching.*

Relevance for inclusive mathematics: *The use of substantial learning environments seems relevant to me to support special needs students in inclusive classrooms.*

Figure 1a, b and Figure 2a, b show the results ( $N = 90$ , missings in Figure 2a): Before the course, many student teachers already know the characteristics of SLEs (Figure 1a) as about 45 % agree to this statement ( $M = 3.32$ ,  $SD = 1.22$ ). This result is plausible as the topic is touched in different courses in the 1<sup>st</sup> and 2<sup>nd</sup> year of the BA-program. Nevertheless, the self-assessed development of competencies is obvious and shows a significant effect (Figure 1b;  $M = 4.98$ ,  $SD = .66$ ), as after the course nearly all student teachers agree to the statement. A similar result occurs with respect to inclusive mathematics (Figure 2a:  $M = 3.91$ ,  $SD = 1.06$ ; Figure 2b:  $M = 4.98$ ,  $SD = .85$ ; significant effects). This shows an important development, as the student teachers' pre-experiences had shown quite different classroom situations they had observed.

**Figure 1a, b: Results for the self-assessment item with respect to SLEs (general)**

**Figure 2a, b: Results for the self-assessment item with respect to SLEs (relevance for inclusive mathematics)**

*Interviews:* For a deeper analysis of these outcomes, one can refer to the interviews, and two exemplary statements are cited:

Transcript 1 (student teacher 1 – ST1):

54 ST1: Well. What I knew before, just as a term and not put into action, were the substantial learning environments. And, well, what I didn't know either before, that you meet the needs of all students with these substantial learning environments. ... I did not know that you can find a task format that students work on for oneself and that differentiation takes place in a natural way. That became clear in my mind by the course. Before, I was aware that you have to work individually but not that you can work with the students on a common topic.

Transcript 2 (student teacher 2 – ST2):

32 ST2: Well, to be honest, before, I had no idea how inclusive education in mathematics should look like. And, well, it did help me that the different learning environments were presented and that it was also said what a learning environment should contain that I can use them for inclusive classrooms.

Whereas ST1 refers strongly to the potential of SLEs concerning inclusive settings, ST2 also links this relevance to the design of SLEs and their characteristics. Both statements focus on the constituting demand of didactical flexibility (see section 2.1), and the mathematical substance or central objectives or principles for teaching and learning mathematics are not named explicitly. It might be that this is too obvious for the student teachers and that the own planning, the fact that those SLEs might fit for all students and the practical experience dominate and might be impressive. Nevertheless, the content related objectives will be stressed in further courses.

## Conclusions

The first results of the course show that the underlying didactical concept of using SLEs and realizing a natural differentiation, is suitable for inclusive classrooms. Moreover, the course concept with the combination of theoretical elements, concrete video examples and pupils' documents (lecture) and practical experiences (interviews at school) with a common reflection (seminar) could reach the above mentioned project objectives. As a consequence, for the overall structure and concept of the course

no changes were necessary. But setting SLEs into practice of this more or less new field of inclusive mathematics is a great challenge for student teachers. However, the value of SLEs became obvious.

Analyses and reflections on videos, materials and examples given in the lecture have a high value. Extended by the student teachers' own experiences and common reflections in a seminar can increase their knowledge and teaching repertoire for the future. The above mentioned aspects are important for all kind of teaching situations, but seem to be more challenging in inclusive settings. On the one hand, student teachers have to cope with the mathematical content and be flexible in reacting to different students with their variety of strategies and ways of thinking. On the other hand, student teachers have to be aware of a variety of difficulties. When being confronted with those difficulties, a tendency of reproducing some of the patterns they experienced at school could be observed, for example more traditional forms of differentiation that special needs students need different learning offers, different tasks and materials on different levels or a prescribed program. These concrete experiences have to be made a subject of discussion to widen the repertoire of student teachers (cf. Scherer & Steinbring, 2006). This was already done when repeating the course, and will be strengthened in the future running of the course.

Moreover, the student teachers' pre-experiences have to be considered. As reported, many of their observed classroom situations did not represent common learning situations but exclusive settings with the separation of students with special needs. Those experiences have to be discussed and reflected in the lecture as well as in the seminars and practical experiences.

The next steps in the project will be the data analyses concerning the specific focal points of the seminars. One of the questions is whether the specific focal point 'inclusive mathematics' shows specific results concerning attitudes and beliefs as well as competence development. In the long-term the connection of mathematics education modules – like 'Learning Mathematics with SLEs' – with mathematics modules will be addressed, so that a coherent program will be developed, as terms and theoretical aspects have to be put into action.

## Acknowledgment

The project is supported by grant FKZ 01 JA 1610 and FKZ 01 JA 1910 in the frame of the program 'Qualitätsoffensive Lehrerbildung' (Quality Offensive for Teacher Education) funded by the Federal Ministry of Education and Research.

# Mathematical discourses of a teacher and a visually impaired pupil on number sequences: Divergence, convergence or both?

Angeliki Stylianidou and Elena Nardi

University of East Anglia, UK

[A.Stylianidou@uea.ac.uk](mailto:A.Stylianidou@uea.ac.uk), [E.Nardi@uea.ac.uk](mailto:E.Nardi@uea.ac.uk)

*Research on the inclusion of visually impaired (VI) pupils in mainstream classrooms is underdeveloped in mathematics education. This paper investigates mathematical discourses of a teacher and a VI pupil in a classroom episode on number sequences. We see that, while the teacher considers the pupil's enthusiastically demonstrated mathematical contribution which differs from the institutional one, she draws on it to guide him in responding within the institutional mathematical discourse. We then see the pupil responding within the teacher's expectations but less enthusiastically. We explore the teacher's reaction in terms of whether it evidences valuing of the pupil's initial mathematical contribution and whether it is potentially excluding. We propose an alternative, more explicitly inclusive way forward in which the teacher can play along with non-prevalent mathematical contributions and bring these also to the whole class, to the benefit of all.*

*Keywords: Discourse, inclusion, VI pupils.*

## Introduction

Inclusive education has been an issue of international consideration especially since the Convention on the Rights of Persons with Disabilities (CRPD) (United Nations, 2006). According to Article 24 of the CRPD, the signatory countries are committed to ensuring the right of persons with disabilities to education within an inclusive education system. Educational benefits from inclusive education are not limited to persons with disabilities though: “[T]here are educational benefits for all children inherent in providing inclusive education” (UNICEF, 2012, p. 11). But is this good intent implemented in the classroom? And if so, how – and, how is it experienced by staff and pupils?

In the study we draw from in this paper – part of the first author's doctoral thesis – we focus on the inclusion of VI pupils in mathematics lessons. We see inclusive education as occurring when the VI pupils are invited to participate in a lesson activity on an equal basis with everyone else in class, albeit not necessarily with the same sensory, material and semiotic tools. Apart from equitable participation, we consider equitable value as an equally important element of inclusive education. With the latter, we denote the value attributed to VI pupils, even in those contributions which differ from the prevalent, institutional ones, potentially as a result of the different tools through which VI pupils may construct and convey mathematical meaning. Reference to participation and value as contributors to inclusive education is present in international documents (e.g. United Nations, 2006) as well as in research studies (e.g. Nardi, Healy, Biza, & Fernandes, 2018). We consider equitable participation and equitable value as interrelated elements of inclusive education: our study's rationale is that one element exclusive of the other does not suffice for implementation of inclusive education. Our discussion of the data we present in this paper evidences the necessity of both elements for what we call “inclusive education”.

In this paper, we first discuss key developments in the inclusion of VI pupils in mathematics classrooms. We then zoom in on the study's focus and research questions and present the study's theoretical framework and methodology. Finally, we sample from the study's data and analysis with an episode from a Year 1 (Y1) class.

## **Literature review and theoretical framework**

A limited number of studies have been conducted in the area of inclusion of VI pupils in mathematics classrooms. The existing literature focuses mainly on the following themes: VI pupils' experiences in mainstream mathematics classrooms (e.g. Bayram, Corlu, Aydın, Ortaçtepe, & Alapala, 2015); VI pupils' forms of accessing, expressing mathematics and development of inclusive teaching strategies (e.g. Nardi et al., 2018); and, design of inclusive mathematics teaching and learning materials to be used by VI and sighted pupils (e.g. Leuders, 2016). While the existing literature has certainly set the foundations towards more inclusive mathematics classrooms, research studies that investigate how VI pupils are included in the classroom are sparse. We argue that an investigation of VI pupils' inclusion in mainstream mathematics classrooms combined with the existing foundations for such an inclusion can lead to even more inclusive mathematics classrooms. As our study explores (e.g. in the episode sampled in this paper), there may be significant gaps between inclusive education policy and practice: while appropriate inclusive education aspirations may appear in international and national policy documents, institutional, curricular and attitudinal constraints may lead to these gaps. Our study aims to investigate these and eventually contribute towards their reduction.

Our study has two phases and investigates: (a) how inclusion and disability are constructed in the discourses of teaching staff and pupils in mainstream mathematics classrooms (both phases); (b) how collaboratively designed mathematics lessons impact upon teaching staff's and pupils' discourses on inclusion and disability (Phase 2). We endorse a sociocultural theoretical framework that draws upon: Vygotskian sociocultural theory of learning (Vygotskii, 1978); Sfard's discursive perspective, known as the theory of commognition (Sfard, 2007); the social model of disability (Oliver, 2009); and, the theory of embodied cognition (Gallese & Lakoff, 2005). We discuss such use briefly in Stylianidou and Nardi (2018) and exemplify this use in this paper.

In the episode we present in this paper, we focus on the discursive activity of a teacher and a VI pupil, in interaction concerning number sequences. Our Vygotskian influence is evidenced in our focus on: the semiotic and sensory tools used by the two interlocutors in the setting of the school classroom; and, the mathematical meaning each interlocutor conveys as a result of using the particular tools. We show how particular elements from Sfard's discursive perspective – word use and visual mediators – are played out in the mathematical discourse of each interlocutor and we examine a case of commognitive conflict (Sfard, 2007) arising as a result of the teacher's and the pupil's different, incommensurable discourses. The visual mediators in the particular episode constitute the gestures, made by both the teacher and the pupil. Apart from speech, the gestures act too as a vital tool for mathematical communication and the construction, and conveying, of mathematical meaning. This role of gestures makes the theory of embodied cognition (Gallese & Lakoff, 2005) pertinent in our analysis of the episode.

In what follows, we present the study's context, participants and methods. We then sample from the data with an episode from a Y1 lesson on number sequences. We conclude with implications that this episode has for our ongoing analyses, particularly those included in the first author's doctoral thesis.

## **Methodology: the context, participants and methods of the study**

Data collection was conducted in four UK mainstream primary mathematics classrooms (Y1, Y3 and two Y5 classes; pupils' ages: 6-10). The VI pupils' presence and the willingness of teaching staff and pupils to participate in the study constituted our criteria for the selection of the classrooms. We collected data after securing ethical approval by our institution's Research Ethics Committee and ensuring participant anonymity, confidentiality and right to withdraw from the study.

We collected data through observations of 29 mathematics lessons (33.5 hours in total); individual interviews with 5 class teachers (6 interviews, 2 hours and 10 minutes in total); individual interviews with 4 teaching assistants (6 interviews, 2 hours and 15 minutes in total); focussed-group interviews with 35 pupils (16 interviews, 2 hours in total); 2 ten-minute individual interviews with one pupil; written transcripts of the teaching staff's contributions in the design of the three Phase 2 lessons; photographs of the pupils' work in the three Phase 2 classes; and, pupils' evaluation forms of the Phase 2 lesson in two classes. During observations, written notes were kept in all lessons. 21 lessons were audio-recorded and 14 lessons were also video-recorded. All interviews were audio-recorded, except four, following interviewee requests. For these, written notes were kept instead.

Data collection for Phase 1 was completed in March 2018 and for Phase 2 in July 2018. Data analysis is ongoing. While a major rationale for Phase 2 is to explore the impact of the co-designed mathematics lessons upon the participating teaching staff and pupils, we note that the Phase 2 episode we have selected to discuss in this paper does not stress the elements of co-design and its impact upon the participants. Instead, our emphasis here is on the mathematical discourses of a teacher and a VI pupil in a classroom incident in which we discern a genuine mathematical contribution by the pupil that diverges from the one expected by the teacher. We discuss the different mathematical discourses of the teacher and the pupil and explore the challenges of implementing inclusion. We first present a factual account – and then a preliminary analysis – of the episode. We conclude with a discussion of the episode in the context of the entire study.

## **A Y1 episode**

### **A factual account of the episode**

The episode is from a lesson on number sequences in a Y1 class. Ned is the VI pupil of this class and has severe, congenital visual impairment in both his eyes. The class has two general teaching assistants who support pupils that need help at particular instances and their role does not focus on supporting the VI pupil specifically. The class was asked to find the next number in a number sequence, which was on a worksheet that each pupil had in front of them. The number sequence was 8 10 12 14 16. The following dialogue occurs between the teacher and Ned:

- 1 Teacher: Is it increasing or decreasing?
- 2 Ned, *happily*: Creasing. *Ned puts his hand straight up, doing a similar gesture to the one the teacher had done when, earlier, she explained "increase".*

- 3 Teacher: Increasing or decreasing? “Increase” means it gets bigger, or is it getting smaller. *Whilst saying “bigger”, the teacher does a similar gesture to the one Ned had just done. Whilst saying “smaller”, she does a gesture, too, pointing down.*
- 4 Ned: Increasing. *He says this with less enthusiasm than before and without doing any gestures this time.*
- 5 Teacher: Yeah. You are right.

### A preliminary analytical account of the episode

#### *Ned’s reaction to the teacher’s question (2)*

Ned responds to the teacher’s question in (1) by resorting to verbal and gestural discourse. His word “creasing” may suggest that he does not recall the difference in the meanings of the words “increasing” and “decreasing”. Ned uses the root word, “crease”<sup>1</sup>, of both verbs to show, possibly, that he refers to one of the two verbs, although it is unclear from his speech per se whether he means “increasing” or “decreasing”, thus whether he answers the teacher’s question correctly.

His gesture, which accompanies his speech, makes it clear that Ned refers to the term “increasing”. Here, the gesture is vital in Ned’s conveying the mathematical meaning he has constructed of what an increasing sequence of numbers is. Ned’s re-enacting of the teacher’s gesture for the term “increasing” resonates with the theory of embodied cognition, according to which concepts are embodied (Gallese & Lakoff, 2005): “the *sensory-motor* system can characterise a sensory-motor *concept*, not just an action or a perception, but a *concept* with all that that requires” (p. 468).

As mentioned above, Ned’s speech alone does not suffice for our understanding as to whether Ned refers to “increasing” or “decreasing”. Similarly, we can argue that his gesture alone does not suffice either for our understanding of Ned’s mathematical expression. His gesture, isolated from his speech, may signify a variety of things, one of which is the term “increasing”. The combination of Ned’s speech and gesture, though, strengthens our speculation that Ned refers to the term “increasing”.

The contribution of both speech and gesture in Ned’s mathematical expression, and in our interpretation of it, demonstrates how merging Vygotskian (1978) sociocultural theory of learning and the theory of embodied cognition (Gallese & Lakoff, 2005) is important in our analysis. Take, for example, Ned’s response in (2) where we need both his speech and his gesture to grasp how he conveys what he means by “increasing”. Both theories – speech as the vital tool for mathematical meaning making and expression (Vygotskii, 1978) and the embodied nature of concepts (Gallese & Lakoff, 2005) – are combined to help us analyse Ned’s response in (2). One theory, deployed exclusively, would not suffice for our interpretation of Ned’s response.

In (2), we mention the adverb “happily”. With our use of an adverb that indicates emotion, we aim to show that we are interested not only in what our participants utter but also in how they feel as they do so. The ‘how’ part may be expressed with tone of voice, facial expressions and gestures and it provides us with information that frequently adds to, and further illustrates, the ‘what’ part. Ned’s

---

<sup>1</sup> “crease” originates from the latin word “crescere” [“grow”, Oxford English Dictionary (<http://www.oed.com/>)].

happiness is evidenced in his tone of voice and facial expression – when he says “creasing” – as well as in his gesture – we see excitement in the way he gestures. We attribute his happiness to a sense of fulfilment he may derive from the correctness of his answer. Later, we see that this correctness is cast into doubt, if not disapproved, by the teacher. Our exploration of the relation between emotion and cognition resonates with discussions in the literature of the relation among mathematical achievement, enjoyment and self-efficacy in mathematics. For example, we agree with Goldin, Epstein, Schorr, & Warner (2011, p. 553) that “affect, cognition and motivation interact to influence students’ mathematical engagement in classroom social environments”. Another reason why we have included a reference to Ned’s emotion is to later compare this emotion to that in his second answer, in (4), and associate the fluctuation between the two with the teacher’s reactions in the two cases.

### ***Teacher’s reaction to Ned’s response (3)***

The teacher does not explicitly react to Ned’s response, either by approving it or by disapproving it. We see in her response, though, implicit dissatisfaction: Ned’s answer does not include any of the two terms that the teacher expects to hear. Hence, the teacher repeats her previous question, albeit with a different sentence and tone of voice.

Her omission of the part “Is it”, which is in (1), and her direct use of the verbs separated with “or” show her emphasis on these two verbs, which she seems to expect from her interlocutor too. She pronounces the underlined prefixes “in” and “de” in (3) in a different tone of voice. This may indicate some concern about Ned’s wording, which does not include any of the two prefixes.

We interpret the teacher’s explanation of each of the two terms in (3) as showing her interpretation that Ned may not recall the meaning of the two terms. As with her question, her explanations suggest, too, her emphasis on the two mathematical words, which she expects to hear from Ned.

While the teacher’s mathematical discourse is mostly verbal-institutional and the teacher expects such kind of discourse from Ned, too, in this part of the episode, the teacher accompanies her speech with gestures. Thus, she creates a verbal-institutional and gestural mathematical discourse, with each of its components – speech and gesture – serving the same purpose: that of explaining the meaning of the key terms. We interpret the teacher’s use of a similar gesture to Ned’s one as a manifestation of “attuning” (in the sense of Nardi et al., 2018) to the gestural part of her pupil’s mathematical contribution and of her approval of gesturing as a form of mathematical expression, albeit not independently from ‘approved’ speech. Through her gesture, we see that the teacher considers Ned’s gesture, too, but – alongside speech – she draws on it to guide him in responding within the mathematical discourse which she, and the educational institution she represents too, approves. Therefore, the teacher seems to be concerned about Ned’s wording but she seems to partially approve his gesture. Her expectation is of an answer within the verbal discourse aligned with institutional (the National Curriculum’s) standards. The teacher’s attuning to Ned’s gesture resonates with the first camp of participants in (Nardi et al., 2018, p. 157): that of using the VI pupil’s contribution to focus on a more conventional contribution.

Drawing upon Sfard’s (2007) theory of commognition, we see evidence of commognitive conflict in the exchange between the teacher and Ned. We define commognitive conflict as the situation occurring when seemingly conflicting narratives originate in different, incommensurable discourses

(Sfard, 2007). We see the different mathematical discourses of two interlocutors, both of whom aim to convey their mathematical meaning of an increasing sequence of numbers. We see the commognitive conflict in the teacher's non-playing by the meta-discursive rules set by Ned: she considers Ned's speech in isolation from his gesture and vice versa. Indeed, as discussed in (1), Ned's speech isolated from his gesture – and Ned's gesture isolated from his speech – do not suffice for conveying the meaning he seems to have constructed of an increasing number sequence. We see that the commognitive conflict arose as a result of the teacher's consideration of Ned's mathematical discourse as consisting of two separate, unrelated elements: speech and gesture. We argue that, had the teacher considered Ned's verbal-gestural discourse as an entity, commognitive conflict might have been avoided: instead, an acknowledgement of two different, but equally acceptable, mathematical discourses might have occurred.

#### ***Ned's reaction to the teacher's response on his answer (4)***

We then see that Ned changes communicational mode from verbal-non-institutional – which was seen as problematic by the teacher (3) – and gestural – which was partially accepted by the teacher (3) – to verbal-institutional – which, as he knows from (3), is accepted by the teacher. Here, Ned responds to the teacher's question by playing by the meta-discursive rules set by the teacher, which, as discussed in (3), puts the emphasis on endorsed forms of speech. However, his shift in communicational mode does not seem to be a pleasant experience. His tone of voice and his facial expression evidence this reduced enthusiasm. This raises issues on how included Ned feels his mathematical contribution in (2) is. We see that in (3) the teacher's non-developing of Ned's mathematical contribution in its own right – the camp of teachers' developing of VI pupils' contributions in their own right is the second camp discussed by Nardi et al. (2018, p. 158) – is excluding. The teacher restricts Ned to responding within the boundaries of an institutionally endorsed mathematical discourse and this limitation seems to dissatisfy Ned. Drawing upon the relation between affect and cognition, we associate Ned's apparently reduced enthusiasm with the teacher's concern over his initial contribution and her expectation of his responding in one, particular way. Ned's non-gesturing here may be attributed to several reasons. It may be attributed to the non-contribution of a gesture to his conveying of his mathematical construction of an increasing number sequence, since his use of speech suffices as an answer to the teacher's question, unlike in (2). It may also be attributed to Ned's interpretation from (3) that gesturing is not a necessary, or even appropriate, form of mathematical communication.

#### ***Teacher's reaction to Ned's response (5)***

We then see that the teacher clearly approves Ned's response: his response in (4) resonates with the teacher's expectations, in which speech seems to dominate over gestures.

#### **Discussion of the episode in the context of the entire study**

This episode is selected to evidence mathematical discourses of a teacher and a VI pupil in a mainstream classroom and discusses the extent to which mathematical communication is achieved between the two interlocutors.

Zooming out to the entire study, we see that, despite the invitation towards VI pupils to participate in the mathematics lesson on an equal basis with their peers, their mathematical contributions – which may differ from the ones expected by the teacher – may not always be as valued as they could. In other words, we see evidence of equitable participation but not equitable value in the mathematics classroom. We see this discrepancy as a hurdle to implementing inclusion. We are unsure whether this discrepancy arises as a result of undervaluing of the mathematical discourses of VI pupils, as a result of a persistent adherence to the institutional mathematical discourse, as a result of both and/or other influences. In the episode we discuss here, though, we do not consider the teacher's concern with the VI pupil's initial mathematical contribution as ableist<sup>2</sup> and we note that there was hardly any evidence of ableism in the observation and interview data from this teacher. We attribute her concern to this contribution's divergence from the prevalent one and we thus stress that her concern in similar cases is likely to occur with every pupil, not just with a VI one.

In the episode, we see the reported interaction as associated – but possibly not limited – to visual impairment. We argue that the pupil's contribution may be seen through existing findings on visual impairment: for example, VI pupils use their hands to construct and convey mathematical meaning (Nardi et al., 2018). We also argue that the teacher's response in (3) was specific to the pupil's genuine mathematical contribution.

Regardless of the reason attributed to the teacher's concern with Ned's mathematical contribution, we set the following questions. Do we, as educators, need to accept only those mathematical contributions that resonate with the institutional ones? Or, do we need to reflect upon the different contributions of our pupils, discern whether they are mathematically valid too and act accordingly to include them in the lesson? Without ignoring the necessity for the pupils' familiarisation with, and endorsement of, established mathematical discourse, we propose that we should heed the reactions of our pupils, even in cases when we, either explicitly or implicitly, have concerns about mathematical contributions which differ from the institutional ones: different pupils construct different meanings of mathematics. This is how we see inclusive education implemented in the classroom: through equitable participation and equitable value. We argue that our valuing, attuning and integrating of pupils' non-prevalent mathematical contributions into lessons may not only encourage participation in the mathematics lesson but may also benefit all pupils in class, who may experience mathematics from a different, and potentially enriching, point of view.

## Acknowledgements

We thank: UEA's Research in Mathematics Education Group and Professor Anna Sfard for their invaluable feedback on the episode, discussed in a commognition workshop at UEA on 21/06/2018; the participating teaching staff and pupils for their commitment to the study; and, UEA for funding the study through a Social Sciences Faculty Doctoral Studentship.

---

<sup>2</sup> Ableism is defined as “a network of beliefs, processes and practices that produce a particular kind of self and body (the corporeal standard) that is projected as the perfect, species-typical and therefore essential and fully human. Disability, then, is cast as a diminished state of being human” (Campbell, 2001, p. 44).

# Do hearing-impaired students learn mathematics in a different way than their hearing peers? – A review

Kinga Szűcs

Friedrich-Schiller-University Jena, Germany; [kinga.szuecs@uni-jena.de](mailto:kinga.szuecs@uni-jena.de)

*In the last few years, the concept of inclusion has become more and more prevalent in school education. Accordingly, teachers in mathematics classrooms have to face not just a wide range of heterogeneity related to social background, language skills and performance abilities, but also various impairments like physical, sensory and mental disabilities. To facilitate gainful inclusive mathematics education, it is important to understand the aspects of mathematical concept formation and of mathematics performance which differ between disabled and not-disabled children. The main focus in the current paper is on the differences between hearing and hearing-impaired students when doing mathematics. Empirical studies from the last two decades are summarized and some guidelines for inclusive mathematics settings with hearing and hearing-impaired children are derived.*

*Keywords: Inclusive education, hearing impairments, concept formation, mathematics education.*

## Background

There is an overwhelming amount of literature related to deaf children's learning, a significant part of which discusses aspects of mathematics performance. Even if it is not possible to seek completeness, a short overview on some well-selected articles can give a useful insight into the main research questions and already ascertained results. For this reason, 24 articles (mainly from two highly relevant journals, the Educational Studies in Mathematics and Journal of Deaf Studies and Deaf Education) regarding hearing-impaired students' learning in mathematics (mainly reports on empirical studies about differences between the performance of hearing and hearing-impaired students) were chosen predominantly from the last two decades, such that all education levels from kindergarten to college are represented. Additionally, some of the papers discuss adults' mathematical performance long after completing school education. The main goal in this paper is to identify relevant differences between hearing and hearing-impaired students when doing mathematics and to derive their possible influence on an inclusive classroom. According to Ziemer (2017), the term inclusion will be used in the current paper as overcoming of all kind of marginalization, discrimination and stigmatization, which includes especially the respect and appreciation of handicapped students in co-educated classrooms.

There is a common agreement in the relevant literature, that hearing-impaired students' performance in school mathematics is on average far below the average performance of their hearing peers and that this delay corresponds to a disadvantage of 2 to 4 school years. However, there is no consensus regarding when this delay first appears, or which parts of the language skills and cognitive abilities are affected. Three different areas of related research can be identified: Studies that mainly focus on detecting and describing cognitive differences between hearing and hearing-impaired pupils, studies that look for reasons for those disadvantages, and studies that suggest interventions for hearing-impaired students and measure their effectiveness. Table 1 shows an overview of all reviewed papers, categorized according to the main focus and the examined educational level. Please note that some

of the papers include more than one study and therefore more than one of these aspects; it also happens, that a study was carried out on more than one education level. Thus, several papers are registered more than once. In the next sections, research results in the identified three areas (differences, reasons and interventions) will be summarized.

<b>main focus</b>	<b>differences</b>	<b>reasons for differences</b>	<b>intervention</b>
preschool	Ansell & Pagliaro, 2006; Kritzer, 2009; Pagliaro & Kritzer, 2013; Zarfaty, Nunes, & Bryant, 2004	Kritzer, 2008	
primary school	Ansell & Pagliaro, 2006; Frostad & Ahlberg, 1999; Nunes et al., 2009	Pagliaro & Ansell, 2002	Nunes & Moreno, 1998; Nunes & Moreno, 2002; Nunes et al., 2009
	Frostad, 1999; Zevenbergen, Hyde, & Power, 2001		
secondary school	Blatto-Vallee et al., 2007; Searle, Lorton, & Suppes, 1974	Kelly, Lang & Pagliaro, 2003; Lang et al., 2007	
	Zevenbergen et al., 2001		
college, university	Blatto-Vallee, Kelly, Gaustad, Porter, & Fonzi, 2007	Kelly & Gaustad, 2007	Marshall, Carrano, & Dannels, 2016
	Bull, Blatto-Vallee, & Fabich, 2006; Kelly, Lang, Mousley, & Davis, 2003; Marschark et al., 2015		
adults	Korvorst, Nuerk, & Willmes, 2007; Kramer & Grote, 2009 Masataka, 2006		

**Table 1: Main focus of the reviewed articles categorized by education level**

Before looking into the content of the papers it is important to remark that, although the term ‘deaf’ is commonly taken to mean profound hearing loss, most of the papers use the term in a wider sense. For example, Nunes et al. (2009) examine the performance of children with moderate to profound hearing loss in their first study and the performance of children with mild to profound hearing loss in their second reported study. In Frostad’s (1999) case study the pupils have moderately severe to

profound hearing loss, and Zarfaty, Nunes and Bryant (2004) also work with children with moderate to profound hearing loss. All these papers use the term 'deaf'. Others, for example Pagliaro and Kritzer (2013) emphasize the difference between partial and complete hearing loss and make use of the term 'deaf and hard-of-hearing'. Because of this inconsistent and confusing use of terms, in this paper the term 'hearing-impaired' will be employed and used in the sense which incorporates all the meanings of related terms in the reviewed papers. So, by hearing-impaired will be meant all kinds of hearing loss, which exceed the threshold of normal hearing (hearing loss 15 dB at the most).

## **Differences between hearing and hearing-impaired students when doing mathematics**

Because of the main consensus about the delayed performance of hearing-impaired students in school mathematics, researchers started to pay more attention to preschool mathematics in order to answer the question of whether those differences are already present before starting school. A surprising and also promising result from Zarfaty, Nunes and Bryant (2004) with children in the age range of 3 to 4 years, is that they could remember and reproduce numbers as well as their hearing peers when the task was offered in a sequence, but they outperformed the hearing children, when the task was organized spatially. Contradictory to these findings, hearing-impaired children did not benefit from the visual-spatial problem presentation in the study of Ansell and Pagliaro (2006). With respect to arithmetic story problems, preschool and primary school hearing-impaired children do not use linguistic markers in the story, instead reacting more to the assumed mathematics operation (Ansell & Pagliaro, 2006). Similarly, not only do 4- to 6-year-old hearing-impaired children already present a developmental delay in both informal and formal mathematics tasks relative to hearing peers, but also, not even participants with high mathematical ability could make relationships between the numbers and the story in a word problem (Kritzer, 2009). The results from Pagliaro and Kritzer (2013) can further differentiate the picture: In their study, 3- to 5-year-old hearing-impaired children showed strength especially in geometry.

In accordance with the results of Ansell and Pagliaro (2006), Frostad and Ahlberg (1999) found that hearing-impaired primary school children typically approach word problems as numbers and procedures without reflecting on the semantic relations in the text. Frostad (1999) found additionally that primary school hearing-impaired children do not use their knowledge base for deriving the answer, instead reverting to counting. Similarly, hearing-impaired primary and secondary school students rely on trigger words in the text as well as ignore key words in decontextualized problems (Zevenberger et al., 2001). In the study of Nunes et al. (2009), hearing-impaired primary school children under-performed their hearing peers in multiplicative reasoning tasks.

At the secondary school level, the findings of Zevenberger et al. (2001) are already reported above. In contrast to that, Searle, Lorton and Suppes (1974) found among grade 4-6 deaf and deprived students that terse and story-free problems are especially difficult for them to solve. Another relevant result in this study was that the length of the word problems did not affect the mathematical performance. Blatto-Vallee, Kelly, Gaustad, Porter and Fonzi (2007) examined the use of visual-spatial schematic and visual-spatial pictorial representations among secondary school and college students when solving word problems. Hearing-impaired students tended to utilize more visual-

spatial pictorial representations, which encode only the visual appearance of objects described in the problem and are therefore on a lower cognitive level than visual-spatial schematic representations, which encode the spatial relationships described in the problem.

Kelly, Lang, Mousley and Davis (2003) examined the consistency hypothesis during solving arithmetic word problems among hearing-impaired college students. The hypothesis postulates that students perform better on word problems in which the order of the information is consistent with the order of the corresponding mathematical operation; supporting evidence has been found previously among hearing students. The results of the Kelly et al. (2003) study support the consistency hypothesis: Hearing-impaired students performed similarly. On the other hand, they made – regardless of reading ability – more goal monitoring mistakes than hearing peers. Bull, Blatto-Vallee and Fabich (2006) found that on subitizing tasks (instantaneous recognition of the cardinality of small sets), both hearing and hearing-impaired college students' performance have a similar pattern. Surprisingly, hearing-impaired students did not perform better on a special skew dot format, even if this was anticipated due to their assumed better visual-spatial skills. Accordingly, Marschark et al. (2015) report that hearing university students outperformed their hearing-impaired peers in visual-spatial tasks. Note, that this contradicts to the findings of Zarfaty et al. (2004) on the preschool level.

Masataka (2006) investigated the number sense of hearing-impaired adults and their hearing peers. In this study the hearing-impaired participants outperformed the hearing peers on tasks which used non-symbolic numerosity, but they did worse, when the same tasks were offered in a formal mathematical way. Kramer and Grote (2009) compared the performance of hearing-impaired adults on basic mathematics operations with that of hearing peers. Even if the performance of hearing-impaired adults is far below the performance of people with the lowest level certificate of secondary school in Germany, the two groups showed in a language-free test almost the same cognitive ability. The authors also found a performance benefit for deaf adults with deaf parents and concluded that the language (not exclusively sign language) used in mathematics classrooms has a negative effect on their learning. In accordance with this, Korvorst, Nuerk and Willmes (2007) found hearing-impaired adults' performance on complex numerical information-extracting tasks was quite similar to the performance of their hearing peers, when the tasks were offered in sign language.

### **Possible reasons for differences in mathematical performance**

At the primary level, Pagliaro and Kritzer (2013) conclude that the detected delayed development of hearing-impaired children related to basic concepts in mathematics can be caused by absent, inappropriate, or misguided learning opportunities. Similarly, Kritzer (2008) found in a qualitatively analyzed case study with hearing-impaired 4- to 6-year-old children and their parents, that the four mathematically based concepts (numbers, quantity, time and/or sequence, categorization) were used more frequently by the parents of children with high mathematical ability than by parents of children with lower mathematical ability. The first group of children was also exposed to mathematically based concepts in a way that was more purposeful and meaningful.

Even if sign language number symbols have many of the characteristics of analogue representations, the efficiency of those numbers for counting can delay the development of conceptual knowledge in hearing-impaired primary school children (Forstad, 1999). So, the use of sign language is beneficial,

but can also lead to disadvantages. Zevenbergen et al. (2001) described a similar dilemma: If the teacher reorganizes the word problems so as to make them more accessible for hearing-impaired pupils, students are not challenged cognitively and do not get access to the highly specific register of the discipline. Totally in accordance with these findings, Pagliaro and Ansell (2002) concluded based on a questionnaire with teachers of third-grade hearing-impaired students, that they do not encounter story problems early enough and often enough, so they are not provided sufficient opportunities to form problem-solving strategies.

Because the study of Zevenbergen et al. (2001) was made with first- to seventh-grade hearing-impaired children, the statement above is also valid for the secondary school level. Additionally, Kelly, Lang and Pagliaro (2003) found that not only do teachers of hearing-impaired students not challenge them cognitively in solving mathematics word problems, but also that they have low perceptions and expectations about the students' abilities and therefore do not offer them meaningful problem-solving situations. Also, the teachers associated limited English skills with a primary barrier to learn, and thus emphasized comprehension strategies rather than problem-solving strategies. However, difficulties can also be caused by other factors: In a case study with teachers, Lang et al. (2007) determined that visual representations of science concepts (among others technical science signs) may lead to misconceptions, but also, that for the majority of science terms there is no published or recorded sign.

There is some evidence that mathematics performance is affected by language abilities, especially at higher levels of education. Kelly et al. (2003) found that, even if the rate of goal-monitoring errors was much higher among hearing-impaired college students than among hearing peers, this rate nevertheless decreased with increasing reading ability. Marschark et al. (2015) examined the executive functioning behaviors (such as comprehension and conceptual learning, factual memory, attention and so on) of hearing and hearing-impaired first-year university students in everyday life with a self-report questionnaire. They found better scores for the hearing than for the hearing-impaired students, but also, that difficulties in executive functioning among participants with cochlear implant are the result of both, language delay and auditory deprivation. In accordance with this, Kelly and Gaustad (2007) could demonstrate, that specific morphological competencies in English in addition to reading ability level, are significantly related to mathematics performance. Bull et al. (2006) concluded that hearing and hearing-impaired students do not differ from each other in the format of numerical representation and the level of automatic activation of magnitude information. Thus, this aspect cannot be the reason for later difficulties with arithmetic.

Based on his study with hearing and hearing-impaired adults, Masataka (2005) concluded that, difficulties in mathematics are related to the formal, symbolic side of the discipline, and that this is modulated by the environment and the culture. Kramer and Grote (2009) came to a similar conclusion: They found the language used in mathematics classrooms to be responsible for the mathematics difficulties of deaf (native sign-language user) individuals, but they also mention missing and deficient opportunities for developing language skills and everyday-life-knowledge. In accordance with this and also with the findings of Bull et al. (2006) above, Korvorst et al. (2007) did not find evidence for core differences between hearing and hearing-impaired adults in solving

bisection tasks, which require the extraction of complex numeric information, when hearing-impaired participants used (their native) sign language.

### **Interventional methods and their effectiveness**

Nunes and Moreno (1998) applied a non-traditional method for calculating, namely the signed algorithm, in a mathematics classroom with solely hearing-impaired primary school children. While solving addition and subtraction problems, the pupils showed systematic errors similar to the ones in written computation related to place value understanding and the mechanics of written algorithms. Thus, the authors suggest to try out this method as an alternative and make use of the systematic errors to optimize teachers' instruction. Nunes and Moreno (2002) also developed an interventional program for hearing-impaired students in primary school which involved two main aspects: Giving opportunities to learn basic mathematical concepts, which can be learnt informally by hearing students, and promoting connections between informal and formal mathematical concepts. The interventional group performed significantly better in the posttest not just in comparison with the baseline group, but also with their own previously estimated performance. The intervention led also to motivational benefits. Furthermore, Nunes et al. (2009) adapted an intervention program on multiplicative reasoning – originally developed for hearing children at risk for difficulties in learning mathematics – for hearing-impaired students. However, the intervention was also applied to a hearing experimental group. Both hearing and hearing-impaired children benefited significantly from the intervention, but in a delayed posttest the performance of the hearing-impaired children decreased. A possible reason for this fact could be the long-term poorer problem-solving environment for hearing-impaired pupils.

Responding to missing everyday opportunities and problem-solving strategies of hearing-impaired students, Marshall, Carrano and Dannels (2016) developed an intervention program based on the concept of experimental learning, on best-practice experiments and on the concept of plan-do-check-act. During the lessons, hearing-impaired students become more and more familiar with the solving of real, work-related problems. The sessions featured sign-supported explanatory videos. Significant improvements were found between the performance in the pre- and posttest for the long term.

### **Conclusions for inclusive mathematics classrooms**

According to Pagliaro and Kritzer (2013), Kritzer (2008) and also to Kramer and Grote (2009), the main focus in the preschool education should be on offering opportunities primarily to develop informal mathematics knowledge such as numbers, quantity, time, events in a sequence, categorization and to improve language skills.

In primary and secondary school, word problems seem to be the most challenging for hearing-impaired students. Intervention programs such as suggested by Nunes and Moreno (2002) and Nunes et al. (2009) could and should be implemented and extended for other areas and for secondary level, for the following reasons: (1) Hearing-impaired students could compensate their deficient informal mathematics knowledge and language skills (2) both hearing-impaired and hearing students could develop high-level problem-solving strategies (3) these activities could also be beneficial for socioeconomically disadvantaged pupils and students at a risk for difficulties in learning mathematics. It is also important to make use of visual-spatial schematic representations when solving word

problems (Blatto-Vallee et al., 2007) and to discuss story-free word problems (Searle et al., 1974). Children with profound hearing loss could use the sign algorithm as an alternative (Nunes & Moreno, 1998) and should use their native language (sign language) (Kramer & Grote, 2009; Korvorst et al., 2007), perhaps with the help of a native sign-user translator. At college and university education level, the support of language skills – including technical (sign) language – is recommended.

*Braille readers create an overview of an expression by reading one braille character after another or listening to a voice saying the expression or equation aloud. The specific skills and knowledge that mathematics teachers need to assist this complicated process are often lacking. The purpose of this study was to investigate the effect of an intervention consisting of a course focused on braille display support in combination with Text-To-Speech synthesizer for mathematics teachers on the mathematical performances of braille readers. A quasi-experimental approach was taken to answer this question. Five teachers of an experimental group received the intervention whereas the teacher of the control group did not. Both the experimental group, consisting of 10 braille readers, and the control group, consisting of five braille readers, took a pre- and post-test. The results indicated that there was a very small positive effect of the intervention.*

*Keywords: Braille display, braille reader, algebra, speech synthesizer, TPACK model.*

### Introduction

Reading and comprehending mathematical expression and equations has always been difficult for students who use braille or braille in combination with speech synthesis as their primary reading medium (hereafter braille readers). Mathematics teachers need to have specific skills and knowledge to assist this complicated process. Braille readers read and comprehend mathematical expressions and equations by touching or hearing in a sequential pattern (Millar, 1994, 1997). They need to build an overview by reading one braille character after another or listening to a voice saying the expression or equation aloud. Expressions and equations have to be represented in a linear notation because braille and speech are both linear output modalities (Stöger & Miesenberger, 2015). Hence, braille readers have a small perceptual view and have to read expressions in a linear notation. This means that they can't benefit from the layout of an expression that helps the sighted student to understand the structure of an expression at a glance (Karshmer & Bledsoe, 2002).

In many countries, braille readers in secondary and higher education use a laptop in mathematics class. Screen Reader software sends the mathematical text on the screen to a refreshable braille display, which is connected to the keyboard of the laptop, or to a Text-To-Speech (TTS) synthesizer. Consider, for example, the next expression:

$$\frac{2x^2+1}{3} \quad (1)$$

In this representation, the expression can't be sent to the braille display or TTS synthesizer. It must first be converted to a linear representation (hereinafter pre-braille notation), e.g.  $(2x^2 + 1)/3$ .

The notation on the braille display is to a certain degree static. This allows for at least a limited spatial overview (Archambault, Stöger, Batusic, Fahrengruber, & Miesenberger, 2007). On the other hand, every character on the braille display has to be read individually and sequentially which makes braille reading exhaustive rather than selective (Hughes, 2011; Hughes, McClelland, & Henare, 2014). That makes it rather difficult to get an overview over an expression or equation (Van Leendert, Doorman, Drijvers, Pel, & van der Steen, 2019). Moreover, braille characters have a low redundancy, which means that the characters are hard to distinguish from each other (Tobin & Hill, 2015). This can lead to errors in decoding the braille characters into correct elements of the expression or equation.

In addition to the braille display, the TTS synthesizer is a useful screen reader device for reading mathematical expressions and equations. The Screen Reader that controls the speech and that we used in this study is JAWS, which stands for Job Access With Speech. An advantage of speech over braille is the pace of reading because spoken language can be much quicker comprehended than braille characters. Mathematical expressions and equations can be spelled or read aloud. When an expression is spelled, each element in the expression is approached separately. When an expression is read, a speech dictionary determines the spoken text. This dictionary can be extended with a mathematics vocabulary (also influencing how non-mathematical text is read) and can be further extended with mathematical symbols on so-called verbosity levels. The way in which an expression is spoken aloud depends on the content of the dictionary and the verbosity levels and on the verbosity level at which the braille reader reads. For example, " $2(x^2 + 4)$ " can result in "two x squared plus four" when using a low verbosity level and in "two open bracket x squared plus four closed bracket" when using a high verbosity level. In this case, the meaning is lost when the braille reader uses a low verbosity level. In general, braille readers (should) use a low verbosity level for reading non-mathematical text and a high verbosity level for mathematical text. By default, the settings are not adjusted to mathematical text. In that case, choosing a high verbosity level doesn't help.

In summary, the Screen Reader's software can be adjusted in such a way that (almost) all expressions are spelled and read in mathematical vocabulary. This supports the braille reader in learning the mathematical vocabulary, which is vital for the development of mathematical skills (Riccomini, Smith, Hughes, & Fries, 2015). Moreover, this vocabulary corresponds to the vocabulary used by the mathematics teacher in the classroom. This is particularly useful for braille readers in inclusive classrooms, because individual support is not always available.

Both assistive devices, the braille display as well as the TTS synthesizer, have their strengths and weaknesses. Ideally, using both devices one combines their individual strengths to overcome the weakness of each of the two methods (Bernsen, 2008). For example, uncertainties in braille can be verified or checked by spelling aloud.

The previous sections demonstrate that reading and comprehending mathematical expressions and equations while using the braille display or the TTS synthesizer is not easy. Teachers often don't know how to guide this complicated process. To map out the qualifications of mathematics teachers, the TPACK model can be used. TPACK includes knowledge of technology (TK), pedagogy (PK) and

content (CK), as well as insight into the complex interaction between these knowledge components (Mishra & Koehler, 2006). The idea behind TPACK is that the pedagogical use of (assistive) technology devices is strongly influenced by the content domains on which these devices are situated (Graham, Burgoyne, Cantrell, Smith, St Clair, & Harris, 2009). For example, the teacher knowledge required to effectively integrate technology in a mathematics classroom may be very different from that required for a language classroom.

This study aims at improving the integration of the braille display and the TTS synthesizer in the mathematics classroom. We addressed the following research question:

What is the effect of improving the knowledge of braille display and Text-To-Speech synthesizer support of mathematics teachers on braille reader's achievement in mathematics?

We expected that braille readers will better perform in mathematics because the adjusted settings of the Screen Reader software are more appropriate for reading mathematical text and the mathematics teachers have the knowledge to teach the braille readers how to use the braille display and the TTS synthesizer in mathematics lessons.

## **Methods**

### **Design**

In this study, the braille readers' mathematics teachers took part in a professional development (PD) course on integrating the braille display and the TTS synthesizer into mathematics lessons. The first part of the course was aimed at assisting each teacher in adjusting the settings of the Screen Reader software. As a result, the braille readers were able to listen to how expressions and equations were spelled and read aloud in mathematical vocabulary. The second part of the course was aimed at improving the knowledge to teach the braille readers how to use the braille display and the TTS synthesizer in mathematics lessons. In order to answer the proposed research question, a quasi-experimental approach was taken, using a pre- and post-test. The experimental group consisted of 10 braille readers whose teachers took part in the PD course. The control group consisted of five braille readers whose teacher did not participate in this course.

### **Context and participants**

In the Netherlands, more than 50% of all braille readers in secondary education go to special schools for students with a visual impairment. Organization A and B provide education for these students. The first author was affiliated with organization A. Therefore, five mathematics teachers from two different schools of organization A participated in the PD course, while the teacher who worked at the school of organization B did not. None of the teachers ever received any training in teaching mathematics to braille readers. The mathematics teachers who worked at organization A were qualified teachers, but they were not, with the exception of one, qualified to teach mathematics. In contrast, the mathematics teacher who worked at organization B was a qualified mathematics teacher. The braille readers of organization A were assigned to the experimental group and the braille readers of organization B were assigned to the control group. This resulted in an experimental group of 10 and a control group of five braille readers. The three schools were very similar in terms of demographic characteristics of students and the degree of educational performance. The braille

readers were all in seventh to twelfth grade in secondary education. They differed in their mathematical skills and in their ability to use the braille display and the TTS synthesizer.

### **Intervention: a professional development course**

Part of the intervention consisted of the adjustments of the settings of the Screen Reader software. The control group worked with the “old” settings, and (often) used one verbosity level when reading. As a result, too few symbols and punctuation marks were read aloud in mathematical text, or too many punctuation marks were read aloud in non-mathematical text. Moreover, (almost) no mathematical vocabulary was used. For the experimental group, the verbosity settings of the Screen Reader were adjusted. The speech dictionary was extended with a mathematical vocabulary and all punctuation marks and symbols, used in pre-braille notation, could be spelled aloud in mathematical vocabulary. The braille readers could choose a verbosity level with which they could read the whole expression aloud in mathematical vocabulary, without missing elements.

The face-to-face PD course consisted of four sessions of three hours each, which lasted over a period of four months. The design of the course was based on TPACK. Much attention has been paid on how to integrate the braille display and the TTS synthesizer into the mathematics lessons. For the first homework task, the mathematics teachers were asked to support a braille reader in obtaining an overview over an expression or equation. For the second homework task, they were asked to write down their experiences with the adjustments of the Screen Reader software and to discuss this with their braille readers. For the third task, they were asked to do an activity to provoke collaborative work and mathematical communication between students.

### **Pre- and post-test**

We decided that we could use identical pre- and post-tests because the time interval was more than four months. The braille readers were asked to answer the two tasks orally, because that would save time and be less tiring for them.

The tasks were not too complex but required careful reading skills due to the use of various operations and brackets. In the first task, “synthetic speech comprehension”, the braille readers had to select information from expressions or equations that were spoken aloud. The items could be spoken aloud several times at the request of the braille reader. The items were:

- a)  $1/7 + 7 - 2/5 + 8 = ..$     What are the fractions in this expression?
- b)  $4 - (5 + -(6 + 3)) = ..$     Where do you start calculating?
- c)  $4 * (.. - 5) = 8$     Solve this equation.

In the second task, “mathematical braille reading skills”, the braille readers were asked to read the mathematical text on the braille display and verbalize this text in mathematical vocabulary. With item b we expected to be able to investigate whether they were supported by context. The items were:

- a)  $y = 2 \frac{1}{2} * 3$
- b) The volume is  $12 \text{ m}^3$
- c)  $y = \sqrt{2/(x + 3)^2}$

(2 1/2 is a mixed number, a combination of a whole number and a proper fraction). Before the start of the pre- and post-tests, the braille readers were interviewed about their visual impairment, their assistive devices and the support they receive in mathematics lessons. This information helped to interpret the results of the tests.

## **Procedure**

The research followed this order: pre-interview, pretest, intervention, post-interview, posttest, all within a maximum of five months. The interviews and the pre- and post-tests took place at the schools of the braille readers. All sessions, consisting of an interview and a pre- or post-test, were scheduled for 25 minutes but sometimes lasted longer due to technological problems with the braille readers' laptops. Within two weeks of completing the pretests, the Screen Reader software of the experimental group was adjusted and the mathematics teachers' development course started. Within a month after the end of the course, the braille readers did the posttest. The control group received the same interviews and pre- and post-tests in the same period but without intervention.

## **Data collection and analysis**

For investigating the research question data was collected during the pre- and post-test through audio and video recordings. For "synthetic speech comprehension", data were collected on whether the braille readers gave a correct answer and on how much time they needed to give this answer. For each group, the average time was calculated. For "mathematical braille reading skills", data were collected on whether the braille readers could verbalize the expression, how much time they needed to give a correct answer and on the kind of errors they made. For each group, the average time was calculated.

## **Results**

The results in Table 1 show that for synthetic speech comprehension, the pretest percentage of correct answers was 57% for the experimental and 47% for the control group. For the posttest, the percentage of correct answers was (again) 57% for the experimental and 80% for the control group. The experimental group needed in the pretest, on average 46.1 seconds (SD = 27.0) and in the posttest, on average, 34.1 seconds (SD = 16.0) to give the correct answers. The control group needed in the pretest, on average, 45.4 seconds (SD = 25.1) and in the posttest, on average, 32.4 seconds (SD = 14.3) to give the correct answers. For both groups, the standard deviations were high.

For mathematical braille reading skills, the pretest percentage of correct answers was 20% for the experimental and 53% for the control group. In the posttest, the percentage of correct answers was 37% for the experimental and 60% for the control group. The experimental group needed in the pretest, on average, 18.2 seconds (SD = 26.8) and in the posttest, on average, 15.3 seconds (SD = 8.7) to give the correct answers. The control group needed in the pretest, on average, 9.0 seconds (SD = 3.1) and, in the posttest, on average 9.8 seconds (SD = 8.4) to give the correct answers. Also for this task, the standard deviations were high. The errors were categorized. E(d) is an error made due to difficulties with decoding the braille characters. This could be ascribed to difficulties with recognizing the location of the raised dots or to difficulties with decoding the braille characters into correct elements of a mathematical expression (e.g., "x" "∧" "2"). E(v) is an error due to difficulties in recognizing and verbalizing the whole expression (e.g. "x squared") and E(b) is an error due to

malfunctioning of one of the technology devices. For both groups and for all tests, almost all errors were decoding errors. For both groups, most decoding errors occurred at decoding symmetric or translated characters (e.g.  $\text{⠠⠠⠠}$  and  $\text{⠠⠠⠠}$ ) and mixing up six dot braille with eight dot braille. The E(b) error occurred only, two times, in the pretest of the experimental group.

**Table 1: Results from pretest and posttest for synthetic speech comprehension and mathematical braille reading skills**

Condition	Number of students	Pretest		Posttest	
		Percentage of correct answers	Average time on correct answers (s.)	Percentage of correct answers	Average time on correct answers (s.)
Synthetic speech comprehension	E (10)	57%	46.1 (SD = 27.0)	57%	34.1 (SD = 16.0)
	C (5)	47%	45.4 (SD = 25.1)	80%	32.4 (SD = 14.3)
Mathematical braille reading skills	E (10)	20%	18.2 (SD = 26.8)	37%	15.3 (SD = 8.7)
	C (5)	53%	9.0 (SD = 3.1 )	60%	9.8 (SD = 8.4)

E denotes experimental and C control group

Finally, we illustrate the decoding practices of two braille readers of the experimental group reading “The volume is  $12 \text{ m}^3$ ” on the braille display (see Table 2). In this example, I. tried to read  $12 \text{ m}^3$  as one number “2393”. He did not recognize the “^” character in braille and stopped. F. also started with reading  $12 \text{ m}$  as one number, but corrected the error. Both braille readers mixed up “m” with “3”. and spent a lot of time reading “ $12 \text{ m}^3$ ” compared to reading “The volume is”.

**Table 2: Results of two individual braille readers on mathematical braille reading skills**

Braille reader I. (pretest)		Braille reader F. (posttest)	
Time (s)	Utterances	Time (s)	Utterances
00– 04	The volume is	00 – 01	The volume is
04 – 17	Two thousand three hundred ninety-three	01 – 19	Eh hundred three and
	Wait two thousand What should this be?		twenty No no twelve I
17 – 22	The volume is		think this is cubic 12 cubic
22 – 40	one, two three no wait a two m s three I		meters
	do not know if that is an s. It looks a bit		
	strange ... {stop}		

## Conclusions and discussion

This study aims at improving the integration of the braille display and the TTS synthesizer in the mathematics classroom. For “synthetic speech comprehension”, the percentage of correct answers for the experimental group (57%) did not change during the intervention. This means that, for this the

task, there was no evidence that the intervention was successful. For the control group, this percentage was 47% in the pretest and 80% in the posttest. It is remarkable that this group achieved much better on the posttest. For “mathematical braille reading skills”, the experimental group improved more than the control group. It is remarkable that the pretest percentage of correct answers of the experimental group (20%) was much lower than that of the control group (53%). In the posttest, the percentage was 37% for the experimental and 60% for the control group. For both groups, most errors were errors in decoding the braille characters showing that braille readers already stumble in the first phase of the solving process. Table 2 shows that braille reader I. and F. needed more time and made more errors when reading mathematical text (“ $12\text{ m}^3$ ”) compared to reading non-mathematical text (“The volume is”). Both braille readers mixed the symmetric characters “3” and “m”, which is a common mistake (Tobin & Hill, 2015). In summary, the results of the tasks on mathematical braille reading show a very small positive effect of the intervention. We expected a greater effect. Finally, the high values for standard deviation, in all tests, showed that the individual differences were large.

This study had some limitations. A first limitation was the small number of braille readers that participated in this study, especially the number of participants in the control group. A second limitation was the limited information we had of the braille readers about the frequency that they used the adjustments of the Screen Reader software in the period between the two tests. From a teacher’s point of view, we don’t know, exactly, if and how they changed their daily practice. This feedback was asked during the second interview, yet the braille readers found it difficult to reflect on this.

Moreover, there were differences between the experimental and control group that may have affected the results. Firstly, the braille readers of the control group were obliged to use the braille display, whether or not in combination with the TTS synthesizer, during their mathematics lessons. This was not obligated for the braille readers of the experimental group. Secondly, the mathematics teacher of the braille readers of the control group was a qualified mathematics teacher. This was not the case for the mathematics teachers, with the exception of one, of the experimental group.

We did not anticipate that braille readers would make so many decoding errors while reading mathematical text. Overall, the control group performed better on both tasks than the experimental group. This may be due to the strict rules for the use of the braille display and the differences in background of the mathematics teachers. This could be examined in more detail in future studies.

Overall, this study adds to the small number of studies into ways to support braille readers in mathematics (e.g. Figueiras & Arcavi, 2014). Findings from this type of research should enable teachers to better support braille readers in doing mathematics.

### **Acknowledgments**

This work is part of the research program ‘Improving the mathematical abilities of Braille-dependent students’ (023004048), which is financed by the Netherlands Organization for Scientific Research (NWO). This study was approved by the medical ethical committee of the Erasmus Medical Centre (MEC-2012-097 and MEC-2012-524) and adheres to the tenets of the Declaration of Helsinki (2013) for research involving human subjects. Informed consent was obtained from the participants.

TWG26 (*Mathematics in the Context of STEM Education*) was introduced in the CERME 11 in recognition of its importance in mathematics education. Science, Technology, Engineering and Mathematics (STEM) education merges a variety of subjects in the fields of science, technology, engineering and mathematics to solve real world problems (Sanders, 2012). Since the discrete subjects of science, technology, engineering, and mathematics were conjoined into the ubiquitous STEM acronym teachers, researchers, policy makers, and funders have worked to integrate the discrete subjects. The process of integration begins with the introduction of new instructional materials and practices, typically through curriculum development, publication of supporting materials, and professional development (Sanders, 2012). The challenge of integrating STEM lies at the nexus of teacher preparation and in-service teacher professional development (deMora & Wood 2014). Teaching STEM in a more connected manner, especially in the context of real-world issues, can make the STEM subjects more relevant to students and teachers (Honey, Pearson, & Schweingruber, 2014). This in turn can enhance motivation for learning and improve student interest, achievement, and persistence (Honey, Pearson, & Schweingruber, 2014).

What level of integration should be strived for, however, is not undisputed. Especially, if and how mathematics fits such an integrated approach is debatable. A specific point of attention concerns the fact that mathematics education asks for careful vertical planning, which might be compromised in an integrated approach. Mathematics encompasses more fields of application than science, technology, and engineering alone. So, real-life applications involving modeling, engineering design and the integration of various disciplines has to be taken into account in mathematics as it prepares students for the future.

This working group particularly aimed at addressing mathematics in the context of STEM education. Mathematics encompasses more fields of application than science, technology, and engineering alone. So, the integration of a broader variety of disciplines has to be taken into account in mathematics to prepare students for the future. Papers and posters submitted to the group focused on tasks, courses, curriculum, students, and in-service teachers mainly using qualitative methodology and interpretative approach. The issues and ideas emerged are discussed in reference to seven central themes. The mathematical contents concerned various topics (e.g., Numbers and Operations, Geometry (i.e., angles, parallel lines), and Data Organisation and Processing, second-order differential equations, matrices, linear equations).

## Thematic areas

Here we present the issues and ideas that emerged in reference to the seven central themes.

### Mathematical preparedness and value

Within this theme two papers were presented. First paper by Lave and Walshe concerned the preparedness of high-school students for tackling the mathematical aspects of STEM courses in tertiary education. The second paper by Nelleke den Braber and et al centered on the value of mathematics for an inter-disciplinary STEM course.

The first paper within this theme concerned the high non-completion/dropout rates in STEM courses at tertiary level in Ireland. It was noticed that even students with good marks might struggle with the mathematical aspects of third-level science and engineering courses. Lave and Walshe therefore searched for other factors that might affect the preparedness of the students. They investigated the perceptions of three stakeholders, teachers, students and lecturers with questionnaires. They further aimed to clarify what teachers and students themselves currently understand by interdisciplinary STEM education.

Factors that were taken into account are,

- students have to know how to use math knowledge in other subjects;
- mathematics has to be taught in an integrated way;
- high-school teachers should teach with students' future third-level degrees in mind;
- teachers are unaware of the benefits of integration.

In the reaction, it was argued that an alternative explanation might be in how mathematics is taught. In this respect a reference was made to Freudenthal, who argued that mathematics should be taught as to be useful. He argued that, "In an objective sense the most abstract mathematics is without doubt also the most flexible. But not subjectively, since it is wasted on individuals who are not able to avail themselves of this flexibility" (Freudenthal, 1968, p.5). Another remark was that next to benefits of integration of STEM subjects, there are also costs. These concern sustained facilities at school level (time, funding, schedule, room), teacher commitment, professional development and teacher support (Gresnigt, Taconis, van Keulen, Gravemeijer, & Baartman, 2014).

The second paper elaborated on the value of mathematics in an interdisciplinary STEM course. The key concept in this paper was that of disciplinary perspectives. It was argued the problems we face in today's world in the context of STEM call for perspectives and knowledge from many different areas. Against this background the researchers tried to get a handle on the value of mathematics in the context of a successful interdisciplinary STEM course in the Netherlands. With open questions Nelleke den Braber and et al investigated how students and teachers think about the value of mathematics. They introduced a model for the value of mathematics for interdisciplinary STEM courses. This encompassed, an overall sense of what mathematics is, ways of working and thinking, modeling, reasoning and problem solving. This model was used to analyze answers of students and teachers on an open questionnaire. It showed that both teachers and students had little awareness of the value of mathematics as a discipline. If the students mentioned mathematics, it was mainly that it was used. It seemed that the role of mathematics was not really noticed by them.

In the reaction it was noticed that the value of mathematics appeared to be equated with its usefulness. Which appeared not to be the intent. It was further argued that in practice the use of mathematics by workers was limited. As the actual mathematical work would be delegated to experts or machines. Therefore, being able to communicate about the mathematics might be more important. Following Kaput (1997) it was further argued that one should understand the key underlying ideas and mechanisms. Freudenthal was quoted again to make a distinction between mathematical activity as “organizing subject matter in reality and organizing mathematical subject matter”. The latter seemed to be missing in the model of the value of mathematics. It was further noticed that Freudenthal would not be surprised about the lack of awareness of the role of mathematics. In 1977 he predicted that, “In 2000 mathematics will have been gone as a separate subject in education. Mathematics is there to be experienced, and lived, just like reading, writing, tinkering, drawing, singing, breathing, in integrated education.”

### **Product and STEM**

In this theme two papers were presented. The first one by Wohak and Frank revolved around the value of inverse problems in making students aware of the role of mathematics in applications. The second one by Bock, Bracke and Capraro aimed at such awareness but tried to realize this with product-oriented tasks.

The first paper made a case for the development of interactive, problem-oriented material for high school students, in order to make students see the potential of mathematics for solving real life problems. The example in the paper concerned so-called inverse problems. The concrete case being the problem of computer tomography. Computer tomography is used to establish the internal structure of an object—such as a human body—on the basis of the entry and exit intensity of the X-ray radiation. The objects are irradiated with parallel beams at different fixed angle settings, and the challenge is to infer the structure of the object from the patterns of the imprint the X-ray make after passing through the object. This is an inverse problem as it is the inverse of predicting what the imprint would be when the structure of the object is known. Where the latter is rather straightforward, the former is complex and not always possible as small variations may cause big errors. Wohak and Frank show that the mathematics for solving a simplified version of this type of problem is doable for high school students. They argue that by working on this problem, students will come to see the potential of mathematics to solve real-life problems.

One of the points of critique was on the strong focus on the mathematical solution of the problem. It was argued that today mathematics is done by computers and that the remaining mathematical work resides in the translation of the practical problem into a mathematical problem. It was further noted that there was little attention for the capabilities that are needed for mathematical modeling. In this respect the detailed list of capabilities that the PISA Mathematics framework offers (OECD, 2017) was mentioned.

The second paper focused on product-oriented modeling. The starting point being the task of making a product brings with it unique characteristics—which are lacking in school problems. For, the success criteria are dictated by whether the solution is actually working and feasible, often decisions have to be made, and restrictions apply. Two product-oriented modeling tasks were discussed. Both were aiming at showing the usefulness of Fourier analysis. The first concerned the

task of making a musical fountain. Two sub-groups decided not to solve the original task but focused on loudness & rhythm instead. So, there was no need for Fourier analysis. One sub-group did find mathematical techniques to smooth the highly irregular amplitude-time-function. The other sub-group worked on an algorithm that could find an underlying rhythm in a song. The second task involved building a light organ. Here also two sub-groups emerged. One worked with electronic frequency filters, and thus did not need Fourier analysis. The other group wanted to use mathematics and was supported in using Fourier analysis (in a piece-by-piece manner).

One of the questions that was brought up by the discussing was whether the students of the last group really understood the Fourier analysis in terms of the underlying concepts and mechanisms. Further similar remarks could be made about the intended use of Fourier analysis as were made on the reverse-problems paper. In this case, however, part of the students was involved in translating practical problems into mathematical problems. As was the case with the loudness and rhythm-problems. Doubts were expressed about the feasibility of upscaling such projects.

### **Engineering design and mathematical modelling processes**

Three papers were presented in this thematic area. The first paper by Abou-Hayt, Dahl and Rump concerned with the exemplification of the integration of the engineering design process (EDP) and the mathematical modelling process in two university students' projects. Abou-Hayt, Dahl and Rump used the characteristics of engineering design process (Tayal, 2013) and mathematical modelling process (Blomhøj & Jensen, 2003) to analyze the projects. Their conclusion was that the both processes were visible in the projects. This paper led to raising some further questions: What is the sign for showing student learn best when they are actively participate and apply theory?; What is students learning in this context?; How is the interaction between the lecturer and students?; How can we compare traditional and this form of teaching outcome?; and What is the meaning of mathematics in abstract and real world?

The second paper by Costa and Domingos elaborated on the development and the implementation of mathematical interdisciplinary task related to STEM integration, in the context of a collaborative Continuing Professional Development (PD) Program targeted at primary school teachers. Costa and Domingos concluded that a PD program can only be successful if teachers can implement the task developed with their students. The following questions led the discussion regarding to this paper: What is the meaning of STEM integration in the context of a collaborative Continuing Professional Development Program targeted to primary school teachers?; How can teacher educators help teachers to develop mathematical interdisciplinary tasks related to STEM integration? Are they different for prospective teachers' education and in-service teachers?; What are the expectations from the teachers while developing mathematical interdisciplinary tasks related to STEM integration?; What are the expectations from the teachers while implementing mathematical interdisciplinary tasks related to STEM integration?; How could different types of knowledge and skills regarding the integration of STEM be promoted in pre- and in-service teacher education?

In the third paper, Ubuz used the characteristics of EDP outlined by Berland, Steingut, and Ko (2014) to analyze the curriculum learning outcome of a Technology and Design course offered to 7th grade students in Turkey. By identifying the most common verbs and objects contained within the learning outcomes of the curricular documents guiding the 7th grade course, Ubuz found that 23

of the learning outcomes contained EDP knowledge and 29 of them concerned EDP skills. The conclusion is that the EDP knowledge and skills recommended by Berland et al. (2014) are largely present in the 7th grade curriculum. Ubuz suggests that these findings can help teachers integrate similar EDP knowledge and skills in science and mathematics curriculum in middle school.

### **Design research**

A paper by Pugalenth, Stephan, and Pugalee was presented in this thematic area. This paper sought to capture the students' conception of angles and parallel lines in order to design engineering context based instructional sequences for middle grades (7th grade) mathematics classroom. This research was comprised of a pre-interview to assess the existing conceptions of angles and parallel lines, design and implementation of engineering-based instructional sequences and a post-interview to assess the changes in conceptions of angles and parallel lines. This research paper, however, focused mainly on the analysis of the pre-interview questions dealing with angles and parallel lines along with preliminary discussion of the design of the instructional sequence regarding designing a residential community. The students' conceptions of angles and parallel lines were traced under three themes: Prototypes or reference images, tracing of the lines, and decoupling versus decomposing. This paper leads to raising some further questions: What is mathematical instructional task with an engineering problem?; How the difficulties identified could be prevented through mathematical instructional tasks with an engineering problem?; How mathematical instructional tasks with an engineering problem let to dive deeply into a topic and use mathematics to create a solution?; How the difficulties identified do lead us to develop mathematical instructional tasks with an engineering problem such as designing a residential community?; How could the mathematical difficulties identified be prevented through designing a residential community?; What is effective STEM integration?; How could we provide training or prior skills regarding engineering content and principles to the teachers?

### **Statistics in STEM**

Under this theme one paper was presented. The paper written by Oliveira, Henriques, and Batista dealt with the preservice teachers (PT) perspectives about the role of statistics in a learning scenario with one 8<sup>th</sup> grade class, fostering the integration of physics and statistics. It was claimed that successful STEM integration depends on teachers' perspectives and their competence to choose learning materials which are suitable in this context. Previous studies showed that teachers had a negative perception of STEM education based on the feeling that they were unprepared to teach within an interdisciplinary curriculum.

The data (group lesson plans and PT's reflections regarding planning and enacting learning scenario) were analysed with a focus on the dimensions of the model of *authentic integration* (Treacy & O'Donoghue, 2014): Application to real-world scenarios, high order thinking processes, and knowledge development, synthesis and application. According to the paper the PTs concluded that the mathematical content (in this case statistics) was not only incidental to the STEM context, but had a great centrality in the learning scenario. Mathematics did not only appear in the sense of calculation methods, since high order thinking processes took place that were supported by statistics. Furthermore, the role of technology, in this case with statistical software, was pointed out. The collaboration with colleagues of other subjects was perceived as beneficial for the PTs.

Questions raised during the discussion were: If teachers gain experience with interdisciplinary classroom activities, do they perform better in a future approach, even if the topic is different? Is it a lack of knowledge from other disciplines or rather a lack of experience that makes teachers feel underprepared?

### **Approaches to introduce STEM**

In this theme two papers were presented. Both had in common that they used game-like structures to enhance the students' motivation in their particular learning environment. One paper written by Viamonte and Figueiredo was about gamification in an e-learning tool for university students. In that paper dropout rates as well as the personal opinion of the students who used the e-learning tool were examined. A significantly lower dropout rate compared to earlier years could be measured, which supports the claim that gamification can be used to stimulate motivation. Also, the students' responses concerning the competitive elements seemed to confirm the expected influence, although not all reactions of the students had been positive. The issues raised to be discussed were:

- Although the statistical data concerning dropout rates show a significant impact, it could be possible that there are effects involved that can't be measured easily (e.g. a new teaching concept increases motivation, but the effect decreases over a longer period of time). One could think about examining further iterations, maybe with slight variations.
- Similarly, could the effect be decreasing if gamification was used in a broader extent (i.e. not only one lecture, but all lectures the students attend during the same semester)?
- The data are probably not representative for the whole university population. The participants were engineering students only, and furthermore most of them (93%) were male. Is it possible to transfer the conclusions to a broader range of students?

In the other paper written by Abboud, Hoppenot, and Rollinde a classroom situation was analysed, where students experienced the orbits of astronomical objects from our solar system in a role-playing activity. The aim was to enhance activity theory (Abboud et al. 2018; Vandebrouck 2012) by the notion of bodily perception. Several implementations of the Human Orrery project were analysed qualitatively with questionnaires and interviews. It was suggested that participating students experience STEM-related concepts from an emotional perspective and describe them as "more real". With regard to this paper the issues raised to be discussed were:

- How can we measure the impact of bodily perception on the motivation at a quantitative level?
- How is it possible, after a certain STEM-related concept was experienced in this framework, to have a smooth transition to a more theoretical approach to the topic? This might be interesting when working with older students.

### **STEM teacher preparation**

In this theme, one collaborative team consisting of mathematics and physics educators from Vietnam and Germany aimed to create a teacher preparation program that invited mathematics and physics teachers to participate in classes that utilize both theoretical and practical aspects of teaching these two disciplines. The theoretical part would provide opportunities for physics and mathematics teachers to compare and contrast epistemological foundations of each discipline,

thereby illuminating the differences and similarities in the mathematics and physics. In particular, teachers would explore the meaning and practices of *modelling* from mathematics and physics perspectives. These theoretical foundations would then support teachers to create lessons that potentially integrate physics and mathematics that they would then use in their classrooms. Although the project is still in development, Krause and et al intend to videotape the implementation of these lessons by project teachers and determine to what extent physics teachers focused on mathematics in their class and how much mathematics teachers integrated physics into their class. The critical issues raised by this paper harken back to earlier papers in which questions about the extent to which modelling from different disciplines can be mutually supportive. It also calls to the forefront what it means to genuinely integrate science and mathematics. Finally, the crucial problem that Krause and et al attempt to solve is how to design appropriate instruction for teachers who are knowledgeable about physics and mathematics separately so that they are knowledgeable about the means of integrating the two.

### Critical issues

We would like to close our introduction by including some critical issues that the participants expressed during the sessions.

- Experts within and across the STEM disciplines model for different purposes and, thus, in different ways; given this diversity of modeling, how do we characterize modeling in STEM?
- Teachers are not experts in all STEM disciplines. In the real world, there is also no such thing as a STEM expert. Rather, discipline-specific experts are invited into a project when there is a need for their expertise. This implies that teachers should work collaboratively to design and implement STEM units. Does this change the goal of STEM education from *STEM integration* to *STEM collaboration*?
- How do we design curriculum so that mathematics is not just a tool for doing the other three content areas? And what is really meant by technology use in curriculum?
- What kinds of research experiments are needed to understand STEM education? While creating nice STEM lessons has potential, there is a need to go beyond studies that make claims about the success of these lessons that are based upon one student. Rather, future research on effective STEM curricula should involve collective student learning.

*We present in this paper an innovative approach to introduce STEM topics in the classroom through the context of the Solar System. Our pedagogical tool consists in a Human Orrery modeling at a human scale the Solar System dynamics. While learners walk along planetary orbits, they enact different mathematical and scientific notions. Previous experimentations were centered on science concepts and have shown an enhanced motivation and well-being and a better understanding. We discuss here the connection with the cognitive science theory of enactivism and with the activity theory, both already used in the field of mathematics education. New pedagogical sequences are proposed that deeply combine mathematics and science contents. Those will be set up in a classroom context before the CERME conference.*

*Keywords: Astronomy, enactivism, instructional innovation, STEM education.*

## Introduction

STEM literacy is a crucial issue for European educational policies today as emphasized by successive trans-European studies since the Rocard report (2006). Numerous difficulties have been revealed by science and mathematics education researchers in knowledge acquisition of scientific notions of movements, velocity, proportionality and functions. Many of them arise from the gap between children's sensorial or everyday life experiences and the abstract scientific explanations.

The study presented in this paper explores the use of astronomy to teach mathematics and physics. We consider that astronomy should not be taught and considered in education science as an independent subject but as a specific application of general laws of physics and of application of mathematics concepts. The European ROSE project (Sjoberg & Schreiner, 2010) has shown that the subject that interests both girls and boys was found to be life outside earth. We confirm in our experiments that the study of the Solar System motivates students to do sciences, while a large number of mathematical subjects may be easily introduced through the observation and understanding of planets' motion. The tool that we use to this purpose is a Human Orrery modeling at a human scale the Solar System dynamics in ways that can enhance the learner's perception of mathematics and physics concepts in a real world apparatus.

In the following sections, we will provide a description of this tool and its affordance and the potentials within a STEM approach. We will also present our theoretical frame and the outcomes of first preliminary experiments. This background presentation enables us then to introduce a large scale project in progress and to give some examples of settings that are being currently designed in order to be implemented, observed and evaluated in several European countries.

## The Human Orrery

An Orrery is a mechanical instrument showing circular orbits of the planets. The first Orrery to be created at a human scale was done in Japan (Dynic Astropark) and then at the Armagh Observatory (Asher, Bailey, Christou, & Popescu, 2007). The design of a Human Orrery is made such that users may walk along orbits of different bodies around the Sun that is located at the center of the design. The Human Orrery that we use is printed in a large map of 12m by 12m (see Figure 1). It allows one to follow the orbits of the inner planets (Mercury, Venus, Earth and Mars) and Jupiter; the inner planets are located inside the asteroid belt that is materialized with a grey color together with the orbit of the largest asteroid known, Cérès. The highly eccentric orbits of two comets are also used: Encke (the smallest elliptical orbit) and Chury. This choice of objects illustrates different type of movements while keeping the size of the Orrery reasonable. Earth is at one meter from the Sun, while Jupiter's orbit has a diameter of 10,5m. The orbits of all bodies are materialized by dots at constant intervals of times, with accurate elliptical shapes. Note that, orbits are near-circular for the five planets and Ceres.

**Figure 1 – Left: The map of the Human Orrery (inner planets and one comet only, see text for details). Right: Pupils walking along the different orbits up to Jupiter.**

The interval of time may be different for each orbit, but is always a multiple of 16 terrestrial days: For Earth, there are 23 dots separated by 16 days, which would make a period of 368 days. For Jupiter, there are 54 dots separated by 80 days, which makes a period of 4320 days instead of the real period of 4332,59 days. A sound (either a clock or hand claps) is heard regularly. The interval of time between two sounds corresponds to 16 terrestrial days. Every user makes one step during this time interval. Then, the person that enacts Earth walks from one point to the next (distance) in one step (duration), while “Jupiter” has to do five steps (five times 16 days) to reach the next point. All rules are described in details in Rollinde (2017). By acting according to those rules, the movements on the Human Orrery illustrate the correct relative velocities of all Solar System bodies.

Both constructing and enacting on Human Orrery involve topics from mathematics and science and enhance a STEM approach of scientific notions usually perceived as abstract concepts by students. We shall discuss in more details the use of the Human Orrery and its future perspective for STEM education after a discussion of the theoretical framework underlying this innovative pedagogy.

## Theoretical framework

The use of a Human Orrery in education is based on the assumption that bodily perceptions help the learning of abstract concepts. In other words, “abstract symbols used in formal education—words and syntax in reading, numbers and operators in math—need to be grounded in bodily experience”

(Glenberg, 2010). In the context of the Solar System, the objects under scrutiny can neither be touched nor seen directly in the classroom, duration is very long, and very little is expected to happen in the classroom situation. By physically enacting the objects and their movements, the situation changes completely: dynamic properties are revealed and experienced; the invisible and impalpable acquire a certain degree of “palpability” allowing learners to deeply understand them as walking along the Human Orrery.

The cognitive science theory of enaction (Varela, Thompson, & Rosch, 1991) may provide a theoretical foundation to those assumptions. Torrance (2005) describes enactivism as the nature of the mind, defined by its relation to the world: “(...) the organism’s world is “enacted”, brought forth by sensorimotor activity: world and organism are co-determined, they co-emerge. [For the mind], awareness of its self and of its world is a central feature of its lived embodiment in the world.” Transposed into Mathematics Education (we refer the reader to the review by Reid, 2014), enactivism theory has been used successfully, for example to explain the emergence of formal mathematical thought from pre-mathematical experiences in the course of a lesson sequence on three-dimensional geometry for 6-year-old children (Roth, 2011). Similarly, in the context of a numerical sequence, Radford (2014) shows that, “through an intense interplay between various sensorial modalities and different signs, the students’ perception and the concomitant mathematical thinking have gained a theoretical dimension that they did not have before”. More generally, learning can be facilitated to the extent that lessons are created that map to and activate sensorimotor systems (see for example Johnson-Glenberg, Megowan-Romanowicz, Birchfield, & Savio-Ramos, 2016 in the context of digital platforms).

This line of argument may sound contrary to early researches in science education that rather tend to show that our observations and interactions with the world often produce naïve conceptions in conflict with formal physical laws (e.g. Hestenes, Wells, & Swackhamer, 1992). Difficulties in knowledge acquisition in science seem to arise from the gap between children’s sensorial experiences and the abstract scientific explanations. We make here the assumption that it is necessary to promote a “mindful attention to perception” (Varela et al., 1991). In the context of the Human Orrery, our goal is to build a complex learning world filled by metaphors: a simple map becomes the empty interplanetary space; series of dots become the elliptical structure of an orbit; peers become planets with different velocities; duration is heard while distance is felt... The Human Orrery (a human-scaled technological object) acquires a meaning through the learner’s cognition and his/her mindful perception of this world and thus activates new cognition.

To theoretically ground our observations, analyses of teaching and learning within the Human Orrery context we plan to make use of Activity Theory as used today in Mathematics education (Abboud et al., 2018; Vandebrouck, 2012). Roth and Jornet (2013) acknowledge that original works on Activity Theory by “Soviet social psychologists explicitly ground their ideas in theories in which thinking, acting and environment are part of the same analytic unit.” Indeed, the Activity Theory, in particular the notion of subject-object interactions mediated by an instrument enables to study the activities of subjects (teachers and learners) using tools (the Orrery itself but also the set of technological tools involved) and their impact on the processes of learning physical and mathematical concepts at stake when experiencing the Human Orrery. Yet, current use of Activity Theory in education does not

mention the role of bodily perception. “Mental processes (speaking, thinking, reading or writing) need to be understood in terms of complex ecologies: neuromuscular and physiological processes AND cultural historical origin and nature” (Roth & Jornet, 2013). Our intention is thus to work towards an “Embodied Activity Theory” which would be a framework adapted to our research and that would develop over time in a dynamic interaction between analyses of data and design and use of theoretical tools.

## **Outcomes from first experiments**

The main use of Human Orrery in the literature has been the introduction of astronomy in open schooling contexts (e.g. Asher et al., 2007; Francis, 2005; LoPresto, 2010). Since 2014, our team focuses on the use of a “human Orrery” to learn science rather than astronomy only in different pedagogical context, from primary school to University. Through our initiative, seven Human Orreries were built in France (one for a science center, one in a public place in Paris, five in primary or secondary schools), one was drawn in a Lebanon school and one map was purchased by a science center in Vietnam. Human Orreries are used thereafter by different teachers (physics, mathematics, technology and sports) in those seven places plus about five other schools who use our trap only. Questionnaires and interviews were used to quantify the amount of learning and the students’ motivation. The sequences are discussed and improved after each application. They have also been used in teacher education for two years, and may be obtained upon request to the authors. More details on these first experiments and derived conclusions as described here may be found in Rollinde (2017).

The implemented sequences have focused on the one side on the motivation and interests of the learners and on the other side on specific scientific notions. Among the key concepts introduced through the Human Orrery are kinematic ones. The embodiment of duration and length allows to alleviate the confusion related to the use of those concepts in the common language. The manipulation of those two concepts to compute the velocity requires to deal with three variables, which is known to be source of cognitive overload. As an example, almost every groups express a confusion between large velocity and small orbital period, or between small period and small perimeter; they all reduce the reasoning to a simple comparison between two variables. The enaction is expected to lighten the abstract mathematical task by providing diverse sensory-motor experiences as proposed in the sequence described in the next section. Additional difficulties encountered regularly include: the Moon that cannot be seen given the scale used (she would be behind the disc of the Earth); the confusion between 24h and one year for one orbital period of Earth (which is strengthened by the 23 dots used for the orbit of Earth); the very low speed of Jupiter is also a source of astonishment. Comments made by undergraduate students actually showed their surprise that so much may be learnt with this tool. For instance, one student declares: “There was joy, emotions. Here, it is wonderful what is going on’. She continues then: ‘Universe is not made of mathematics numbers and equation of physics, this is something else, and it has to be understood in another way.’” Another student suggested that “illustrating a concept with a movement makes it more real. We feel that we live it.”.

## **Project and examples of settings**

The authors of this paper aim at incorporating more STEM contents into future works. We propose in the following an example of such settings, that we are currently designing, tackling the study of

speed's meaning and proportionality factor. More examples could be given particularly concerning the construction of the Human Orrery and associated mathematical notions at play, but this goes beyond the scope of these proceedings.

### **A detailed enacted sequence on speed**

In the science class, speed is understood as the length of a displacement for a given time unit (e.g. year or second). This sequence will provide a way to enact three concepts (time, distance and speed) using bodily perceptions and tools. In the mathematic class, speed is understood as the proportionality factor in the relationship between distance and duration. Ayan and Bostan (2018) have shown that proportionality relationship is often approached by superficial characteristics of the problems, namely the monotonous relation expected between two variables, and lack clear, quantitative, arguments. Modestou and Gagatsis (2010) express the metacognitive aspect that underlines the awareness of (non)-proportionality and may explain this lack of coherence in reasoning about proportionality. There is thus an obvious need for a renewed approach to proportionality and speed.

The sequence we designed uses the Human Orrery, a clock that sounds regularly (each sound is called a clap) with a given tempo, blue ropes and red ropes and markers (to materialize different positions along the ropes). There are four stages: (i) Enaction of space and time while walking freely on the Orrery under spatial and time constraints. (ii) Following a right planetary walk to enact different displacements for different durations. (iii) Enaction of the speed of the planets and the proportionality relationship. (iv) Determination of the speed of the planets (optional). The first two stages can easily be implemented in primary school; the second two are more adapted to lower secondary school.

### **Enact space and time**

The initial proposed goal is to invent a coherent way to walk on the Human Orrery. The action is then to walk, while focusing on two perceptions: looking and hearing. The students' task explained by the teacher may be: "you have to find a way to walk coherently while accounting for dots on the map and claps. At the end, you will have to explain your choices." We expect that different rules may be proposed. For instance, each step should last the duration between two claps or each step should go from one dot to the next one, whether the students focus on what they hear or what they see. According to the rules proposed, we seek for answers to questions such as: Are they going to make a connection with speed too? Are they going to use local rules (their steps only) or global rules (the entire orbits or their relation with each other)? Are they going to describe what they are doing or global observations (who is going faster or when to end)? All those possible and expected actions (or wording here) will be useful to understand what is enacted and how.

According to the effective actions, different proximity-in-action (Abboud et al., 2018) may be foreseen to ensure coherence among the group. The students' activity could either remains on a minima level e.g. by proposing to focus on one set of dots that follow one orbit or at on a maxima level, e.g. by going faster or slower and to propose different ways to use the rhythm or the dots

### **Enact the planets' movement**

The first action will probably end up with different solutions for a coherent walk. In the process, most learners should have noticed that the drawing is related to the Solar System. The teacher confirms

and describes the different orbits. The learners want to know and understand their own role in this planetary walk. The next goal is then to measure their movement while walking as planets.

The associated task requires organisation and mathematical skills: “You will work by groups of 3. Each group chooses either Earth or Jupiter. You start to walk when you hear one sound and continue to walk until you hear “n” additional sounds. You must then find a way to show to the entire class the length of your displacement in order to compare or combine the different measures”. The number “n” is explicitly given but is different for each group. For Earth, some group will work with 3 claps, some with 7 claps. For Jupiter, some will work with 5 and some with 9. Those numbers are chosen so that none is a simple combination of others by the use of addition, in order to favour the use of multiplication later on. To achieve this task, each group has a rope (blue for Earth and red for Jupiter) and markers that can be attached to the rope.

Due to the complexity of the task (follow the rules, do not measure the line but the circular length, keep record of the measured length for comparison), specific proximity-in-action are required to go through it. First, every group has to respect the planetary rules. Then, the length of a circular displacement will be measured with the rope and some markers. For groups that have completed the first task, the teacher may propose to measure the distance while starting from another point in the same orbit or to do the same measurement for another orbit with a different rope. It is important to ask them to walk and measure simultaneously, in order to enact the displacement together with the duration.

### **Enact the proportionality relationship between length of displacement and duration**

To keep the learners focused on the subject of planets, the next goal is directly related to planets while the action will be made on ropes only. By this shift, the reasoning is made slightly more abstract. The required task is not a physical action but a reasoning one in order to answer the question: “how do the speeds of Jupiter and Earth compare?” This may sound like a simple task if it was a simple account of what they have played. Indeed, it is to compare the speed of Jupiter and Earth during the planetary walk. To avoid this shortcut, the teacher asks for a material, or visual, proof using the ropes. This reformulated task becomes complex and fully associate science and mathematics skills and concepts.

A first prediction may be searched for: How should the length of the rope of the faster planet compare to the slower one (a minima)? Such a comparison requires using a common duration, or the same number of sounds. This is our first sub-task. Let’s call N the common number of claps associated to this common duration. N may be equal to 10 (this number may be obtained with the available lengths through the sum of 7+3 for Earth and the product 2 times 5 for Jupiter).

The next sub-task is then to derive the length that would have had the rope of the two planets for this common duration. The teacher proposes then to measure the length of the displacement after one clap only. To realise this task, one has to divide the rope in N parts and then use the ruler... or use the ruler for the full length of the rope and divide by N!

### **Enact a non-proportionality relationship**

Exposing learners to a non-proportional situation is a way to face the well-known bias of proportionality and to encourage students to develop a critical mind. The Human Orrery provides us

with an interesting situation: the case of a comet. Unlike the planets' orbits which are near-circular, the orbit of the comet Encke is a highly eccentric ellipse. During the movement on its orbit, the speed of the comet varies strongly: learners have to make either very large steps near the Sun or cannot even put one foot between two dots far away from the Sun. This usually creates either laugh or stress but never leave the learners insensitive in that case, duration and travelled distance are thus related monotonously, but are not proportionally linked. Using the same methodology as for Earth and Jupiter, learners will discover that the length of the rope measured for different initial position and different duration is not proportional to the duration.

The examples of pedagogical sequence that we presented above are the first of a set of settings that will be designed and implemented in several countries and in different cultural contexts as part of a European project we are currently setting up. We note that activities on the Human Orrery may also be used as an introduction to more formal mathematical activities; for example, on the derivation of Kepler laws using power laws and interpolation or on the understanding of Newton laws using differential equations.

## Conclusion and perspectives

The perspective that we adopt in our project is that of STEM being taught through an interdisciplinary approach that incorporates an embodied dimension and draws on real-world modeling. The use of the Human Orrery enables students to enact or “experience” scientific concepts and the dynamics of their properties by evolving in an adapted environment. Until recently, we only focused on the dissemination of Human Orreries and on a proof-of-concepts in terms of motivation and interest. Different sequences have been co-constructed by teachers and researchers and have led to preliminary positive results on learning too. The current dynamic of the project is to motivate more classes from different levels and teachers from subjects other than mathematics and physics such as art, technology, music, languages (native or foreign), physical education and sport. In 2018-2019, four additional classes have decided to join the project in France: two primary schools in the context of interdisciplinary projects and one secondary school through a project on Mars involving science and technology. At the European level, we are expecting to submit a H2020 project involving research in mathematics and science didactics together with science centers (museum, observatories and associations). Our next objective is then to design sequences that fit into the STEAM approach and that will be used as experimental situations for the theoretical framework of enactivism, complemented with the framework of Activity Theory in the context of science education. Our focus will be as much on the didactical learning as on the motivation and awareness of the learners during the activity.

# Integrating the methods of mathematical modelling and engineering design in projects

Imad Abou-Hayt,<sup>1</sup> Bettina Dahl,<sup>1</sup> and Camilla Østerberg Rump<sup>2</sup>

<sup>1</sup> Aalborg University, Denmark; [imad@plan.aau.dk](mailto:imad@plan.aau.dk), [bdahls@plan.aau.dk](mailto:bdahls@plan.aau.dk)

<sup>2</sup> University of Copenhagen, Denmark; [cr@ind.ku.dk](mailto:cr@ind.ku.dk)

*In this paper, we show how an integration of the engineering design method and the mathematical modelling method can be applied in engineering. This is exemplified through two student projects in the first-year modules ‘Dynamics and Vibrations’ and ‘Models, Mechanics and Materials’, which are compulsory in the Sustainable Design engineering programme at Aalborg University, Denmark. We first describe and discuss the definitions of the two methods and argue that they have many similarities and that the differences appear to vanish once they are combined in an introductory engineering project. We argue that when students experience how the two methods are applied in a project, they may develop a better holistic understanding of the problems they may encounter as future engineers. They are thus better equipped to solve future real-life problems by having applied mathematics and engineering sciences as integrated activities.*

*Keywords: Engineering design, mathematical modelling, problem-based learning.*

## Introduction

One of the major functions of design engineers is to solve problems for the society in which they live. Design engineers work on products and systems that involve adapting and using engineering and mathematical techniques and they usually work with a team of engineers and other designers to develop conceptual and detailed designs that ensure a product works and is suitable for its purpose. In this paper, we will describe and discuss an example of how the engineering design process, mathematical modelling, and problem-solving activity are integrated through introductory first-year projects in the Sustainable Design engineering programme at Aalborg University (AAU) in Copenhagen, Denmark. Underlying the example is an assumption that by combining the engineering design process and the mathematical modelling process in an engineering context, students will be much more prepared to tackle the real-life problems that they might encounter in their future profession as engineers.

As we will show in this paper, the integration of the two methods conforms to the method of Problem-Based Learning (PBL) that AAU has adopted since it was founded in 1974. As argued by Kolmos, Holgaard, and Dahl (2013), there is not one single AAU PBL model, but nevertheless, the programmes at AAU are all organized around shared PBL principles described by Barge (2010) and Askehave et al. (2015). These principles are problem orientation, project organization, integration of theory and practice, participant direction, a team-based approach, and collaboration and

feedback. The students therefore work in teams on open problems and the work includes all the steps from problem identification and problem analysis to problem solving. PBL is thus a student-centred learning method that uses real problems as a stimulus or starting point for the acquisition and integration of new knowledge. The teacher acts as an initiator and facilitator in the collaborative process of knowledge transfer and development. Parallel to the projects, the students also undertake modules which typically follow a more traditional style with lectures and exercises. The major characteristics of PBL projects include adaption to students' *prior* knowledge and experience, *integration* of knowledge, and teaching in relevant *contexts*.

The purpose of this paper is to show how to integrate the teaching of mathematics and engineering mechanics within the framework of PBL in order to enhance the students' understanding of both subjects as well as to introduce them to real-life situations, where the real problems they meet are mostly combinations of engineering, technology, and mathematics. When working on such problems in the real world, engineers, designers and applied mathematicians work together as a team to create new products. We aim to “transfer” these situations to the classrooms so that the students can develop an early acquaintance with the “real thing”. This requires carefully designed teaching scenarios that help make both mathematics and engineering interesting to learn.

The main research questions of this paper are therefore: Can we design didactical situations that integrate mathematics and engineering mechanics through design projects that resemble practical problems? Is it possible to teach mathematics in connection with engineering courses so that the students can capture the essence of both subjects through design projects? To answer these questions, we investigate mathematics teaching through design projects, using mathematical modelling as a didactic tool. The problem that we address here is the lack of interest in mathematics courses among engineering students (Härterich et al., 2012). This issue may eventually lead to poor understanding and performance on engineering science courses that depend on the mathematical concepts taught in traditional mathematics modules. The significance of the paper is therefore that it suggests a method that might solve this problem by offering teaching experiments that integrate some real-life problems with some central concepts in engineering mathematics. The aim of the student projects is to make mathematics more interesting for engineering students and to improve their understanding of engineering and mathematics courses.

## **The processes of mathematical modelling and engineering design**

### **Mathematical modelling as a design process**

Mathematical modelling is used in a variety of disciplines. A mathematical modelling competence is considered central in both engineering and mathematics education. When doing mathematical modelling, a part of reality is encoded into a set of mathematical rules and equations. There are in fact many “models” or descriptions of the mathematical modelling process. Due to page restrictions, we show only one example of such a model (Blomhøj & Jensen, 2003). The one chosen was developed for use in education and is thus relevant. Every mathematical modelling process must begin with a problem or an observation, which is a process that fits well with a PBL project which also starts with open problems that require a solution. The problem can be either a well-defined physical question requiring a mathematical solution or a loosely described technical

problem requiring a solution but with no obvious choice of mathematical model. However, since a mathematical model is an abstraction and mathematics itself is an abstract discipline, the starting point of the modelling process is to decide which aspects of the “real world” to observe and which to ignore.

The mathematical modelling process is as creative as the engineering design process, as engineers need to model devices and processes if they want to design these devices and processes. Just like the design of a certain product, a model of a specific physical situation may be good or bad, simplistic or sophisticated, aesthetic or ugly, useful or useless, but a model or design cannot be considered true or false. A mathematical model is therefore designed to correspond to a prototype, which may be a physical, biological, social, or psychological entity or yet another conceptual one. According to Tayal (2013), the engineering design process is a sequence of steps that a designer takes to go from identifying a problem or need to developing a solution that solves the problem or satisfies the need. If we just replace the words “design” and “designer” with “modelling” and “modeller”, we arrive at a definition of mathematical modelling that is close to the one described above by Blomhøj and Jensen (2003). The engineering modelling process is therefore the set of steps that a modeller takes to go from first identifying a problem or need to ultimately creating and developing a solution that solves the problem or meets the need. Thus, the two processes have *identical* objectives and, in fact, can be broken down into a series of *similar* steps, as seen in Table 1. The table constitutes the theoretical framework of this article. Both processes are different from the scientific method although they also have some things in common. As argued by Dowling, Carew, and Hadgraft (2013), the two processes begin with an open task, but while the engineering process begins with a problem or a need, the scientific method begins with a question. Furthermore, engineers look for suitable solutions while scientists look for suitable hypotheses to answer the question, that is, ultimately some generalized knowledge. Thus, engineers create new products using a more pragmatic modelling approach in which the models are convenient approximations to specific parts of reality.

**Table 1: A comparison of the modelling and design processes**

<b>The mathematical modelling process</b>	<b>The engineering design process</b>
<b>1a)</b> Begins with a problem	<b>1b)</b> Begins with a problem
<b>2a)</b> Select relevant objects, relations, and data and idealize these	<b>2b)</b> Do background research to define suitable criteria and constraints for problem solution
<b>3a)</b> Translate the objects into a mathematical representation	<b>3b)</b> Specify requirements for solutions
<b>4a)</b> Use mathematical methods to arrive at results	<b>4b)</b> Evaluate the solutions against the criteria. Are there alternative solutions?
<b>5a)</b> Interpret the results in relation to the initial question	<b>5b)</b> Choose a suitable solution and build a prototype
<b>6a)</b> Evaluate the model	<b>6b)</b> Make recommendations; test and redesign as necessary
<b>7a)</b> Communicate the results	<b>7b)</b> Communicate the results

The table shows that the mathematical modelling process and the engineering design process are quite analogous. Below, we design two teaching situations that can provide some justification for Table 1 as these situations integrate mathematics and engineering mechanics in realistic design projects.

### Mathematics in an engineering context: An example

The study of differential equations has always been a major part of the mathematics curriculum in engineering education. This is expected as many engineering problems involve equations that relate the changes in some key variables to each other. Therefore, differential equations are used to investigate a wide variety of problems in sciences and engineering.

Below we present a classical problem from engineering dynamics that illustrates the use of Table 1 in differential equations, specifically second-order differential equations. The mechanical system is shown in Figure 1. Besides being a standard textbook problem, it is also seen in real-life problems such as modelling the suspension system of a car or the vibration of a wind turbine blade. Such real-life problems fit a PBL education model well as they can be quite open and can thus be approached by a problem-based strategy. At the same time, they also fit the framework shown in Table 1, as items 1a and 1b in Table 1 indicates that the starting point is a problem. The problems require analysis and simulation before a solution is reached. The analysis and simulation can be identified as items 2–5 for both processes in Table 1:

- Create the idealization and formulate constraints (items 2a and 2b)
- Encode the system into mathematical language, specify the requirements (items 3a and 3b)
- Solve the resulting equation(s) and check the results (items 4a and 4b)
- Interpret the results and build a prototype (items 5a and 5b)

To apply Table 1, we begin by assuming constant parameters for the spring and the damper (items 2a and 2b). Using Newton's second law, the mechanical system can be described by the second-order linear differential equation with constant coefficients (items 3a and 3b):

**Figure 1: A mechanical system**

$$m\ddot{x} + b\dot{x} + kx = f(t) \quad (1)$$

Here  $x(t)$  is the position of the mass  $m$ ,  $b$  is the damping constant,  $k$  is the spring constant, and  $f(t)$  is the force applied on the mass. The students have already completed a mathematics module involving *linear* second-order differential equations. The purpose is to illustrate the different solutions of Equation (1) by changing the values of the constants  $b$  and  $k$ . By plotting the response

$x(t)$  for some chosen values of  $b$  and  $k$  (items 4a and 4b), students can see the different behaviours of the system and gain a better understanding of the underlying mathematics of the mechanical system, thus accomplish items 5a and 5b. To choose appropriate values of  $b$  and  $k$  requires that tests and a redesign be carried out, thus accomplishing items 6a and 6b. It is therefore pedagogically sound to base the teaching of *linear* second-order differential equations on systems whose behaviour students *already* intuitively understand. This illustrates that PBL, through working with open problems, can help the students achieve a better understanding of mathematics by using mathematical modelling as a didactic principle in teaching engineering mechanics and mathematics itself through the process illustrated in Table 1. Finally, the students accomplish items 7a and 7b through communicating the results to their peers and teachers as part of the module.

The students' ability to solve linear differential equations by using standard methods or formulas is therefore insufficient to understand fully the link between the mathematics learned and the other modules and projects. Students may eventually ask how we know that the parameters of the spring and the damper are constants. There are typically two different answers, we can give the students:

- Real springs and dampers have approximately linear behaviour.
- By assuming constant parameter values for the spring and damper, we can use the standard methods to solve linear differential equations, as we have a complete theory of linear differential equations, and not, e.g., a complete theory of *nonlinear* differential equations.

These answers can, however, be disputed by the fact “almost all systems are nonlinear to some extent” (Hilborn, 2000). Besides, many of the student projects in which the first author was involved as a supervisor involve nonlinear phenomena. However, as the students were only introduced to linear second-order differential equations in their mathematics module and are still in their first year of study, we will at this point assume linear behaviour of the systems involved.

## Mathematical modelling in action

### Model of a Lego van and a caravan: Example 1

In a project in the second-semester module “Dynamics and Vibrations” for the Sustainable Design engineering programme, the students should construct a mathematical model of the popular van and caravan playset by the Danish company Lego. In the context of Table 1, the problem of the project is to determine the response of the caravan if the van moves on a straight road with a constant acceleration  $a$ . This corresponds to items 1a and 1b in Table 1. Ideally, the caravan should follow the *kinematics* of the van as closely as possible. The project can illustrate the use of PBL as a framework in teaching an engineering mechanics module, where mathematics and mechanics are integrated in a realistic project through the process of mathematical modelling. The PBL project thus conforms to Table 1, as it starts with a problem that requires mathematical tools to arrive at acceptable results. A simplified model of the system is shown in Figure 2. Many students immediately see the similarity of this concrete system with the ideal one in Figure 1: The constant acceleration of the van gives rise to a constant force on the caravan. Some also realize that the *flexible linkage* between the van and the caravan can be *modelled* as a spring and a damper.

**Figure 2: A model of the Lego project**

If we let  $x_1(t)$  and  $x_2(t)$  denote the positions of the van and the caravan respectively, Newton's second law (Hibbeler, 2017) leads to the differential equation of the model:

$$m\ddot{x}_2 + b(\dot{x}_2 - \dot{x}_1) + k(x_2 - x_1) = 0 \quad (2)$$

As the van's acceleration is constant, we have  $\dot{x}_1 = at$  and  $x_1 = \frac{1}{2}at^2$ , where the initial conditions are assumed to be zero. Equation (2) can finally be written as

$$m\ddot{x}_2 + b\dot{x}_2 + kx_2 = abt + \frac{1}{2}akt^2 \quad (3)$$

Comparing Equations (3) and (1), the students see that  $bat + \frac{1}{2}kat^2$  corresponds to the force  $f(t)$ . We are led to a second-order non-homogeneous differential equation where the unknown function is  $x_2(t)$ . This is exactly the type of differential equation, which the students have met in their mathematics module; they now meet it in an *engineering context*. Thus, Table 1's items 2a, 2b, 3a, and 3b are now satisfied. The students now see an old friend in action! Thus, we anticipate that this will offer some justifications to the students in answer to their eternal question "Why do we need to study differential equations?" in the context of their experience.

### Student simulation of the model

The students were given the values  $m = 0.50$  kg and  $a = 1$  m/s<sup>2</sup> for which they ran a simulation of the model for two different combinations of the spring constant  $k$  and the damping constant  $b$ :

- $k = 10$  N/m and  $b = 0$  (no damping)
- $k = 10$  N/m and  $b = 0.50$  N · s/m (with damping)

The students used MATLAB to plot the position  $x_2(t)$  of the caravan in the two cases (Figure 3).

**Figure 3: Response of the caravan. Left: no damping; Right: with damping**

The case without damping obviously leads to an unacceptable model of the system. In contrast, the presence of damping ensures a smooth response of the caravan. Many students now realize why a damper should be included as a part of modelling the linkage, even though it is not out there! Thus, by changing the value of  $b$  (and of  $k$  for that matter) we get two different *designs* and *that* will result in two different mathematical *models*. By referring to items 4 to 6 for both processes in Table 1, we see that these are accomplished, as we are testing the models and comparing designs. The design process and the mathematical modelling process are therefore closely related to the extent that, in real-life engineering practice, separating the two processes would not be easy. It is therefore artificial to separate modules in mathematical modelling and engineering design in teaching situations, as engineering programmes ought to correspond to and be compatible with realistic situations that the future engineers might encounter.

### The connection between mathematical modelling and engineering design: Example 2

To further illustrate the relation between the mathematical design process and the engineering design process, we mention here an example taken from a project by the first author introduced in the first-semester module “Models, Mechanics and Materials”. Briefly, the problem is to find the internal forces in the three cables of the hanging lamp (see Figure 4) and to redesign it if possible. The students themselves should provide realistic values for the weight and dimensions of the hanging lamp. They should also measure the lengths and diameters of the wires. The students should first make a model of the hanging lamp and then try to redesign it. This is an open problem with several solutions.

**Figure 4: A hanging lamp**

The modelling process consists of writing the equilibrium equations of the lamp using statics. The students discovered that they could not find the internal forces in the three wires: They got two equations with three unknowns. By arriving at an indeterminate system of equations, the students then had a justification for why the middle wire was *redundant*. Some other students added the extra equation using deformation theory in the topic of strength of materials. In that way, they could determine the internal forces in the three wires by writing them down in matrix form. Changing the geometry and materials of the wires (i.e., design) leads to another system of equations (i.e., a new model). Other students chose to remove the middle wire, thus arriving at a consistent system of equations with a unique solution. Thus, the design the students choose will affect the mathematical model of the lamp. Conversely, the mathematical model of the lamp will influence its design and redesign. Here, we can see that the items of each pair in Table 1 interact together in a fusion process to produce a solution to the problem. The main purpose of this course project is to relate topics from mathematics, specifically matrices and linear equations, to engineering mechanics and materials in

the framework of Table 1. We believe that through these kinds of course projects, mathematics teaching will be more motivating for the students, so they can see the relevance of the mathematical topics they encounter in their study programme.

## Discussion and conclusion

In the paper, we have used Table 1, which incorporates the engineering design and mathematical modelling processes as a theoretical framework for two student projects. The items in the table can be identified in the processes the students go through in two design projects. Here we also saw that the items in both the mathematical modelling process and the engineering design process became visible. We believe that this identification strengthens the argument that *engineering* mathematics should be taught in *an engineering* context, through well-designed teaching situations that allow engineering students to work with real-life problems. As stated in the introduction, design engineers work on projects that involve adapting and using engineering and mathematical techniques, and *in reality*, these are intertwined. We also believe that this strategy can be generalized to other situations where STEM integration is involved.

# Mathematics and art in primary education textbooks

Teresa F. Blanco<sup>1</sup>, Valeria González-Roel<sup>1</sup> and Jose Manuel Diego-Mantecón<sup>2</sup>

<sup>1</sup>University of Santiago de Compostela (USC), Spain; [teref.blanco@usc.es](mailto:teref.blanco@usc.es)

[valeria.gonzalez.roel@rai.usc.es](mailto:valeria.gonzalez.roel@rai.usc.es)

<sup>2</sup>University of Cantabria, Spain; [diegojm@unican.es](mailto:diegojm@unican.es)

*Keywords: Mathematics, primary education, school textbooks, STEAM, visual arts.*

## Introduction

This research aims to analyze how the relationship between art and mathematics is established in the Spanish primary education. We analyze the art-mathematics connections in school textbooks, as this is the educational tool most widely used by teachers. In recent years, the educative community has become increasingly aware of the impact of modern art on society and the emergence of new forms of artistic expression. In fact, official documents promote interdisciplinary learning through a STEM approach that incorporates the creative and aesthetic dimension of Art into the so-called STEAM education. According to Holland (2017) students who follow a learning process based on STEAM develop creative skills, becoming better problem solvers and critical thinkers. The Spanish curriculum (MEC, 2014) specially connects Mathematics and Visual Arts. The Mathematics curriculum emphasis a competency-based learning grounded on the applicability of mathematics into daily life contexts, and aiming to connect this subject with the science, technology and art disciplines. Similarly, the Visual Arts subject offers a valuable opportunity to interact with other school subjects in particular, with mathematics (Brezovnik, 2015), through the analysis of different art forms including drawing, painting, sculpture, and photography (Freedman, 2003).

## Method

The present study was undertaken under a documentary analysis approach (Bardin, 1991), adopting a simplified version of Diego-Mantecón et al.'s (2018) framework which lays down six dimensions that we turned out into four: (1) the use of 'artistic representations' and 'mathematical objects' with an *ornamental purpose*; (2) the use of art and mathematics as *a context to carry out activities*; (3) the use of art as a way of *learning mathematical concepts* and the use of mathematics to *illustrate artistic concepts*; and (4) the *creation* of art through mathematics. The data were collected from a purposive sample of 72 Mathematics and 24 Visual Art school textbooks, being the one most often used in the Spanish primary education. The textbooks analyzed cover all six years of compulsory primary education (6 to 12 years old). Textbooks were released between 2009 and 2015. The analysis focused on identifying 'artistic representations' (e.g. sculpture, drawings, and mosaics) and 'mathematical objects' (e.g. identification of types of lines and proportion relations) in the Mathematics and Visual Art textbooks and analyzing how the art-mathematics connection is established in the textbooks.

## Results and conclusions

As Figure 1 shows, the analysis revealed that in both the Mathematics and Visual Arts textbooks the ornamental dimension (1) prevails (81,18% in Mathematics and 40,74% in Visual Arts Education textbooks) over the remaining dimensions. In Mathematics textbooks Art works fundamentally as a purely illustrative and decorative element, without any reference to the name of the artistic work nor to its author. In Visual Arts textbooks, Mathematics plays a more active role, expanding part of the artistic content with geometric concepts and measurement procedures which contextualize the exercise (39,81%, contextual dimension (2)). In Mathematics textbooks, this dimension has one much lower percentage (16,85%). By other side, in Mathematics and Visual Arts only 5,94% and 13,89% respectively of the artistic manifestations and mathematical objects are included in the conceptual dimension (3). Creative dimension (4) is non-existent in Mathematics textbooks, and it has a very limited presence in the Visual Arts books (15,74%).

**Figure 1: Percentage of dimensions in textbooks**

From this, preliminary results, we can conclude that the textbooks analysed do not reflect the art-mathematics connection, at the level suggested in the Spanish curriculum.

# Mathematical modeling of musical fountains and light organs

## – where is the M in interdisciplinary STEM projects?

Wolfgang Bock, Martin Bracke and Patrick Capraro

Technische Universität Kaiserslautern, Department of Mathematics, Germany;

[bock@mathematik.uni-kl.de](mailto:bock@mathematik.uni-kl.de), [bracke@mathematik.uni-kl.de](mailto:bracke@mathematik.uni-kl.de), [capraro@mathematik.uni-kl.de](mailto:capraro@mathematik.uni-kl.de)

*We discuss a modeling project, in which students have to build a device that acts simultaneously to music – either a musical fountain or a light organ. We show how the incorporated university level mathematics can be reduced to the level of secondary education. Being product oriented, the modeling activity has a strong interdisciplinary character. We focus on two implementations of the project with high school students and discuss their results. Here we draw the attention to the role of mathematics in a STEM project, where the presence of programming and engineering seems more obvious than the mathematical content.*

*Keywords: Interdisciplinarity, modeling, product orientation.*

### Introduction

Some of the most important real-life applications of mathematical modeling we find in engineering and related activities, where products are developed and improved. At the university of Kaiserslautern industrial mathematics plays an important role in research and teaching. It also had an influence in mathematical modeling activities with high school students (see Bock & Bracke, 2015). In these cases, the process of mathematical modeling is closely connected to the product that should be developed.

In Kotler et.al. (2006), p. 230, the term *product* is defined from an economical point of view as “anything that can be offered to a market that might satisfy a want or need”. Hence a product can take various forms, it can be a device that is actually being assembled, it can be a computer software or just the answer to a question. Here the production process closely affects the modeling activity. Even a sophisticated mathematical model has its flaws, if it can’t be applied in the desired situation or if it doesn’t solve the given problem adequately. Furthermore, the more production steps are needed to advance from the mathematical model to the product, the more impact the production process has on the mathematical model (compare to Bock, Bracke & Capraro, 2017).

Product oriented mathematical modeling immediately calls for high interdisciplinarity and involves all aspects of STEM, especially if the product is not only a theoretical concept, but the implementation of the solution actually takes place (Bock, Bracke, Capraro & Lantau, 2017).

In our technology driven world, complex computations can easily be done by computers and other electronic devices. Often there is no need for the programmer (or engineer) to know all the details of the involved mathematical tools. Here the question arises, if product oriented mathematical modeling and engineering in general can be done with a minimum of mathematical activity (see also Tosmour-Bayazit & Ubuz, 2013).

Here we present a modeling project, in which students have to build a musical fountain or a light organ. Both projects contain similar mathematics at a university level (Fourier analysis), which can be hidden in numeric tools and used by students with a basic mathematical knowledge at a secondary school level. The project has a strong interdisciplinary character, since programming is essential for data processing, and building a working model of the product or at least creating a simulation is requested.

We have a look at two implementations of the project. We find that even if the computer is used in a large extent, there still are enough mathematical challenges for students.

## The modeling task and mathematical background

The students are given the task of modeling the regulation of a musical fountain or a light organ (both lead to similar mathematical problems). The students get a short introduction in a programming language to be able to read audio files and get access to the raw data. Furthermore we teach basic ideas of Fourier analysis to enable the students to compute frequency spectra and analyze them.

```
from scipy.io import wavfile
from scipy.fftpack import fft
import matplotlib.pyplot as plt
import math
import numpy as np
[Fr,g]=wavfile.read('test.wav')      #Fr=frame rate, g=sample data
if(len(g.shape)==2):                #if stereo, combine the channels
    channel1=np.array(g[:,0])
    channel2=np.array(g[:,1])
    g=channel1+channel2
G=fft(g)                             #Fourier transform
p=plt.plot(abs(G))                  #plot sqrt(A_n^2+B_n^2)
plt.show()
```

**Listing 1:** A code example in python. The program reads a wav-file and plots the frequency spectrum.

Fundamental is the Fourier series, that states that a  $T$ -periodic function  $g$  (with certain conditions to integrability or Lipschitz-continuity) can be decomposed to a series of trigonometric functions

$$g(t) = A_0 + \sum_{n=1}^{\infty} A_n \cos(2\pi n f t) + B_n \sin(2\pi n f t), \quad f = \frac{1}{T}, \quad (1)$$

where the coefficients  $A_n$ ,  $B_n$  give the amplitude of the corresponding frequency  $nf$ . By the orthogonality of trigonometric functions, we can derive formulae for the coefficients

$$A_n = \frac{2}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} g(t) \cos(n2\pi f t) dt, \quad B_n = \frac{2}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} g(t) \sin(n2\pi f t) dt. \quad (2)$$

From this the Fourier transform (3.1) arises, which gives the frequency spectrum  $G$  of the function  $g$ . If we process the data  $g$  on a computer, it isn't given as a function but rather as a vector with finitely many entries. In this case we have the discrete Fourier transform (3.2), where the integral becomes a sum

$$G(f) = \int_{-\infty}^{\infty} g(t) \exp(2\pi i f t) dt, \quad (3.1) \quad G_m = \sum_{t=1}^n g_t \exp\left(\frac{2\pi i}{n}(t-1)(m-1)\right). \quad (3.2)$$

Two more results about discrete Fourier transform are substantial when the spectra are going to be interpreted. For a data vector  $g$  with  $n$  real valued entries, we have  $G_m = G_{n+1-m}^*$ , i.e. the second half of the spectrum is just a (complex conjugate) copy of the first. Furthermore, we have the sampling

theorem, which states that for a data sample  $g$  with frame rate  $Fr$ , the spectrum can be computed for frequencies up to  $Fr/2$ . For a data set of  $n$  samples, the value  $G_{n/2}$  corresponds to the frequency  $Fr/2$ .

## Breaking down Fourier analysis to high school level

Fourier analysis involves mathematical concepts that are located at the final years of high school education or even at university level, like integrals, complex numbers and convergence of functions. Nevertheless, if we see Fourier analysis as a numerical tool, the barriers to implement it in school are quite low. Fourier transform can be introduced as a black box. Certainly, for all well known programming languages there already exists an implementation of the code and that's all we need to know. On the other hand, if there is enough time to do so, the discrete Fourier transform (equation 3.2) can easily be understood and applied as soon as the students know the concept of trigonometric functions.

## Understanding overtones and the Fourier series

The Fourier series is strongly connected to instruments and the concept of overtones: If we play a tone on an instrument, we do not only produce the fundamental frequency  $f$  of the tone itself, but also overtones with frequencies  $2f$ ,  $3f$ ,  $4f$ , etc. From a mathematical point of view this is obvious, since acoustic waves are represented by periodic functions. The period of the acoustic wave is the same as the period of the fundamental frequency. Hence the overtones do not disturb the pitch of the observed tone.

**Figure 1: The frequency spectrum of a violin. The fundamental frequency is 440 Hz. The peaks around 0 Hz are possibly due to edge effects or noise.**

The characteristic sound of an instrument is strongly determined by the relative intensities of these overtones. This real-life phenomenon can be used as a motivation to understand and use the ideas of Fourier series.

If the students do not know the concept of overtones, we could create and analyze frequency spectra (e.g. by playing tones on instruments, recording them and using computer software to obtain the spectra, compare to Fig. 1). The pattern in the graphs that are created could motivate a further investigation of the mathematical concepts behind. This could also be the starting point for an interdisciplinary project between mathematics, music and physics classes.

## How to deal with complex numbers?

Fourier transform involves complex numbers and the complex exponential function. As we know, the exponential function with imaginary exponent decomposes in real and imaginary parts with trigonometric functions and real valued arguments. Hence, we have the interpretation, that the vector entries in  $G$  take 2-dimensional real values

$$G_m = \left( \sum_{t=1}^n g_t \cos\left(\frac{2\pi}{n}(t-1)(m-1)\right), \sum_{t=1}^n g_t \sin\left(\frac{2\pi}{n}(t-1)(m-1)\right) \right). \quad (4)$$

The intensity of the frequency represented by  $G_m$  is then given by the length of the vector.

### Deriving formulae for the Fourier coefficients

Equation (2) is a consequence of the orthogonality relations of trigonometric functions

$$\int_{-\pi}^{\pi} \cos(nt) \cos(kt) dt = \int_{-\pi}^{\pi} \sin(nt) \sin(kt) dt = \begin{cases} \pi, & n = k, \\ 0, & n \neq k, \end{cases} \quad \int_{-\pi}^{\pi} \cos(nt) \sin(kt) dt = 0.$$

Older students who know the concept of integrals can prove these identities. The basic idea is to use integration by parts two times, until right hand side and left-hand side show the same integral (with a prefactor and an additive constant).

With equation (2) the definition of the Fourier transform can easily be understood. Hence in this case there is no need to see the Fourier transform as a black box tool or a formula given by the teacher without any theoretical background.

### Sampling theorem

If the students are using a discrete Fourier transform to obtain frequency spectra, they surely will encounter two questions: Why is there an axial symmetry in the spectrum? And how can we read the frequencies on our axes? To answer these questions, we can give the students the above mentioned results about the Fourier transformed data vector  $G$ . A quantitative discussion why these results are true is omitted due to the complexity of the involved mathematics.

### Two examples for interdisciplinary modeling projects

In Kaiserslautern, mathematical modeling activities involving acoustic phenomena have been implemented in various situations with high school students and university students. Here we present two cases.

#### Modeling of a musical fountain with a time frame of 15 hours

This implementation was done in August 2018 with 6 high school students who participated at a *Fraunhofer math talent school for girls*. The participating students (upper secondary level) came from different schools in Germany and worked on 4 different projects at the *Fraunhofer institute for industrial mathematics* in Kaiserslautern. The students had the opportunity to vote for their preferred projects. In the musical fountain project 5 of 6 students told us that they had a strong connection to music (all 5 played an instrument) and therefore chose this project. Also, the sixth student voted for the project as her first choice. Some of the students had programming experience, some of them didn't. The group was supervised by two university members.

There were 4 working phases (3 hours each) at the first two days. At the third day, there were 3 hours for preparation and execution of the presentations. Due to the restricted time frame, the students were given selected mathematical input at the beginning of the course.

*First working phase:* Introduction to Fourier analysis (frontal instruction); reading audio files and plotting spectra with python (frontal instruction and exercise); after a strongly teacher driven

opening, the students had the chance to create audio files and analyze them with python or other computer software, like audacity. They did this in groups of 2 students.

*Second working phase:* The students were asked to develop mathematical criteria that could be used for the regulation of the fountain, but had no further instructions. They chose to stay in the previously formed groups and analyze different aspects of the graphs they could create (group work). After first ideas were established, an additional programming course in python was given (frontal instruction and exercise).

*Third working phase:* The ideas of the second working phase were implemented in python code. Some ideas were dropped, others could be improved. One group found mathematical techniques to smooth the highly irregular amplitude-time-function, another one worked on an algorithm that could find an underlying rhythm in a song.

*Fourth working phase:* It was discussed, if the students wished to build a real-life model of a small fountain with 4 solenoid valves. The students preferred to do a computer visualization of their mathematical results instead. The students used the remaining time to further develop their python code and to decide how their result should be used to regulate the fountain. They also started to work on the visualization.

*Presentation day:* The students had 2 hours to prepare their presentations and finish the work on the visualization of the fountain regulation. Each of the 4 project groups had 15 min. for their presentation.

In the simulation, the analyzed song and the visualization of the processed data were replayed simultaneously. It became apparent that the data and the perceived sound matched adequately.

**Figure 2: Loudness of a song vs. time. The students wanted to use *increasing and decreasing loudness* to control the fountain. Since the irregularity of the sample data caused problems, they found methods to smooth the data (left: first iteration of the smoothing process, right: second iteration).**

### **Modeling of a light organ with a time frame of 5 days**

The light organ was one of 8 projects at a mathematical modeling week in February 2018. At a modeling week the students (upper secondary level) spend 5 days at a youth hostel and work on their own responsibility for 4 days (from 9 am to 18:30 pm with several breaks for lunch and coffee as well as an excursion on one afternoon). On the 5<sup>th</sup> day the presentations are given.

The students can choose their preferred project. There were 4 students working on the light organ. They chose the project with different motivations, concentrating on different aspects of STEM. They were supervised by one university member and by 2 teachers. For the teachers, the participation was part of a teacher training.

With a rather generous time frame, the projects at the modeling week are open to a great extent. The students were asked to build a light organ that would work without a microphone. Instead they should get the data directly from the electronic device, where the song is played, or use digital information. They were provided with electronic components such as a Raspberry Pi, Arduino microcontrollers, LEDs, cables, resistors, etc.

One of the students immediately took the initiative and started to work on his idea of building electric circuits that would work as frequency filters. He started with some first experiments involving the Arduino microcontroller and the question how to record the audio signal. The other students helped him but didn't participate in the creative process.

During the last hours of the first day the group experienced a crisis: 2 of the students were unsatisfied with the progress that was mainly based on ideas from physics and electrical engineering. Both wanted to focus on mathematical and computational aspects of the project. They discussed their ideas with the supervisor. Together a solution was worked out that would be based on the audio information that is stored in music files. From this point on the students worked on two different solutions.

At the second day, the students with the mathematical and computational focus asked for some mathematical background about frequencies. They were given the same information as in the musical fountain project. Only this time not as frontal instructions, but rather in a *piece by piece* manner. The students were given some mathematical input and had the chance to do some experiments or online research. When they asked deeper questions, they received further details.

**Figure 3: The light organ. The yellow LED is controlled by the loudness, the RGB LED by the frequency-spectrum.**

Later they were able to implement a Fourier transform in python and run the program on a Raspberry Pi. At this point the students worked on 2 tasks simultaneously, one improving the python program, the other controlling an RGB LED on the Raspberry Pi. Questions to the supervisor were mainly about the involved programming languages and the operating system of the Raspberry Pi. At the end, they could split a piece of music in time intervals, compare the intensity of different frequency intervals and assign color and brightness of the LED to the frequency values.

From a mathematical point of view, the students had to deal with problems related to esthetical questions: How should the frequencies be assigned to different colors, such that the light effects won't be too monotonous? If the brightness of the lights is going to be related to the loudness of the music, which level of loudness should be defined as 100%? Are these thoughts independent of the music

genre? Is it sufficient to analyze the song locally (i.e. each time frame individually) or do we need global data?

To questions like these there is no right answer, but rather a wide range of possible approaches. Here mathematical experience helps us to give a structure to our problems and quantize the vague questions asked above. Mathematical skills help us to evaluate the information that is hidden in the given data

The other group with the focus on electrical engineering worked almost without supervision. Their main problem was the lack of capacitors with a suitable capacity. This could be solved when one of the supervising teachers asked at a nearby school if she could borrow some material.

In this group mathematical activities took place on a rather basic level, e.g. when the students had to choose the threshold of their frequency filters and compute the resistance and capacity of the electric components that were needed.

### **Misconceptions of the students about algorithms and computers**

When confronted with a subject that most people know very well from their everyday life (like music in our case), the students come up rather quickly with interesting ideas. Some of them are based on the misconception that computers can do complicated tasks on their own, while the programmer doesn't need to fully understand the situation.

In the musical fountain project, there were ideas about recognizing different instruments in the music or finding certain patterns in the rhythm automatically. Those tasks are difficult to implement in an algorithm. The students were surprised how complicated their mathematical model had to be to find a quite simple rhythm in their song (and they didn't even elaborate further steps to make the algorithm work for arbitrary music). In the light organ project, similar situations took place.

The project clearly helped the students to get a better idea of what algorithms are capable of and where the limitations could be. One of the main consequences in the project was that if we want an automated solution to a problem we have to provide a detailed mathematical description.

### **Conclusion**

Using acoustic phenomena in terms of mathematical modeling is a rich field for interdisciplinary activities. It naturally includes physics and music. The link between both topics we find in Fourier analysis, where concepts of music theory, like overtones, become obvious in the mathematical description of waves.

Computer science (or rather programming) is not only helpful, but essential to manage huge amounts of data and extensive computations. Technical aspects can be included by posing a product oriented problem. Hence all aspects of STEM can be addressed.

If all calculations are done by computers, one might fear that the mathematical aspects of such a project will only appear in theory lessons, but won't be applied by the students. In our examples, we have seen that there still is a strong potential to include mathematical aspects that go beyond the computational part. The raw data could be in a bad state for data processing (compare to Figure 2), where elaborate mathematical ideas are needed to overcome the problems. On the other hand, like

in the case of the light organ, assumptions have to be made and decisions have to be taken, where an intuitive evaluation of the given data is necessary.

Of course, with a modeling task that is openly posed, there always is the possibility that students find another way of solving the problem. One part of the light organ group used a completely technology based approach, where no mathematics beyond basic arithmetic was needed. On the other hand, from our experience it is essential to let the students choose their approach with the least amount of regulation. Otherwise, if the teacher tries to force certain solutions and mathematical tools, this could have a devastating impact on the students' motivation.

This can lead to serious difficulties for the teacher, since he or she must be able to adapt the ideas of the students quite fast and try to figure out possible outcomes or obstacles for an approach that wasn't considered beforehand. If this new approach requires expert knowledge from another discipline, either the teacher has to have that knowledge (or acquire it fast enough). If this isn't the case, the teacher must be confident that the students can work on their solution relying on their own expertise (why would they have chosen this approach if they don't have any knowledge about the topic?). Additionally, not knowing all the details of a solution for a given problem is an unfamiliar situation for most teachers. It requires a certain amount of self-confidence to let the students proceed anyway.

## Acknowledgements

The close collaboration with the Fraunhofer Institute for Industrial Mathematics as well as the financial support of the European Social Fund for the modeling weeks are thankfully acknowledged.

### **The I SEE ERASMUS+ Project**

The EU ERASMUS+ project I SEE (inclusive STEM Education to enhance the capacity to aspire and imagine future careers) stems from the awareness that one of the main challenges for mankind today, above all for the young, is to recover a good relationship with time, merely with the future. We live in a multi-speed society in which the capacity to predict sudden changes are decreasing and this causes a compulsive search for opportunities. The educational system is not able to keep up with social acceleration. This project bet on STEM education as a breeding ground for preparing young people for uncertainty and making them developing future scaffolding skills, i.e. skills that enhance their capacity to aspire, envisage themselves as agents of change, and push their imagination towards future careers in STEM (Branchetti, Cutler, Laherto, Levrini, Palmgren, Tasquier & Wilson, 2018). STEM education can give two main contributions in this direction, one epistemological and the other technical. From the epistemological point of view, the issue of uncertainty related to future predictions is intrinsic to science: the perspective of complexity values uncertainty and probability as sources of a non-deterministic and non-linear paradigm which opens horizons of possibilities, instead of a unique inescapable path and ground the discourses about possibilities on a rational basis. On the technical side, STEM disciplines investigate potentialities, limits and applications of innovations in the present, hypothesizing their possible impact on the future; this enlarges students' and teachers' imagination towards future challenges and careers.

### **The structure of I SEE modules and the case of Artificial Intelligence**

Among the results of the first two years of research within the project, there are concrete teaching/learning modules for high-school, already tested in real contexts with 18-19 years old students. Although the issues addressed are very different (e.g. climate change, artificial intelligence, quantum computing), all the modules have a common structure in which the students are encouraged to: i) encounter the focal issue; ii) engage with the interaction between scientific ideas and future; iii) synthesise the ideas and put them into practice (Branchetti et al., 2018). The design and implementation of the Italian module about Artificial Intelligence (AI) were carried out by a team of researchers in Mathematics, Physics and Informatics education, together with high school teachers and experts in engineering, applied physics, epistemology of science and complex systems. The students encounter the focal issue thanks to a group activity, about AI applications in many fields, and two seminars, about: i. the relationship between AI and complexity science; ii. the history of AI. In the second phase, they are showed different approaches to AI (imperative,

logical/declarative, machine learning) applied to the Tic-Tac-Toe game; then, they are introduced to applications of AI in STEM research and to the future-relevant concepts of complexity (system, feedback, projection, scenario, non-linearity, agent/model-based simulations). In the last phase, students are involved in group activities about the imagination of a future ideal city, more or less influenced by AI, and are asked to design actions to do in the present with an eye to desirable futures, thinking about future careers, also in the STEM fields.

### **STEM analysis of the I SEE module on AI: Integration and “Big Ideas”**

Since the project aims to propose guidelines and examples of inclusive and future-oriented STEM education, we wondered what aspects of our research could be relevant for contributing to the emerging debate about how STEM education should be conceived and concretely realised. As framework we chose the STEM “big ideas”, defined as key ideas that link various discipline understandings into coherent wholes, mediating the construction of in-depth knowledge (Chalmers, Carter, Cooper & Nason, 2017). We analysed our module separating its S-T-E-M components, discussing their integration and searching for different kinds of big ideas underlying it (encompassing, cross-disciplines, and within-disciplines big ideas).

The STEM disciplines are all included and structurally integrated within the module, since the topic allows to show the dialectic relationship between the technology/engineering and pure scientific/mathematical issues. Mathematics is relevant, not only in terms of concept and methods technically necessary, but also of thinking tools and skills. As content encompassing big ideas, we recognised AI and Future. As conceptual encompassing big ideas, we identified paradigms like linearity/complexity or practices like problem posing and solving. The cross-discipline big ideas we used are the concepts like algorithm, which are transversal to the STEM domains. There also within-disciplines big ideas that have an application in the other disciplines, like cost function, which is a mathematical optimization concept relevant to other STEM disciplines.

### **Results and conclusions**

The main results of our analysis are three: a) the lens of the “big ideas” is effective to flesh out the connections among the S-T-E-M disciplines within our module on AI; b) the analytic separation of the contributions of the different disciplines and the search for their integration allows to emphasise the specificity of each of them; c) our module can be considered an example of a meaningful integration between disciplines, with STEM “big ideas” connecting them.

## Introduction

A growing number of studies and reports, all over the world, refer to the importance of integrating Science, Technology, Engineering and Mathematics (STEM) in order to meet the increasing challenges of the 21<sup>st</sup> Century (Baker & Galanti, 2017; Rocard et al., 2007). In addition, integrative approaches among STEM subjects have positive effects on student attainment, with better results in elementary school (Becker & Park, 2011). In particular, “Integration of mathematics with Science, Technology and Engineering (STE) provides students with the context in which they can make meaningful connections between mathematics and STE subjects” (Becker & Park, 2011, p.25).

This paper aims to contribute to research by presenting an empirical study about the development and implementation of mathematical interdisciplinary tasks related to STEM integration, in the context of a collaborative Continuing Professional Development Program (CPDP) targeted to primary school teachers. In this regard, our research question is: how to promote the teaching of mathematics in the framework of STEM integration? In our STEM integration framework, we refer to tasks related to all the STEM subjects, i.e., tasks that integrate Science, Technology, Engineering and Mathematics. In these tasks, we intend to emphasize Mathematics. Based on the case study of a

primary teacher, who participated in the CPDP, we analyse the STEM tasks designed and implemented by the teacher.

## Literature Review

Despite the increasing calls for the promotion of STEM education, there is no agreement about a definition. In this regard, Baker and Galanti (2017) refer that the academic community “struggle to define STEM integration” (p. 2). For example, several authors refer to STEM by only integrating two disciplines (Ríordáin, Johnston, & Walshe, 2016; Treacy & O’Donoghue, 2014). Concerning this matter, Stohlmann (2018) refers different interpretations of several authors and claims that mathematics should be more emphasized in STEM integration. In this sense, STEM education can be a form of innovation for teaching mathematics (Fitzallen, 2015) and to increase mathematical performance (Stohlmann, 2018).

However, despite relating STEM subjects has been widely advocated by several authors, there is lack of research about STEM integration and there is a need for more empirical research about this subject (Becker & Park, 2011). Also, there is the need to develop research to understand how STEM integration can promote mathematics education (Baker & Galanti, 2017). In particular, there is lack of research about science and mathematics integration (Treacy & O’Donoghue, 2014), mainly concerning in-service teachers (Ríordáin et al., 2016).

Kim and Bolger (2017) sustain the creation of a curriculum that integrates STEM, being crucial to involve teachers into interdisciplinary lessons adequate to this approach. In this regard, there is the need to promote their Professional Development (PD) by providing mentoring and support to face the multiple challenges related to sustainable STEM pedagogy (Baker & Galanti, 2017). Also, resources are crucial for teachers and they shape them according to their individual preferences, this being a process of interpretation and design of the resources (Pepin, Gueudet & Trouche, 2013). For Gimeno Sacristán (2000), tasks are teaching and learning activities, carried out in school environments, being inserted into the curriculum in action. The way how tasks are introduced and conducted by the teacher in the classroom is essential for teaching effectiveness (Ponte, 2005).

To improve teaching and learning, it is crucial to develop a partnership between researchers and designers, in order to develop appropriate pedagogical approaches to integrate tasks in the classroom (Geiger, Goos, Dole, Forgasz, & Bennison, 2014). Also, it is fundamental to create a network that motivates teachers and contributes to the sustainability of their professional development (Hewson, 2007; Rocard et al., 2007). A PD program will only be successful if teachers can apply in their classrooms what they learned and experienced during training (Buczynski & Hansen, 2010). In fact, a PD only achieve real effects if innovation is appropriated by the teachers and transformed into their own practice (Zehetmeier, Andreitz, Erlacher, & Rauch, 2015).

## Methodology

Based on the literature review recommendations, a partnership amongst university teacher’s educators, local schools and a *Continuing Training Centre* was established, in 2015, in order to develop a CPDP that is adequate to local primary school teachers’ needs (Costa & Domingos, 2017, 2018). With a total duration of 26 hours, the program lasts an entire school year (September to June)

and includes STEM related workshops with a 2-3 hours duration. By the end of each school year teachers present a portfolio with a critical account on the CPDP and their proposals and implementation of innovative practices. In this context, teachers may choose a science theme to develop in the classroom with their students by integrating with the other STEM topics. So far, more than 70 teachers participated in the CPDP from 2015/2016 to 2017/2018 school year.

In this research, we use a qualitative methodology and an interpretative approach by resorting to a case study. According to Yin (2005), a case study is an empirical investigation that looks at a contemporary phenomenon within its real-life context, allowing a generalization of the obtained results. Data collected include participant observation (first author of the paper is a participant observer) and portfolios compiled by the teachers (Cohen, Lawrence, & Keith, 2007). Participant observation takes place in the workshops with the teachers (to learn and practice what they are expected to implement) and at their classrooms (to support and observe them in action). When necessary, some semi-structured interviews are conducted to better interpret the case. In a first stage documental analysis was performed in teachers' portfolios in order to look for evidence of STEM contents. It was verified that most teachers chose astronomy or sound to implement in the classroom, and electricity is always at the bottom of their choices. This is the main reason why we decided to present the case study of Josefina (fictitious name) who chose electricity experiments to develop mathematical interdisciplinary tasks.

Teacher Josefina (42 years old, 18 years of service, in charge of a 3<sup>rd</sup> and 4<sup>th</sup> grade class) participated in the CPDP during the school year 2016/2017 and decided to conduct electricity experiments in her classroom with the educators help. The teacher's educators visited her class for two afternoons to observe and/or to help her implement some hands-on tasks. At the end of the CPDP, teacher Josefina (like all the other teachers) presented a portfolio with a critical account about the CPDP and documentary evidence of the activities that she performed with her students.

## **Data analysis, results and discussion**

In this section, we begin by analyzing the case study of teacher Josefina that shows the development and implementation of mathematical tasks within the context of STEM integration, in particular related to electricity.

### **Josefina's case study**

Based on classroom observations, semi-structured interviews and the teacher's portfolio, we realized that, in the first session, Josefina introduced the electrical current topic by calling students' attention to sustainable development using videos and information from the Internet. After, she asked the students to bring to class batteries that they had at home and that did not work.

In a second class, using the batteries, she asked the students to organise them according to their sizes and models (Figure 1). Next, they counted the different types of batteries and with this data, students produced graphics and diagrams, amongst other mathematical tasks.

In another class, with the educators' help, the teacher introduced concepts like potential difference (p.d.) and asked the students to verify if the batteries still had "energy" using multimeters. The students were organised in groups, and each group used a multimeter to measure the p.d. of each

battery. After measuring they registered the p.d. (in volts) in a table. The batteries with more p.d. were saved to be used in future hands-on experiments.

**Figure 1: Collection, organisation and processing of data from the batteries**

In a third session, teacher Josefina organised her students in groups of two or three, in order to implement several hands-on tasks. After training how to create electrical circuits to light one or two lamps (some of them used the batteries they saved in the previous class) the teacher decided to work mathematics. She gave a battery to each group and asked the students to measure and register the battery p.d. in volts (V). Then, she introduced biological batteries using fruit or vegetables and asked to measure their p.d., amongst other measurements (Figure 2).

**Figure 2: Potential difference and intensity measurements from fruit and vegetables**

The following excerpt of a dialogue shows how the teacher conducted the hands-on tasks using inquiry:

- Josefina: What is the potential difference (p.d.) of the orange?
- Student: It is 0,51 volts.
- Josefina: How much p.d. does the lamp need to light up?
- Student: It needs 1,5 volts. Look! It's almost the triple!
- Josefina: Then ... how many oranges do you need to light up the lamp?
- Student: Three.
- Josefina: If you cut the orange in two pieces, what is the p.d. of each piece?

- Student: It will be about half of the orange.
- Josefina: Cut the orange in two pieces and measure the p.d. of each piece!
- Student: No! It's not right! It gave almost the same as the orange!
- Josefina: Cut those two pieces in another two pieces and measure again! What do you think it will happen?
- Student: Maybe it will happen the same! Yes! The size of the fruit doesn't count!
- Josefina: Do you need three oranges to light the lamp?
- Student: No! Let's see ... I think three pieces are enough. Let's see what happens...It worked!

After an explanation and discussion about the experiments, the teacher continued the inquiry. Each group had different pieces of fruit or vegetables at their table.

- Josefina: Each group is going to choose different pieces of fruit or vegetable and measure its potential difference and give me the result!

While students told the results, the teachers registered them on the black board. After having all the results registered, she continued the inquiry:

- Josefina: Which is the fruit with the bigger potential difference?
- Student: The tomato!
- Josefina: Which biological battery has the least potential difference?
- Student: The mushroom!

The teacher continued asking questions while introducing the concepts. For another section, she created a worksheet to perform more mathematical tasks such as organisation and processing of data from the measurements obtained in the last class. She also created problems to be solved by students. The above dialogue shows that she was able to perform mathematical tasks from the hands-on experiments, in particular mathematical tasks in the framework of STEM integration.

Indeed, Josefina developed hands-on tasks based on concepts and procedures from mathematics and science while incorporating the design methodology of engineering and using appropriate technology (Shaughnessy, 2013). In particular, mathematics was worked in all the tasks, namely "Numbers and Operations" when students organized and counted the old batteries; "Geometry" when they organized the batteries according to their patterns and sizes and draw the different types of batteries; and "Data Organisation and Processing" when building tables to register and work the collected data from the batteries (Figure 1). Also, Josefina was able to introduce biological batteries and to teach the students to perform several measurements such as the p.d. in volts (V) and to develop the hands-on tasks using inquiry to lead the students to reflect on the performed experiments and discuss in order to obtain conclusions.

Concerning the way teacher Josefina introduced and implemented the tasks, we consider these are exploratory, investigative tasks. In this regard, students performed the tasks guided by the teacher who asked questions to lead them to search for answers. One example is related to the question "How much potential difference does the lamp need to light up?" and "Do you need three oranges to

light the lamp?” To answer the questions students developed several activities in order to understand and gain knowledge about this theme.

Table 1 shows the contents of the STEM tasks developed and implemented by teacher Josefina.

Table 1. Contents of the tasks implemented by teacher Josefina

Science	Technology	Engineering	Mathematics
Electricity.	Computer	Planning,	Measuring the p.d. of the batteries in volts.
	Internet	designing and	“Numbers and Operations” when students organized and counted batteries.
	Video	performing	“Geometry” when they organized the batteries according to their patterns and
	Multimeters,	electrical	sizes and draw the different types of batteries.
	Lamps, interrupters,	circuits.	Data Organisation and Processing” when building tables to register and work
	etc.		the collected data from the batteries.

Next, we present some excerpts of the teacher’s reflections that she wrote in her final report.

I was able to apply some new practices and methodologies in the context of the classroom, incorporating mathematics and science experiments (Josefina final report, June 2017).

The overall results of this training workshop are clearly positive: (...) enabled me to acquire / apply new knowledge in the context of the classroom (...); as well as collaboration including the sharing of good practices and the difficulties experienced (Josefina final report, June 2017).

In summary, teacher Josefina recognised that she gained skills to innovate her practices by highlighting the collaborative context of the CPDP. In addition, she developed exploratory, investigative tasks to work mathematics topics related to STEM.

## Final considerations

This paper aims to contribute to existing literature by presenting an empirical study about the development and implementation of mathematical tasks in the framework of STEM integration. To face challenges related to STEM integration it is recommended to develop an adequate teachers’ PD context (Baker & Galanti, 2017; Treacy & O’Donoghue, 2014), being crucial to provide a collaborative environment that supports the teachers to innovate their practices (Capps & Crawford, 2013; Costa & Domingos, 2017). According to Buczynski and Hansen (2010), a PD program will only be successful if teachers can implement, in practice, with their students, what they learned and experienced during their training. Also, Zehetmeier et al. (2015) sustain that innovations should be appropriated by those who implement them and transformed into their practice to have real effects. We believe this is what happened to teacher Josefina who designed and implemented interdisciplinary tasks that are not part of teachers’ traditional practices. In fact, Josefina was able to introduce commercial and biological batteries and to teach the students to perform several measurements such as the p.d. in volts (V). She also developed several hands-on tasks using inquiry to lead the students to reflect on the performed experiments and obtain conclusions.

Based on Josefina’s case study, it was verified that she implemented several mathematical tasks in the framework of STEM integration (Table 1). Indeed, Josefina developed hands-on tasks based on concepts and procedures from mathematics and science while incorporating the design methodology of engineering and using appropriate technology (Shaughnessy, 2013).

Josefina's example shows how to develop exploratory and investigative mathematical tasks from hands-on STEM experiments. Mathematical tasks proposed by the teacher and performed by the students included problems and exercises related to several topics of the Portuguese curriculum such as "Numbers and Operations", "Geometry", and "Data Organisation and Processing", including tables, graphics and diagrams.

We observed that teacher Josefina promoted mathematics teaching in the framework of STEM integration by developing and implementing several interdisciplinary tasks in the classroom related to these subjects. Teacher Josefina's example shows that it is possible to work mathematics while performing several hands-on STEM tasks in class. We conclude that to promote mathematics' teaching in the framework of STEM integration it is necessary to provide teachers with a collaborative professional development context that supports them in the development and implementation of interdisciplinary tasks.

*Rationales for interdisciplinary STEM courses are often based on the fact that the problems we face in today's world call for perspectives and knowledge from many different areas. In many cases this includes mathematics because it is used in many research fields and because it is part of everyday life. At the same time interdisciplinary literature suggests that mathematics gains the least from integration. In this paper we use a successful interdisciplinary STEM course in the Netherlands to illustrate how students and teachers think about the value of mathematics. To analyse teacher and student statements concerning the value of mathematics a model is introduced for a disciplinary mathematics perspective for interdisciplinary STEM courses and the opportunities this model can provide are discussed.*

*Keywords: Mathematics in STEM, secondary education, value of mathematics, perspective taking*

## Introduction

While studying epithelia tissue and the shapes of the epithelium cells in animals, biologists had questions about the shapes of densely packed cells in curved layers. Sharing their questions with mathematicians, these formalised it as a precisely defined new shape. Computer scientists then programmed the shape as a computer model, which was analysed by physicists, who confirmed the shape would be stable packed at the scale of epithelial cells. Knowing what to look for, biologists then found the modelled shape (Parker, 2018).

This example of the finding of the new mathematical shape called the scutoid is an example of how disciplines work together to solve a problem. Looking specifically at the role of mathematics it became clear that mathematical knowledge was used to model and predict a possible shape and that it therefore played a valuable role in the research process.

In general, mathematics is used in many research fields and is part of everyday life. According to the National Research Council (2013, p.2) the mathematical sciences are “becoming an increasingly integral and essential component of a growing array of areas of investigation in biology, medicine, social sciences, business, advanced design, climate, finance, advanced materials, and many more”. The Dutch branch of Deloitte tried to quantify the contribution of mathematics to the Dutch economy (Deloitte, 2013). They found that the full time equivalent of about 900,000 highly educated employees use mathematical sciences in the Netherlands, 11% of total employment and 35% of higher education employment in the Netherlands. “They include scientists, who use mathematics all the time, as well as bankers, who spend some of their time computing the value of assets, and

physicians, who use maths to interpret medical tests” (p.5). These examples indicate that mathematics is seen as valuable for society because of its frequent use.

In both reports recommendations are made about mathematics education, stating that it should reflect the development and stature of the field to have “more and better usage of mathematical sciences” (Deloitte, 2013, p.21). One way to show the use of mathematics is through interdisciplinary educational courses that require mathematics and other disciplinary knowledge to solve real-life problems, such as the epithelia problem.

In literature, such as that mentioned above, we keep coming across phrases that contain the words ‘use’ of mathematics and the ‘value’ of using mathematics. These two concepts ‘using’ and ‘valuing’ mathematics seem connected and therefore worth a closer look. In this paper we examine the distinction and the relationship between these concepts and we use the interdisciplinary STEM course NLT in the Netherlands as a case study to illustrate a model of disciplinary perspective.

## Background of NLT

The Dutch curriculum for upper secondary education contains a course called ‘Nature, life and technology’ (NLT). Since its introduction in 2007 at pre-university and higher general level, the general aims of this elective interdisciplinary STEM course are to let students experience the importance of interdisciplinary coherence in the development of science and technology and to increase the attractiveness of science education for students (Stuurgroep NLT, 2007). The course is intended as a supplement to the existing disciplines in the Dutch curriculum: physics, chemistry, mathematics, biology and physical geography. It aims to offer both a broader and more in-depth educational programme for science and mathematics and is not meant as a replacement of other courses.

Within the boundaries of an examination programme teachers construct their own curriculum and can select teaching materials from a wide range of small booklets, called *modules*. Each module introduces a contemporary, context-oriented science problem that can only be solved by involving different (disciplinary) perspectives. As a consequence, it is preferred that the course is taught by a team of teachers, preferably representing the relevant disciplines. In the Netherlands such a team is called a NLT-team.

In the examination programme of NLT the nature of the course is made explicit by formulating four characteristics which should be visible throughout the curriculum (Krüger & Eijkelfhof, 2010). The nature of NLT is characterized by attention to ‘interdisciplinarity’, ‘the relationship between science and technology’, ‘the orientation on higher education and occupations’ and ‘the role of mathematics in science’. Concerning the ‘role of mathematics in science’ it is said that NLT shows how mathematics is used in the sciences. However, how this should manifest itself is not clear (den Braber, Krüger, Mazereeuw & Kuiper, 2019). Our study shows that more than 20% of students doesn’t mention mathematics when asked about the disciplines that play a role in NLT. When asked why mathematics is not a part of NLT some say that only low-level mathematics is required, or that it is not similar to what they do in mathematics class. Besides this, the research shows that mathematics teachers seem to struggle more with their role in NLT than science teachers. Besides this, the added value of having mathematics teachers in an NLT-team is not always clear. When it comes to mathematics in the NLT course, the question arises, how to equip future (mathematics) teachers so

that they can help their students recognize the value of mathematics in NLT and other interdisciplinary courses.

NLT experts elaborated on the concept of interdisciplinarity by describing learning goals that state that students should have knowledge and appreciation of the different disciplines and their ways of working and thinking and how they contribute to solving a real-life problem (Eijkelhof, Boerwinkel & Krüger, 2017).

This is in accordance with Repko, Szostak and Buchberger (2017) who state that “an important step towards developing competence in interdisciplinary studies is to understand the concept of disciplinary perspective and the role of perspective taking” (p.124).

## Conceptual framework

Ng and Stillman (2007) provided a framework in which the value of mathematics, mathematical confidence, and the interconnectedness of mathematics are three affective domains directly associated with interdisciplinary learning involving mathematics. In turn, they divided the domain of the value of mathematics in three categories: current relevance or usefulness of mathematics, importance of mathematics for further education and career choice, and value of mathematics in society.

In literature we see more categorizations of the value of mathematics where usefulness or current relevance of mathematics is one of the categories. Williams (2012), for instance, makes the distinction between exchange-value, enjoyment and use-value of mathematics, where the latter is viewed as a means to understand or practise competently, e.g. in engineering or science.

Ernest (2010) states that useful or necessary mathematics is primarily relevant in view of the benefit for employment and functioning in society. He declares functional numeracy or ways of thinking as being useful, but what exactly constitutes the usefulness is not made explicit. The definition of *mathematical literacy* from the PISA mathematical framework provides another perspective on what is needed to be functional in society:

Mathematical literacy is an individual's capacity to formulate, employ, and interpret mathematics in a variety of contexts. It includes reasoning mathematically and using mathematical concepts, procedures, facts and tools to describe, explain and predict phenomena. It assists individuals to recognize the role that mathematics plays in the world and to make the well-founded judgments and decisions needed by constructive, engaged and reflective citizens. (OECD, 2016, p. 5)

The role that mathematics plays in the world brings us back to the idea of disciplinary perspective as described by Repko et al. (2017). When solving a problem requires different perspectives a mathematical perspective may well be one of them. A disciplinary perspective includes knowledge of the studied phenomena, the assumptions, the epistemology and the ways of acquiring knowledge which are characteristic to the discipline (Repko et al., 2017). To translate these ideas to secondary education we define disciplinary perspective as ways of looking at the world and ways of working and thinking that are characteristic to the field (Janssen, Hulshof & van Veen, 2018).

To specify the way mathematics looks at the world, the perspective on reality or the ‘overall sense’ (Repko et al., 2017), we look at the phenomena studied in mathematics. Defining mathematics as the science of patterns (Devlin, 1998), mathematics studies patterns or abstracts structures. A symbolic notation evolved to facilitate universal communication. The study of patterns requires abstracting and

structuring. In addition to these two, manipulating formulas, modelling, problem solving, and reasoning are formulated as mathematical thinking activities that conjoin key concepts in the Dutch mathematics school curriculum (cTWO, 2012). These six activities belong to the disciplinary perspective shown in table 1. In NLT mathematical concepts are used, but in general no new concepts are introduced. Consequently, if we compare the mathematics curriculum with the NLT examination program, abstracting and structuring seem less relevant. Further, manipulating formulas, will be taken as part of modelling. We will elaborate on the three remaining activities.

**Table 1: Description of disciplinary perspective in real-life interdisciplinary context**

Ways of looking at the world	
Overall sense	<p>Maths contributes to understanding the world (to describe, explain and predict phenomena)</p> <p>Maths is the study of patterns and abstract structures (with structuring, generalizing, abstracting, symbolizing)</p> <p>Maths uses a symbolic, formal and technical way to communicate</p>
Ways of working and thinking	
Modelling	Modelling processes: Formulate, Employ (working mathematically), Interpret/Evaluate
Reasoning	(logical) reasoning, argumentation and proofing
Problem solving	Devising strategies, heuristics use

The motivation for creating and interpreting mathematical models in real-life situations is to mathematize a realistic situation for the purpose of answering a practical question (Gravemeijer, Stephan, Julie, Lin & Ohtani, 2017). These authors therefore argue the importance of modelling in education as something that prepares students for the digital society of the future. There are many models that describe the modelling process (Borromeo Ferri, 2006). The PISA framework (OECD, 2015) mentions three processes, namely *formulate*, *employ* and *interpret/evaluate* to capture the complexity of the modelling cycle in real-life situations. *Employ* refers to the use of mathematical concepts, facts or procedure, also known as working mathematically (Blum & Ferri, 2009). It includes applying mathematical facts, rules, algorithms, and structures when finding solutions, manipulating formulas and using mathematical tools, including technology, to help find and approximate solutions with given models.

*Problem solving* can play an important role in working in real-life problems when we see problem solving as the activity of using a heuristic approach (van Streun, 2001) or devising strategies as mentioned in the PISA framework. *Reasoning* is a way of thinking that can be of use in an interdisciplinary context (Eijkelhof, Boerwinkel, & Krüger, 2017). For instance, to critique arguments, to identify weaknesses and flaws in logic, to revise arguments, and to submit to peers review (Mayes & Koballa, 2012). It is a supporting process throughout the modelling process, e.g. to

check a justification that is given, or provide a justification of statements or solutions to problems (OECD, 2015).

Summarizing, we describe the disciplinary perspective of mathematics in an interdisciplinary STEM course as shown in table 1. The model describes the contribution mathematics can make to interdisciplinary real-life problems, specifically in secondary education. It does not include the knowledge or ability required to use this disciplinary perspective even though we recognise mathematical confidence as an important domain in interdisciplinary mathematics education as also stated by Ng and Stillman (2007).

## Data collection and analysis

To study how mathematics manifests itself in NLT (den Braber et al., 2019), data was collected through interviews, document analysis and teacher and student surveys over three years. The surveys in 2017 contained several additional questions related to the relevance or usefulness of mathematics to provide an insight in students and teachers perceptions of the value of mathematics in the sciences. For this paper we analysed student answers to one question and teacher answers to a related question, see table 2. The students were in their final year of secondary education and had studied NLT for two or three years. The teachers were NLT teachers with different disciplinary backgrounds.

**Table 2: Analysed survey questions and number of answers**

	Question	Type	Completed surveys
Teachers	What do you discuss with your students about the role of mathematics in the sciences?	open	84
Students	According to you, what is the importance of mathematics to the science?	open	416

We used table 1 to code the answers of students and teachers. Categories were ‘overall sense’, ‘modelling’, ‘reasoning’ and ‘problem solving’. For answers not fitting to any of the categories we used the category ‘other’. As subcategories of modelling we used ‘formulate’, ‘employ’ and ‘interpret’. The code ‘general’ was related when -part of- the answer reflected the process of modelling in general. If an answer contained more than one statement that could be in different categories the statements were coded accordingly, 445 coded student answers and 95 teacher answers. An example is shown in table 3. A single code was assigned to 389 student and 75 teacher answers.

**Table 3: Example of coded student statements from one student answer**

Highlighted statements	category	subcategory
<b>The way of thinking (problem solving)</b> and dealing with and converting numbers and formulas	Problem solving

## Results

The data shows that not all answers referred to the posed questions, for both teachers and students. Instead they might express an opinion about the course, the level of mathematics or what modules were taught. These were coded as ‘other’, as were students’ statements like ‘don’t know’ or ‘don’t care’. This category was also used to code general opinions like ‘great importance’ or ‘not a lot’ and 29 students who gave general statements claiming the importance of mathematics as ‘the basis of sciences’ or other synonyms as ‘the foundation’. Also 14 teachers used general statements, using words such as ‘supportive science’ or a ‘tool’. The number of coded statements is seen in table 4.

**Table 4: Number of coded statements in the categories from student and teacher answers**

Category	subcategory	Students		Teachers	
		Number of statements (n=445)	Percentage of students (n=416)	Number of statements (n=95)	Percentage of teachers (n=84)
Overall sense		36	9	6	7
Modelling processes	General	4	1	4	5
	Formulate	8	2	3	4
	Employ	212	51	9	11
	Interpret/evaluate	14	3	4	5
Reasoning		14	3	0	0
Problem solving		8	2	2	2
Other		148	36	65	77

In the category ‘other’ we find 35 teacher statements, all science teachers, reflecting that they say nothing or little about the role of mathematics and there is no teacher answer mentioning reasoning or proving something. Even though we find students answers in all categories, almost half of the students reflect on the aspect of working mathematical with many statements containing the words calculate or formulas.

Inter- rater reliability with three raters was 0.79 using Fleiss Kappa.

## Discussion

Rationales for interdisciplinary STEM courses are often based on the fact that the problems we face in today’s world call for perspectives and knowledge from many different areas. The possibilities for mathematics in such a course is described by Williams et al (2016) as:

interdisciplinary mathematics education offers mathematics to the wider world in the form of added value (e.g. in problem solving), but on the other hand also offers to mathematics the added value of the wider world. (p.13)

For students, however, it is not self-evident what the added value of mathematics is. For almost one third of the students it is hard to give a description of what the relevance of mathematics is or they refer to general terms as ‘great’ or ‘mathematics is the basis of the sciences’. When they do refer to categories of disciplinary perspective it is mostly ‘working mathematically’ by doing calculations and using formulas. This is in accordance with Wolfram (2010) conclusion that not all phases of a modelling cycles are equally visible in mathematics education. We can argue that the same goes for interdisciplinary education. This might also indicate that in the current NLT course, of all disciplinary perspectives the value of the mathematical perspective is recognized the least and has a lot to gain.

We see students who say that mathematics is not very important to the sciences or student who don’t acknowledge the relevance of it. Here the role of teachers becomes even more apparent. If they don’t address perspectives it seems logical that for students this remains hidden and the benefits of perspective taking in interdisciplinary situations withheld. For teachers it requires knowledge and an attitude that might be different from what they are used to since a part of interdisciplinary perspective taking is “that when taking on other perspectives often involves temporarily setting aside your own beliefs, opinions, and attitudes” (Repko et al., 2017, p. 125). This means that the metaphors of mathematics as a servant or as the queen of other disciplines are irrelevant. The goal of disciplinary perspective is not to marginalise one discipline or to promote another but the goal is to value each discipline and use the possibilities each discipline brings to the table in a real-life situation (Braber et al, 2019).

In this paper we provided a conceptual framework for the disciplinary perspective in STEM education which can be used as a conceptual tool that may help future teachers with explicating the role or usefulness of mathematics in an interdisciplinary course. The warrants and backing in our reasoning need further elaboration. Such as reasons to include elements of the PISA framework or the statement that modelling is the most important process in the disciplinary perspective and that other processes (reasoning and problem solving) are mainly supporting the modelling process. Thereby also making a distinction between an overall sense of what mathematics is about and which processes contribute to answering an interdisciplinary question.

## Introduction

Mathematics is at the core of many areas of everyday life in our society, in science, technology, and the economy. According to the PISA study, the aim of mathematical education is to develop an understanding of the relevance of mathematics in these areas. This should enable high school students to deal with and explain mathematical questions and problems with respect to real world life so that they can act as responsible citizens (cf. OECD, 2014). But process-oriented competences which belong to the educational standards of mathematics are often neglected due to the fact that mathematics lessons are often strongly content-oriented. Therefore, it is essential that the tasks are open, complex, realistic, authentic, problem-oriented and can be solved by carrying out a modeling process (cf. Maaß, 2006, p. 115). This is where the project Computational And Mathematical Modeling Program (CAMMP) intervenes: It offers extra-curricular possibilities for students to participate in modeling events which last between one day and one week. These events show the close connection of several subjects such as engineering, mathematics and computer science. By integrating such questions into interdisciplinary project teaching, mathematical modeling is extended by the dimension of independent experience and practical application. Students solve problems from everyday life or scientific research by using mathematical modeling. Thus, we understand CAMMP as a chance for students to solve real problems by mathematical modeling independently and to develop important future-oriented competencies. Our experiences show that by participating in CAMMP events students discover, among other things, the role of maths in our everyday life. Since the students should not use the modeling cycle as an abstract entity, but as a concrete help for the modeling process, CAMMP presents a simplified variant of Blum's modeling cycle with the four steps *simplifying*, *describing mathematically*, *computing* and *interpreting* (cf. Blum & Borromeo-Ferri, 2009, p. 46). As an example, a workshop lasting one day (CAMMP day) on the topic climate research is introduced.

## Didactic reduction and realization of Climate Change Analysis in a CAMMP day

There are various simulations that predict a warming of the average temperature of the earth's surface by up to four degrees Celsius by 2100. Such warming would lead to further effects, from the emergence of deserts to rising sea levels and the disappearance of entire countries. However, many people ignore or deny climate change or the dramatic consequences that inaction would have. The report of the Intergovernmental Panel on Climate Change (IPCC) distinguishes various indicators that point to a climate change. Since climate change is a complex research field with many different forces affecting each other, a good didactical reduction is needed for teaching mathematical models

representing earth climate to high school students. Therefore, the CAMMP day – which we are currently designing – focuses on temperature analysis, an everyday parameter used to describe climate and often used in the media as a yardstick for climate change.

**Figure 1: Global average surface temperature**

The first step of modeling “Does a climate change exist?” we ask “Has the temperature increased significantly?” To answer this, the global average surface temperature from 1850 to 2018 is examined (see Figure 1). Furthermore, a linear trend is used to describe the trend since it is assumed in the IPCC report (see IPCC, 2013). For this purpose, the students first develop the methodology of regression analysis independently. One possible mathematical description is first to calculate the sum of least squares of the difference between the measured temperature function and the regression, called  $e(Y_j)$  for each year  $Y_j = 1900, \dots, 2018$ . In a second step the sum of the least squares is minimized. The mathematical problem can be written as  $\sum_{j=0}^n e(Y_j)^2 = \sum_{j=0}^n (T(Y_j) - \tilde{T}(Y_j))^2 \rightarrow \min$ , where  $T(Y_j)$  the measured temperature and  $\tilde{T}(Y_j) := mY_j + b$  the modeled temperature value of the regression function with the unknown parameters  $m$  and  $b$  in the years  $Y_j$  are. Here the concept of differentiation is needed. It becomes obvious why the least square method is used: It is easier on high school level to differentiate a polynomial of grade 2; otherwise the absolute value function would be needed. Using real data this results in a linear trend function of  $\tilde{T}(Y) = 0.008^\circ\text{C}/\text{year} - 15.578^\circ\text{C}$  which needs to be interpreted with respect to the real-world problem. Here the question of the quality of the adjustment for the data arises. The coefficient of determination is introduced and computed for the given data as  $R^2 = 0.8$ . As an additional exercise, interested students can prove that in all cases  $R^2 \in [0,1]$  holds and find out which  $R^2$  indicates a good adjustment. These results lead to the presumption that  $\tilde{T}(Y)$  approximates the data well and that the temperature rises by  $0.008^\circ\text{C}/\text{year}$ . In order to investigate whether the temperature rises significantly in the last century, the coefficients of the regression function are tested with a so-called t-test. The high school students formulate the null hypothesis ( $H_0$ : the temperature does not rise significantly) on the basis of the question as well as the test statistics. Inserting the corresponding values leads to the acceptance of  $H_1$ . Further steps are to evaluate the influence of human being in this increase. These results do not only lead to a well-founded view on the topic of climate change, but also show the relevance of mathematics in society.

<sup>1</sup>University of Siegen, Germany; [krause@mathematik.uni-siegen.de](mailto:krause@mathematik.uni-siegen.de)<sup>2</sup> Hanoi National University of Education, Vietnam

*The benefits of interdisciplinary teaching and learning in school have been discussed for some time, but to make it be more than the additive juxtaposition of elements of knowledge from different disciplines, the universities should implement holistic concepts for integrative teacher education. In the first phase of the teacher training should clarify the advantages and tackle the challenges of an interdisciplinary education. The Inter TeTra project is a DAAD subject-related partnership between the University of Siegen (Germany) and the Hanoi National University of Education (HNUE, Vietnam). The primary outcome of this project is the design of a permanent module for the subjects mathematics and physics at the HNUE and to perform interdisciplinary on the job teacher training with the subjects mathematics and physics.*

*Keywords: Developing country project, interdisciplinarity, relationship of physics and mathematics, teacher training curriculum development.*

### Motivation of the Inter TeTra-project

A primary goal of the OECD and the educational capacities in Vietnam is to reform their educational policy by developing a more competency-oriented curriculum (Communist Party of Vietnam, 2013). Germany has two decades of experiences with these types of reforms. The adjustments of the curricula since the mediocre results of German students in the TIMSS and PISA study show the opportunities and challenges such reforms can present (KMK, 2004) and the importance of teacher training for the success of school reforms (Hattie & Beywl, 2013). The cooperation between German and Vietnamese educators offers the opportunity to avoid well-known problems in implementing such reforms. In addition, it can generate new knowledge out of the cultural and structural differences between the two societies, allowing the further development and implementation of novel and distinctive curricula. Consequently, the DAAD (German Academic Exchange Service) endorses the Inter Tetra-project (the name of the project is a short form for Interdisciplinary Teacher Training), a subject-related partnership established between the University of Siegen and the Hanoi National University of Education (HNUE). The outcomes of this project are the design of a permanent module for the subjects mathematics and physics at the HNUE and the performance of an interdisciplinary pre-service and in-service teacher training. One of the distinguishing features of this course is the view beyond the subject boundaries of mathematics and physics. Since 2000, the advantages of interdisciplinary work in teaching and learning in schools have been emphasized, mostly in the form of problem-based and cross-disciplinary teaching that is organized in projects (Labudde, 2014 or Moegling, 2010). In order to achieve the greatest educational benefits, numerous

variants of these demanding and complex learning concepts have been developed (Caviola, 2012; Labudde, 2008). The ability to systematically combine, apply and reflect knowledge from different disciplines is the goal of this project. However, in spite of all the educational advantages, interdisciplinary work also reveals many challenges. The combination of different methods of the participating subjects, overcoming communication difficulties, the identification of common research subjects, the handling of prejudices as well as the handling of group dynamic processes are only some of the problems of interdisciplinary cooperation (Defila & Di Giulio, 2002, 24). The didactic potential of subject-linking teaching and learning has been discussed for some time, especially in mathematics, natural sciences and technology (English, 2017; Kelley & Knowles, 2016; La Force, 2016; Michelsen, 1998).

Despite the many benefits of interdisciplinary teaching and learning at school, the teacher training at German as well as Vietnamese universities is still largely organized in a discipline-oriented manner. The first phase of the teacher training should clarify the advantages and tackle the challenges of an interdisciplinary education. To make interdisciplinary teaching and learning in schools be more than the additive juxtaposition of elements of knowledge from different disciplines (Wellensiek, 2002), the universities should implement holistic concepts for integrative teacher education. The inadequate fit of non-integrated teacher education with the requirements of interdisciplinary teaching (Bröll & Friedrich, 2012) is repeatedly cited by teachers in schools as an objection to integrated instruction (Jürgensen, 2012; Rehm, 2008). If interdisciplinary teaching at school is to succeed, teacher training must also be adequately designed (Brown & Bogiages, 2017; Cormas, 2017). Studies show the importance of the preservice teachers' knowledge of interdisciplinary pedagogy (An, 2017). However, it has become apparent that experienced teachers in particular have reservations about interdisciplinary teaching (Thibaut 2018). For this reason, the Inter TeTra project is planning an interdisciplinary master course and in-service teacher training. Appropriate didactic concepts have already been developed at some universities (Krause & Witzke, 2017; Witzke, 2015). The University of Siegen works currently on interdisciplinary education projects such as MINTUS, FäMaPD<sub>i</sub> and InForM PLUS (Holten & Witzke, 2017; Krause, 2017). For this purpose, the subjects of mathematics and physics seem to be the most appropriate, since these subjects have numerous epistemological parallels (Krause, 2016). First approaches for establishing subject-linking lessons already exist in Vietnam (Nguyen, 2015). In contrast, the present project does not initially focus on interdisciplinary teaching in Vietnamese schools but starts earlier by adding an interdisciplinary module to teacher education. In this way, the connecting element in the subject-linking lessons of the future is not only the common subject of instruction (which is viewed from the perspective of different subjects) but rather the embedding of lessons in the comparative discussion of didactic theories in the participating subjects from the very beginning, with the goal of concretization and implementation in the Vietnamese curricula. This approach is an innovation especially for Vietnam, where teacher training is currently very isolated and compartmentalized. While the modern application-oriented teaching of mathematics looks to physics didactic concepts for experimentation, modern physics teaching also requires mathematical didactic knowledge to deal with technical problems via mathematics (Schwarz, 2016). Consequently, the repertoire of future teachers will become richer by incorporating the didactics of neighboring subjects. So this project aims to make a meaningful and lasting impact through teacher training, combining classroom teaching with practical instructions. The aim is the

development of a competence-oriented curriculum for teacher training in Hanoi. The Vietnamese partner university is the authoritative body of educational policy reforms within the country, ensuring later dissemination of the developed module. The previously mentioned projects at the University of Siegen have demonstrated that interdisciplinary teaching in teacher education provides a deeper insight into the didactics (Witzke, 2015). The combination of didactical theory and teaching practice is particularly important to our approach.

## **Concept of the courses in the Inter TeTra-project**

### **General information**

The duration of the Inter TeTra-project will be four years. In the first year (2018) the colleagues from Vietnam have joined the referring projects in Siegen - the FäMaPDi and InForM PLUS projects (Krause & Holten, 2018) and both sides discussed the theoretical framework of the project. The courses for the HNUE will be designed in the year 2019 and will take place in Hanoi in 2020 and will be repeated in 2021. The idea is the implementation of an interdisciplinary course for pre-service teachers in the teacher training curriculum at the HNUE and the offering of an interdisciplinary course for in-service teachers with the subjects mathematics and physics. These courses will be composed of a theoretical and a practical part.

### **Theoretical part**

The aim of the courses is to enable students to compare the didactical theories of their own discipline, which they have come to know during their studies, with the didactical theories of the other subject. Since only a limited number of sessions are available for the theoretical part, only a selection of topics can be found that is relevant for both subjects. In order to combine subjects in a meaningful way, one should compare the common “Big Ideas” of the subjects (c.f. Chalmers, 2017). One research desideratum that the Inter TeTra Project focuses on is to explicate topics, which are relevant for mathematics and physics education. For this reason, handbooks and conference-proceedings of mathematics and physics education will be compared systematically to identify intersections. Even if this research is still in process an exemplary selection of topics, which are suitable for an exchange between mathematics and physics education, can be listed:

**Nature of science vs. beliefs of mathematics:** What is physics? What role does the experiment play in physics? To what extent does a physical theory depict reality? Because questions of this kind are crucial for teaching-learning processes, the didactics of physics has been dealing with them for some time under the heading “nature of sciences” (Aydeniz et al., 2013; Dass, 2005, Höttinge & Rieß, 2007; Kahana & Tal, 2014; Kartal et al., 2018). Likewise also the mathematics didactics researches on the different views on mathematics (e.g. Grigutsch et. al, 1998; Witzke & Spieß, 2016), because the individual conceptions determine our concrete activities in science. What similarities can be identified between perceptual research in mathematics didactics and NoS research in physics didactics? What are the differences? Interesting approaches can be found in the literature: Lawson (2008) talks about Nature of Science and mathematics. Rolka and Halverscheid (2011) talk about mathematical worldviews of students.

**Modelling:** Modeling is considered in some publications to be a linking element between disciplines. (Blum & Niss, 1991; English, 2009; Michelsen, 2006). In physics, models (such as atomic models)

are an integral part of the theory canon. Accordingly physics education has to clarify how to deal with models in the teaching-learning process (Gilbert, 2004; Oh & Oh, 2017). It is not so common to stress that models should not just be taken over, but rather to emphasize the process of creating models. In mathematics education modeling has been discussed for many years (Burkhardt, 2006; Frejd & Bergsten, 2016; Guerro-Ortiz et al., 2018; Kaiser & Schwarz, 2006). Several models for modeling - so-called modeling cycles - have been developed. So it seems that physics education focuses on the general product while mathematics education is more interested in the process of individual modelling. It is obvious that both sides can learn from each other in this matter, even if it is more laborious than it seems (Neumann et. al, 2011).

**Preconceptions:** In physics didactics preconceptions are treated to different physical contents. They are often negatively connoted as misconceptions. In mathematics education one rarely speaks about misconceptions, trying to highlight positive pre-theories among learners. The term "Grundvorstellung" (vom Hofe, 1992) is certainly prominent in this context in Germany. At the same time, mathematics educators have developed more general theories on context-related learning, which can also be applied to other subjects. For example, the approach of Heinrich Bauersfeld to "Subjektive Erfahrungsbereiche" should be mentioned (Bauersfeld, 1983). Krause has sketched the transfer of this theory to physics and discussed the question of how on the other hand mathematical didactics can be fertilized by approaches of physics didactics (Krause, 2015).

### **Practical part**

In addition to the theoretical sections the courses mentioned and planned in this project will also include lessons at schools. The fact that the didactics of a neighboring subject can be relevant to one's own subject should be clarified by the conception, implementation, and reflection of lessons that try to combine school mathematics and physics in a meaningful way. For this purpose, the interdisciplinary comparison of theories on learning and teaching mathematics and physics in schools will be used to develop research questions in the seminar, which will be examined in the course of the lesson designs developed in the seminar and tested at the cooperation school. These lessons will be videotaped and incorporated into the previously discussed theory. This combination of theoretical lessons and review is established in North Rhine-Westphalia during the practical semester in teacher training (Hoffart & Helmerich, 2016). Such a theory-based classroom reflection research is not yet part of teacher education in Vietnam. However, evaluation criteria do not refer primarily to how the lessons themselves succeeded, but to how the teaching process can be analyzed and classified on the basis of the theoretical sessions. At this stage of the seminar, students should be able to evaluate and justify didactic decisions based on theory.

## **Research**

### **Explication of relevant content**

The selection of topics in the theoretical part should not be made ad hoc but should reflect the intersection of mathematics and physics education research in terms of content and points of contact. The contents presented in Chapter 2 were determined by the lecturers themselves during the pilot phase in Germany. For the realization of the teaching interventions in Vietnam (which is to take place for the first time in 2020), the theoretical topics are to be systematically selected. For this

purpose, the project participants will carry out a qualitative content analysis (Mayring, 2010) of current manuals and proceedings with the question: *Which contents are relevant for an interdisciplinary exchange of mathematics and physics didactics?* Results of this analysis are still pending.

### **Evaluation of the teaching interventions**

The evaluation of the Master's course and the teacher training should contribute to answering the following research question: How aware are the participants of the relevance of didactic theory of the other subject for their subject? Especially in Vietnam, where teachers are only trained in one subject, it is important to raise the awareness that mathematics didactics is important for physics teaching and that physics didactics is also important for teaching mathematics. The participants will be interviewed at the beginning and end of the theoretical part with an open questionnaire (which is still in the conception phase). What is special about the Inter TeTra project is, that in the practical part the participants are to hold a lesson which will be evaluated video-based. This evaluation also takes place exclusively under the question at which points of the lesson the didactics of the other subject are relevant. This approach was also used in the pilot implementation in Germany. First results may be found in Holten and Krause (2018).

### **Conclusion**

The project's research goals are to clarify relevant topics for an interdisciplinary exchange between mathematics and physics didactics, to design and implement a corresponding course in the teacher training curriculum and a course for in-service teachers at HNUE. The performance of the courses will be evaluated in order to assess the effectiveness of interdisciplinary teaching in the subjects mathematics and physics during the training of preservice teachers.

In this project, an intellectual exchange between four institutes is taking place. Each institute will be focusing primarily on the mathematics and physics disciplines in Hanoi and Siegen as well as four components of teacher training and further education, hence the derivation of the name Inter-Tetra from the Latin "Inter" (between) and Greek "Tetra" (four) and its dual connotation for Interdisciplinary Teacher Training.

# Student mathematical preparedness for learning science and engineering at university

Ciara Lane<sup>1</sup> and Gráinne Walshe<sup>2</sup>

<sup>1</sup>University of Limerick, EPI\*STEM, School of Education, Limerick, Ireland; [ciara.lane@ul.ie](mailto:ciara.lane@ul.ie)

<sup>2</sup>University of Limerick, Science Learning Centre, Limerick, Ireland; [grainne.walshe@ul.ie](mailto:grainne.walshe@ul.ie)

*This paper describes a novel study that aims to explore students' mathematical preparedness for STEM education at tertiary level in the Irish context. The study addresses the issue of student retention in STEM degrees by investigating the perceptions of three stakeholders – teachers, students and lecturers – on the mathematical preparedness of students for studying science and engineering at tertiary level. The study also examines the existence and perception of interdisciplinary STEM education in preparing students for the transition to tertiary level STEM learning. In this paper, we describe the rationale and design of this pilot study at an Irish university, including the development of questionnaire instruments for teachers, students and lecturers. Further advancement of the study is also discussed, as well as the intention to design targeted support for first year students of science degrees.*

**Keywords:** *Interdisciplinary approach, mathematics, science, student attrition, STEM education.*

## Introduction

Internationally, there has been increased emphasis on Science, Technology, Engineering and Mathematics (STEM) education and the exigent need to provide quality STEM education at primary, secondary and tertiary levels, in order to increase the number and quality of STEM graduates (DES, 2017; Friedman, 2005; Sanders, 2009). With augmented political and economic focus in the last 20 years, STEM education and integration has come to the forefront of national and global policies. While recommendations have been made for integrative STEM education (see e.g. Breiner et al., 2012; Kennedy & Odell, 2014; Sanders, 2009), there remains some hesitancy about how exactly STEM should be integrated in an educational context (Blackley & Howell, 2015). In Ireland, there is a particular concern that students entering higher education are under-prepared to engage effectively with learning in STEM courses (DES, 2011). Mathematics and science especially are central to many STEM courses at tertiary level, with first year undergraduates often lacking the skills and knowledge in these subjects to successfully engage with their STEM degree. This paper describes a pilot study of students' mathematical preparedness for learning science and engineering at tertiary level in the Irish context. The authors aim to investigate the students' mathematical preparedness from three perspectives: first year students enrolled in science and engineering degrees at an Irish university; science and engineering lecturers teaching first year modules at the university; and senior cycle post-primary (second-level) mathematics and science teachers; as well as the existence and perceptions of interdisciplinary STEM teaching and learning. In addition, the way in which these groups use social media to develop informal networks between second and tertiary level education will be analysed. As data collection through questionnaire surveys is in process, this paper describes the rationale and design of the study.

## Study rationale

Concerns about student retention in higher education is an international phenomenon, because of the very high drop-out rate from first year, and because Higher Education Institutes (HEIs) are held more accountable for students' success (Coertjens et al., 2016). In New Zealand, Jia and Maloney (2015) found that students enrolled in STEM degrees had the highest course non-completion rates. This is consistent with Rask (2010) and Chen and Soldner's (2013) findings in the US that grades and student retention rates are systematically lower in the STEM subjects of Sciences, Computing, Mathematics and Engineering. Similarly Malm *et al.* (2012) report that at the School of Engineering at Lund University, Sweden, the percentage of matriculating students who successfully complete their MSc engineering degree is about 60%. Most of the students who drop out do so during the first year, with a 21% attrition rate found in one particular year. Student progression and retention is now a national priority in Irish Higher Education, and is a major focus of national policy in recent years (HEA 2016). There has been a steady increase in student enrolments in higher education in Ireland over recent decades, with an increase of 7% between 2011 and 2016 of full-time undergraduate new entrants (HEA 2016). A report from the Higher Education Authority in Ireland found that the overall rate of non-progression (from year one to year two) was 11% for level 8 degrees in universities in the year 2012/13 (HEA 2016). Notably, prior academic achievement has been found to be the strongest predictor of non-progression in higher education (HEA, 2018). Therefore, there is a strong rationale for investigating students' transition to university, particularly for students enrolled in STEM degrees.

While several factors may impact on student progression, for science and engineering students, their level of mathematical knowledge is crucially important (HEA 2016), but even students with good marks in school mathematics can struggle with the mathematical aspects of third-level science and engineering courses. It is important to have good mathematical knowledge, but even more so to know how to use that knowledge in other subjects. However, very often mathematics is not taught in an integrated/interdisciplinary fashion at second level. Science and mathematics can be very separate as school subjects even where they share overlapping content (Czerniak & Johnson, 2014). It has been found that school mathematics teachers are often unfamiliar with the science subjects, and vice versa for science teachers (Walshe, Johnston, & McClelland, 2017). It is possible also that second level teachers are not teaching mathematics with students' future third-level STEM degrees in mind. Thus, the authors aim to address the following research questions in their study:

1. What are teachers, lecturers and first year students' perspectives on the level of mathematical preparedness of students for science and engineering degrees?
2. What understanding do teachers, lecturers and students have of STEM education, and in particular, integrated approaches to teaching STEM subjects?
3. Does social media indicate that networks exist that connect various actors across second and third level, such that the students' process of mathematical preparedness might be enhanced?

These research questions will be addressed in the first exploratory phase of the research. The authors aim to design and implement a pilot intervention for students at risk of failing their first-year science modules in the second phase which will be informed by the findings of this study.

## **Interdisciplinary education in STEM**

Both in Ireland and internationally, education initiatives have often focused on improving individual disciplines in STEM (discipline silos) rather than integrating the collective. These efforts aim to enhance students' learning in each of the STEM disciplines through a focus on inquiry, problem solving and constructivist learning, which are essential skills for the 21<sup>st</sup> century. However, researchers have argued that for students to be fully prepared for future STEM careers in the real world, there needs to be an emphasis on interdisciplinary thinking (Asghar et al., 2012; Breiner et al., 2012). In conceptualizing what STEM means, many people do not have an interdisciplinary understanding of STEM (Breiner et al., 2012). *"Everybody who knows what it means knows what it means, and everybody else doesn't"* (Angier, 2010). In their study of faculty members' conceptualization of STEM, Breiner et al. (2012) found diverging views from both STEM and non-STEM disciplines. Becker and Park (2011) conducted a meta-analysis of STEM integration studies and found that STEM teachers are often unaware of the benefits of integration and school administrators often do not support integrative approaches as a means to motivate students' learning in STEM. Teachers' self-efficacy plays a vital role in successful teaching (Stohlmann et al., 2012) and teachers' content and pedagogical knowledge can influence their teaching self-efficacy. Stohlmann et al. noted that teachers' comfort with teaching integrated STEM lessons was also affected by their commitment to future integrative STEM teaching. Laboy-Rush (2011) avers that the success of integrative STEM initiatives is very much dependent on teachers' attitudes to changes in their teaching practice, and these attitudes can be influenced by teaching efficacy (De Mesquita & Drake, 1994). Teachers' attitudes to adopting an integrative STEM teaching approach can affect their commitment to such initiatives as well as influence their students' interest and motivation in STEM (Al Salami et al., 2017). In analysing the conceptual changes of teachers towards interdisciplinary STEM teaching, Al Salami et al. found that a year-long professional development programme elicited little or no change which is consistent with previous studies on teacher change. Findings did indicate however, a significant positive association between teachers' attitudes towards interdisciplinary teaching and attitudes to teamwork, and also between attitudes towards interdisciplinary teaching and teaching satisfaction. It should be acknowledged that while there are benefits to integrating STEM subjects, there are also costs to teachers and schools in terms of time, resources and developing expertise (Gresnigt, Taconis, van Keulen, Gravemeijer, & Baartman, 2014).

There are many definitions of interdisciplinary teaching and learning or integration, and many approaches and models suggested for how it can be applied in teaching (Hurley, 2001, Pang & Good, 2000). Terms used in the literature to describe integration include: interdisciplinary; multidisciplinary; transdisciplinary; thematic; integrated; connected; nested; sequenced; shared; webbed; threaded; immersed; networked; blended; fused; correlated, coordinated, and unified curricula (Berlin & Lee, 2005; Czerniak & Johnson, 2014). A common definition of integration does not exist, and this ambiguity is inherent in the sheer number of terms used to describe it.

Moreover, these terms can mean different things to different researchers (Czerniak & Johnson, 2014; Kysilka, 1998). Berlin and Lee note in their analysis of the literature on science and mathematics integration from 1990 to 2001 that while many theoretical models have been proposed; there is a ‘critical need for careful conceptualization and additional research on integrated science and mathematics teaching and learning’ (2005, p. 22). As part of this study, the authors aim to clarify what teachers, lecturers and students currently understand by interdisciplinary STEM education, with a view to developing interventions that could address any gaps or shortcomings that are found to exist in their current conceptualisations and practice.

## Study design

The methodology for this study is Educational Design Research, characterized by iterative design and formative evaluation of interventions in complex real-world settings. Working with all stakeholders, i.e. practitioners and end-users, to inform, design, pilot and refine the elements of an educational intervention is an essential part of this methodology (Plomp & Nieveen, 2013). This paper describes the first phase of our study which is chiefly designed as exploratory, inductive research. Exploratory research aims to apply “new words, concepts, explanations, theories and hypotheses to reality with the expectation of offering new ways of seeing and perceiving how this segment of reality works, how it is organized, and more specifically how and in what way different factors relate to each other causally.” (Reiter, 2017, p. 139). This understanding of exploratory research frames our phase 1 study design in investigating students’ mathematical preparedness for learning science and engineering in first year of university. Our study is underpinned by the constructivist position that people construct knowledge and its meaning from their experiences (Driscoll, 2000). The authors hypothesize that university students’ learning of science and engineering is affected by their knowledge of mathematics and their experience of learning mathematics/science in post-primary education. The authors further hypothesize that students’ exposure to integrative, interdisciplinary-based learning in mathematics and science at post-primary level affects their mathematical preparedness for studying science and engineering at university. These hypotheses led to the formation of our four research questions in the introduction section of this paper. To answer our research questions, three questionnaires were designed, aimed at first year university students in science/engineering degrees, science/engineering lecturers and post-primary teachers teaching science and mathematics at senior cycle (the final 2 years of post-primary education in Ireland). Both quantitative, fixed-response items and qualitative, open-ended questions are employed in all questionnaires. To aid in comparative analysis, questionnaires contain similar sections and items, adapted where necessary to suit the intended participant.

All three questionnaires aim to determine the target groups’ understanding of STEM education and interdisciplinary teaching. Items were adapted from Bayer (2009) to suit the Irish context, and to suit the target audience (teachers, lecturers or students). Each questionnaire also had items specific to the target group. For example, the teacher questionnaire addressed participants’ team-teaching and collaborative planning experience, as research has suggested a link between teachers’ attitudes to interdisciplinary teaching and attitudes to teamwork (Al Salami *et al.*, 2017). Relevant parts are adapted for mathematics or science teachers. They are also asked about their use of specific teaching practices which have been highlighted in the literature as optimal in science and

mathematics teaching, and which may also be useful for interdisciplinary teaching (Stohlmann *et al.*, 2012; Zemelman *et al.*, 2005). Teachers' views on their role preparing students for third level education, and their familiarity with third-level STEM courses is also investigated. For the lecturer questionnaire, respondents are asked to rate their level of knowledge of Senior Cycle science and mathematics subject curricula, as well as the relevance of mathematics to the first year module(s) they teach. An important aspect of the lecturer questionnaire is to investigate their perceptions of the mathematical gaps that new university students may have in terms of learning science/engineering at third-level. It has long been reported that students experience difficulties with transitioning into third-level for a variety of reasons, including the very different style of learning and teaching compared to school (Harvey *et al.*, 2006; Lovatt & Finlayson, 2013). The student questionnaire therefore investigates student perceptions of their preparedness for learning at university generally, for example in terms of time management issues, critical thinking and conducting independent research (National Forum, 2015), as well as their preparedness for (understanding of and attitudes towards) utilizing their school mathematics within third-level science/engineering modules.

The second phase of our study involves distribution of the questionnaires with a sample of first year science/engineering students, science/engineering lecturers and post-primary teachers teaching senior cycle mathematics/science (currently in process). The student and teacher questionnaires are being distributed in paper form and the lecturer questionnaire will be an online version (SurveyMonkey). Once the questionnaires have been returned, the data will be analysed. Fixed-response items will be analysed statistically using the Statistical Package for the Social Sciences (SPSS). Analysis will include descriptive statistics, reliability testing and correlation of items and variables. Comparative analysis will be performed within and between participant groups. Open-ended items will be analysed using inductive content analysis to derive themes relating to the research questions. A search of social media sites such as Facebook, Twitter and Instagram will be conducted to examine existing networks between second and tertiary level in relation to student preparedness for STEM degrees.

Findings will be used to design an intervention aimed at supporting students at risk of failing first year science modules. It is intended that a more in-depth study on the issue of students' mathematical preparedness for studying science and engineering degrees as well as the existence and perceptions of interdisciplinary STEM teaching and learning will be conducted in light of the findings of this pilot study. A limitation of the pilot study is that the teachers who participate in the survey are not sourced as the prior teachers of the first year students participating in the study. As such, in the subsequent study the authors will aim to survey teachers from the post-primary schools previously attended by the first year students to enhance insight into the issue of transition to science and engineering degrees. Further study will also involve the implementation and evaluation of the designed intervention for first year science degree students.

## Conclusion

This paper has described an innovative pilot study in the Irish context. The study aims to address two issues of utmost importance to STEM education interests on a national and international level.

The first issue, relating to student transition to STEM degrees and student retention in STEM degrees, is a priority not only for educators, but also for policy makers and industry. The authors seek to gain new insight into the preparedness of first year students in science and engineering courses, with a particular focus on students' mathematical preparedness. This insight will be enhanced through the perceptions of three stakeholders in the student transition process; post-primary teachers, university lecturers and students in first year of university. Our findings in this study will also be used to develop targeted support for these students. The second issue we address is perceptions and understanding of interdisciplinary STEM education, which has received increasing attention from researchers internationally, but little research exists in the Irish context. Our study seeks to fill this gap and contribute to the international research. In particular, we take a novel approach in examining the role of interdisciplinary STEM learning in student preparedness for STEM education at tertiary level.

# Pre-service teachers' perspectives on the role of statistics in a learning scenario for promoting STEM integration

Hélia Oliveira<sup>1</sup>, Ana Henriques<sup>1</sup> and Mónica Baptista<sup>1</sup>

<sup>1</sup>Instituto de Educação, Universidade de Lisboa, Portugal

hmoliveira@ie.ulisboa.pt; ahenriques@ie.ulisboa.pt; mbaptista@ie.ulisboa.pt

*This paper reports on a teacher education project aiming to prepare pre-service teachers (PTs) of mathematics and of physics for developing STEM integration activities in school. In this study we aim to analyze pre-service teachers' perspectives about the role of statistics in one interdisciplinary learning scenario to foster the integration of physics and statistics using technology, enacted with 8<sup>th</sup> grade students. Data collected from the group lesson plans and the written individual reflections of the 10 PTs enrolled in the project, qualitatively analysed, reveal that PTs of both subject areas recognize the central role of statistics in the learning scenario in relation with the three considered dimensions of the model of Authentic Integration adopted. However, they also document that the knowledge synthesis of the two areas involves a high level of complexity, and identify several challenges they faced concerning that process.*

*Keywords: Pre-service teachers, teacher education, statistics, STEM.*

## Introduction

A successful STEM integration depends on teachers' perspectives and knowledge to adopt this pedagogical practice, namely to choose effective learning materials and topics suitable for that integration and feel confident in adopting teaching methods beyond traditional ones (Kim & Bolger, 2017; Ní Ríordáin, Johnston, & Walshe, 2016). Thus, it is fundamental that, in their initial teacher education, future teachers have the opportunity to experience interdisciplinary situations to fill their lack of knowledge to develop experiences of articulation between diverse disciplines (Ní Ríordáin et al., 2016). However, in the case of mathematics, some studies show that this is the subject with less benefits in the STEM context (Becker & Parker, 2011) and that quite often mathematics is incidental to the purpose of the integration activities (Fitzallen, 2015). Emerging from a teacher education project with mathematics and physics secondary pre-service teachers (PTs), this study intends to contribute to the debate concerning the preparation of future mathematics teachers for STEM context. We formulated the following research question: what are PTs' perspectives about the role of statistics in a learning scenario with one 8<sup>th</sup> grade class fostering the integration of physics and statistics?

## Theoretical framework

### Pre-service teacher education on STEM integration

One of the main reasons for teachers' negative perception of STEM education is that they feel underprepared to teach within an interdisciplinary curriculum, due to the targeted scope of their own education (Frykholm & Glasson, 2005). In answer to that, several studies suggest introducing

pre-service teachers to curriculum integration during their teacher education programs by engaging them, for example, in developing STEM lesson plans as course work and including hands-on activities and inquiry-based strategies, in order to improve teacher effectiveness and confidence (Kim & Bolger 2017; Koirala & Bowman, 2003). The results of prior studies (e.g. Kim & Bolger, 2017) have shown that the experience of developing STEM lesson plans within the methods course had a positive influence on elementary prospective teachers' attitudes toward STEM. Specifically, the authors saw significant gain on: subject awareness; prospective teachers' perceived ability to create materials for STEM education, confidence and commitment to enact such lessons in their future classroom; their perception of the potential of integration for helping students learn in a fun and interesting way that makes learning meaningful, allowing them to see the connection between science and mathematics and its use in their lives; their perception of the necessity for using team work to accomplish that integration. Other studies (Koirala & Bowman, 2003; Ní Riordan et al., 2016) reported on how PTs viewed the challenges and benefits of firsthand experience developing STEM lesson plans. Many preservice teachers appreciated the emphasis on integration used in the course, which develop their understanding of key aspects of practice that need to be taken into consideration when planning such type of initiatives.

Despite the benefits of engaging PTs in STEM lesson planning within teacher education courses, this is a challenging activity as most of the teachers are unsure of the extent of individual topics that could be integrated within their lesson plans and of the breadth in their own content knowledge needed for teaching in multiple subject areas, due to their limited understanding of both science and mathematics concepts they are expected to teach (Brown & Bogiages, 2019). The same authors emphasized that, in order to be effective on mathematics and science integration, mathematics teachers need to be aware of the potential of science to provide meaningful contexts within which to set, for example, statistical investigations. Similarly, science teachers, who are developing methods for implementing investigations and scientific argumentation in their classrooms, need to be aware of the close ties of statistical tools with decision-making.

To explore authentic integration of science and mathematics, various authors suggest collaboration between mathematics teachers and science teachers as a way to develop their content and pedagogical content knowledge (Frykholm & Glasson, 2005). Though in many teacher education programs prospective mathematics and science teachers get to attend some pedagogy courses together, it is not usual having them discussing interdisciplinary issues of both scientific areas or cooperating in interdisciplinary projects, foreseeing their future teaching practice.

### **The model of “Authentic Integration”**

Research has suggested diverse pedagogical approaches to meet the specific needs in the integration of mathematics and science in classrooms. Such suggestions offer important elements regarding the nature of the lessons that would provide opportunities to students to experience the recognized benefits of integrating mathematics and science. Several studies recommend that the lessons content should be contextualized and taught in an authentic manner involving hands-on, group work, inquiry, and discussion (Frykholm & Glasson, 2005; Treacy & O'Donoghue, 2014). Based on research, Treacy and O'Donoghue (2014) developed a teaching model for integrating mathematics

and science entitled “Authentic Integration” that is rooted in constructivism and requires lessons to be based on rich tasks, which relates to the real world and ensure that group work, inquiry and discussions play a central role in the classroom. The model embodies four characteristics that are considered to be fundamental for allowing that integration. The first characteristic – *knowledge development, synthesis and application* – is related to the integration of knowledge from diverse fields of Mathematics and Sciences, in which students must be able to apply knowledge of both areas to solve a problem in a real context. Another key feature of the integration model is *focused inquiry, as a means of enabling students to develop higher-level thinking* processes. Inquiry, in this study, it is understood as the work around multifaceted tasks that involve in an active way students in: making observations, posing questions, searching in diverse sources of information, planning research, reviewing what is already known about the experiment, using tools to analyze and interpret data, exploring, making predictions to answer the question, and communicating the results (Lederman, 2006). In this type of activity, students are encouraged to use evidence to answer questions and develop their arguments by linking them to scientific knowledge (Lederman, 2006). This kind of activities place students at the center of their learning, promote understanding of phenomena, support argumentation and communication, as well as their reasoning processes and critical thinking (Carlson, Humphrey, & Reinhardt, 2003). Another characteristic of the model is its *application to real-world scenarios*, allowing students to solve problems related to everyday life and to better understand phenomena that are familiar to them. Finally, the model requires lessons to be based on rich tasks, that is, these must *entail challenges based on problems that are transdisciplinary*. This model has proven to be effective in sense that, when the Authentic Instruction model was applied in the classroom, the learning which took place was relevant (Treacy & O’Donoghue, 2014).

## Context and methods

This study is based on an innovative preservice teacher education project aiming to assist 10 Portuguese prospective teachers, enrolled in the first year of master’s programs in the teaching of Mathematics (n=6) and of Physics and Chemistry (n=4) at middle and secondary school levels, in developing knowledge about how to develop integrated STEM activities in school. The project involved one Didactics of Mathematics course and one Practical Preparation course of each program and was developed collaboratively by three teacher educators (the authors) who were responsible for co-teaching these courses. The Didactics of Mathematics course used an inquiry based pedagogical approach with a focus on pedagogical content knowledge to facilitate effective mathematics teaching and to help PTs to understand how to appropriately engage children in learning mathematics, particularly statistics. During one semester, the PTs attended the Practical Preparation courses together, having the opportunity to discuss interdisciplinary issues in these scientific areas and to cooperate among them (working in interdisciplinary small groups of three or four) in planning and enacting an interdisciplinary learning scenario. This learning scenario included a sequence of three lessons to be taught with one 8<sup>th</sup> grade low achievers class, based on a perspective of articulation of the two scientific areas, around an inquiry task (Thaw in Alaska) using technology. The task was created by the teacher educators in collaboration with the PTs and physics cooperating teacher of the class, aiming to promote students’ understanding of the physical

phenomenon of ice breaking by integrating statistical and physical concepts, and working autonomous and collaboratively. The context of the task is realistic as it is based on a contest that occurs every year in Nenana city, Alaska (*Nenana Ice Classic* – [www.nenanaakiceclassic.com](http://www.nenanaakiceclassic.com)). The task asks 8<sup>th</sup> grade students to formulate conjectures on the most probable day of the year and moment of the day to occur the river's thaw, based on statistical data over the last 100 years that were available and explored by them using *TinkerPlots*<sup>TM</sup> software (Konold & Miller, 2005). Simultaneously, these students were required to use their knowledge from physics, to interpret the icebreaking phenomenon in that river and to give scientific arguments that could explain the moment when it occurs. Therefore, this inquiry task motivates students to mobilize and connect knowledge from statistics and physics.

For this study we collected the group lesson plans and the individual assignments of the 10 PTs (mentioned by fictitious names) written after they taught the planned lessons to the 8<sup>th</sup> grade class, where they were asked to reflect about their experience of planning and enacting the learning scenario in school. The qualitative data analysis carried out focuses on three dimensions of the Authentic Integration model: *application to real-world scenarios*, *high order thinking processes*; and *knowledge development, synthesis and application*. For data analyses purpose we searched in the PTs' individual assignments for instances where they explicitly mention elements concerning statistics present in the task or in students' intended or actual activity with the task, for each of the three dimensions of the model. Additionally we read all lesson plans as complementary information to the PTs' written reflections.

## Results

### Application to real-world scenarios

There is a shared recognition on part of these PTs that the task has a strong connection with a real-world scenario. For instance, the PTs value the fact that the situation proposed to students is related to a contest that actually occurs every year. The learning scenario is seen by the PTs as an opportunity for showing students that the statistics and physics they learn at school can be applicable to real life. From the point of view of some PTs, and due to its interdisciplinary nature, the task helps students to perceive that concepts of these two areas are not “only vague concepts and useless in the real world” (Elsa).

The specific role of statistics in the task, in relation to its context, is also recognized by the PTs. The fact that students are asked to analyse real world data is seen as an opportunity to develop new knowledge about the world and not just something they have to do to give an answer to the questions included in the task:

This task gave students the opportunity to develop their knowledge about the real meaning of statistical data and also about physical processes that occur in nature (...); this allows students to gain knowledge about the tangible world. (Carlota)

Some PTs also mention that students can explore a large amount of data by using *Tinkerplots* software, which contributes to a deeper understanding of the situation. The software potentiality to help students in the interpretation of data and to establish relationship with the real-world situation

is highlighted by some PTs: “[The software] by facilitating the interpretation of the data allows students to draw better conclusions about them and also to assign more meaning to them in the context in which they belong” (Daniela). Therefore they acknowledge the centrality of statistics in the task by the exploration students are asked to do of real data.

An aspect that is less mentioned by PTs is that the learning carried out around a real context, in this case a contest, can be mobilized in other situations. However, one of these PTs mentions that students may face challenges in the future:

that require skills and competences developed here. In fact, it is important to have the capacity to look at data and to observe how they can provide important information for future challenges, as the students looked at provided data and tried to understand how they could help them make the best bet. (Madalena)

### **High order thinking processes**

During the work carried out in designing the learning scenario with the PTs, the teacher educators emphasized the intention that students could be involved in inquiry processes. Therefore, it is not surprising that, in their reflections, PTs’ classify the task as an inquiry and describe some high order thinking processes related to statistics present in students’ activity, such as, to make predictions and conjectures, explore and interpret data and draw conclusions, and present scientific arguments and counter-arguments. For instance, one PT recognizes several processes according to the different parts of the task as they had different features:

if an inquiry perspective is adopted for the task; in the section “My idea is ...” students have to formulate hypothesis and to investigate the veracity of these hypotheses by integrating the technology (in the section “The data collected indicate that ...”), and finally to draw conclusions, communicate the results obtained and justify them on the basis of their investigations. (Carlota)

As PTs reflect about students’ work with statistics around the exploration of data with the software, they describe high order statistical processes fostered by the task always in that context. They recognise that technology has a central role in supporting students in analysing variables in different representations to draw conclusions:

The study of the variables related to the moment of day and moment of month (...) allows clarifying the analysis done, and promotes not only a greater diversity of graphical representations and the consequent development of the capacities of reading and graphic interpretation, as well as a deepening of the conclusions obtained from these. (Madalena)

Some PTs also recognize the important role of technology in association with the inquiry task to promote other thinking processes such as interpretation and reflection: “Technology allows differentiated contact with statistics and learning is promoted by the fact that the task requires students’ interpretation and reflection and not only a mechanical work” (Elsa). By high lightening these processes, these PTs show that they ascribe an important and central role to statistics in the learning scenario.

The experience of task enactment in the classroom made it possible to recognize that the involved processes are very demanding for many students. PTs relate the difficulties they have noticed in

students both with their knowledge of mathematics and physics and their unfamiliarity with this type of proposal. For example, one PT mentioned that:

the students also showed some difficulties in being able to justify their ideas (...) and to present a scientific justification for the conclusions written from the analysis of the data, using the technological resource. (Cristina)

Also the software's potentiality of generating multiple representations has represented a difficulty for students, as they have to find out the representations that best support them in interpreting the data and drawing conclusions.

### **Knowledge development, synthesis and application**

Within the learning scenario that has been designed there was no intention of teaching new topics in statistics or physics but to create a situation where students could mobilise their knowledge from those two subjects to support their thinking. PTs seem to have well understood that perspective and as such they have identified certain statistical topics in students' activity with the task, such as treatment and analysis of data, measures of central tendency or the concept of probability. This last concept has been mentioned by one of the Physics PTs, which is something interesting in this context: "By analyzing the students' answers, it is possible to verify that there are students who have managed to apprehend the probabilistic meaning [of the required answer] when they refer *at 15h it will be more likely to occur the thaw*" (Micaela).

The knowledge synthesis of the two areas is a key aspect in the adopted model of "authentic integration" but at the same time it encompasses a high level of complexity. When reflecting on the planning of these lessons, the PTs recognize that they haven't given the necessary attention to this process in order to support students:

I also stress the [students'] difficulty in relating the data obtained in *TinkerPlots* with the physical explanation. Some students had a tendency to respond that the temperature was responsible for the thaw, however, they did not relate the months obtained in *TinkerPlots* and the particular case of Nenana [river]. (António)

Some PTs point out the structure of the task as a limitation but also their planning and enactment of these lessons, where they could have promoted a systematization of ideas in order to help student to make connections between the reasoning they have developed within each of the two scientific areas. In fact, some PTs recognize they have conducted the whole class discussion of students' work in a way that did not provoke the intended knowledge synthesis:

We also failed in the discussion moment as we did not make a projection [to the whole class] of the students' solutions using *TinkerPlots* (...) that would have allowed debating in depth the topic of central tendency measures and (...) to give a scientific explanation for the obtained results. (Matilde)

Additionally, PTs have admitted that has been quite challenging to them to work with topics from the other subject. Their content knowledge preparation in only one of the areas was also felt by some of them as a constraint to be able to promote the synthesis of knowledge:

there is no doubt that it is a big challenge to integrate the two subjects in a single task, as during our academic trajectory we only had contact with the design of tasks that only making use of mathematics. (Cristina)

However, every PT mention the opportunity to work in small groups with colleagues from the other area which represented from their point of view an essential contribution to design and enact the learning scenario in the classroom: “some statistical concepts that I could no longer remember, the colleagues in my group helped me to remember them, and I tried to help them with some physical concepts that would be necessary to solve the task” (Carlos).

## Conclusions

The design and enactment of a learning scenario within statistics and physics, adopting the model of “authentic integration” (Treacy & O’Donoghue, 2014), has proven to be an opportunity for these PTs to acquire real experience of STEM practice, which they highly value. When reflecting on this one semester experience, PTs show an awareness of the role of statistics in different activities that have been carried out in relation with the three considered dimensions of the model. In opposition to other studies where mathematics tends to be incidental to the STEM context (Fitzallen, 2015), both groups of PTs in this study considered that statistics assumes great centrality in the learning scenario that has been developed. One reason for the recognized visibility of statistics may be related to the features of the task itself as it requires students to analyse real world data (the 1<sup>st</sup> dimension considered in the model). These PTs highly value this dimension of the task in the sense of making learning meaningful and showing the usefulness of statistics (and also physics) to students, results also present in the study by Kim and Bolger (2017).

PTs also perceive that the task demanded high order thinking processes (the 2<sup>nd</sup> dimension) that were supported by statistics. The inquiry nature of the task required the exploration and interpretation of statistical data in order to make conjectures and draw conclusions, something that put into evidence the role of statistical tools for decision-making in STEM contexts (Brown & Bogiages, 2019). PTs also stress the important role of technology for promoting inquiry processes (Lederman, 2006), in this case with the statistical software.

From the formative point of view, it is also relevant that PTs show a critical stance regarding the effective opportunities provided for knowledge synthesis of the two subject areas (part of the 3<sup>rd</sup> dimension). Acknowledging that this process involves a high level of complexity, PTs recognize the challenges they faced and the need to give particular attention to this aspect when planning the lessons (Koirala & Bowman, 2003; Ní Riordan et al., 2016).

This study shows the feasibility of developing an interdisciplinary learning scenario in a pre-service teacher education program with two distinct areas, using a specific model. However, as this is a time consuming activity in its different aspects (Brown & Bogiages, 2019), from designing the task to the elaboration of the lesson plan, it needs to be reflected when designing the courses. Collaboration among peers from two different subject areas has revealed to be quite beneficial for these PTs and of significance in supporting an integrative approach to teaching mathematics and physics. Therefore the model of “authentic integration” seems to be adequate to support teachers from diverse subjects to work together in a STEM context.

*As a result of focused efforts to promote STEM education, there is an increased interest in understanding the use of engineering and technology contexts to teach mathematics in K-12 classrooms. This design research was conducted in a grade 7 classroom of a suburban school. Analysis of student interviews revealed that the students possess a rudimentary understanding of parallel lines and lack a conceptual understanding of angles. These notions were used to design and develop mathematical instructional tasks with an engineering problem as the context in order to motivate students understanding to more sophisticated notions of angles and parallel lines.*

## Introduction

The intricacies of today's technologically advanced world have pushed educators to rethink the set of core skills and knowledge that current students should learn. Included among these skills is problem solving, gathering data, evaluating evidence, making sense of information and communicating findings with others. Science, Technology, Engineering, and Mathematics (STEM) education provides students with opportunities to develop such skills and knowledge and also the application of that knowledge (Mahoney, 2010). STEM education started as a way of providing additional rigor and depth for gifted students, but over the years it has proven effective with a range of students and, in fact, has improved disadvantaged students' motivation and performance (Kim & Law, 2012). This understanding of the importance and necessity of student-centered approaches has pushed researchers and policymakers' work towards increasing student-learning opportunities in United States (Brown, 2012). Given the emphasis, there is no surprise that there is a huge push for educational standards reforms by organizations such as National Council of Teachers of Mathematics, the National Research Council, and the International Technology Education Association. Recent educational standards reforms such as *Next Generation Science Standards* (NGSS) and *Common Core State Standards for Mathematics* (CCSSM) encourage integration of engineering and technology in science and mathematics classrooms (Kuenzi, 2008).

The underlying intent of these mathematics standards is to enculturate students into the mathematical practices that will encourage deeper understanding of the concepts (cf. Standards for Mathematical Practices, CCSSM) and help students apply mathematics to the world around them (Brown, 2012). STEM-based mathematics learning, at its heart, is an investigative process that allows the learner to dive deeply into a topic and use mathematics to create a solution. A student centric approach like STEM-based learning becomes not only a viable method of teaching and learning, but possibly a highly effective method as well (Bybee, 2010). The central idea with STEM education is promoting pedagogical practices that are student centric. That is, teachers play the role of facilitators as opposed to the traditional knowledge provider.

Teachers employ several instructional strategies including student-led presentations, problem-based learning, brainstorming sessions, small group discussions, simulations, student-led experiments and engineering designs and so on (Fairweather, 2008). In the world of mathematics, STEM-based learning allows students to use mathematics within the context of other subject areas to solve problems. This process requires students to learn math to apply to the formation of a solution or solutions. The math is never separated from other disciplines, thereby making the construction and the application of knowledge easier (Fairweather, 2008). STEM-based learning accesses the students' knowledge and engages students to be part of a community collaborating together on activities (Blumenfeld, Krajcik, Marx, & Soloway, 1994). Thus, students share what they already know with other students in the group toward finding solutions for the tasks at hand. Students discuss, justify, and argue about the mathematics as part of this collaboration. This research paper is a part of a larger research study that aimed to contribute to the ongoing dialogue regarding the efficacy of genuine STEM integration. Specifically, this study explored the process of design and implementation of a classroom-learning trajectory (Stephan, 2014) that integrated mathematics and engineering in an authentic manner to evoke STEM practices more generally. Our goal was to explore the feasibility of using engineering contexts to teach mathematics and to develop a conceptual framework for effective STEM integration. The rationale behind choosing a design based research approach was the ability to contribute to development of theory and educational practices together given that the inter-relation between them is complex and dynamic (Plomp & Nieveen, 2007).

## **Literature review**

This review highlights the research on two notions that form the core of the arguments presented throughout the paper. The first section encompasses the present nature and understanding of STEM integration in K-12 education and the subsection on student conception of angles and parallel lines summarizes the framework for the analysis of the related student interviews.

### **STEM integration**

While there has been a nationwide push to increase STEM in secondary schools, the debate regarding the best practices for integrating STEM across multiple subjects still exists (Stephan, Pugalee, Cline, & Cline, 2016). Therefore, new theories of best integration practices in STEM are still being conceptualized and pursued. One of the greatest challenges facing secondary STEM teachers today is seamlessly and effectively integrating STEM content as well as the related processes into their core classes. A common barrier for this integration is accurately navigating the multiple static components of a STEM curriculum. The introduction of engineering as a critical component of STEM education is especially problematic for educators who have little training or prior skills with engineering content and principles. When STEM integrated lessons are based in systems thinking, the teaching of multiple subjects becomes less rigid. Kelley and Knowels (2016) conceptual framework for integrated STEM education alludes to this idea with their pulley system model. However they place the emphasis heavily on engineering design and scientific inquiry, which can lead to fewer instances for mathematics and technology to be a central part of the STEM system. Wang, Moore, Roehrig and Park (2011) showed that successful STEM integration is

possible using their case study of three middle school teachers. Their important findings included that teachers need more content knowledge especially in engineering and technology and that their STEM classroom practices depend on their perception of the use of STEM integration, which is influenced by their primary discipline. Also, typically mathematics is taught first to solve an engineering challenge whereas in our approach instructional sequences are designed to use an engineering challenge to motivate students thinking of mathematics.

### **Student conception of angles and parallel lines**

In this research, students' current conceptions of angles and parallel lines are explored through their concept image. Tall and Vinner (1981) defines concept image as "...the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p.152). Keiser, Klee, and Fitch (2003), in their action-based research with 77 sixth grade students, highlighted the limitation posed by definitions of mathematical concepts as, "the truth is that all definitions, by their very nature, tend to limit concepts because they establish boundaries" (p.117). The idea is that a definition can focus on one aspect of the concept, which may lead to students not having a well-developed concept image. Keiser (2004) further expands this notion of angle as a concept: What exactly is being measured when referring to the size of angles?, Can angles contain curves?, and difficulties with conceiving of  $0^\circ$ ,  $180^\circ$ , and  $360^\circ$  angles. Fyhn (2008) summarized the research on cognition of angles and the key ideas of angles: Angle as a static geometric shape, dynamic notion, and as measure; and Angle without arc (as linked line), with arc (angle space), with arrow (part of a plane) and with rotation arrow (creation can be described by rotation of a ray). Happs and Mansfield (1989) identified the following as the common misconceptions about parallel lines that students bring to lessons: parallel segments must be aligned; and presence of arrows or dots on the ends of lines affects whether or not those lines are parallel.

### **Methodology**

The research reported in this paper aims to capture the students' conception of angles and parallel lines in order to design the engineering context based instructional sequences for a middle grades mathematics classroom. The research was conducted in a 7th grade mathematics classroom of a STEM middle school in a suburban school district in the southeast region of United States. The classroom teacher was part of the design team along with faculty specializing in mathematics education, chemistry, and engineering at a large urban university and a mathematics education faculty member from an international university. This research is comprised of a pre-interview to assess the existing conceptions of angles and parallel lines, design and implementation of engineering-based instructional sequences and a post-interview to assess the changes in conceptions of angles and parallel lines. This research paper focuses mainly on the analysis of the pre-interview questions dealing with angles and parallel lines along with preliminary discussion of the design of the instructional sequence.

Before developing the instructional sequences, 4 students (2 male and 2 female students) at different academic performance levels (as identified by the classroom teacher) were interviewed. The student's cumulative performance on prior assessments in their current classroom was used as the criteria to classify the four academic performance levels as *high*, *above average*, *average* and

low. These four students engaged in a pre-interview with questions designed to probe their understanding of angles and parallel lines and an engineering problem. The purpose of these interviews was to learn the students' current conceptions of these mathematical and engineering ideas and design the instructional sequences appropriately for the entire classroom. The interview questions probed for the students' conceptual understanding of angles, parallel lines and their strategies in solving the engineering problem. The first angles question prompted the students to identify the biggest and smallest angle from a set of angles represented diagrammatically (Figure 1). The second set of angles questions asked the students to identify the number of angles in various diagrams such as a triangle (Figure 1) and validate their solution with a mathematical argument. Similarly, the parallel lines questions asked students to identify if the given lines, curves and geometric shapes (e.g., Figure 1) have anything parallel in them and validate their solution with a mathematical argument.

**Figure 1: Sample questions from the pre-interview questionnaire**

In analyzing the student responses, the constant comparative method (Glaser, 1965) was utilized in order to identify themes that are grounded within the data. The student justifications were broken down into discrete incidents. Researchers simultaneously coded and analyzed these specific incidents to inductively reason the categories for codes and their properties. Three researchers met and analyzed the student responses from the videos and identified emerging categories as the students communicated his/her mathematical arguments. The analysis also took into account the hand gestures of the students. Select portions of the videos were transcribed later for inclusion in the research. Constantly identifying and comparing the relationships between these categories led to the final themes. Once a theme emerged, data analyses were continued to either support or refute the theme until all the student responses were analyzed. This process was the same for both the angles and parallel lines questions, but analysis for each topic was performed separately.

## Findings and discussion

This analysis of the students' conceptions of angles and parallel lines comes from the pre-interview data, before instruction with an engineering context to teach the same mathematical concepts. The following three themes emerged from the angles questionnaire analysis: Using Prototypes or Reference Images, Tracing of the Lines, and Decoupling versus Decomposing.

### Theme one: Using prototypes or reference images

The first theme that emerged from the data analysis was the idea of using prototypes or reference images of angles to identify and define angles. All of the students shared this notion where they used reference images such as  $90^\circ$ -,  $180^\circ$ - and  $360^\circ$ -angles or used the definitions of acute and obtuse angles. The students associated the word  $90^\circ$  or  $180^\circ$  with the diagrammatic representation of the same without any understanding of what it means that a right angle is  $90^\circ$ . For instance, the

student below expressed their confusion with straight angle and straight line, likely, as they had seen a straight line referred to as both a straight angle and a straight line in the past.

Student: This is a straight...

Interviewer: Straight what?

Student: It is either a straight line or a straight angle because this is a whole 180.

### Theme two: Tracing of the lines

A second theme that emerged from the data analysis was the idea of tracing the line to see if it changes direction as a rationale to identify if there is an angle. For instance, the student below, when asked to identify the number of angles in the given diagrammatic representation of the right triangle in Figure 1, reasoned that there was one angle because there was a corner which makes the line go in two different directions. The student viewed the rays of the angle dynamically in that a dot could be used to trace along one ray and then change direction to follow the other ray, thus, producing an angle. A different student traced the line as well, but the conception of angle was not as dynamic. The student viewed the two lines as two static entities connected at a point to form an angle.

Student: So here's the main line and then it's starting to go up as in 90 degrees.

Interviewer: The main line is going this way (horizontal), then the other line this way (vertical)

Student: Yes, in a 90 degree angle.

### Theme three: Decoupling versus decomposing

A third theme was the idea of dissociating the original angle from the two new angles when the original angle is split into two by a new ray. In other words, the students counted the whole angle as an angle and the two new split angles; each as one but they did not worry to check if the sum of the two new angles equals the original angle when they were asked to estimate the angles.

Figure 2: Decoupling of angles

In Figure 2, the student estimated the three angles of the equilateral triangle to be  $75^\circ$  and then the two split angles on the top to be  $25^\circ$  each. We also observed another case, where the student expressed that the original angle is no longer available when it is split and only the two new angles are left. In other words, they view the new right-angled triangles as a decoupled shape as opposed to decomposing the angle from the equilateral triangle into two right-angled triangles.

The following two themes emerged from the parallel line questionnaire analysis: Never Touch and Same Shape Pattern.

### Theme one: Never touch

The first theme that emerged from the data analysis was the idea that something is parallel if they never touch. This is evident in one student's use of railroad tracks as an example. The questionnaire began with sets of lines oriented in different angles and were misaligned the reasoning that they will never touch was predominately used by all students for these questions with lines.

Interviewer: How about these?

Student: Parallel, I see this mainly because they still won't touch.

### Theme two: Same shape pattern

Another theme that emerged from the data analysis was the idea that for two lines or curves to be parallel they must have the same shape pattern and align in the same direction. This reasoning of having the same shape pattern emerged only when curves were introduced in the questions.

Interviewer: How do you know that they are never going to touch each other?

Student: As long as this pattern is maintained, they're never going to touch.

However, two of the students extended the curves into a line to show that either the two lines/curves touch or not touch to justify their argument of whether they are or are not parallel. For instance, in Figure 3, the student extended the curve at the bottom as a line to touch the straight line on the top instead of following the pattern of the curve at the bottom. This shows that the students preferred the never touch rule over the same shape pattern when justifying their argument as to whether they are or are not parallel.

**Figure 3: Parallel lines/curves never touch**

From our analysis of students' existing notions of parallel lines, the students' mathematical arguments were rudimentary and based on their prior experiences of parallel lines either in mathematics or other subject areas. This is evident in the classic railroad track example followed by the justification that the two tracks never touch. Students demonstrated difficulty in extending the notion of the lines that never touch to more sophisticated notions such as that the lines are equidistant from each other. This exploration of student's understanding of angles and parallel lines combined with perspectives from the literature was utilized to design the context of the engineering based instructional sequence for the classroom.

### Design of engineering problem based instructional sequences

Gravemeijer and Doorman (1999) highlight the role of context problems as, "...context problems are intended for supporting a reinvention process that enables students to come to grips with formal mathematics" (p. 111). Combining this notion with the understanding of the students' concept images of angles and parallel lines which is rudimentary as revealed in the findings above, the instructional sequences of building parallel roads in a residential community and constructing 3D models of two-story homes was developed. The problems within the sequences were designed to capitalize on students' current conceptions of angles and parallel lines (as revealed in the

interviews), yet utilizing contextual features to revise those conceptions. The instructional activities were designed to develop students' understanding of measuring angles as the degree of turn and parallel lines as the same distance apart. Designing a residential community is the engineering problem used to provide context for the mathematical task where the students identified the design constraints from an architect's brief. In essence, the students played the role of an architect and were asked to develop the Phase II of an existing residential community given a map of Phase I.

One of the constraints was to build a road parallel to the existing road on Phase I for aesthetic reasons, the context for the first mathematical instructional sequence. Student groups explored the possibility of using pre-drawn, existing parallel roads in Phase I and measuring the distance between the two existing roads to create new parallel roads. This led to the discussion of the concept of equidistance in parallel lines. Similar instructional sequences were used to develop the notions of parallel lines using angles. A post-interview was conducted to study if the engineering based instructional sequence, which was designed based on the pre-interview questionnaire analysis helped the students improve their understanding of the mathematical concepts related to angles and parallel lines. Due to page limitations, the analysis of the post-interview and additional instructional sequences are not discussed here and instead was discussed in detailed at the congress during the presentation. Post-interview analysis revealed that there was an overall improvement in conceptual understanding of angles and parallel lines among the four students.

Current in-service mathematics teachers are asked to design and teach in STEM integrated classrooms, yet most of them are not academically trained in engineering and technology. This study is part of a larger investigation focused on a research-based framework for STEM integration. The analysis of student thinking relative to angles and parallel lines is important to this study as a foundation for informing the larger design research process. The analysis of student thinking revealed several limitations in students' current conceptualization of angles and parallel lines, both of which are critical components in the target instructional tasks embedded within the engineering context of planning the roads and houses in a community. The students' current perspectives with limited understanding of angles and parallel lines inform the larger design research study by setting up instructional tasks that specifically address these issues. This study underscores the role of visiting and revisiting student thinking as a necessary step in the design research process.

# Opportunities to engage in STEM practices: Technology and design course

Behiye Ubuz

Middle East Technical University, Ankara; [ubuz@metu.edu.tr](mailto:ubuz@metu.edu.tr)

*Technology and design courses hold a potential to contribute to the STEM agenda. In this study I seek to explore the nature of STEM education across the courses, particularly examining 7<sup>th</sup> grade intended curriculum in Turkey in terms of engineering design process and knowledge base. By extensive examination and coding of learning outcomes together with explanation provided under each one I identified instances of engineering design process and knowledge by learning areas. 52 learning outcomes (27 with emphasis on knowledge and 25 with engineering design) were identified in the intended curriculum.*

*Keywords: Engineering design process, knowledge, STEM, technology and design course.*

## Introduction

Technology and Design (T & D) courses, or similar forms, have been taught in many countries around the world. T & D courses hold potential to contribute to the Science, Technology, Engineering and Mathematics (STEM) education agenda, however currently this is not wholly examined how. The purpose of this study was to explore the way T & D course in Turkey contributes to the STEM education agenda. Specifically, the aim was to explore how existing 7<sup>th</sup> grade T & D course intended curriculum (Milli Eğitim Bakanlığı, 2017) concretize engineering design process (EDP) together with knowledge base combined with it, with the ultimate purpose of providing direction in understanding STEM education. EDP combines knowledge and skills from a variety of fields with the application of values and understanding of societal needs to create systems, components, or processes to meet human needs (NAE, 2009, p.9). The research questions of the study were:

1. To what extent is engineering design process present in the 7<sup>th</sup> grade T & D course intended curriculum in Turkey?
2. What are the central knowledge of engineering and technology that are present in existing curriculum?
3. What are the central knowledge of mathematics and science that are present in existing curriculum?

This study provided a window into the nature of STEM education across T & D courses. This information provided educational researchers, policy makers, and K-12 teachers with a detailed picture of what STEM education is, especially when that vision of STEM education includes engineering and technology. This study was significant in order to demonstrate possibilities for a systematic integrated framework for engineering and technology in K-12.

## What is the engineering design process?

EDP is the iterative process for creation and manipulation of the human-made world. It is one of the six tenets for successful STEM education (Moore et al., 2014). A number of core characteristics of

EDP are (1) the design process begins with problem definition; (2) design problems have many possible solutions and engineers must find systematic approaches to choosing between these; (3) design requires modeling and analysis; and (4) the design process is iterative (Berland, Steingut, & Ko, 2014, p.706). Figure 1 summarizes these four characteristics of engineering design, articulating the key aspects of each characteristic and highlighting the aspects that create the most opportunity for mathematics and science integration.

Characteristic of design process	Key aspects of the characteristic as identified in the literature
Defining the problem	Interviewing users and stake holders Identifying the need that will be solved Identifying sub-problems and goals Exploring existing solutions <i>Describing the need in terms of quantifiable success criteria</i> <i>Understanding key math and science principles</i>
Generating and selecting between multiple possible solutions	Identifying multiple possible solution  <i>Developing systematic approach for choosing between solutions by balancing different goals of the project</i>
Modeling and analysis	<i>Modeling parts of the existing system into which the solution must fit</i> <i>Collecting, modeling, and analyzing performance data</i>
Iteration	Revisiting previously completed steps in order to improve designs <i>(some steps may require revision of math and science use previously completed)</i>

Note: Italics indicate the quantitative aspects that create the strongest opportunities for integration of traditional math and science content. Taken from Berland, Steingut, and Ko (2014, p.708)

**Figure 1: Summary of the four characteristics of engineering design**

## Methodology

T & D course is a school subject offered as a compulsory course at the 7<sup>th</sup> and 8<sup>th</sup> grades in Turkey for two hours a week. In this context, individuals who complete the T & D course can observe and interpret objects, events, and facts in their surrounding in an analytical perspective, can develop creative and original alternative suggestions to the problems identified, and can make evaluations of these suggestions and decide on the appropriate one. T & D course intended curriculum was created according to the learning area approach. Learning areas are (A) Technology and Design Basics, (B) Design Process and Introduction (promotion), (C) Built Environment and Product, (Ç) Needs and Innovations; and (D) Design and Technological Solution.

To accomplish the aim of the study, I examined the 7<sup>th</sup> grade T & D course intended curriculum learning outcomes together with the explanations provided under each one. Learning outcomes helps to identify assumptions about what knowledge and skills the students need to bring to succeed. Although learning outcomes might differ in the ways they are written, they all express the

same idea and that is what the learner should know, do, or feel. Explanations provided under each learning outcomes assists teachers in building knowledge and skills in accordance with learning outcomes. Content analysis of learning outcomes was conducted using line-by-line analysis. The operational definitions of EDP (see Figure 1) and the five components of learning outcomes proposed by Gagné and Briggs (1974) guided the initial open coding of the outcomes. The unit of analysis during all phases of coding was the phrase. While coding the learning outcomes individually as phrases, a word analysis was deemed helpful in locating and portraying the big ideas of EDP and knowledge base. The most common verbs (see Figure 2) and objects (see Figure 3) found in the learning outcomes regarding EDP and knowledge base are provided below.

<b>EDP</b>	<b>Knowledge</b>
Apply	Compare
Create	Describe
Design	Provide
Evaluate	State
Prepare	
Present	
Reinterpret	
Restructure	
Show	
Tell	

**Figure 2: Most found verbs in EDP and knowledge**

All outcomes were coded using the following two primary categories: EDP, or knowledge. Outcomes that fit the category of EDP went into one of the four categories of EDP provided in Figure 1 as well as a new category labelled as presentation. Outcomes that fit the category of knowledge went into one of the three categories: Design, technology, or design and technology. An example learning outcome was: “7.A.2.1. State the elements of art/design”. This statement implies knowledge as “state” refers to capability verb pointing out verbal information and “the elements of art/design” refers to object that the learner will produce as a result of action. Additionally, the opportunities for using or integrating mathematics and science in these two main categories were also examined. Inter-rater reliability verified consistency among two individuals through descriptive statistical measures.

<b>EDP</b>	<b>Knowledge</b>
Design	Design concepts
Model	Design principles
Prototype	Elements of art/design
Product	Examples
	Technology concepts
	Technological developments

**Figure 3: Most found objects in EDP and knowledge**

## Results

A close analysis of the 7<sup>th</sup> grade T & D course intended curriculum reveals EDP together with knowledge base in technology and design. 52 learning outcomes (27 with emphasis on knowledge and 25 with EDP) (see Table 1) were identified in the intended curriculum. Core characteristics of the EDP and knowledge base are presented in Figure 4 and 5, respectively. Some explanations were found to have explicit references to mathematics and science. Regarding mathematics, two-three dimensional space appeared for producing or demonstrating a design, ratio-proportion as one of the design principle, measurement for analyzing physical dimensions of architectural structures or buildings, and graphing for representing a design. Explicit references to science were about energy, force, pressure, durability, resistance, balance, corrosion, or geography (geographical and climate conditions).

**Table 1: Number of learning outcomes at the 7<sup>th</sup> grade on knowledge and EDP by learning area**

	Learning Areas					Total
	A	B	C	Ç	D	
<b>Knowledge</b>						
Design	3	10	7	-	-	20
Technology	2	-	-	1	-	3
Both	2	1	-	1	-	4
<b>EDP</b>						
Defining the problem	1	1	-	1	1	4
Generating and selecting between multiple possible solutions		1			2	3
Modeling and analysis	1	2	4	2	1	10
Iteration	1	1	1		2	5
Presentation		1		1	1	3
Total	10	17	12	6	7	52

Because of the space restriction, learning outcomes together with their coding are given only regarding to the two learning areas (see Figure 6 and 7).

## Conclusion

This investigation provided a window into what STEM education look like in a T & D course within middle school. This curriculum could support teachers' integration of STEM disciplines, particularly an understanding of the nature of EDP skills that would develop their ability to effectively integrate EDP into their science and mathematics instruction. This has great implications if integrated STEM is to include EDP. The degree of integration, however, would be related to the teachers' awareness of how to make explicit and meaningful connections between the disciplines.

This study also showed that the ideas expressed by Berland, Steingut, and Ko (2014) related to characteristics of EDP were present in the document analyzed together with the new additional characteristic named as presentation and key aspects of them. This will provide opportunity to compare the results found here with what courses offered in other countries.

Characteristic of design process	Key aspects of the characteristics as identified in the curriculum
Defining the problem	Investigation of examples according to different criteria based on venue, lighting, colour, texture, physical measurements, geographical conditions, forms of life, manufacturing processes, necessary resources, security measures, environmental factors, user, applications, material Following and reading published public spots, visual-print media news, and scientific research
Generating and selecting between multiple possible solutions	Developing solution alternatives and choosing the appropriate one based on the criteria pointed out in defining problem
Modeling and analysis	Creating model, prototype, drawings, or maquette of the design
Iteration	Revisiting previously completed steps in order to re-interpret or restructure designs based on the predetermined criteria or evaluation
Presentation	Short films, computer aided presentations, promotional card, poster, flyer

**Figure 4: Summary of the five characteristics of EDP identified in the curriculum**

Knowledge		
Design	Technology	Design and Technology
Industrial design	Invention, discovery, science, techniques, technology, industry, industry 4	Relation between them and how they affect each other
Graphic design	Historical development of technology	Positive and negative contributions of them to daily flow of life
Architectural design	Technologies to acquire energy	The importance of them to solve problems
Environmental design		
Elements of art/design		
Ergonomics		
Mechanical properties of design

<sup>2</sup>P.Porto, ISEP, Math Department, Portugal; [ipf@isep.ipp.pt](mailto:ipf@isep.ipp.pt)

*Today, although teachers continuously seek novel pedagogical approaches, it is largely agreed that schools face major problems around student motivation and engagement. In this context, gamification can have good effects, since the gamification, when used as a teaching strategy, favors learning and the motivation. Though the gamification is a subject that is very discussed in the educational field, still's little implemented, especially in higher education. In this work we present one gamification experience with first year and first semester students in a mathematical curricular unit. The goal was reduced school dropouts, which have a traditionally very high rate in these curricular units and increase the motivation to empower students for better learning and a higher passing rate. Although this experience does not allow for conclusions, it can be verified that the students were more motivated, the dropout rate was lower, and the approval rate was good.*

*Keywords: Gamification, higher education, pedagogy.*

### Introduction

Traditional schooling is perceived as ineffective and tedious by many students and in a special way a large group of students in the first year of engineering courses, does not like math classes which leads to high dropout and failure rates. At a time when most of the young audience plays computer and video games, the gamification can be a good help, because gamification tries to harness the motivational power of games and apply them to real-world problems, in our case, students' motivational problems.

A lot of papers reporting experiences with gamification have appeared in the last years, but the idea of using thought and game mechanics to solve problems is old (Viamonte, 2018). According to Zichermann and Cunningham (2011), was the Scottish philosopher David Hume who first laid the groundwork for understanding the player's motivations at three hundred years ago. But Gamification is not only about introducing game elements, such as the distribution of rewards and medals for a given product, but it requires an in-depth approach to decide which elements will be incorporated and their conformity with the context of the goal. According Gurjanow and Ludwig (2017), prior to implementing game elements, recommend analyzing the projects target group, the conditions and the inherent activities. The result of the analysis is the definition of goals that gamification should achieve. The next step is to design and implement game elements based on the defined goals. Finally, evaluation and monitoring are useful to make further improvements (Gurjanow & Ludwig, 2017).

There is no consensus about gamification, for example, while some authors highlight the following elements of games to be observed in gamification: objective, rules and voluntary participation, Werbach and Hunter define the PBL Triad: Points, Badges, Leaderboards (Franco et al., 2015). But we can see that when we use the 'gamification' in the classroom, some transformations always occur, such as, students who become players, more challenging classes, students working autonomously

and/or in groups and working to earn points, receive medals, achieve the highest scores and enter the leaderboard...

In this work we pretended study the question: Is gamification effective in reducing dropout?

## **Gamification**

According to Iosup and Epema (2014), gamification may have originated in the early-Communist thought and matured in the Soviet era, as a substitute for monetary incentives to perform at work and saw a reemergence in the U.S. in the early 1980s. More recently, in the 2000s gamification received various definitions, and was used with promising results in various curricular and organizational settings. For Espíndola (2014) the gamification is the use of game mechanics and dynamics to engage people, solve problems and improve learning, motivating actions and behaviors in environments outside the context of games.

According to Kapp (2015) gamification is a tool with advantages and disadvantages in different situations and environments. Gamification only uses a few game elements. Learners don't play an entire game from start to finish; they participate in activities that include video or mobile game elements such as earning points, overcoming a challenge or receiving badges for accomplishing tasks.

McGonigal (2011) highlights the following elements of games to be observed in gamification: objective, rules and voluntary participation. Werbach and Hunter (2012) define the PBL Triad (Points, Badges, Leaderboards) as an initial parameter consisting of the following elements: points, medals and rankings. The authors of this work also divided the main elements into three categories, dynamics: constraints (imposed limitations), emotions, narrative, progression and social relation; mechanical - elements that stimulate actions and involve the player: challenges, competition, feedback (performance), randomness, cooperation (teamwork), rewards and victory and components: medals (visual representation), rankings (visual representation of evolution), points (numerical representation), levels of progression, team formation, final challenge, collections and unlocking content after accomplishing the mission. (Viamonte, 2018)

## **Methodology**

In this work we present one gamification experience that we did in a Linear Algebra course. Gamification was used in the students evaluation, and for this the classification were replaced by points that were attributed to the students as they went doing the tasks in the classes or online. The students could have earned points for completing a lesson or for doing extra research about the lesson. At the beginning of the semester, all students had a hundred starting points, and after classes started, all they did or did not, was giving them or taking them points. Each hundred points corresponded to one level and there were twenty levels corresponding to grades from zero to twenty. During the semester there were several evaluation moments, such as Moodle's tests, challenges and individual tests, that corresponded to tasks that the students had to do and there were also some medals or bombs. The medals were rewards attributed to the students for doing certain tasks, such as participating in forums, solving challenges, among others. Obtaining a medal rewarded the student with a predetermined amount of points. The bombs were penalties attributed to the students for not doing

certain required tasks such as homework, Moodle tests, among others. Bombs penalized students by taking a predetermined amount of points from them. One task that was proposed to each student at the end of each topic was the resolution of a problem related with his course and where he needed the concepts he had just learned for his solution. These problems were often suggested by the professors of engineering disciplines. Other component of the evaluation were the Moodle's tests. The students took these tests biweekly and on the weekend. During the semester, the student had to do six tests in Moodle. When he opened the test, the student chose the level he wanted to do, easy or difficult, knowing that the difficult level allowed him to get double the points he could reach with the easy level. But each student had to do at least one test of each level. In each test to perform in Moodle the student always had the possibility to make two attempts, but he knew that his classification in this test was the one obtained in the last attempt. The purpose of allowing two attempts was, when the first attempt had gone wrong, lead the student to reflect on what had not gone well on the first try, so he goes to study or look for information to solve correctly this test. So, when he tried the second time, he would be better prepared to do the test. To force this reflection, between the first and second attempts the student had to wait at least sixty minutes between the two attempts. The second attempt was optional, but if the student chose to do it, it had to be of the same level as the first.

An easy level test involved only operations with real matrices, and a difficult level test involved operations with matrices of complex numbers and matrix properties. A difficult level test could be, for example, the one presented below.

1. If  $A = \begin{bmatrix} 1 & i & 0 \\ 1+i & -1 & 1 \\ 2i & 2 & 1 \end{bmatrix}$ ,  $B = \begin{bmatrix} -i & 1+i & 0 \\ 1 & -i & 2i \\ 2 & 1-i & -2i \end{bmatrix}$  and  $C = \begin{bmatrix} 2 & -2 & 1 \\ 0 & 1 & 0 \\ 1 & -1 & 0 \end{bmatrix}$ ,

then  $\bar{B} + A^t C$

$$\ddot{y} \begin{bmatrix} i & 5+2i & 1 \\ 2 & -1+i & 2+i \\ -i & 1-i & -1+2i \end{bmatrix}$$

$$\ddot{y} \begin{bmatrix} 2+3i & -2i & 1 \\ 3+2i & -3-i & -i \\ 3 & 1+i & 2i \end{bmatrix}$$

$$\ddot{y} \begin{bmatrix} 2+3i & -i & 3 \\ 3+i & -3-i & 1+2i \\ 1 & -2i & 2i \end{bmatrix}$$

$\ddot{y}$  None of the others is correct.

2. The statement:

"If A and B are idempotent and permutable matrices, then AB is also an idempotent matrix."

It's

☐ True

☐ False

Challenges were another component of evaluation. Each challenge had multiple choice questions related to the subjects taught from the beginning of the semester up to that time and had three levels, easy, medium, and difficult. The students started at the easy level and went up the level. To level up, the student needed to correctly solve all questions at that level. If he missed a question, he would lose a life, but he could try a new challenge of the same level again. At each challenge, the student had three lives that he could use. The final number of points depended on the number of lives he used and the level at which the student arrived. During the semester, the student met three challenges.

In the easiest level the students needed to do 3 questions that were about the subjects taught in the class. In the medium level the students needed to do 2 questions that were about the subjects taught in this class but related to a subject taught in another class of the same year and the same course. And in the difficult level the students needed to do 2 questions that were related with another subject. As they were students of Electrotechnical Engineering, a question of the medium level was, for example the one presented below.

1. Consider the electrical circuit shown in Figure 1.

**Figure 1: electrical circuit**

The potential difference between the battery terminals, measured in volts (V), produces a current that leaves the positive pole of the battery (indicated by the side containing the longest vertical line). The capital letters represent the nodes of the electric circuit.

The letter  $i$  represents the current between the nodes and the arrows indicate the direction of flow, but if  $i$  is negative then the current flows in the opposite direction to the indicated one. The currents are measured in amperes and the resistors in ohms.

Based on Kirchhoff's laws for electrical circuits, determine the currents in the meshes.

During the semester students performed 2 individual exams, the first in the middle of the semester and the second at the end of the semester, but with the gamification, exams were the biggest missions to perform. The grades were the result of the number of points earned through the accomplishment of the missions, and two types of missions were planned: individual and group. Students could choose to do the challenges individually or in groups. If they chose to do as a group, the group would be chosen by them, would have between 3 and 5 students and all the challenges in the semester would have to be made by the same group. Thus, each student earned points based on their individual performance and the performance of his group, which stimulated the collaborative character of the process. Each group had good and weak students and it was noted that the best students were pulling the weak so that the group performed well. Group tasks generally involved group competitions, which potentiated the competitive side of the games, but interacted with the cooperative aspect because each group functioned as a whole. A list of activities to be carried out was published weekly in Moodle and this list also indicated the medals available this week and what students would have to do to reach them. It was also published weekly in the Moodle the Leadership Chart in the form of a list, arranged in descending order of number of points, indicating the points of each student and the level of each student, and were highlighted the students placed in the first 15 places. There was a lot of competition and it was also discovered that the students made a great effort to be in the first places of the list.

At the end of the semester, students completed an inquiry into the use of gamification and how they felt in the game. The questionnaire, which was answered anonymously and via Moodle, was

developed with open and closed questions and aimed to collect data to identify a brief profile of the participants. It was intended to listen to students' opinions about the advantages and disadvantages they felt about motivation and learning.

## Results

We worked with all students enrolled in the first year of the first semester of this engineering course (two hundred and ninety-four). As for sex, as one would expect in an Electrotechnical Engineering course, the majority were men, two hundred and seventy-four (93%) and only twenty (7%) of these students were women.

When gamification was introduced, classes became a more challenging experience due to the new method used. For each class in which the student was present and participated, the student earned a small amount of points until reaching the maximum stipulated, there being a large increase in the number of classes that each student went. Traditionally, in mathematics subjects from the first years of an engineering course, the percentage of students per class is small, principally in theoretical classes, this year there was a considerable increase of student's number in theoretical and practical classes. We also found that this year the rate of students who dropped out was much lower than in previous years as can be seen in Figure 2.

**Figure 2: percentage of students who dropped out in the last years**

As they wanted to “win” the game, winning all possible medals, overcoming all the challenges to reach the last level, they worked harder during the semester and this was reflected in the learning and consequently the Final Approval Rate. The percentage of students leaving the course was very low (17%) compared to usual in previous years (31% to 36%) and the rate of failed students was also lower (33%).

The survey to listen to students' opinions about the advantages and disadvantages was answered by most students (97%) and 95% said they were more motivated and worked harder, which was reflected in the average frequency and passing rate. Of the students who answered, 38% considered the experience of using gamification excellent, 42% very good and 20% good. Although some students said that the gamification experience was very laborious, none of them rated it as bad or very bad, see Figure 3.

**Figure 3: The feeling about gamification experience**

In the questionnaire that was placed in Moodle at the end of the semester, the last question asked each student to identify which were in their opinion the positive and negative aspects of the gamification experience that they had done. The positive points more presented were

- § motivation and stimulation of learning;
- § playful and dynamic way of learning;
- § self-improvement and persistence.

And negative points more presented were

- § harder than in previous years;
- § over-competitiveness;
- § mechanization: the student plays for playing and not for learning.

In this questionnaire they were placed other following questions:

Q2 - Which type of evaluation do you prefer

Q3 - Gamification was useful for my learning

Q4 - The gamification didn't help me anything

Q5 - The gamification helped me in studying

Q6 - The gamification didn't promote my self-motivation

According their opinion the students filled for Q2 (only assessment, assessment with gamification) and for remain questions they filled (Strongly agree, Agree, Neither agree nor disagree, Disagree, Strongly disagree).

In order to verify the effect of type of evaluation, we performed a Chi-square test who revealed significant difference between two categories from question 2, as shown in table below by p-values results ( $<0.05^*$  and  $0.01^{**}$ )

	Q3	Q4	Q5	Q6
Q2	0.010*	0.016*	0.002**	0.008**

**Table 1: The effect of type of evaluation**

The gamification had a significant contribution in motivation for doing the assessment. We detail in below the process. We assigned 100 points to each student at the beginning of the gamification process. The students had been subjected at 7 moments of evaluation corresponding to 6 moments to

Moodle actions and the other one, on the first assessment. The scores obtained by students had also a significant performance along the process of gamification.

We observed a great enthusiasm between at the beginning of the process, showed by graph, figure 4. Until the 3<sup>rd</sup> moment (before the first assessment) these good results went on, but the remains didn't give the previous impression. We observed some outliers in some moments, explained by the penalties according to the rules of the game. The outlier's presence caused a negative impact in general results which provoked the existence of significant mean differences as we can observe in Table 2.

**Figure 4: Scores Game**

	M1	M2	M3	M4	M5	M6	Final
Mean	17.21	16.43	15.69	14.20	13.90	12.54	13.45
S.d.	0.30	0.33	0.33	0.33	0.34	0.33	0.31

**Table 2: Means of Scores Game**

The table above show difference significant between all moment's means (t-test,  $p < 0.001$ ). We observed higher results at the first three moments followed by a significant break in four last moments. However, the variability has not suffered a significant changing along the gamification process.

## Conclusion

During this semester, we realized that the elements of the game are valuable tools, but we need to use them with care and knowledge to get the expected results. Nowadays, most people play electronic games, so games have a strong psychological effect on people's behavior. Gamification becomes then a valid alternative to arouse emotions and, particularly in education, the gamification contributes to the student's motivation during the execution of tasks. In the learning scenario, this proposal allows a more active and practical participation of the students. But to obtain its potential benefits and reduce the risk of the student to be interested only extrinsically by the approach, aiming only rewards, fun and entertainment. It is necessary to plan the educational objectives, discuss the strategies to be used and analyze the experiences already promoted. In this work we did not do a quantitative approach because it is not possible to compare the results of this year's educational success with those of previous years because the students are different, and it is also difficult to compare with the results of other curricular units of same year because the degree difficulty is also different. To use a

quantitative approach, we would have to have a test group to make comparisons and this was not possible. However, in this semester the dropout rate was low, and the students were very involved in the classes and in the activities of the curricular unit. These facts may indicate that the impact of gamification on learning has been successful.

The positive and negative points pointed out by the students at the end of the semester were very interesting, presenting diverse and yet very coherent opinions. The listed positive points outweighed the negative ones, with motivation being a very prominent aspect. They found too the applying problems difficult but interesting as they helped them to better understand the usefulness of learning mathematics in an engineering course. The main negative point presented by the students was the fact that the curricular unit this semester was more work, which in our opinion is not negative, and was reflected in the good approval rate. Although evaluating activities as laborious, students reported feeling more motivated and interested and it may be noted that no student considered this experience to be bad or very bad.

# Complex Modeling: Insights into our body through computer tomography – perspectives of a project day on inverse problems

Kirsten Wohak<sup>1</sup> and Martin Frank<sup>2</sup>

Karlsruhe Institute of Technology, Steinbuch Centre for Computing, Germany;

<sup>1</sup>[wohak@kit.edu](mailto:wohak@kit.edu), <sup>2</sup>[martin.frank@kit.edu](mailto:martin.frank@kit.edu)

*How does an autonomous vehicle recognize a traffic sign? How can seismic measurements be used to determine the origin of an earthquake? How do you get a three-dimensional tomographic reconstruction of a body part from a medical scanner? The methods used to answer all these questions come from the field of so-called inverse problems and are central to our society. They are omnipresent in technology, science and in everyday life and include mathematics without any people being aware. The process of mathematical modeling is used to solve inverse problems. Complex problems are simplified in such a way that mathematical models are developed and then accurate solutions can be calculated. The question now arises as to whether high school students are able to independently and accurately solve these kind of questions while only using their mathematical school knowledge and the computer. An approach to show how this could be done is given in this paper.*

*Keywords: High school mathematics, inverse problems, mathematical modeling, MATLAB, problem-solving.*

## Introduction

When taking a look at maths classes in school you often find students asking: “Why do I need to study this?” Schoolbooks are very method-oriented which has the effect that students can use certain algorithms and formulas but do not recognize the usefulness of mathematics for everyday life. This is why the development of interactive, problem-oriented material for high school students should be increased. Using this kind of material as an addition to the existing units students see the potential of mathematics to solve real life problems<sup>1</sup>.

The project presented here will be part of the CAMMP (Computational and mathematical modeling program) project of the Karlsruhe Institute of Technology<sup>2</sup> and the RWTH in Aachen<sup>3</sup>. For several years, similar projects have been carried out in one-week and one-day formats with students of different ages in Aachen (One example can be found in Greefrath & Siller, 2018, p. 137-163). Until now over 400 students have participated in a modeling week and over 2900 in a modeling day. Since the beginning of 2018 the project is also being realized in Karlsruhe.

CAMMP wants to offer ways to innovative mathematics teaching in terms of content, didactics and methodology. Concepts for this were developed and tested. CAMMP is not only involved in mathematical modelling projects with pupils and teachers, but also in research and teaching in the

---

<sup>1</sup> We understand the word problems in the sense of Heinrich, Bruder and Bauer (2015).

<sup>2</sup> <http://www.scc.kit.edu/forschung/CAMMP>

<sup>3</sup> <https://blog.rwth-aachen.de/cammp/>

field of mathematical modelling didactics. The goal is a didactics of problem-oriented mathematical research, in particular a creative handling of mathematics. Tasks and projects are always as problem-oriented as possible and actively dealt with by the students. Adapted to the given framework conditions (e.g. modeling week, -day, regular school lessons), innovative concepts are developed to balance the dimensions active-passive and method-oriented<sup>4</sup> problem-oriented.

These projects are needed because a change in teaching mathematics must take place. Many graduated students do not know a lot about mathematical modeling even though it is one of the process-related competencies of the core curriculum. And according to the educational standards of the Conference of Education Ministers, all students should be able to model mathematically by the end of their school career. That means they should be able to go through the elementary steps of the mathematical modeling cycle independently (Kultusministerkonferenz der Länder in der Bundesrepublik, 2012). Real life is not about calculating as much as possible to exercise a certain algorithm (Maaß, 2015, p. 70). Mathematics should not be used for its own sake, but rather as a tool for solving problems (Consortium for Mathematics and Its Applications, 2016). It is clear that the necessary competence for the creation of models can only be built up if the pupils carry out their own modeling independently and regularly during their school years (Maaß, 2011, p. 8). However, modeling is new and unknown to many teachers and learners. Each step of the modeling cycle represents a cognitive hurdle for the students (Heiliö & Pohjolainen 2016). On the one hand they find it difficult to understand the real situation, on the other they expect teachers to evaluate the correctness of their solution, neglecting the validation step. If teachers face each of these challenges, studies have shown that the treatment of authentic modelling has a significant positive impact on their opinion of mathematics (Borromeo Ferri, Greefrath & Kaiser (Hrsg.), 2013, p. 30-34).

The project presented in this paper makes an important contribution to developing interactive, problem-oriented material by presenting a way to include computer tomography as an example of inverse problems into maths classes. It shows that the abilities of students should not be underestimated. The basics needed to understand inverse problems are already taught during school mathematics.

## **Inverse problems in school and everyday life**

When having a look at cause-effect relationships one can either calculate the effect with given causes or turn the problem around and draw conclusions from given effects on the cause. If you have a look at image processing you can ask yourself what a clear image would look like if the camera were focused incorrectly. When turning the problem around you get the inverse problem, which means trying to deblur an image that was taken by an incorrectly focused camera. In both cases you have to solve a system of equations, but in mathematics there is a difference between the equations you use for the two problems. In real life you never have flawless data, which means that by using some kind of measuring tool you get errors in your data. If the error stays in the same magnitude while computing

---

<sup>4</sup> By method-oriented we mean the application and practice of mathematical methods to solve purely mathematical problems without reference to application. In the problem-oriented treatment of tasks, certain mathematical methods are only applied when they are needed to solve a real extra-mathematical problem (Heinrich, Bruder & Bauer. 2015).

the solution, everything is perfectly fine. However, what happens if a tiny error in the given data leads to enormous errors in the solution?

These problems are so called ill-posed inverse problems. Jaques Hadamard described three conditions through which one can determine whether the problem at hand is well or ill-posed (Engl, Hanke & Neubauer, 2000, p. 31): There must be at least one solution (existence). There may be no more than one solution (uniqueness). The solution must depend continuously on the data (stability).

At the moment schools mainly deal with tasks in which direct problems occur. Data is presented and a function must be applied to it. This means that you start with the cause and calculate the consequence (Lasanen, 2014). This type of task only requires students to perform prescribed operations. Students are therefore often limited in their mathematical thinking (Gardiner, 2016). In the long term, however, the inverse problems are important, since through them students learn to work more freely, flexibly, playfully and application-oriented with the mathematics they have learned (Gardiner, 2016). From the teacher's point of view it is more challenging to discuss inverse problems in school because the approaches of students to inverse problems are far more open and are therefore not well predictable. These open tasks make it more difficult to have a joint discussion in class since there are many different calculations that lead to a correct solution. On top inverse problems are a lot more complex to grade in an exam. Eventually, due to the lack of discussion, confrontation and exercise, students achieve results a lot worse when having to solve inverse problems than when dealing with direct problems (Gardiner, 2016). Thus to prepare their students and give them the opportunity to think freely in terms of mathematics, teachers should include more inverse problems into their classes especially ones that are similar to the one presented in the following.

## **Perspectives of a project day about computer tomography**

The aim of the project day for one is to show the working principle of computer tomography, but moreover it should also show the relevance of mathematics and simulation sciences in society in general. The students should realize that already with their knowledge they can understand and compute the basic methods behind complex processes. The material is formulated in a way that different approaches are possible and welcome. By using the software MATLAB the requirements regarding programming are set very low. The students are given a prepared code in the form of a gap text in which they only have to enter missing formulas or equations, which are then checked as they run the code. This means that students receive feedback on their considerations at all times. On top it is possible to include worksheets into MATLAB, so that the surface looks rather like a digital working sheet with code lines in between than a programming software. Through all of this, one hope of the developer is that students become more involved with mathematics.

### **Computer tomography**

For computer tomography, the internal structure of an object is determined depending on the entry and exit intensity of the X-ray radiation and conclusively depicted (Grumme, Kluge, Lange, Meese & Ringel, 1988). The objects are irradiated with parallel beams at different fixed angle settings to determine the absorption coefficients  $f(x_1, x_2)$  of the different materials of the object (Mueller & Siltanen, 2012). Depending on the material the intensity of the incoming X-ray beam decreases differently. Thus, the out coming intensity depends on the absorption property  $f(x_1, x_2)$  but also on

the layer thickness  $z$  of the material through which the X-ray beam passes. If a single layer is penetrated by a beam with the intensity  $I_0$ , the output intensity is calculated by the following equation:

$$I(z) = I_0 \cdot \exp(-f(x_1, x_2) \cdot z).$$

With the help of the a transformation, the parallel beams passing through the object are described mathematically as straight lines. By doing so, the function that was originally dependent on the Cartesian coordinates  $x_1$  and  $x_2$  is transformed so that the function is now described along a straight line with the angle  $\theta$  and the distance to the origin  $s$  (see Figure 1). The points lying on the beams are described with  $\vec{x} \cdot \vec{\theta} = s$ , with  $\vec{\theta} = \begin{pmatrix} \cos(\theta) \\ \sin(\theta) \end{pmatrix}$ .

**Figure 1: Illustration of the radon transformation**

If you now look at different distances  $s_0$  from the line to the origin, the straight line moves to the right for  $s_0 > s$  (see Figure 1, blue line) and to the left for  $s_0 < s$  (see Figure 1, red line). This is of great importance since an object gets scanned by parallel beams. So the mathematical model also has to include several beams with a constant distance between one another. In addition, the X-ray tube is rotated around the object so that the beams are sent through the object at different angles. Due to the symmetry, it is sufficient to only look at the angles between  $0^\circ$  and  $180^\circ$  and therefore only to run a semicircle. Considering both factors one gets  $N \cdot J$  beams and therefore  $N \cdot J$  equations in total when having  $N$  parallel beams and  $J$  angle positions.

### Assumptions and simplifications

Before the students establish a system of equations and have a look at its solubility and the reconstructed inner structure of the scanned object, simplifications must be made. Strictly speaking, an object, like a human body, consists of an infinite number of different absorption coefficients. For a first model however, it firstly is sufficient to approximate the cross-section of an object as a square and secondly to allow only a small number of different absorption coefficients. The idea is to cut the square into smaller squares called pixels and to assume that each pixel only consists of one particular material and therefore only has one absorption coefficient  $f_i$ , see Figure 2. In addition, the absorption law is simplified. Instead of looking at the influences of the absorption coefficients, where the integral would have to be used, the object is described by gray values and these are weighted and added along one beam. Thus, the measured values, depicted as  $m_i$  with  $i = 1, \dots, 5$  in Figure 2, do not represent intensities but simply weighted and added gray values  $f_i$ ,  $i = 1, \dots, 4$ , which must be correctly distributed to the respective pixels for the reconstruction of the object.

**Figure 2: Five beams through four pixels**

### Worksheet 1: First radiography of a simplified object

With the first worksheet the students get familiar with what actually happens during computer tomography. The students start into the task, where they try to reconstruct the gray values of the pixels for the first time. Because of the simplifications and assumptions that were made beforehand the students have a first impression of how the gray values of the pixels can be reconstructed, namely simply to solve a linear system of equations. So the students are given four values for  $m_i$  with  $i =$

1, ..., 4. By doing so a lot of questions arise: Can numerical values for the pixels be found so that the row and column sums are satisfied? If there are such entries, how are they determined and can they be determined in a unique way? If they do not exist, why not?

With the help of these questions, the students can independently work out the conditions of the concepts of existence and uniqueness and work out connections for solubility. They notice that with these values they do not have enough information to uniquely determine the gray values for the reconstruction of the object even though the students have four equations and four variables. The solution is not unique because the equations are not linearly independent. This first approximation to the mathematical description of the problem is done without formulas but instead using examples of possible gray values that the pixels could have with the given values  $m_i$ . Students should find a gray scale distribution and then either by comparing their own solution with other groups of students or by realizing mathematical considerations recognize that their distribution is not a unique solution. After this realization, the students are faced with the challenge of extending the problem in such a way that the gray values of the pixels can be explicitly solved. To do this, they must transmit a further beam through the object and determine the measured values of these new beams. For example it is possible to add a diagonal beam (see Figure 2), which leads to the system of equations (1) which has a unique solution.

$$\begin{pmatrix} m_1 \\ m_2 \\ m_3 \\ m_4 \\ m_5 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ \sqrt{2} & 0 & 0 & \sqrt{2} \end{pmatrix} \cdot \begin{pmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \end{pmatrix} \quad (1)$$

When you increase the number of pixels you keep having the same problem. Looking at the object subdivided into nine pixels (see Figure 3) it is again not enough to send nine beams through the object. The problem why this system of equations also is not uniquely solvable is that you only have eight linearly independent equations. So even more beams have to be used. Since the system of equations keeps growing it makes sense to write an algorithm that describes the beams mathematically and creates the matrix one needs to solve the system of equations. At this point of the project the algorithm can be developed, as the students have now completely penetrated the problem. In addition, the number of equations is still manageable, which also means that drawings of the object and the beams can be made without being confusing. This way errors and new solutions can be found more easily.

**Figure 3: Nine beams through nine pixels**

## Worksheet 2: Mathematical description of the beams

The main goal of this worksheet is to find a mathematical model to describe the beams more generally for any number of parallel beams and angle settings, since so far the students only had the situation shown in Figure 3. The idea is to describe the beams as straight lines in  $\mathbb{R}^2$  and then come up with an algorithm that calculates the length that a beam spends in each pixel. The last important step then is to not only get the individual lengths but to know where in the matrix the value has to be written.

For this task the students get the starting vectors  $(X_{1,s} \ X_{2,s})^T$  of the points where the beams enter the object including the value of the associated angle  $\theta$  for a given number of parallel beams and different angles. The standardized direction of the beam is described through the vector  $\vec{r} = \begin{pmatrix} \cos(\theta) \\ \sin(\theta) \end{pmatrix}$ .

Therefore the beam itself can be described as  $\begin{pmatrix} X_1 \\ X_2 \end{pmatrix} = \begin{pmatrix} X_{1,s} \\ X_{2,s} \end{pmatrix} + s \cdot \begin{pmatrix} \cos(\theta) \\ \sin(\theta) \end{pmatrix}$ . Students know this way of writing straight line equations from school. Nevertheless, help cards are also available to the students as support, since they may have difficulties, for example, with the use of the cosine and sine.

The points of interest are always those where either the  $x_1$  or  $x_2$  coordinates are equal to one of the pixel borders, namely  $-1.5, -0.5, 0.5$  or  $1.5$  (see Figure 3). Thus to determine the interceptions the equation for the beam needs to be separated coordinate wise and solved for  $s = \begin{pmatrix} s_1 \\ s_2 \end{pmatrix}$ :

$$s_1 = \frac{X_1 - X_{1,s}}{\cos(\theta)}, \quad s_2 = \frac{X_2 - X_{2,s}}{\sin(\theta)}.$$

Again at this point the students have the possibility of using help cards, since they have to think of separating the coordinates and solving the equations. Some students have difficulties with deformation calculation steps. As feedback and an output of MATLAB the students get a depiction of their description of the beams through the object, so that they themselves can see whether the result seems to be consistent.

**Figure 4: Illustration of the pixel number determination**

Once the students achieved this task they can easily calculate the length between two neighboring interceptions which is the length a beam spends in a pixel. The hard part is to figure out in which column and row of the matrix the length has to be written. One approach is to calculate the distance between the center of the pixels and the middle of the considered distance (see Figure 4). The center to which the distance is smallest is the pixel in which the beam spends the particular length. A second approach would be to have a look at the  $x_1$  or  $x_2$  coordinates of both interception points. After having numbered the pixels and defined the possible values for the  $x_1$  and  $x_2$  one can check to which both points belong and therefore determine the pixel number. While defining the pixels you have to include the border of the pixels each time.

### Worksheet 3: Reconstruction of an object

After this mathematical model for the beams the students get the chance to reconstruct an image such as the first one in Figure 5. To get this first reconstruction the students have to find the gray values  $f_i$  so that the difference between  $A \cdot \vec{f}$  and the measured values get minimized. To make it a little less complicated for the students they calculate with a small matrix  $A$  and small vectors  $\vec{f}$  and  $\vec{m}$ :

$$h(\vec{f}) = \|A \cdot \vec{f} - \vec{m}\|^2 = (A_{1,1} \cdot f_1 + A_{1,2} \cdot f_2 - m_1)^2 + (A_{2,1} \cdot f_1 + A_{2,2} \cdot f_2 - m_2)^2$$

From school they know that they have to differentiate  $h(\vec{f})$  after  $f_1$  and  $f_2$  which leads the students to the gradient of  $h(\vec{f})$ . They then have to set the gradient to zero to find the  $\vec{f}$  that minimizes the equation:

$$\nabla_{\vec{f}} h(\vec{f}) = 2 \cdot A^T \cdot A \cdot \vec{f} - 2A^T \cdot \vec{m} = 0.$$

The formula that results for the gray values that is, when multiplied with  $A$ , closest to the measured data, is the following:

$$\vec{f} = (A^T \cdot A)^{-1} \cdot A^T \cdot \vec{m}$$

If one uses data without errors the reconstruction is perfect. However, using flawless data does not depict reality. Every measuring device creates some kind of error so that you have to use data with a small error. Besides that in reality the scanned objects consist of more than nine different materials and therefore more than nine different absorption coefficients or in our case gray values. So on top of adding noise one has to increase the number of rows and columns in the object, which also leads to a higher number of parallel beams and more angles. If one adds 5 % noise one can already no longer recognize the original object (see Figure 5, picture 3). This is due to the fact that the problem is not stable since the matrices are singular and therefore badly conditioned. Thus the problem has to be slightly modified, so that one gets a more stable problem. This can be achieved by different mathematical methods which deliver results that come very close to the original picture (see Figure 5, picture 4 and 5).

**Figure 5: The object and different forms of reconstructions with 5 % noise**

The aim is that the students should be guided as little as possible during the project. It would be optimal if they could independently develop a method to improve the reconstruction. At the moment this seems very hard to achieve but will be improved once the project has been realized with students.

## Outlook

In the future, the existing material will be realized with high school students. Furthermore the workshop will be evaluated in order to assess what the students learned and how the material could be changed. The material will then be iteratively improved. Moreover material will be developed so that the implementation of the project can be adapted to school hours and thus be carried out in units. In addition, a draft of the described problem for an exam task will be developed.

In conclusion this project shows a possibility to treat authentic and relevant problems with the help of mathematical modeling in such a way that students are not only able to understand them but can also solve these. This should show that it is also possible to treat modelling competence in such open questions at school. The students' knowledge of mathematics is sufficient to understand the basics of

these problems from their everyday life. This example should encourage teachers to address more complex problems in class in order to train and further develop their students' mathematical modeling skills. For example, parts of this workshop can be incorporated into the classroom, allowing students to directly see an authentic application of mathematics.

# Addendum Thematic Working Group 11: Comparative Studies in Mathematics Education

# Cultural effects on mathematics lessons: through the international collaborative development of a lesson in two countries

Stéphane Clivaz<sup>1</sup> and Takeshi Miyakawa<sup>2</sup>

<sup>1</sup>Lausanne University of Teacher Education, stephane.clivaz@hepl.ch

<sup>2</sup>Joetsu University of Education, miyakawa@juen.ac.jp

*This paper analyses two grade 4 mathematics lessons given in Switzerland and in Japan by student teachers (pre-service teachers) in the context of a project-based international exchange program. The lesson, initially planned together by the nine student teachers of the two countries, was finally realised in quite different ways in Switzerland and in Japan. Using the notion of levels of didactical codetermination, the analysis makes explicit the differences of the two lessons and identify cultural elements that shape such lessons.*

*Keywords: Comparative education, lesson study, levels of codetermination, cultural context.*

## Introduction

International comparative studies have been carried out so far on different aspects of mathematics education. Large-scale studies such as PISA, TIMSS, and TALIS provide extensive information on the education, while small-scale studies carried out by individual researchers complement the large-scale studies and allow understanding in-depth on the specific aspect (Cai, Mok, Reddy, & Stacey, 2016). We are interested in the small-scale comparative studies on the mathematics lessons. Previous comparative studies on mathematics teaching have shown the large differences between Asian and other countries (Cai & Wang, 2010; Clarke, Emanuelsson, Jablonka, & Mok, 2006; Clarke et al., 2007; Stigler & Hiebert, 1999; Stigler & Perry, 1988). One of the complexities of classroom comparative studies is to have comparable data. Mathematics teaching one may observe in the classroom may vary from one lesson to another under the effects of so many different factors inside and outside classroom.

We recently obtained data in the context of an international exchange of student teachers and their educators. The student teachers from Switzerland and Japan prepared a lesson together and realised it separately in each country. As the lesson is developed collaboratively, the differences we may identify in the implemented lessons would be deeply rooted in the educational culture of each country. We think that such data allows an interesting comparative study on mathematics lessons. The aim of our study is thus to advance understanding of mathematics teaching and learning of different countries, what are the characteristics and what elements shape such characteristics, through an analysis of the data collected in the project-based international exchange program.

## Theoretical frameworks

One issue on the methodology of international comparative studies of mathematics classroom is to set up a common criterion to analyse the data collected from two countries. It is not necessarily easy to decide what to compare, because it would vary according to how we characterise the classroom activities and what we consider important with mathematics lessons. The lesson structure is one of aspects which has been compared in the previous studies (Clarke et al., 2007; Stigler & Hiebert,

1999). In such studies, it is important to find out a lesson structure of reference which includes significant phases in terms of mathematics learning.

In our study, we draw attention to the lesson called *mondai kaiketsugata jugyō* in Japan (structured problem solving lesson in English; see Stigler & Hiebert, 1999) and to *the theory of didactical situations* (TDS hereafter; Brousseau, 1997). The former lesson usually consists of four or five phases: introduction of a problem, individual work and/or group work, *neriage* (whole class collective work), and *matome* (synthesis) (see also Shimizu, 1999). The latter characterises the process of mathematics teaching and learning, in terms of the states of mathematical knowledge—*situation of action*, *situation of formulation*, and *situation of validation*—as well as the process the teacher concerns—*devolution* and *institutionalisation*. For the analysis of lessons in our comparative study, we adopt the characterisations of these previous studies with some adaptations in order to take into account the specificities of Japanese lesson as well as the different states of mathematical knowledge during learning.

While these frameworks provide us with the aspects of classroom activities to be compared, they do not allow us to characterise the exterior factors that shape the lesson. To deal with this issue, we rely on *the anthropological theory of the didactic* (ATD hereafter) which directs us to investigate the factors beyond the classroom (Bosch & Gascón, 2006; Chevallard, 2002). In this theory, the lesson implemented in the classroom is considered as a result of *didactic transposition* which is under the influences of the *conditions* that support the realisation of such lesson and the *constraints* that hinder it. ATD implies that these conditions and constraints may have the different nature beyond those identifiable in the classroom, and proposes a classification called *the levels of didactic codetermination: civilisation – society – school – pedagogy – discipline – domain – sector – theme – subject* (Bosch & Gascón, 2006; Chevallard, 2002). The study by Artigue & Winsløw (2010) shows that this perspective allows us to capture, in the context of international comparative study, the extensive factors that affects mathematics education. We also consider that such perspective helps us to identify different cultural effects that shape the lessons of our project.

## Context of this study

Our principal methodology of comparative studies is based on the collaborative development of a mathematics lesson by Swiss and Japanese student teachers. This happened in the more general context of students and professors exchange program, called PEERS (Projet d'Étudiants et d'Enseignants-chercheurs en Réseaux Sociaux, Student and Researcher Social Networks Project) carried out by Lausanne University of Teacher Education (HEP Vaud). This project articulated student exchanges around a jointly defined research project by a group of students from the HEP Vaud in association with a group of students from the partner university. Each PEERS is supervised by a teacher-researcher of each institution, combining face-to-face (one week in fall and another week in spring) with distance collaborative work phases. PEERS with Joetsu University of Education was supervised by the two authors of this paper.

The group first met through Skype meetings organised three times in fall 2017, and decided the general theme of PEERS and the mathematical theme: the collaborative development of a problem solving geometry lesson for grade 4 pupils, like the lesson study process (Hart, Alston, & Murata,

2011). The group spent one week in Joetsu in October 2017 for designing a task, studying the topic and planning the lesson together. At the end of this week, a first draft of lesson plan was ready.

During the winter, the two groups developed their lesson separately and taught them several times. For the Japanese group, the lesson was taught two times as a mock lesson and two times in grade 4 classes with about 35 pupils in the attached school. For the Swiss group, the lesson was taught by each Swiss student in her/his practicum classroom of about 20 pupils with the observation by the rest of the group, and followed by a post lesson discussion. This discussion led to changes in the lesson plan for the next lesson. After three Skype meetings, the Japanese group spent one week in Lausanne in February 2018. During this week, the group observed the last Swiss lesson, watched the video of the last Japanese lesson, and discussed the differences and commonalities.

The problem the group selected was the one in the Swiss textbook (Danalet, Dumas, Studer, & Villars-Kneubühler, 1999). The question is: “Divide a square into several squares, but not more than 20. Find as many solutions as possible”. The lesson plan by the Swiss students is available on the websites of Lausanne Laboratory Lesson Study ([www.hepl.ch/3LS](http://www.hepl.ch/3LS)).

**Figure 1: Some of the possible solutions for 4, 6 and 7**

## **Methodology: data collection and analytical tools**

The data were collected from the above-mentioned exchange project. We videotaped most of the activities related to the collaborative development of mathematics lesson and its implementation: Skype meetings, discussions in the face-to-face meetings, preparatory lessons, implementation of lessons, post lesson discussion, etc. In this paper, we principally analyse, for the comparative study, the last versions of lesson plan and the video data of the last lesson from the two countries. The first draft of lesson plan was collaboratively written in English. Then, the detailed lesson plans were written separately in both sides in students' own languages (Japanese and French) and revised several times after the lessons. They were translated later in English for sharing in the project. The Japanese video data was transcribed first and then translated into English, while the Swiss data was transcribed in French and then only the parts necessary for writing this article was translated in English, because both authors understand French.

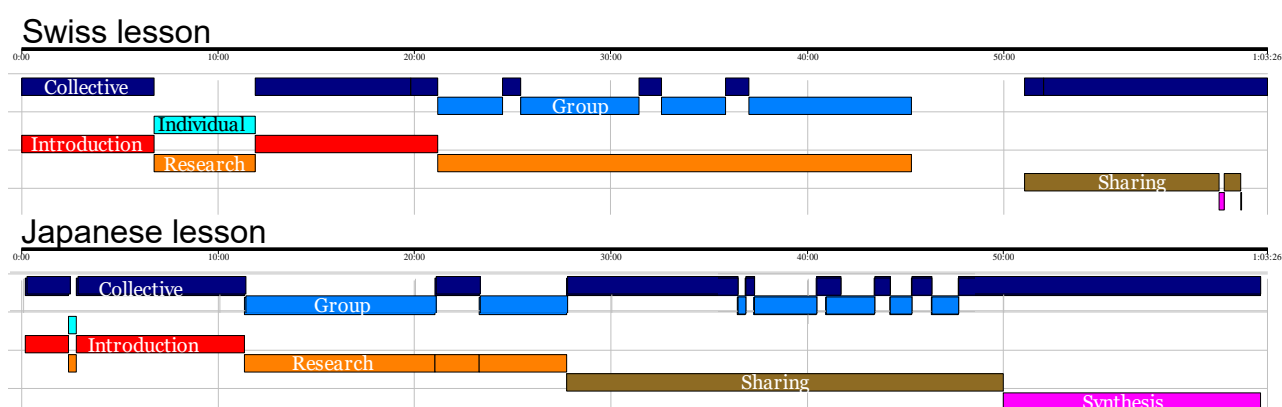

For the comparison of lessons, we characterise the process and structure of lesson by identifying the modes of students' and teacher's works in the classroom from two aspects of teaching and learning activities. The first is the interaction among pupils and teacher that implies three kinds of works: individual work, group work, and collective or whole class work. This aspect allows us to describe the overall activities in the classroom as well as the roles played by teacher and pupils. The second aspect is the mode of working in terms of the process or phases of problem solving: introduction, research, sharing, and synthesis. In this way, we are able to capture the structure of the lesson with the description of overall classroom activities. These two aspects are consistent with the structure of Japanese problem solving lesson.

Further, we investigate the characteristics of activities throughout different phases of the lesson. Adopting the viewpoint of TDS that characterises the evolution of mathematical knowledge, we analyse the devolution process—how the responsibility on the given task moves to the pupils—, the validation—how the teacher validates pupil's answer; how the teacher makes pupils find the validity of their answer—, and the institutionalisation process—what kind of knowledge is institutionalised as an object to be learnt.

While the student teachers designed a single task together, their implementation should be under the several implicit constraints of each country, and it is expected that we may identify several differences between the implemented lessons, due to the factors which are deeply rooted in the teaching culture they are belonging to. We try to identify these factors according to the levels of didactic codetermination, by focusing on the differences identified in the comparative analysis and by exploiting all available resources at our disposition.

## Comparative study of Swiss and Japanese lessons

Even though the task was designed collaboratively in the face-to-face workshops organised in Japan, its implementations in Switzerland and Japan were very different. We found the differences between the two countries in different phases, both between the structures of the lessons (see Figure 2) and between each of these parts. In what follows, we focus on the differences of the validation during the research phase and the sharing phase.

**Figure 2: Structure of the two lessons**

The issue of validation is at the heart of mathematics (Balacheff, 1987; Lakatos, 1976) and it was the principal and recurring difficulties for Swiss students as well as Japanese students when designing, teaching and discussing the lesson. When finalising the planification in their own languages, Japanese and Swiss students are not specific about validation. Japanese lesson plan says:

When an incorrect answer is given, the teacher takes it up to the whole class when necessary and checks why it is wrong.

The Swiss lesson plan is not more precise about the criteria for validity, but it is more specific about a list of incorrect solutions.

Show on the board correct and [...] incorrect solutions (diagonal, cut in half). Define the criteria for a correct solution together with the pupils, write them down on the blackboard to make a check-list

[of incorrect solutions] to which the pupils will have to refer before coming to show a solution to the teacher.

This list reflects the main preoccupation of the Swiss team to deal with many pupils coming to the teacher during the group research phase (in orange in Figure 2) to ask him/her: “is this correct?”. In fact, during the research phase, the Swiss teacher takes care of pupils one by one in front of the board and tells if the solution is correct or not:

Pupil: Teacher, is it okay?

Teacher: Ah, a box inside the square. [...] unfortunately, [first name], your solution, I cannot accept it, because squares in the square, in the square ...

In comparison, the Japanese teacher moves from one group to another and asks questions:

Teacher: This one, are they really all squares? Could you think about it?

Pupil: Okay. [Teacher leaving]

In fact, the way of validation of the solutions by the Japanese team is close to the definition of validation by Margolinas (2004): “the pupil decides by himself about the validity of his work [...] thank to the interactions with the *milieu* (p. 24)”. In contrast, the Swiss team is making an evaluation: “the validity of the pupil’s work is evaluated by the teacher in the form of an irrevocable judgement (p. 24)”.

This characteristic can also be found in the sharing phase (in bronze colour in Figure 2), usually called *mise en commun* (putting in common) in French and *neriage* in Japanese. This can be seen in the transcription of the lessons and the student teachers are aware of these differences. After observing together the Swiss lesson and watching the video of the Japanese lesson, they write in English in their collective reflections:

Validation of answers during “neriage”: JP = others students / CH = the teacher mostly.

In Japan [it] is very important to exercise the students/children to think about HOW they find a solution. By explaining from peers to peers (and not the adult explaining), other students will understand it more because it comes from another student like them. It also helps the students to confirm that he understood well the problem and it’s induce a discussion and deep-thinking on the topic. (Notes of workshop, PEERS week in Lausanne)

The student teachers’ sharp and concise description of the difference between who is validating the solutions in the two lessons comes quickly to the search of more general reasons. The differences concerning the validation between Japanese and Swiss lessons here could be summarised in the differences of two aspects of mathematics lesson which are mutually related. The first aspect is the overall form of mathematics teaching: *collective teaching* and *individualistic teaching*. In Japanese lesson, the *neriage* is a moment for the whole class, including pupils and teacher (actually it was the teacher who manages this phase), to validate pupil’s answer and further develop their ideas, and even in other phases, the teacher often tries to control the whole class (see the duration of collective work of Japanese lesson in Figure 2), while in the Swiss lesson the teacher individually validates pupils’ answers in both research and sharing phases. The second aspect is the *didactical contract* (Brousseau,

1997) that determines what can be done by pupils and teacher: the teacher may directly validate pupils' answers in the Swiss lesson, while not in the Japanese lesson; the pupils may ask the teacher to validate their answer in the Swiss lesson, while not in the Japanese lesson. In the actual lesson, the Japanese teacher might not always play well her role as she was still a student, but she was trying to leave the responsibility of validation to the individual pupils or group in the research phase and to the whole class in the *neriage* phase. The question we ask is: what makes such differences? We investigate and discuss the cultural effects on these two aspects in the next section.

## Cultural effects on mathematics lessons

### Collective teaching or individualistic teaching

One obvious factor that supports, or even requires to carry out, the collective teaching in Japanese class is the number of pupils. In the classroom of 35 pupils (about 20 pupils in Swiss case), it is difficult for the teacher to take care of them one by one individually. The whole class validation in the *neriage* phase is a solution for this constraint. In addition, the Japanese classroom is equipped so that the teacher can control the whole class: the blackboard in front in addition to the large display at the side (see Figure 3). These are the conditions or constraints that afford or hinder collective teaching at the *school level* in terms of the codetermination.

**Figure 3: The blackboard and the large display in a Japanese classroom.**

Another factor that supports collective teaching is the homogeneity or the idea of equality at the *society level*. In Japan in general, the teacher tries to control the whole class, so that every pupil could learn in the same way. The teaching should not be for a particular learner in the classroom. This is why the teacher shared pupil's solutions even in the research phase in the classroom. The phases, *neriage* and *matome*, as a whole class is presumably the effect of such factor<sup>1</sup>. In contrast, in Switzerland, or even in Europe, there is an idea of individualism and “differentiation” seen as a way of promoting equity. What is necessary for each learner is different, and therefore teacher's individualised intervention is necessary.

### Teacher's roles and pupil's roles

At the levels of *pedagogy* and probably *discipline*, we consider that the idea on teaching shared in the teachers' community in each country is one of crucial factors that shapes the teacher's role related to

---

<sup>1</sup> Highly developed teacher's skill of *bansho* (board writing, see Tan, Fukaya, & Nozaki, 2018) would be also a result of this factor.

the validation in the classroom<sup>2</sup>. In Japan, the national curriculum emphasises students' autonomous and independent learning (MEXT, 2008). And in general, Japanese teachers share more or less the idea that in the *problem solving lesson*, the teacher should not directly validate pupil's answer, and it is rather the role of other pupils. The pupils in our lesson knew well this contract, and there were a few pupils who asked the teacher to validate their answers. In contrast in Swiss teachers' community, *the problem solving tradition* is shared. The important is put more on the solving process than its products. This effect is obvious in the Swiss mathematics textbook (Danalet et al., 1999) which includes only the problem-situations, and no explicit concepts or ideas for pupils to learn. In the Swiss lesson of our project, there was almost no synthesis phase, and the teacher did not take much time for introducing the problem and did not intervene often while solving the problem, since it is important for pupils to manage by themselves autonomously according to the problem solving tradition. What is interesting here is that, the problem solving is a shared idea in both countries. The *problem solving lesson* is often considered as an effective lesson and recommended to the teachers in Japan, and our Japanese lesson was also following more or less the process of such lesson. As the name suggests, the idea of problem solving was involved in the development of lesson organisation in Japan (Hino, 2007). However, the lessons in the two countries are very different in their realisations. The interpretation of problem solving and its further development are therefore very different.

## Conclusion

Our research shows that teacher education is under the strong effect of cultural factors. We use a project-based international exchange program as a methodological tool for uncovering cultural factors (conditions and constraints) that shape ordinary lessons of a specific country. These factors can particularly be detected in pre-service teachers' efforts of improving the lesson. Pre-service teachers have a conception of an ideal mathematics lesson developed through their learning experience as a pupil, as a student and also during their pre-service teacher training. Levels of didactical codetermination allow us to identify conditions and constraints of higher levels which are often taken for granted and rarely discussed within the country.

## Introduction and research interest

According to recent studies, high dropout rates in STEM subjects at university can be explained at least in part by a lack of basic knowledge and comprehension of secondary school mathematics (Blömeke, 2016), among which specific secondary arithmetic areas like fractions, and especially other areas such as powers or logarithms need to be subsumed. Therefore, many universities provide so-called “bridging courses” for students beginning a STEM subject at their institution. Sometimes, the tasks for diagnostic and supporting measures rely on theoretical frameworks outside mathematics (e.g. Bloom’s taxonomy), sometimes the theoretical base is not made explicit but seems to follow expectations as expressed in local coursebooks.

Hence, for diagnosing basic knowledge and comprehension in secondary school arithmetic, a comprehensive yet concise overview of the important aspects of this area is needed. While there is extensive educational literature on the formation of basic arithmetic skills in elementary operations or fractions, we do not focus on the formative, but on a summative view on how students should master the various fields of secondary arithmetic at the transition from school to university. Thus, our research question is: *Which central aspects of knowledge and comprehension in secondary school arithmetic can be identified in relevant literature and how can these be summarized for diagnostic and supportive measures at university entry level?*

The methodological base is a systematic literature review (Durach, Kembro, & Wieland, 2017). Hereby, relevant didactic literature as well as formative literature about formation of concepts in secondary school arithmetic as mentioned above is considered. A qualitative content analysis of the literature found and subsequent clustering gives the aspects of the frame of reference.

Following Pinkernell, Düsi, & Vogel (2017) two a priori settings are given: *contents* (answering the question: Which are the basic elements of secondary school arithmetic?) and *understanding*. Understanding is subdivided into *knowing* in the sense of declarative knowledge (Anderson, 1996) and *acting*, broken down into *structuring* as a meaningful reading of area-specific expressions (Musgrave, Hatfield, & Thompson, 2015: substitutional equivalence), *transforming* as restructuring the area-specific expressions into equivalent forms (ibid: transformational equivalence) and *interpreting* as coherent change between different forms of representation or possible extra-mathematical contextualization of the same mathematical object (Duval, 2006).

## A theoretical framework for analyzing and constructing tasks in secondary school arithmetic – a first draft

The outcome of this research takes on a tabular form, in which the various findings in literature have been clustered into nine aspects of knowledge and comprehension of secondary school arithmetic. Out of these we mention two here. As contents or basic elements of secondary school arithmetic *numbers and quantities* as well as *terms* arise in the frame of reference. Variables appear too, but are only used in the sense of the generalized number.

- “to change within the same numerical representation” – A numeric number or quantity is converted into another, equivalent numeric number or quantity.
- “to switch between different forms of representation” – A coherent change between numerical and other inner-mathematical forms of representation as well as verbal representations.

The model is still subject to further development. As it is planned for the German project optes+ (www.optes.de) it will – in its final stage – serve as both a reference for analyzing existing tasks and constructing new ones and a conceptual base for discussion about what is considered necessary for successful studies in STEM subjects at university entry level.

*In this paper we analyzed a mathematician's journals of 5-day teaching episodes on eigenvalues and eigenvectors in a first-year linear algebra course, as well as his students' responses to a survey. We employed Tall's (2013) three world model, to follow the mathematician's and his students' movements between the three worlds. The study revealed that despite the mathematician's efforts in demonstrating a more holistic view of the concepts, many students found linear algebra very abstract and gravitated more toward symbolic thinking.*

*Keywords: three worlds of mathematical thinking, eigentheory, concept images, reflections.*

### Theoretical Background

Building on Tall and Vinner's (1981) notions of *concept images* and *concept definitions*, Vinner (1991, p. 69) added that, "We assume that to acquire a concept means to form a concept image for it. To know by heart a concept definition does not guarantee understanding of the concept. To understand, so we believe, means to have a concept image". Developing these two notions further, Tall's (2010; 2013) three-world model of mathematical thinking (embodied, symbolic, and formal) endeavored to lay out an individual's mathematical journey from childhood to research mathematician. According to Tall (2010), the embodied world is based on "our operation as biological creatures, with gestures that convey meaning, perception of objects that recognize properties and patterns...and other forms of figures and diagrams" (p. 22). In Tall's (2010, p. 22) words, "The world of operational symbolism involves practicing sequences of actions until we can perform them accurately with little conscious effort. It develops beyond the learning of procedures to carry out a given process (such as counting) to the concept created by that process (such as number)". Tall defines thinking in the formal world as that which "builds from lists of axioms expressed formally through sequences of theorems proved deductively with the intention of building a coherent formal knowledge structure" (p. 22). The overall goal of the first author's research program is to: (a) Examine the three-world model of mathematical thinking as a possible lens for understanding how mathematical content is conveyed by a mathematician-teacher with a view toward serving students' learning; (b) Develop and extend the three-world model further. In this study we are focusing on goal (a).

Many researchers have maintained that reflection is an essential part of teaching. For example, according to Dewey (1933), reflection is "active, persistent, and careful consideration of any belief or form of knowledge in the light of the grounds that support it and the further conclusions to which it tends" (p. 9). Using Tall's (2013) model, Stewart, Thompson, and Brady (2017) investigated a mathematician's (and co-author) movements between the three worlds while teaching algebraic

topology. The instructor reported that students experienced the most difficulty in moving from the embodied world into the formal world. Believing the struggle would stimulate mathematical growth in his students, this instructor “refused to give students proofs that were pre-packaged. More specifically, he desired to provide students with intuitions and pictures that would help them understand the conceptual nature of the proof and ultimately lead them to it” (p. 2262). In a similar study, Stewart, Troup, and Plaxco (2018) examined a mathematics educator’s (and co-author) movements as well as decision making moments while teaching linear algebra. In a different study, Stewart (2018) created a set of linear algebra tasks designed to help students move between the three worlds. These studies indicate that movements between the worlds is worthy of ongoing investigation.

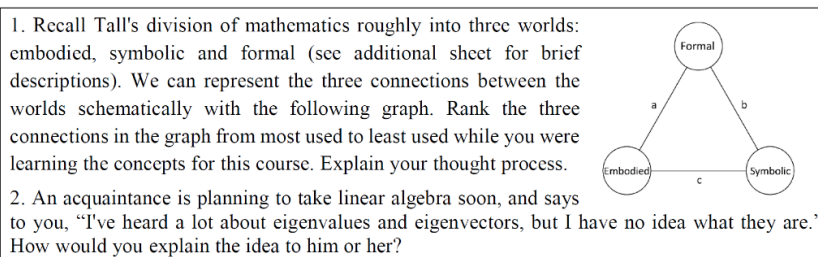

Since the present study was focused on eigentheory, naturally recent literature on students’ reasoning with eigentheory is acknowledged. While several studies have highlighted students’ difficulties learning the eigenvalue and eigenvector concept, they have also provided methods whereby these difficulties can be alleviated. For example, Thomas and Stewart (2011) investigated students’ conceptual understanding of eigenvalues and eigenvectors. They discovered that students appeared confident with symbolic procedures (i.e., calculating the characteristic polynomial), but not embodied ones (linking diagrams and eigenvector properties). While the students referred to “being stretched,” or “unchanging direction,” when describing eigenvectors, it appeared very few were able to implement this definition in context. Thomas and Stewart (2011) also noted that despite their relative strength in symbolic manipulation, the students were not able to give justifications for the change of the equation  $A\mathbf{x} = \lambda\mathbf{x}$  into the equivalent equation  $(A - \lambda I)\mathbf{x} = \mathbf{0}$ . They claimed that thinking about eigenvectors as invariant appeared to be a useful embodied concept for the students, even while they operated within the symbolic world. Gol Tabaghi and Sinclair (2013), and Caglayan (2015), reported that usage of dynamic geometric environments (DGEs) appeared to help students learn the eigenvectors and eigenvalues concepts, perhaps by encouraging related embodied thought as Thomas and Stewart (2011) suggested. Salgado and Trigueros (2015) claimed that via a model designed to capture student interest, the students constructed an object conception of eigenvalues and eigenvectors. They presented modeling as a powerful tool that can elucidate the problems students are having with the associated concepts, make learning the concepts easier and more approachable for the students, and supply students with a broader range of strategies with which to approach problems. These studies suggested that learning eigenvalues and eigenvectors requires students to be able to consider multiple aspects of the concept: geometric, algebraic, and structural. The presentation of eigenvectors and eigenvalues geometrically as a stretching direction and a stretching factor seems to be considered particularly useful. Thus, the research questions guiding this study were:

*(a) When and why did the teacher decide to move between the three worlds? (b) Were the students willing to move with him and what were their challenges? (c) What were some of the challenges for the mathematician-teacher in moving the class to the formal world?*

## Methods

This qualitative narrative study is intended to examine a linear algebra instructor’s and his students’ mathematical thought processes using Tall’s (2013) model. The study took place over the course of a semester at a Southwestern research university in the US. The research team consisted of a

mathematician specializing in differential geometry (the instructor, postdoctoral fellow, and co-author), two mathematics educators, and an undergraduate research assistant. The analysis of the data focused on the instructor's observations, as recorded through journal entries, over a five-day period, while implementing tasks from the Inquiry-Oriented Linear Algebra (IOLA) curriculum (Wawro et. al, 2013). These 50-minute classes were structured around a sequence of four IOLA tasks using the ideas of “stretch direction” and “stretch factor” of a linear transformation to develop the formal notions of eigenvector and eigenvalue. Several of the requisite concepts, such as bases, coordinates and matrix representations of linear transformations, were covered earlier, so that the IOLA sequence could be used. The instructor was introduced to the three-world model, but taught the class as he originally planned and the research team never made any comments on how or what to teach. Introducing the three worlds was done to help him articulate his thoughts and to provide a language for reflection in his teaching journals. His dual role as a teacher as well as a researcher was indispensable in every aspect of this research. In addition, the instructor presented Tall's (2013) framework to his class. Throughout the semester, the instructor recorded his thought processes as well as observations on how his class reacted to his teaching. He also met with the research team regularly throughout the semester and the following summer to discuss these experiences and reflections. This allowed the research team to triangulate data via member checking with the instructor directly and additionally

**Figure 1: The Survey**

afforded him ample time to share a wide variety of teaching experiences, as well as his reasoning while making these decisions. To collect additional data on the student's perspective, the research team administered a survey (see Figure 1), and provided some excerpts defining the three worlds. The students (16 from a class of 30) were mainly engineering students and were already familiar with the notions of embodied, symbolic and formal. To analyze the instructor's journal, in line with a narrative study, the research team performed a retrospective analysis of the journal (Creswell, 2013) by iteratively coding the data. The team started with a combination of themes developed from the previous study (Stewart, Troup, & Plaxco, 2018) and an open coding (Strauss & Corbin, 1998) scheme to allow for the possibility of discovering new themes unique to this study. The themes were: Teaching, Students, Class Activities, Math (instructor's math, students' math), Reflection, and the Three Worlds. By instructor's math, we mean the math he was doing and talking about, and by students' math, we mean his reflections on students' mathematical abilities, and mathematical conversations in class. Under each theme we considered further fine-grained ideas and assigned codes. For Teaching, we considered IOLA tasks (TtIOLA); other tasks (TtOther); pedagogical decisions (Tpd); responses (Tr); lecture style (Tsl); group work style (Tsgw); and class discussion style (Tscd). The themes that emerged from students' survey were, movements between the three worlds as well as static presence in each world. Other themes were students' elaboration on the worlds' appearance in their own line of thinking, or the course itself, as well as the connections between the concepts.

## Results

In analyzing his 5-day teaching segments, we examined the instructor's (a) movements between Tall's (2013) worlds, (b) pedagogical decisions, and (c) reflections on self and students. In the students' survey we examined (a) their views and preferences on each world, and (b) their thoughts on eigenvalues and eigenvectors and their connections to other concepts. The IOLA unit on eigentheory consists of four one-page worksheets designed to introduce the notions of eigenvalue and eigenvector through the ideas of "stretching factor" and "stretching direction" for a linear transformation.

### An analysis of the instructor's journals on teaching eigenvalues and eigenvectors

**Day 1: Blending embodiment and symbolism.** The first IOLA task started by describing a linear transformation geometrically (see Figure 2), in terms of "stretch directions" and "stretch factors". First, the students were asked to sketch the image of a figure "Z" centered at the origin. Next, they were asked to sketch the image of two vectors and then compute the images numerically. Lastly, they were asked to produce a matrix representation of the linear transformation. This task is primarily situated in the embodied and symbolic worlds. The students must grapple with the action of the linear transformation before considering a matrix representation.

*In the direction along the line  $y = -3x$ , the transformation stretches all points by a factor of two.*

*In the direction along the line  $y = x$ , the transformation keeps all points fixed.*

Figure 2: IOLA Task 1

The instructor noted that "They had a lot of trouble with this. So, after a few minutes, we went through the exercise collectively." Among the concepts that he recalled were "for every linear transformation the zero vectors gets sent to the zero vector," and "points are identified with vectors." In order to show how the image of any vector can be computed, "we converted the two vectors into linear combinations of vectors in the stretching direction. Then used the linearity of the transformation to find their images. I'm not sure if this made sense to them."

Figure 3: IOLA Task 2

**Day 2: Embodied, symbolic and formal thinking.** The second IOLA task continued with the same linear transformation introduced in task 1. It presents  $\mathbb{R}^2$  with the standard coordinate grid (referred to as the "black" coordinates) overlaid on the one determined by the stretch directions (referred to as "blue" coordinates) together with a discrete collection of points (see Figure 3). The students were asked to 1) label each point with its "black" and "blue" coordinates, 2) determine two matrices that will systematically rename points from the blue coordinate system as points in the black coordinate system and vice versa, and 3) compute the images of new points in the black and blue coordinate systems. The instructor quickly noted that "most students don't have a facility with coordinate vectors. Even

if they remembered how to compute the coordinates of a vector, they have not connected that to the picture of a grid determined by a basis.” After expressing some frustration that “Even after the class, another student asked...how was I finding the ‘blue’ coordinates,” he related that “his follow-up question was very good: what does the symbol ‘a’ represent when we write  $[a]_{\text{blue}}$ . This indicated that he was starting to abstract the notion of a vector and separate it from its various coordinate representations.” Prior to the class, the instructor made the pedagogical decision to present the formal definitions of eigenvalue and eigenvector after this task, and the last sentence of the journal entry for this day is, “Finally, I was able to define eigenvalue and eigenvector.”

**Day 3: Reinforcing Day 2.** The instructor made the pedagogical decision to use day 3 to recap and consolidate the various embodied, symbolic and formal aspects of eigentheory that the students have thus far encountered. His journal entries for this day contain almost no mention of the students, but instead focused on the mathematical connections that he aimed to convey to the students. First, he showed how the two matrix representations of the linear transformations are related by conjugation by the change of coordinates matrix. Then, to demonstrate how “The ‘stretch factors’ and ‘stretch directions’ correspond to eigenvalues and eigenvectors, respectively,” he used GeoGebra to show “how you can spot the stretch directions by moving around a vector, or by looking at what happens to the unit circle. Through several examples, he “presented the definition of eigenvalue/vector as a way to find the stretch factors and directions.” He even pushed these ideas into the realm of infinite dimensional vector spaces by considering differentiation operators on function spaces.

**Day 4: Symbolic and formal thinking.** He returned to the IOLA sequence with task 3 (a standard textbook exercise). For three distinct two-by-two matrices, the students were asked to 1) find the stretch factors given the stretch directions 2) find the stretch directions given the stretch factors, and 3) find both the stretch factors and directions. The instructor “expected most students launch themselves into finding the eigenvalues and eigenvectors.” But, “Instead, I was surprised to see how many were unsure where to start.” He made the pedagogical decision to guide the class and used the opportunity to present several connections.

**Day 5: Symbolic and formal thinking.** The fourth IOLA task considers a single linear transformation of  $\mathbb{R}^3$ , presented as a matrix. It is found that a certain stretch factor has two stretch directions, i.e. the corresponding eigenspace is two-dimensional. The third and final part posed a rather provocative question: given that 2 and 3 are stretch factors and the former has two distinct stretch directions, could there be additional stretch factors? He observed that “every student's work that I saw was the same. To decide if there was another eigenvalue or stretch direction they all computed the characteristic polynomial to see if there was another root.” Although this was a valid approach he was eager to present a more sophisticated approach that connected to earlier concepts. “I then presented a solution that crucially uses the fact that all three eigenvectors form a basis for  $\mathbb{R}^3$ . I did not get very much feedback from the class on whether they were internalizing this.” In summary, the instructor used four IOLA tasks, supplementing with lecture where necessary. His goal was to build a concept image of eigentheory by presenting the fundamental notions via all three worlds of mathematical thinking. Moreover, he emphasized the formal definition of eigenvalues. For activities situated in the embodied and symbolic worlds the students were encouraged to explore independently, while the active guidance provided by the instructor was primarily to connect those worlds back to

the formal. Although, many of his pedagogical decisions were dictated by time pressure, he made sure each day to bring the class closer and closer to the formal world.

### **An analysis of the student survey**

In response to describing the meaning of eigenvalues and eigenvectors most students gave a symbolic view of the concepts (9/16). Most students also included a symbolic representation, namely the equation  $Ax = \lambda x$ , with the exception of S14 and S16, who only used words. We noticed that their reasoning within this world (symbolic) were mostly reasonable.

S11:  $\det(\lambda I - A) = 0$ . An eigenvalue is the variable  $\lambda$  in the equations  $\det(\lambda I - A) = 0$  or in the equation  $Lx = \lambda x$ . Eigenvector is the variable  $x$  in  $Lx = \lambda x$ . Eigenvector of  $L$  associated to the eigenvalue  $\lambda$ .

S16: An eigenvector is a vector associated with a matrix. An eigenvector multiplied by this matrix equals a scalar multiple of the eigenvector. The values that eigenvector is scaled by are called eigenvalues.

The symbolic world seemed the most comfortable world for students in which to express their thoughts, and some even felt that moving from the formal world to the symbolic world “solves most problems” (S10). In general students used more positive language in describing this world. For example one student wrote, I feel as though I thrive in the symbolic world. For linear algebra, the matrices and vectors make the most sense to me in symbolic form (S14). The students’ views on the usefulness of the embodied world were mixed. For example, one student wrote, “I am able to understand easier if I can visualize something” (S15). “The embodied world really does not help me understand what is going on in problems” (S14). At one end of the spectrum, a student wrote, “my actions in the symbolic world are determined by understanding in embodied world. I refer to the embodied world to initially understand the formal world, but usually don't go back.” (S10). Another student claimed that “the embodied world is useful for getting the big idea” (S12) and understanding the question before moving to the symbolic. In agreement another student wrote: “we took complex problems and simplified them to embody and represent a bigger picture” (S9). At the other end of the spectrum, one student went so far as to isolate the embodied world completely, writing that the “embodied and symbolic worlds” (S16), seldom interacted in her/his viewpoint. Students did not elaborate as much on the formal world. One student believed that the formal world is useful, or at least prevalent in class, but difficult to work with (S12). Others believed that “most of the class was abstract proofs” (S8), “learning concepts required a lot of formal proofs” (S13), and “linear algebra relies on a formal understanding” (S16). As for moving between the worlds, one student wrote: “I start in symbolic and move to formal for proofs” (S14). Although, most comments were directed toward the class or the course in general, one student conveyed her/his thoughts as, “Formal is the worst that I have a problem with” (S15). In connecting between the concepts, students referred to determinants, linear operators, linear transformations, basis, special solutions, system response, system stability, and even music.

## Discussion and concluding remarks

The mathematician-teacher in this study has negotiated the mathematical journey himself, and knows the path well. He viewed the formal world as the destination and wished to bring his students there. However, this was not straightforward and required time and perseverance. Since the instructor's objective was a mathematical treatment of eigentheory, he used IOLA tasks to present a web of connections surrounding the formal definitions. Although, he valued the embodied and symbolic worlds as part of the concept image, the instructor's goal of reaching the formal world became apparent in many of his journal writings. For example, his decision to present the definitions of eigenvalue and eigenvector at precisely the midpoint of the unit reflected their significance, representing a single idea uniting the various notions from all three worlds. A mathematical understanding of eigentheory (to him) involved primarily the definitions and how those definitions manifested themselves in the embodied, symbolic, and formal worlds. For example, he was able to think of a definition of eigenvector in symbols as described by the equation  $A\mathbf{x} = \lambda\mathbf{x}$ , in the embodied world as a picture of an image vector collinear with its preimage, and additionally various properties related to eigenvalues and eigenvectors in the formal world. The instructor believed the more connections between eigentheory and other linear algebraic concepts that he can convey to the students, the more robust their concept image. In Tall's (2013) view "formal mathematics is more powerful than the mathematics of embodiment and symbolism, which are constrained by the context in which the mathematics is used" (p. 18). It was interesting to notice that even a mathematician that values all three worlds of mathematical thinking, still gravitates toward the formal world as the most important part of a mathematical concept. He seemed to consider them complementary to the formal world. Also, what appears "rote" and part of his "everyday" mode of thinking is completely foreign to the typical undergraduate linear algebra student. Hence the connections between the formal definitions and surrounding concepts that appeared so strong to the instructor were quite tenuous with the students. Although the IOLA curriculum was utilized to highlight the embodied world and draw out its connections to the other two worlds of mathematical thinking, nonetheless, the students gravitated toward symbolic thinking. We speculate on two reasons for this. First, living comfortably in all three worlds and moving between them is a big hurdle for most novice students of mathematics. Second, a significant part of students' motivation is derived from "answering the question". As such, students may value the world that seems most helpful in doing so. From the mathematician-instructor's point of view the world most amenable to evaluation is the symbolic world. Hence the class setting establishes an incentive for students to remain safely in the symbolic world, and any desire to branch out must be internally motivated.

Our study suggests exploring ways of motivating students to achieve a more holistic understanding of linear algebra concepts across the three worlds. The three-world model gave the mathematician-instructor a language that he felt accurately reflected his own thought processes. It also empowered the students by providing them a language to express their mathematical thought processes.

*In this paper, we investigate the mathematical discourse of undergraduate biology students when working on biology tasks. Our data consists of students' and the lecturer's discussion when working on two tasks in an Evolutionary Biology course. In our analysis we make use of the commognitive framework and focus on the use of mathematical routines. We observed that although the overall aim of students' engagement with routines was exploratory, the way they engaged with mathematical routines when working on biology tasks was ritualized. However, students were aware of the need of using construction routines when trying to mathematize a biological phenomenon although the lack of familiarity with relevant construction routines constrained their ability to deal with certain task situations.*

*Keywords: Commognitive perspective, mathematical discourse, mathematics in biology, routines, rituals and explorations.*

## Introduction

In the last four decades, the role of mathematics in the science of Biology has greatly increased. This has influenced undergraduate and graduate biology students who need to be mathematically capable to meet the demands of this science (i.e. Labov, Reid & Yamamoto, 2010). Students need to understand and work with contemporary mathematical models and frameworks that are applicable in analysing the overwhelming flow of biological data. However, various studies have shown that biology students face many challenges and difficulties in their biology courses when mathematics is used as an analytical tool (i.e., Speth et al., 2010; Brewer & Smith, 2011). These difficulties can be partly explained by a prevalent epistemological perspective on the connection between mathematics and other disciplines that Barquero, Bosch and Gascón (2011) have called “applicationism”. According to this view, common at the university level, “first mathematical tools are built within the field of mathematics and then they are ‘applied’ to solve problematic questions from other disciplines, but this application does not cause any relevant change, neither in mathematics nor in the rest of disciplines where the questions to study appeared” (ibid, p. 1940). Barquero, Bosch and Gascón argue that such a perspective has problematic effects particularly on mathematical modelling practices, since these require a solid understanding of the connection between the mathematical tools and the context in which they will be used.

This paper, which is based on the pilot study of a doctoral research project aimed at exploring and characterizing the mathematical discourses of undergraduate and graduate biology students, investigates students' group-work in a biology course in a Norwegian university when engaging with biology tasks that use mathematics as an analytical tool. Taking a discursive approach, we analyse students' and the lecturer's mathematical discourse when working on two tasks aiming to explore the routines that students engage with and the character of this

engagement, and to provide insights into the kind of mathematical discourse that the lecturer expected students to engage with.

### **Commognitive framework**

This study is grounded in the commognitive framework (Sfard, 2008). In this framework, mathematical knowledge is conceived through a community's established modes of communication called discourses. A discourse is defined as a "specific type of communication made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions" (ibid., p. 297). In other words, discourses are different types of communication set apart by certain characteristic features. In particular, mathematical discourse is described by four features: word use, visual mediators, endorsed narratives and routines.

Our focus in this paper is on the students' use of routines. Sfard (2008) originally defined routines as "repetitive patterns characteristic of the given discourse" (ibid., p. 134). However, recent work by, for instance, Lavie, Steiner and Sfard (2019) elaborates further of the notion of routine. They define routines using the notions of task situation, task and procedure. First, task situation is understood as a setting in which "a person considers herself bound to act – to do something" (ibid., p. 7). Second, a task is "the set of all the characteristics of the precedent events that she (the person) considers as requiring replication" (ibid., p. 9). The task refers to a person's interpretation of a given task situation; and, by precedent event, the authors mean all that happened in the precedent task situation. Third, a procedure is "the prescription for action that fits both the present performance and those on which it was modelled" (ibid., p. 9). The procedure is implemented by the task performer in response to a given task situation. Lastly, a routine which is performed in a given task situation by a given person is the task, as seen by the performer, together with the procedure the person executes to perform the task. Routines are distinguished as practical if the person interprets the task situation as requiring a change, re-organizing or re-positioning of objects; or discursive if the person interprets the task situation as requiring a communicational action (Lavie, Steiner & Sfard, 2019). Moreover, a routine is characterized as exploration if it is oriented towards the outcome; and, as ritual if it is a process-oriented performance. Thus, while an explorative task aims at producing a new "historical" fact about mathematical objects, a ritual is appreciated for its performance and not for its product. Explorations according to Sfard (2008) are divided into three categories: construction (a process resulting in a new endorsable narrative), substantiation (deciding whether to endorse previously constructed narratives) and recall (the process of citing a narrative that was endorsed in the past). According to Lavie, Steiner and Sfard (2019), students participate in unfamiliar discourse in a ritualized way. However, in further learning, their routines are expected to "undergo gradual de-ritualization until they eventually turn into full-fledged explorations" (ibid., p. 2). A person performs a certain mathematical routine in the present task situation because of its "precedents – to past situations which she (the person) interpret as sufficiently similar to the present one to justify repeating what was done then, whether it was done by herself or by another person" (ibid., p. 8). The precedents are chosen with the help of "precedent identifiers – to those features of the current task situation that a person considers as sufficient to view a task situation from the past as a precedent" (ibid., p.8). The analysis in this paper examines this relation focusing particularly on the following research

questions: “What characterizes students’ mathematical discourse when engaging with biology tasks?” and “How does students’ mathematical discourse relate to the lecturer’s intended solutions of the tasks?”

## Method

This research is a case study of the course Evolutionary Biology, an undergraduate biology course at a large Norwegian university. The study was conducted during the spring semester of 2018. All students enrolled in the course were required to have taken at least one course in Calculus and one in Statistics. The aim of this course is to provide students with a deeper insight into the evolutionary processes that can explain the genetic composition of populations, form, behaviour and distribution of organisms, and to acquaint students with the basic methods of analysing evolutionary relationships between species. Moreover, students are introduced to different mathematical models of evolution. During the course, three sessions are dedicated to students’ group-work. In these sessions, students are asked to work on different questions related to the topics that have been presented by the lecturer in the lecturing sessions. In this paper, we present data from one of these group-work sessions. In this particular session, students were asked to work in groups on a quiz with multi-choice questions. Students had 30 minutes available to finish the quiz. They were first to work individually for 10 minutes, then discuss their answers in small groups. The lecturer also handed out an answer sheet, enabling the students to check if the proposed alternative was the right one. After the small group discussion, the group had to agree upon a correct answer, which was then evaluated using the answer sheet. As students were working on the quiz, the lecturer circulated among the groups, providing help if needed. At the end of students’ group-work, the lecturer discussed each question of the quiz in front of the class.

In our analysis, we focus on two questions: *Heritability Equation* and *Genetic Correlation*. The first question (see Figure 1) requires students to find the correct formula of heritability ( $h^2$ ) which is given as a proportion of response ( $R$ ) to selection ( $S$ ).<sup>1</sup> This formula derives from the definition of heritability as the degree to which a certain trait in individuals is genetically (rather than environmentally) determined when the genetic construction of an individual and the environmental factors have a normal distribution. This equation had been introduced in a previous lecture. The second question (see Figure 2) requires students to reason about negative and positive correlation between variables. Although this specific question had not been previously discussed, the lecturer had previously introduced the theoretic background on genetic correlation between variables.

For the purpose of this study, we video and audio-recorded two groups of five students each (in total there were 32 students in the class, divided into groups of five or six) and the lecturer’s discussion afterwards. The two groups of students were chosen randomly. All collected data was transcribed. Students’ and lecturer’s discussions were conducted in English. When analysing the data, we focused on the identification of students’ and lecturer’s mathematical routines. We analysed separately the transcripts of each students’ group-work and the lecturer’s discussion, looking for instances where they were engaged in mathematical routines. Then we

<sup>1</sup> $R$ - is the response to selection for certain trait,  $S$ - is the selection differential, defined as the mean phenotypic difference between selected individuals and the population mean (see, Falconer and Mackay, 1996).

compared the findings from each students' group work with the lecturer's discourse. In the process of data analysis, we also looked for signs of exploratory or ritualized engagement, for instance, whether students' routine use was aimed at producing or justifying mathematical claims, or if they appeared to be engaging in routines without a regard for their relevance for the task at hand.

## Results

In this section, we will analyse each question separately, considering both the students' group-work and the lecturer discussion where he presented his expected solutions.

<p>4. One way to calculate heritability is by looking at the response to directional selection. Which equation is correct?</p>			
$a) h^2 = \frac{S}{R};$	$b) h^2 = \frac{R}{S};$	$c) h^2 = \frac{R^2}{S^2};$	$d) h^2 = \frac{R^2}{S}$

**Figure 1: Heritability equation**

Analyzing students' work on the Heritability Equation task, we observed that as the first step toward finding the correct response, students would engage with recall routines – trying to recall the equation given during the lectures or written in their textbook. Of the two groups of students that we video-recorded, only one student was able to remember the correct form of the equation, and she still expressed some doubt concerning her choice: “I think the right answer is *b*). I’m just trying to remember what was written in the book but I’m not sure about it”. After failing to recall the correct equation, students tried engaging in construction routines. They started discussing what the variables in the equation stood for and how they were defined. Although students were able to identify them biologically, they could not recall the meaning behind these variables: ‘I think *h* is everything that is heritable, and *R* is of course response and *S* the selection, but I don’t remember what they mean or how you actually use them’. Being unable to explain what these variables represent biologically urged students to look for other solutions. They tried reasoning mathematically using the properties of ratio and squared numbers. As shown in the dialogue below, through the use of these mathematical routines, the students tried to construct a new endorsable narrative (the equation of heritability).

- Student1: I’m guessing *b*) or *d*) ... because that would be response squared divided by selection, so the higher the response, the higher is the heritability; the higher the selection, less heritability.
- Student2: Yeah, but you can also see that there is only one answer where is the opposite which leads to one of these to be right.
- Student1: Yeah, but the question is which one should we square?
- Student2: They can both be squared.
- .....
- Student3: Why would you have it squared?
- Student2: To negate the possibility of a negative answer. Just square something and it cannot be negative.

Despite engaging in construction routines, the students in the first group were unable to come up with an answer, since these routines were not helpful enough for justifying any of the proposed alternatives. Thus, they decided to postpone the question. They had a further reason for this: since the following question was directly asking for the definition of heritability, they believed that the alternatives given there would help them to find the expected definition of heritability. After students had spent some minutes working on the quiz, the lecturer asked them if they needed help with the questions. He suggested using another definition of heritability given during lectures, but the group still felt lost and, in the end, the group gave up and just skipped the question. Meanwhile, the second group, after some discussion, agreed upon alternative (d), arguing that if you have a higher selection in the numerator then the response is higher in the denominator, although without explaining why that would make sense biologically. Checking the answer sheet and realizing that they had selected the wrong answer, they merely exchanged this for the correct answer. Thus, we can observe that in this exercise, although students used construction routines with the overall aim of formulating a new endorsable narrative, they engaged with the mathematical routines in a ritualized way – employing the routines without much regard to their relevance for the problem at hand, and consequently failing to come up with a meaningful narrative.

In the follow-up discussion of the first question, the lecturer began by saying: “I told you, you have to learn these equations and some of you didn’t”. Although the lecturer was laughing as he said this, suggesting that he was perhaps not entirely serious, it still implies that he was not really expecting students to come up with the correct alternative from scratch. Rather, he just expected them to remember it. In other words, he expected them to use recalling routines rather than construction routines. However, he also explained how the model could be constructed and how the form of the equation could be justified using the graph of normal distribution which describes the relation of differential selection and response. Hence, during his explanation of the task, he used construction routines that differed from the ones the students used in their solution attempts. Neither normal distribution nor the alternative definition suggested by the lecturer to the first group, were mentioned by any of the students.

7. Here, are two questions dealing with genetic correlations, using a real-world example. Pick the alternative which has the correct answer for both questions.

The genetic correlation between %\_Fat and Kg\_Food/Kg\_Gain (Feed Conversion Ratio) is positive, +33. (Hint: Think of Kg\_Gain as 1, and Kg\_Feed getting higher or lower). The genetic correlation between %\_Fat and Days\_to\_Market (how long it takes to reach the weight at which the pig is sold) is negative, -20.

7A) What will be the effect of selecting for leaner pig (less fat) on Days\_to\_Market?

7B) What will be the effect of selecting for leaner port on feeding costs?

- a) 7A) Days\_to\_Market will be longer; 7B) higher feed costs.
- b) 7A) Days\_to\_Market will be longer; 7B) lower feed costs.
- c) 7A) Days\_to\_Market will be shorter; 7B) higher feed costs.
- d) 7A) Days\_to\_Market will be shorter; 7B) lower feed costs.

**Figure 2: Genetic Correlation**

The second question (see Figure 2) focused on genetic correlations of three different variables. This question, unlike the first one, could not be solved using only recalling routines. Since the task required actions for deciding whether to endorse previously constructed narratives, the solution will involve substantiation routines. Working on this task,

both groups struggled with the same issue as in the first question: converting variables into their biological context. However, in this case, students were able to come up with the meaning of genetic correlation, but as shown in the dialogue below, they struggled with making sense of the biological interpretation of their result.

Student2: But if there is a negative ratio between fat and days to market, that means that if fat increases then days to market decrease, right? ... Then, that would mean that less fat, more days to market? And if we apply the same logic to the first one, then fat decreases, then we need less food.

Student3: Yeah, I thought that when I read it. I thought it was the amount of fat correlates to the Days to Market so that means that the percentage of fat...the amount of days at the market would lower the percentage of fat by a factor of 0.2.

Student2: Which does not make sense.

.....

Student4: I understand your point. I just guessed something because I was thinking about what is the effect of selecting leaner pork on feeding costs. If you think logically, then it would take shorter time to get a leaner pork than a fat pork which means lower feeding costs, right? So, I just kind of started thinking without the mathematics.

After some discussion, both groups came up with the right answer. Still, the second group first tried drawing a conclusion through reasoning biologically, rather than considering the quantitative relations between variables. However, due to a mistake in their biological reasoning, they ended up with the wrong answer. Realizing that, they started re-examining the correlation between the variables, noticing that just considering the relation between variables would lead to the right answer. In his discussion of the solution to this question, the lecturer suggested that it should have been based on the meaning of genetic (negative or positive) correlation, which fits with what the students did. Thus, his expectation on the kind of routines that students should have used during the exercise were fulfilled (despite the fact that the second group failed in their first attempt).

## Discussion

In this paper we have analysed students' and the lecturer's discourse when working on two biology tasks involving mathematical elements: *Heritability Equation* and *Genetic Correlation*. These two tasks set by the lecturer in a group-work session differ from each other concerning the expected routines that students were required to use when solving them. In the second question, the mathematization of the problem had already been done, meaning that the relation between variables was given, and the students just needed to use that relation. Thus, they were expected to use substantiation routines in order to endorse previously constructed narratives. In the first question, on the other hand, the mathematization of the problem was not given. Students had two possibilities in this case – use recall routines

to remember the correct form of the equation from previous lectures or use construction routines to construct a mathematical model for the problem.

Working on *Heritability Equation*, when the students were unable to remember the correct equation, they used construction routines. However, considering that they did not remember the biological meaning of any of the variables, students were not left with many choices other than identifying other features of their current task situation that would allow them to repeat precedents from their past situations. The choice to use properties of ratio and squared numbers as a step to overcome the constraints of the task, shows that they were trying to apply familiar routines in unfamiliar task situations aiming at innovation. However, we observed that students employed these mathematical routines – by identifying precedents that allowed them to use properties of ratio and squared numbers – without any apparent regard for their relevance for their task situation. Rather, they appeared to engage in familiar routines in a purely process-oriented manner and not towards a specific goal. This is in accordance with the findings of Viirman and Nardi (2019) where biology students were seen to employ mathematical routines in a ritualized way, even when their engagement with the biological content of the tasks was exploratory.

On the other hand, from the lecturer's discourse we can observe that his expected solutions to the task build primarily on recall routines. This fits with the aims of the course, which focused on learning how to use mathematical models rather than constructing them (although he did show the construction of the models during his discussion). Still, we do not exclude the possibility that the lecturer expected students to explore the exercise mathematically using construction routines since he gave a hint on how the problem can be modelled using the alternative definition of heritability. We note that when the lecturer gave the hint to the first group, he assumed that students knew the meaning of variables ( $h^2$ ,  $R$  and  $S$ ), which was not the case. However, as Lavie, Steiner and Sfard (2019) suggest, although the lecturer's own mathematical discourse can be a model for the students to follow, it is necessary to put a conscious effort into establishing whether the explorative nature of the task gets through to the students clearly enough (ibid., p. 20). We suggest that helping students with the biological meaning of the variables might have supported their engagement with construction routines. This being said, the lecturer was unaware of the students' difficulties since they did not mention that they were struggling with understanding the variables. Concerning *Genetic Correlation*, despite some struggles in the beginning, students were able to use substantiation routines in accordance with the lecturer's expectations. It is worth emphasizing that, contrary to the second task, the nature of the *Heritability equation* encouraged students to engage in explorative participation. The mathematization of the first task required engagement with an unfamiliar task situation, as suggested by the students' inability to use the hint that the lecturer gave them during group-work, and by the absence in the students' discourse of any of the routines used by the lecturer in his construction of the heritability model.

We are aware of the limitations of our study, and that the limited amount of data does not allow us to draw any general conclusions. Still, we find it noteworthy how the students' engagement with the tasks corresponded well with the lecturer's expectations, and that difficulties mainly occurred when they failed in invoking the kind of routines he had expected. We claim that relying purely on recall routines can be potentially problematic for students. We suggest that providing students with some opportunities for working with construction routines can be helpful for their learning. In the continuation of this doctoral project, it is our intention to observe a greater number of biology students' over a longer period of time, investigating what happens to their mathematical discourse as they participate in a course more closely connecting mathematical modelling with biology.

# Recall and substantiation routines in exam scripts: injective and surjective functions

Athina Thoma, Elena Nardi

University of East Anglia, United Kingdom, [a.thoma@uea.ac.uk](mailto:a.thoma@uea.ac.uk)

*In this paper, we focus on first-year university students' engagement with university mathematics discourse in the context of a final examination question on injective and surjective functions. The data consists of twenty-two responses as well as excerpts from an interview with the exam-setting lecturer. Our commognitive analysis focuses on student engagement with recall and substantiation routines: how they recall and provide relevant definitions, and how they substantiate whether a function is injective or surjective. We identify three issues that are exemplified with samples from the data: ambivalent word use, and visual mediation, relating to equivalence; partial justifications regarding the injectivity of  $h(n) = 3n$ ; and, conflation of justifications for a function's surjectivity in  $\mathbb{Z}$  with those used for functions in  $\mathbb{R}$ . We conclude by discussing the notion of precedent events as evident in students' engagement with routines in a range of mathematical topics.*

*Keywords: Substantiation, recall, routines, injective, surjective function.*

## From secondary to university mathematics

Transition from secondary school to university mathematics is a topic of growing interest (Gueudet, 2008). While differences between secondary school and university mathematics vary across countries, there are aspects of this transition which seem to be common in different contexts. In the larger study from which this paper stems (Thoma, 2018), we explore this transition through analyses of Year 1 examination questions, lecturers' perspectives on designing and using these and students' responses. Functions, one of the topics examined in these questions, have been identified as a key mathematical topic in the transition from secondary to university mathematics (Winsløw, Gueudet, Hochmuth, & Nardi, 2018) and research has reported issues around students' learning about functions for a long time (Bansilal, Brijlall & Trigueros, 2017). Analogous attention has been given by researchers to students' deployment of formal definitions and proofs (Selden, 2011), their use of mathematical notation (e.g. Mamolo, 2010) and their difficulties with mathematical objects that have different meanings in various mathematical areas (Kontorovich, 2018). Here, we focus on one aspect of learning about functions that has received relatively little attention: what students think a surjective and an injective function is and how they decide whether a function is injective or surjective.

In this paper<sup>1</sup>, we focus on twenty-two students' responses to a Year 1 examination question on injective and surjective functions. We take a discursive approach, the theory of commognition (Sfard, 2008), in analysing the data, and we aim to characterise the routines that students engage in when answering the questions. Building on previously reported work (Thoma & Nardi, 2018a; 2018b), we examine the relevant definitions students provide and the procedures they use when substantiating that a given function is (or is not) injective or surjective.

<sup>1</sup> An earlier version of this paper was presented as a PME42 Oral Communication (Thoma & Nardi, 2018b).

## Commognitive routines: recall and substantiation

A discursive perspective which is being increasingly used in university mathematics education research is Sfard's (2008) theory of commognition (Nardi, Ryve, Stadler & Viirman, 2014). In this perspective, mathematics is defined as a discourse (Sfard, 2008) which can be described in terms of the following four characteristics: *word use* (e.g. injective), *visual mediators* (e.g. algebraic and logical symbols), *endorsed narratives* (e.g. definitions) and *routines* (e.g. proving). Sfard (2008) describes three types of routines: *deeds* ("an action resulting in a physical change in objects", p. 236), *rituals* ("creating and sustaining a bond with other people", p. 241) and *explorations* ("producing endorsed narratives", p. 259) with the exploration routines further categorised as *recall* (e.g. recalling the definition of an injective function), *substantiation* (examining whether a given function is injective) and *construction* (e.g. constructing a function that is injective). Of relevance to our analysis here, are exploration routines, which often develop from rituals. This process has been described through the notion of *task-situation* in which an individual feels a need to act and which is taken as "the set of all the characteristics of the precedent events that she considers as requiring replication" (Lavie, Steiner & Sfard, 2018, p. 9). Thus, explorations can emerge as changes in the way learners search for precedents in task situations. In our study, we deploy *task* to mean a part of an examination question which the students are asked to engage with. These task situations are interpreted by the students, who draw on *precedent events*, which include previous examples or exercises each student has engaged with before and which they see as relevant to the present *task*. Sfard (2008) describes the *procedure* (or *course of action*) and the *when* of a *routine*, with the latter further described in terms of its *applicability* and *closing* conditions (pp. 208-209). The applicability conditions are "circumstances in which the routine course of action is likely to be evoked by the person" (p. 209, *ibid*) and closing conditions "[signal] a successful completion of performance" (p. 209, *ibid*).

Here, we explore how students recall the definitions of an injective and surjective function and how they engage in substantiation routines, in order to examine whether functions defined on the integers are (or are not) injective or surjective. Previous research has documented "how lack of flexibility in working across different representations influences students' encounter with the concept of function" (Nardi, 2008, p. 161) and has posited that students' prior experience with functions and sets may have contributed to this lack of flexibility (Bansilal et al., 2017). However, there is little insight from prior research into students' engagement with injective and surjective functions in various numerical domains (e.g. reals and integers). In the UK educational context of the study we report in this paper, engagement with various numerical domains is different in school and university mathematics. In school mathematics, students are initially introduced to the domain of integers. Later, they are introduced to real numbers and discursive activity with integers is subsumed within that of the reals. The tasks they engage with here are in the context of real numbers. At university, students are expected to engage with various numerical domains, often within the same task. Being aware of this variety and of the various restrictions within each domain is therefore crucial.

Our study aims to provide some insight into this through exploring the following research question:

What engagement in mathematical routines can we observe in students' scripts when they examine whether given functions are injective or surjective?

To answer this research question, we examine students' use of mathematical terminology and notation which may be incompatible with the mathematical discourses they are expected to engage with when responding to the task at hand. We also examine the closing and applicability conditions of the routines, in which the students are required to engage in when solving the question within the various mathematics discourses present in the question (e.g. discourse of functions, integers, reals). We examine the written scripts of the students which capture the output of students' engagement with these mathematical discourses.

### **The exam question, the participating students and the exam-setter's intentions**

The data on which we focus are examination scripts from 22 students taking an exam on a *Sets, Numbers and Probability* Year 1 module. In this module, the focus is on *Sets, Numbers and Theory* in the first semester and on *Probability* in the second semester. The final examination consists of six questions, three coming from each part of the module, one compulsory and two optional from each of the two parts of the module. Here, we focus on one sub question of one of the optional questions from *Sets, Numbers and Theory*, on surjective and injective functions. During the year, the students were asked to engage with the properties of injectivity and surjectivity in exercise sheets and coursework with functions defined in different numerical domains. In this paper, we discuss students' responses to this examination sub question:

Suppose  $A$  and  $B$  are sets and  $f: A \rightarrow B$  is a function. Define what is meant by  $f$  being *surjective* and what is meant by  $f$  being *injective*. For each of the following functions decide whether it is injective, surjective (or both, or neither). Give brief reasons for your answers.

(a)  $g: \mathbb{R} \rightarrow \mathbb{R}$  where  $g(x) = 1/(1 + \sin^2(x))$  for  $x \in \mathbb{R}$ .

(b)  $h: \mathbb{Z} \rightarrow \mathbb{Z}$  where  $h(n) = 3n$  for  $n \in \mathbb{Z}$ .

Fifty-four students took part in the final examination and the marks of their responses to the whole question (the first sub question is given above and the second dealt with modular arithmetic) ranged from 0 to 20 marks with an average of 14.31. The scripts of 22 students were selected by the first author to represent a variety of marks (for more information on the selection process, see Thoma, and Nardi, 2017, Fig. 3 on p. 2269). We analyse students' scripts according to the definitions they recall for injective and surjective functions, and their substantiations that the given functions are (or are not) surjective or injective. In our discussion of the students' scripts, we bear in mind also the following selected quote from an interview, conducted soon after the exam, with the lecturer who taught the module and set the examination task. This quote illustrates the lecturer's concern with a perceived discrepancy between "knowing how to write down" a definition for injectivity and knowing what injectivity "means". We return to this quote towards the end of paper.

"somehow they know what injective means, they just don't know how to write down the definition (...) it is a very strange experience to see that a student knows what injective means but can't write down what it means, it's something about maybe not even about mathematics, it's about language and about logic (...) They need to see this transition between (...) the symbols and the meaning and the logic of things and it's one of the most important things and it is one of the hardest things to teach"

## Recall and substantiation routines in students' scripts

In the sub question under consideration, students are first asked to provide the definition of injective and surjective function (recall); then, to determine whether two functions are injective or surjective and provide brief explanations for their choices (substantiation). Here, we highlight three issues that emerged from the analysis of the scripts: ambivalent word use, and visual mediation, relating to the object of equivalence ( $\Leftrightarrow$ ) instead of implication ( $\Rightarrow$ ) in the definition of injective function; partial justification of the injectivity of  $h(n) = 3n$ ; and, conflation of justifications for a function's surjectivity in with those used for functions in . We discuss each case providing also examples from students' scripts.

### Ambivalent word-use and visual mediation relating to the object of equivalence

In the scripts of four students, there is ambivalent word use and visual mediation relating to equivalence (either using the logical symbol  $\Leftrightarrow$  or phrases that signal equivalence) in the definition of injective function, illustrating confusion between the definition of injective function and the definition of a function. In the definition for an injective function, student [02] writes “one to one relationship” and comments on the relationship between the elements of the domain and the codomain

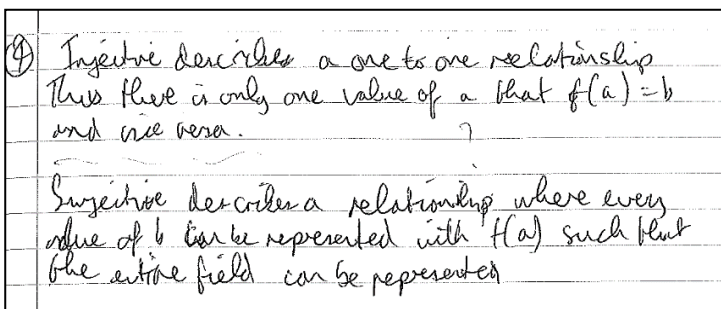

Figure 1: Student [02]'s definitions

of the function (Figure 1). However, later, the student, in trying to clarify what this “one to one relationship” is, writes “ $f(a)=b$  and vice versa”. This phrase is not further explained and is also used when the student examines whether the given function  $h$  is injective, signaling a confusion between the definition of a function (which must be single valued)

and the definition of an injective function. Additionally, we note that the logical quantifiers “for every  $b$ ” and “there exists  $a$ ” in the definitions of injectivity and surjectivity are missing from student [02]'s response. This absence of logical quantifiers and the ambivalent use of logical phrases (“vice versa”) highlights a difficulty with the logical connections between the various mathematical objects that are part of the definitions. Furthermore, we observe the difficulty to state the definition formally. The phrases used by the student (e.g. “only one value”) are ambiguous and are not clearly showcasing whether the student discusses injectivity, which would be “at most one value” or bijectivity (“there exists one and only one value”). The ambiguity between the single valued function and the injective function is also illustrated in definitions given by student [06] (Figure 2) and two more students.

Figure 2: Student [06]'s definitions

This use of equivalence (either in the form of the symbol (Figure 2) or using the phrase “vice versa” (Figure 1)) in the definition of injective function highlights difficulties in students' engagement when recalling and writing the definitions. This may lead to difficulties in the substantiation part of the question, illustrating the close connection between definitions of the properties of the functions and

the substantiation routines. This ambivalence between definitions and substantiation routines could be explained by considering students' precedent events. The focus in secondary school is on the properties of a mathematical object. However, the students are rarely required to provide a set of conditions to serve as a definition of a mathematical object. In that occasion providing more conditions and properties is not considered incorrect. This is not the case at university level. The expectation at university mathematics is to provide a minimal set of conditions which suffices for the function to be injective without reiterating the definition of function. The examples from the students' scripts discussed above, highlight the need to alert the students to the characteristics of the routine in the context of university mathematics.

We now turn to students' engagement with substantiation routines in examining whether the function which is defined in integers is injective or surjective.

### Partial justifications regarding injectivity of $h(n) = 3n$

In the scripts of ten students, we have partial justifications regarding the injectivity of the function  $h$  defined in  $\mathbb{Z}$ . One of these scripts is in Figure 3. Student [22] claims that  $h(n)$  is not surjective by providing a counterexample and then tries to prove that  $h(n)$  is injective. We note here that [22] writes “surjective” instead of “injective” in the second part of the script. When discussing why the function

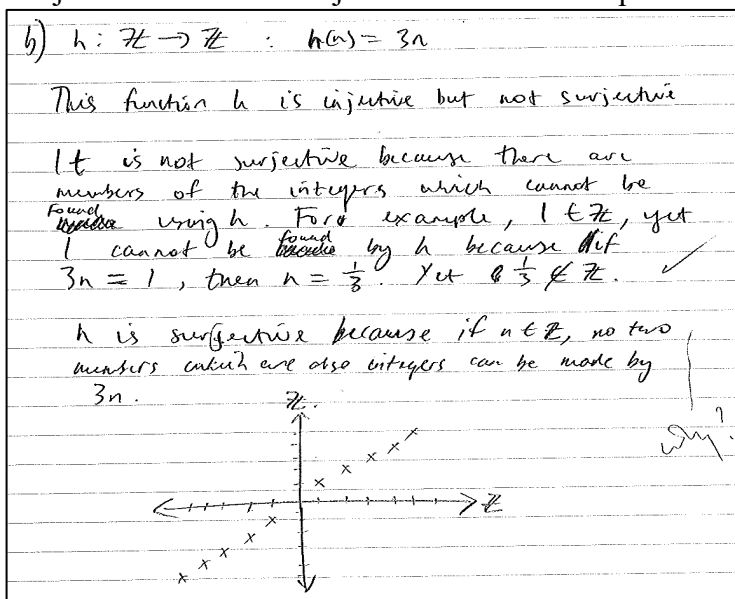

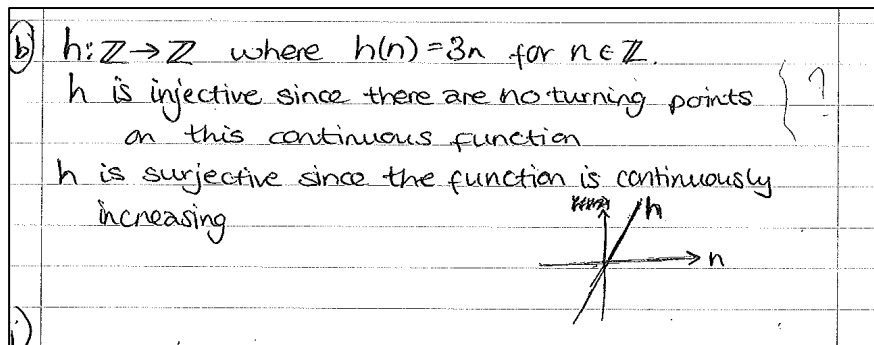

Figure 3: Student [22]'s response to (b)

is injective s/he says that “no two numbers which are also integers can be made by  $3n$ ” and provides a graph to support this claim. In the graph produced by the student, and from their answer regarding surjectivity, we can see that [22] sees  $h(n)$  as a discrete function. However, the argument accompanying the graph (“ $h$  is surjective because ... can be made by  $3n$ ”) is not sufficient. The relationship between two elements of the codomain and the corresponding elements of the domain is not clear. We note, that the difficulty here is in the closing conditions of the routine.

### Conflation of justifications for a functions' surjectivity in $\mathbb{Z}$ and in $\mathbb{R}$

In seven student scripts, the procedure of substantiation that an integer function is or is not surjective is conflated with procedures that could be used when a function is defined in  $\mathbb{R}$ , not in  $\mathbb{Z}$ . One such example is shown in Figure 4. When substantiating, the student does not use the definition of the injective function but relies on other procedures. S/he talks about “turning points on this continuous function” and “continuously increasing”. These properties of the function are describing functions which are continuous and defined in  $\mathbb{R}$ . This conflation of functions in  $\mathbb{Z}$  and  $\mathbb{R}$  is also illustrated in the graph produced by student [11]. We observe that the arguments are based on the graph of the

function, even though there is a symbol  $n$  at the  $x$ -axis, the values in the  $x$ -axis,  $y$ -axis and the line showing the function is a straight line without gaps. This engagement is ritualistic as the students seem to be drawing on familiar precedents: in the past, the majority of the tasks the students engaged with were dealing with functions in  $\mathbb{R}$ . The students are examining the function but do not take into account the domain as a significant precedent identifier regarding the routine that they should follow. This suggests that the student does not consider the integers as the domain of this function but thinks of the function as a function in the reals, highlighting that the applicability conditions of the substantiation routine are not being examined and thus a routine being used typically for a continuous function is used here for a discrete one. We should note that there is a relationship between properties

of functions in  $\mathbb{R}$  which are restricted in  $\mathbb{Z}$ . However, if this relationship is used, then this relationship between the real function and its restriction to integers should be examined as part of the justification provided by the student.

Figure 4: Student [11]'s script to (b)

Returning to the lecturer's quote, it seems that the phrase "they know what it means" indicates the students' ability to decide whether a function is injective or surjective. This routine of deciding whether an object has certain properties has precedents in secondary school mathematics. However, in university mathematics, the substantiation routine is at least as important as deciding on the properties of a mathematical object, and the lecturer would like to see the substantiation of students' decisions relying on an accurately recalled definition, which often was not the case. This new routine of substantiation is challenging for students for many reasons; in the precedent space acquired in secondary school, decision tasks do not typically require the recall or reconstruction of definitions, nor do they require substantiation based on a definition. At university level, the students must become familiar with recalling and providing definitions, focusing on a minimal set of conditions rather than providing all the properties that they can recall relating to the mathematical object in question. In the definition of injective function, they must identify the domain and the codomain of the function, engage with different elements in the domain and with logical quantifiers that connect statements with elements from the domain and the codomain, and use all these in their substantiation.

### The potency of a commognitive lens: Routines and precedent events

Our analysis suggests that, in these exam scripts, students face difficulties when they recall the definition of an injective function, particularly in relation to word use and visual mediation relating to the object of equivalence pertaining to the definition of injectivity and to conflating injective functions and the fact that a function is single valued. Furthermore, the closing conditions of the substantiation routines are not met. This may relate to differences between secondary and university mathematics in the UK context of our study. While in the context of secondary mathematics, students

have engaged with examining whether a mathematical object has a property or not; they have not necessarily done so with the explicit requirements for rigour and logical connectedness expected in a Year 1 examination at university. Finally, students' ways of exploring whether function  $h(n)$  is surjective indicate that they base their responses on their prior experiences which are usually with functions defined in the reals. However, these procedures are not necessarily applicable in the context of the integers and this results in conflating the discourses on the two. We see the students' responses as underlain by a commognitive conflict: integers are seen as a subset of reals and not as a domain in which there is no closure for the operation of division.

The analysed students' scripts and the comment from the lecturer illustrate the importance of the precedent events. In aiming to deritualise students' engagement with these routines, a more nuanced search for the precedent events is needed – and one which focuses clearly on the identifiers of the precedent events. This is illustrated in the comments of the lecturer as well as those student scripts which showcase ambivalent word use and visual mediation. Both of these cases highlight the difference with the precedent events in secondary school regarding the definition of a mathematical object. Then, the scripts illustrating partial justifications are also showing that students' engagement with precedent events at secondary school, where the justification whether an object satisfies a given identity does not necessarily require the depth of justification needed at university level. Finally, in the last category, the importance of the identifiers regarding the precedent events is further elaborated, as it showcases that the focus should not only be on the object (the function) but also on the domain of the function which is a substantial precedent identifier in terms of the routine required.

Our results offer further insight into students' engagement with routines of proving and recalling definitions, and the relationship of the two in the context of a question on injective and surjective functions. While previous research regards students' prior experience with functions and sets (Bansilal et al., 2017), our results highlight the importance of examining the applicability conditions of substantiation routines in different mathematical contexts (e.g. integers and reals). These results illuminate instances where the lecturers could highlight more explicitly the differences between university and secondary school discourses; and, discourses of reals and integers. Similar results to the ones reported in the paper with students' engagement with recall and substantiation routines are visible to students' responses to other examination questions (Thoma, 2018) relating to: the definitions of reflexive, symmetric, and transitive relations and the substantiation of these properties; and, recalling Fermat's Little Theorem and applying it to find the remainder of a power (e.g.,  $27^{313}$ ) divided by a prime number. We credit the commognitive lens for the insights into the student scripts that our analysis allows, and particularly the recent efforts (Lavie et al, 2018) to associate task situations, precedent events and the ways students engage with mathematical routines.

*We report on a collaborative project at university level involving students as partners in task design for a bridging mathematics module (known in the UK as a Foundation module) which is part of gaining access to first year degree studies. Three teacher-researchers met regularly with four student partners who developed a set of tasks on matrices and on complex numbers which were trialled with students on this Foundation module. We show the mediational processes by which the tasks developed from 'static' designs to more 'dynamic' designs using the software Autograph. Our analyses highlighted various tools in the mediation of the learning of mathematics, in the mediation of task development and in the mediation of the engagement of all team members in collaboration.*

*Keywords: Student-partner, computer-based task design, mediation and tool use, collaborative research, developmental research.*

### Background and literature

In 2011/12 findings from the ESUM project (Jaworski & Matthews, 2011; Jaworski, Robinson, Matthews & Croft, 2012) pointed to a problematic difference between teacher culture and expectations and those of students when researching students' use of mathematical tasks in a computer environment – when those tasks were designed for students by their teacher. In the current project we are trying to address this difference by engaging students in the design process and studying the emergent learning for the students and the researchers. The project was designed by three teacher-researchers (TRs, authors of this paper) to engage four students as partners in the design of mathematical tasks in a computer environment. Thus, the project is a collaboration between students (we refer to them as student-partners, SPs) and teacher-researchers (TRs) in the design of tasks. Several aspects were explored within this project: the development of mathematical tasks in a computer environment, SPs' perspectives on task design and participation in a research team, and the use of the tasks with current students studying on a Foundation module.

While there is research into the engagement of students as partners in course design at university level (see Mercer-Mapstone et al., 2017), few of these are within mathematics education (see however, Duah, Croft & Inglis, 2014; Fayowski & MacMillan, 2008). Our project builds on the work of Duah and Croft (2011) who involved student interns in the design of resources for two 2<sup>nd</sup> year mathematics modules experienced as difficult by students. Both the lecturer of the module and student interns learned considerably from this collaboration (Duah, 2017).

Our aim for initiating this project and recruiting SPs was to foster and study a deeper understanding of mathematics in a Foundation mathematics module, specifically the two topics of complex numbers and matrices. The Foundation Studies Programme is a one-year course intended for

students who wish to study for a STEM subject at our university but do not satisfy the entry requirements for their chosen degree. All must take a Foundation mathematics module as part of their programme.

We focus on complex number tasks for this paper. The decision to use dynamic software in task design was taken by the TRs in order to connect algebraic and geometric representations of the arithmetic operations on complex numbers. We consider geometry and algebra as fundamental to all mathematics (Atiyah, 2001) and hence to its teaching and learning. While we are aware that providing geometric insights can potentially be problematic (it can both help and hinder, see Gueudet-Chartier, 2004), we align ourselves with those who value these as a means of connecting with students' more intuitive notions of a concept (Stewart & Thomas, 2009; Uhlig, 2003).

### **Theoretical and Methodological Perspectives**

We take a socio-cultural perspective on teaching and learning. Central are the Vygotskian notions of mediation and tool use – the idea that attaining an object of activity is achieved better through the mediation of some tool, artefact, person or process (Vygotsky, 1978, Wertsch, 1991). All members of the project were learners: the SPs learned how to design mathematical tasks and work with the other members in a research environment; the TRs learned about student perspectives and the process of involving students in task development. Mediation was similarly diverse: all participants mediated the learning of others through the collaborative process. There were various tools: computer-based resources in the form of *Autograph*<sup>1</sup> files that were accessed by Foundation students in the tutorials; paper-based resources such as lecture notes and problem sheets, additional instructions on the use of Autograph, and questions in relation to the Autograph files. We return to mediation and tools later.

The research team consisted of nine people: three teacher-researchers (TR1, TR2 and TR3, the first three authors), two doctoral students (the last two authors who helped with data collection and analyses) and four SPs. All were engaged in developmental research within a community of inquiry, seeking to create knowledge, improve practice and the mathematical learning experience of students (see Jaworski, 2006). All participants took part in design meetings and were involved in an iterative design-research approach where participants *inquire* into the processes in which they engage. The SPs learned mathematics through inquiry into task design. They particularly learned task design through several iterations of the design process (inherently an inquiry process) in which drafts of their tasks were critiqued by other members of the team.

Our approach used ethnographic methods with data collected that could help answer our research question. Data collected included (1) audio-recordings of project design meetings, (2) written reports by SPs reflecting on their experience of task design, (3) interviews with SPs, (4) computer-based tasks (Autograph files), (5) various field notes. We took a grounded approach to data analyses. As part of this process data reductions were made of all design meetings. For a data

<sup>1</sup> Autograph <https://www.autograph-maths.com> is a piece of software which dynamically links 'objects'. This allows the user to 'see' the result of moving/changing one object – other objects are linked and move/change with the first object.

reduction one of the researchers listened to the audio-recording while simultaneously making time-related factual notes on the content. This resulted in a factual summary in tabular form with interpretative comments written in a separate column alongside suggestions for areas of transcription. With these summaries we aimed to capture key points of the task design in order to chart their development, written reports were read and used to support the analysis in respect of the recordings; interview data were partially transcribed and key points summarised; computer-based tasks were recorded as screenshots; field notes were read and integrated into summaries.

In this paper, we focus on the SPs' design of tasks in complex numbers and specifically on their transition from thinking in terms of the nature of tasks with which they were familiar from their past mathematical experience, to developing more dynamic forms of the tasks. We ask:

What was the process by which SPs' generation of tasks developed?

### **The development of the complex number tasks**

The tasks were developed for use with students taking a mathematics module in their Foundation Studies Programme. The SPs were recruited from former Foundation students via an interview process. The four students, chosen from the sixteen who applied, were those who had achieved a good grade in their Foundation mathematics module and who showed interest and initiative in thinking about their potential involvement. All had begun their first year of an Engineering or Science degree (Chemistry, Physics, Mechanical and Chemical Engineering).

The SPs' first task in the project was to review their notes from the Foundation module on two topics, matrices and complex numbers. To initiate the project, the whole team met for an introduction to the computer environment (Autograph) by an expert in its design and use. The SPs knew TR2, the lecturer of the Foundation mathematics module and were introduced to the other project members. Audio data from the meeting shows that SPs participated in a discussion on the use of Autograph and expressed views on experiences from their Foundation studies. These were of particular value and interest to the TRs, who gained insight into student perspectives on teaching and mathematical learning. Following this initial meeting, SPs engaged in designing tasks and bringing their current designs to successive 'design meetings' (DMs) where designs were discussed and modifications suggested.

The computer environment, Autograph, can be seen as a *tool* in two ways: first, it was to be a tool for the design of tasks as we discuss below. Second, and more immediate in the initial meeting, it became a catalyst for drawing the SPs into a discussion with the team in a non-threatening way. The team was relatively new to Autograph and so all could ask questions and talk about the use of the software. TRs engaged in a mediational process of drawing the SPs into the team via questions to the expert about how to use Autograph and the dynamic nature of its commands. The SPs were asked to use Autograph to produce first (and successive) drafts of tasks to be used with the new cohort of Foundation students. Gradually, roles and relationships were established, with the researchers taking the lead initially and the SPs showing a growing confidence in participation in the project.

### **Design of tasks and the Design Meetings – an iterative process**

The first design meeting (DM1) was a significant staging post in the developmental process. It involved the team and the expert in a discussion of the tasks which the SPs had brought to the meeting. Each task had a mathematical element and an Autograph element. The SPs presented their initial ideas, one of which involved a multiple-choice style task on addition of complex numbers based on the type of questions that they were used to on problem sheets, such as ‘If  $z_1=2+5i$  and  $z_2=3-6i$ , what is  $z_1+z_2$ ?’ The Autograph file displayed the complex numbers as vectors including also the correct answer (one variation was to include some incorrect answers with Foundation students asked to choose the correct one). The initial task made use of the commands within Autograph such as ‘hiding’ and ‘unhiding’ lines and objects and ‘dragging’ a complex number  $z$  to see what happened to a linked object such as  $z_1+z_2$ ,  $z_1z_2$  or  $z^3$ .

In SPs’ initial designs, the mathematical element came first and the Autograph element followed. The SPs’ expectation was for Foundation students to work out solutions on paper first and then use the software to view complex numbers in an Argand diagram and verify their results. Thus, the Autograph element was a tool to illustrate the mathematical relationship but it was left up to Foundation students to make the link. In the meetings the whole team discussed the tasks. In DM2, one member (TR1) commented that a task seemed rather “static”. Discussion followed as to what aspects contributed to the task being static, and what a task that was more dynamic and exploratory might look like. TR1 wrote in a reflection afterwards: “So far, we are seeing quite ‘static’ tasks – tasks in which there is something to find, with a right answer.” In this sense, the initial tasks mirrored typical questions on problem sheets that the SPs had been used to. TR1 continued writing, “A challenge now is to use the power of the software to offer more interactive, open-ended, exploratory tasks”.

The word “static” acted as a tool in the mediational process. It was used briefly in DM2 with TR1 commenting that tasks might follow a “sequence from straightforward ‘How do you work out this...?’, straightforward questions like that, ... but work towards something that is more open-ended and more exploratory, so that they [the Foundation students] have to actually do something themselves, to explore a situation” (DM2, 40:08). Discussions in the subsequent design meetings ensued. As team members expressed their view on a ‘dynamic’ task, a sense emerged of the mathematics of the task becoming more integrated with its representation(s) in Autograph and Foundation students engaging with these representations and the computer environment. In an end-of-project interview when reflecting on the early design process, one of the SPs (SP1) recalled how the word “static” had been a catalyst for new ways of thinking about the tasks. He said that, as a Foundation student, he had been familiar with procedural tasks on the problem sheets. He and his partner (SP2) started from such a point of view to represent the tasks in Autograph with lecture notes and associated problem sheets acting as mediational tools, guiding their initial perceptions.

Working on the complex number tasks and communicating electronically, the two SPs had shared potential examples of dynamic tasks. As they exchanged ideas, they said, a clearer sense of possibilities emerged. These exchanges were themselves mediational; we interpret the oral and written words of the SPs as saying that different versions of the tasks acted as tools to promote new thinking and subsequent modifications. Discussion of static versus dynamic tasks in design meetings opened up new ideas and dimensions, again a mediational process. For example, the first

iteration of the design process produced procedural tasks with expected answers while subsequent iterations shifted the nature of tasks to involve SPs in inquiry processes as they explored the questions asked. Team members expressed their ideas in different ways, encouraging a group perception of the nature of dynamical tasks (exemplified below). We see here a significantly new mode of mediation. The discussion of tasks allowed team members to question and share their own views with the SPs contributing alongside the other members of the team.

### Finalising the tasks

The SPs developed six complex numbers tasks: adding and subtracting two complex numbers, multiplying together two complex numbers, multiplying a complex number and its complex conjugate and raising a complex number to a power. All final designs had their genesis in the ideas presented in DM1. SPs undertook major revisions of the tasks between the first and the second design meeting. Critiquing the tasks in the second design meeting, team members spent a lot of time discussing mathematical ideas, ways of viewing complex numbers (as a number, a point or a vector) and ways of solving. Thus in discussions involving all member of the team, the tasks were tools that mediated SPs' mathematical learning as part of the iterative design methodology and the mode of inquiry in our project. SPs offered Autograph files and mathematical explanations that gave insights into their development of mathematical sophistication – for example, working fluently with vector representations in constructing complex number addition geometrically – with the teacher-researchers learning from this activity about student expectations and culture. TRs saw the tasks as designed to mediate Foundation students' learning of mathematics in tutorials and, to this end, constructed written instructions to accompany the Autograph files for the Foundation students.

In subsequent design meetings the team focussed almost entirely on technical aspects for improving the Autograph files. All tasks presented after DM2 had a 'dynamic' element such as 'dragging' a complex number around the screen until 'it fitted' a desired location, or exploring the relationship between the complex numbers by varying one or more of the linked objects. We provide examples of two tasks in more detail below.

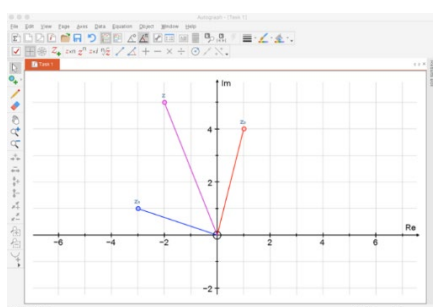

Figure 1: Task 1

Figure 2: Task 1 with  $z_2$  moved

The first task centred on the addition of complex numbers. SPs designed the initial addition task by following closely the type of question they had encountered on problem sheets: Given  $z_1$  and  $z_2$ , find  $z_1 + z_2$  and (making explicit the Autograph element) use Autograph to check that your answer is correct. After receiving feedback in DM1 the SPs set about 'reverse-engineering' the questions which SP1 described as looking at the answer and working backwards in order to design the task with the visualisation (Autograph) providing the information. Hence, for addition of complex

numbers, the final task was set out to display three complex numbers,  $z_1$ ,  $z_2$  and  $z$  where  $z$  was equal to  $z_1 + z_2$  (see Figure 1). The instruction for Foundation students was to keep  $z_1$  fixed and to move  $z_2$  until  $z$  reached the position  $6 + 5i$  (see Figure 2). At this point several lines on the screen moved as the linked object  $z_1 + z_2$  moved dynamically with the movement of  $z_2$ . The task was to find  $z_2$  and determine the (arithmetic) relationship between  $z_1$  and  $z_2$  (addition) and its geometric representation (parallelogram law). Foundation students followed instructions on a separate hand-out on how to proceed with the Autograph files and could ‘check’ final answers by using the ‘Unhide All’ command in Autograph.

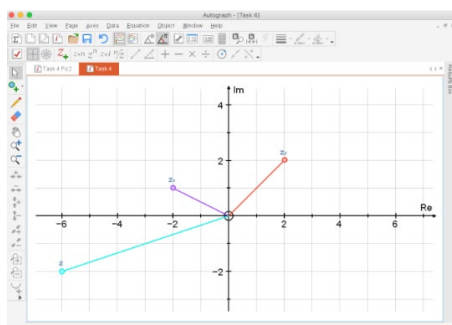

Figure 3: Task 4

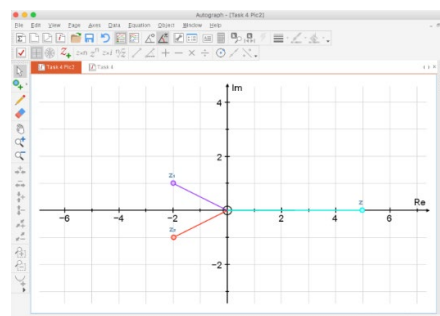

Figure 4: Task 4 with  $z_2$  moved

The task in our second example centred on the multiplication of a complex number by its complex conjugate. Presenting their ideas in DM2 one of the SPs (SP2) said that “there are some [of our tasks] that are quite similar. [But] we purposely put some in to try and be tricky” (DM2, 54:07). He was referring to the complex conjugate task. The idea originating from the design meeting was to display a complex number and its complex conjugate together on one screen as well as their product. One of the researchers (TR2) commented how nice this task was exclaiming “Oooh, I like that!” (DM2, 55:10) because you could see the angles cancelling out – one angle taking a positive value while the other (while equal in size) was negative. Foundation students were asked to explore and comment on this task with TR1 suggesting to use the polar grid representation because “it would be quite nice to show the angles there” (DM2, 55:32). Hence, in the final design there were three complex numbers,  $z_1$ ,  $z_2$  and  $z$  where  $z$  was equal to  $z_1 z_2$  (see Figure 3). The task was to notice what happened to  $z$  when  $z_2$  was moved into the position of the complex conjugate of  $z_1$  (see Figure 4). In this task design the SPs made no reference to any numerical value for  $z_1$  or for  $z_2$ , or their product. This task has a very different character and is more general, inviting exploration.

In the end-of-project interview, one of the SPs (SP1) suggested that “these tasks invited a deeper understanding than standard [problem] sheets” and that while many students may know that the multiplication of a complex number and its complex conjugate results in a real number, they, as partners in the project – knew ‘why’ that was the case.

All six tasks were trialled with Foundation students over a two-year period with two different cohorts of students. Tasks were integral to the syllabus and formed part of the Foundation students' undergraduate learning experience. Analyses of these data are ongoing.

## Summary of the project collaboration

The project involved students as partners in the design of tasks in complex numbers (as well as

matrices – not reported here). Few examples in the literature exist but those that do point to the benefit of such a collaboration for both staff and students (see Bovill, Cook-Sather & Felten, 2011). Duah & Croft, (2011) found as we did that the SPs gained a deeper understanding of the mathematics studied, in our case the mathematics of complex numbers. For example, SP1 recalled that “When I came across complex numbers in my third year [of degree study]..., it was immediately clear to me why the solutions appeared as complex conjugate pairs while many students had to spend time revising the principal.” In our analyses we see multi-layered mediational actions. One layer relates to the mathematical learning of the SPs mediated by tools. These are the tasks themselves, the software used to create the tasks, the SPs’ discussions when working together as a pair, and the inquiry mode in design meetings when all members of the team discussed drafts of the tasks.

A second layer relates to the work of the research team as a community of inquiry where we inquired into the design of computer-based tasks and into the learning processes of SPs and other team members. The SPs were drawn into the inquiry-based activity of designing dynamic tasks through the mediational nature of becoming familiar with Autograph and discussing its use together with other members of the team. Autograph acted as a tool for stimulating thinking and sharing of mathematical ideas and possibilities; it also acted as a tool for integrating SPs as partners in the task design process within the team.

We observed how the response of a team member using the word “static” was mediational in exerting a shift in SPs’ perception of mathematics tasks: from static forms towards consideration of more dynamic forms of tasks using Autograph. Thus ‘static’ itself acted as a tool to promote a new perception of the nature of tasks. The word “static” was not planned. It emerged through the interactivity, and resulted in a stimulus for the SPs towards more dynamic forms of tasks.

At a third level, our engagement in research led to additional data being collected outside the design meetings. Interviews with SPs, where they were encouraged to reflect on their activity and learning at different stages in the project were revealing for the researchers. The interview process itself was mediational in allowing the researchers to perceive the stages in development of the SPs’ thinking and perception – from their experiences with questions on problem sheets towards their design of dynamic tasks to engage Foundation students in mathematical inquiry.

In summary, we have characterised learning as a mediational process involving a variety of tools. Our analyses contributed to our understanding of the task design process where we see a new way of mediation that drew SPs into the collaboration as partners. Our project and analyses are contributing new knowledge in the field of students as partners in curriculum and course design and to the scarce body of literature in this area.

# Post-secondary students' enactment of identity in a programming and mathematics learning environment

Amanjot Toor, Joyce Mgombelo and Chantal Buteau

Brock University, Canada; [atoor@brocku.ca](mailto:atoor@brocku.ca); [jmgombelo@brocku.ca](mailto:jmgombelo@brocku.ca); [cbuteau@brocku.ca](mailto:cbuteau@brocku.ca)

*This paper draws from year one of a 5-year research study that seeks to examine how post-secondary mathematics students learn to use programming as a computational thinking instrument for mathematics. It focuses on how post-secondary mathematics students' identities as mathematics learners are enacted as they engage in a programming-based mathematical investigations and applications learning environment. Specifically, the paper offers a discussion of a case of one student's enactment of his identity while simultaneously learning to program and to use it for this kind of mathematical work. This paper highlights the importance of identity in learning mathematics and its role in the development of productive dispositions in learning to program for mathematics investigation and modeling.*

*Keywords: post-secondary, identity, appropriation, community of practice.*

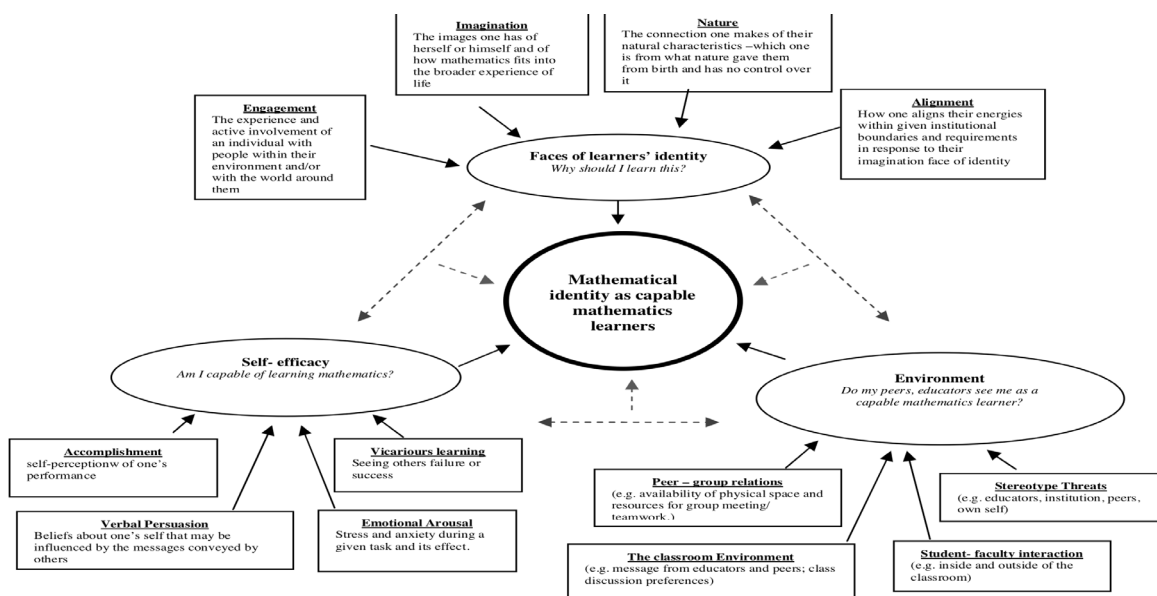

## Introduction

The Canadian federal government predicted that jobs in STEM fields will grow by 12% between 2013 and 2022, and that 35% of such jobs will be computer science-related ("Back to School", 2015). Few academic institutions attempt to prepare their graduates for the STEM workforce by integrating "Computational Thinking" (CT) in their programs. This integration of CT in STEM studies points to the need for research on what Healy and Kynigos (2010) describe as, "the complexities associated with the appropriation by the user of tools [such as programming]" (p. 66). This paper draws from year one of a five-year ongoing research study, funded by the Canadian Social Sciences and Humanities Research Council (SSHRC), entitled "Educating for the 21st century: Post-secondary students' learning to use computer programming for mathematical investigation, simulation, and real-world modeling" (referred to onward as 'progmatcs'). The research addresses the need to better understand how post-secondary mathematics students come to appropriate programming as an instrument for mathematics investigations and applications. It is a naturalistic study that takes place in a sequence of three programming-based mathematics courses called Mathematics Integrated with Computers and Applications (MICA I–III), implemented in the mathematics department at a Canadian university in Ontario since 2001. In these courses, future mathematics teachers and undergraduate students majoring in mathematics learn to design, program, and use interactive computer environments to investigate mathematics conjectures, concepts, theorems, or real-world applications (Muller, Buteau, Ralph, & Mgombelo, 2009). The research project is framed by interrelated theories and concepts in mathematics education that articulate the complex mutual shaping of the learner (user) and artefact (programming) (Buteau, Muller, Mgombelo, & Sacristán, 2018), including Lave and Wenger's social theory of learning and theory of situated learning. Lave and Wenger's (1991) analysis of situated learning is embodied in their productive concept of "legitimate peripheral participation." Legitimate peripheral participation is supported by systems of relationship in community between newcomers and old-timers, as well

as relationships with outside communities and with other newcomers. Legitimate peripheral participation offers a two-way bridge: between the development of knowledgeable skills and identity—the production of persons—and the production and reproduction of communities of practice. In this sense, the newcomers become old-timers through a social process of increasingly centripetal participation, which depends on legitimate access to ongoing community practice. This paper focuses on identity. We are interested in exploring how post-secondary students (newcomers) enact their identities during their process of appropriation of programming as a mathematical instrument as mathematicians (old-timers) would do, as they engage (i.e., legitimately peripherally participate) in ‘progmatics’ tasks. Specifically, the paper offers a preliminary discussion of student enactment of identity while learning ‘progmatics’ in a first year MICA course through a case of one student, Roy (pseudonym).

## Conceptual Framework

In this paper, the concept of identity is further articulated from three perspectives, namely *self-efficacy*, *environment*, and *four faces of learner's identity*, developed in our previous work (Toor & Mgombelo, 2013); see Figure 1. Researchers in the field believe that self-efficacy is learned, and that self-efficacy expectations are acquired through various sources including accomplishment, vicarious learning, verbal persuasion, and emotional arousal (Bandura, 1977). Accomplishment as a source of self-efficacy refers to the way in which one’s successful or unsuccessful experience on a given task increases or decreases the self-efficacy connected to that task. Another source, vicarious learning, can affect one’s self-efficacy where one sees others—peers and classmates—succeed or fail on a given task, assessment, or course. Other sources of self-efficacy are verbal persuasion and emotional arousal. In verbal persuasion, beliefs about one’s self are influenced by the messages conveyed by others. Emotional arousal refers to the stress and anxiety in a given task and its effect on self-efficacy.

**Figure 1: Conceptual framework: Mathematical identity as capable mathematics learners (Toor & Mgombelo, 2013, p. 2458)**

Identity is influenced by one's environment. In other words, identity is greatly formed by individuals' relationships with others from the past to present, stretching into the future (Wenger, 1998). As individuals progress through the post-secondary level, they develop a stronger sense of who they are as mathematics learners through their mathematics experiences, such as in lectures, classrooms, and seminars, interactions with teachers and peers, and in relation to their anticipated future (Sfard & Prusack, 2005). In addition to self-efficacy and environment, mathematical identity can also be explored from Anderson's (2007) four faces of learning mathematics—*engagement*, *relativity/imagination*, *alignment*, and *nature*. Engagement looks at one's direct experience and active involvement of others within their environment and/or with the world around them. Relativity/imagination focuses on the images one has of him/herself and of how mathematics fits into the broader experience of life. The alignment face of learning mathematics refers to how one aligns their energies within given boundaries and requirements in response to their imagination face. Nature looks at the connection one makes of their natural characteristics. These characteristics refer to what nature provided one with from birth and over which one has no control.

## Methodology

A mixed methodology approach is being used throughout the five-year ongoing study. The study uses an iterative design to refine and develop the research tools for yearly data collection and analysis. This paper draws from data that was collected in year one of the study, where six participants were recruited from the MICA I course. Data collected included each of the participants' four 'prognostics' project assignments (referred to as Exploratory Objects or EO), and reports, and semi-structured interviews with each of the participants after completing each of the four assignments (referred to as A1–A4). In addition, data collected included post-laboratory session reflections and a questionnaire. After each of the 10 weekly two-hour MICA lab sessions, participants recorded online their reflections on their learning during the lab session, L1–L10 (guiding questions were provided). All participants filled an online questionnaire (Q0) before the beginning of the MICA I course. This was followed by interviews where participants were asked to elaborate upon their questionnaire responses. The purpose of this questionnaire (and the first interview) is to serve as baseline information about participants' background of mathematics learning with technology.

Data analysis followed Cresswell's (2008) general principles of qualitative data analysis: preparing and organizing data, exploring data, describing and developing themes from the data. To begin the data analysis, codes were developed according to categories informed by our theoretical framework (Buteau et al., 2018). Each participant's qualitative data were coded individually by two researchers, who then jointly completed a thematic analysis of the data. Themes were consolidated among six participants' analyses, leading to the development of sixteen overall themes. These themes were further regrouped into five meta-themes, one of which was identity. The first author was assigned to analyze one of the six participants' data, which was later further analyzed in order to explore the identity meta-theme specifically through the lenses of self-efficacy, environment, and four faces (see Figure 1) of learners. In this paper, we present and discuss the findings of the case of this participant, Roy's, enactment of identity in the MICA I course.

## Findings and Discussion

### Description of the case: Roy

Roy was in his first year of the Bachelor of Science in Mathematics program when he enrolled in MICA I. Prior to MICA I, Roy's experience with programming included programming in Julia (just the basics), R (just the basics), Maple, Wolfram, and Python, as well as HTML. In the first questionnaire (Q0), Roy noted that he did not have any prior knowledge of Vb.net (programming language used in MICA I), as he had, "never really heard about it" (Q0, 4). When asked to complete a statement about his feelings regarding the fact that the significant component in MICA I is computer programming, Roy responded "Very confident" (Q0, 5). When asked for his reason for his response, Roy said, "[m]ost languages have the same components just different syntax" (Q0, 5). Roy indicated that learning to program for mathematical activities is very useful because "it can be used in almost every area of science or just for figuring out proof that would take years for a human mind to do" (Q0, 6). According to Roy, students learn mathematics by learning how to derive the "equations of the proof and learning how to use the equations". He personally learns mathematics by, "teaching it to someone else" (Q0, 9). When asked, "What does 'doing mathematics' mean to you?", he responded, "It means solving a problem in the most logical way" (Q0, 10).

As part of the first MICA I assignment (A1), Roy was asked to select or state a conjecture, and to create and use his EO to explore it. When asked to describe his conjecture, Roy said:

Opperman's conjecture, [for every integer  $x > 1$ , there is at least one prime number between  $x (x - 1)$  and  $x^2$ , and at least another prime between  $x^2$  and  $x (x + 1)$ ] I did and that has to do with every real number greater than two...if you square it and then you minus that number and plus that number, in between those two zones there is at least one prime. (A1, 3)

In the second assignment, Roy implemented the RSA encryption algorithm, including encoding, decoding, and randomly generating keys. In the third assignment, Roy created an EO to explore the dynamical system based on a cubic (two parameters involved) and describe its behaviour. For the fourth EO, students choose a topic of their interest and work individually or in groups of two or three. Roy worked with a partner on the idea of trying to predict human population.

### Roy's enactment of identity

Analysis of data from Roy indicates two ways in which Roy enacted his identity while learning 'pragmatics' in MICA I: through ideal images and through his direct personal experiences (Toor, 2013). Roy describes his perception of an ideal image of a mathematics learner in MICA I by describing his experiences in other non-MICA courses. When asked about his plan regarding taking the MICA II course, he responded that he was not planning to continue with MICA II as he did not find it engaging. When asked about the reason why he thought the course was not engaging, he responded:

With my straight math course, there were some things...Like being able to prove the volume of a sphere just through calculus. I find that very interesting cause then it's just like something you show people or... I found that interesting, whereas I didn't have that feeling with MICA I. (A4, 31)

It is clear from above that Roy's idea of a learner in MICA I is based on an ideal image of a learner in other non-MICA traditional courses, such as calculus. This ideal image of a learner in traditional courses manifests in a tension Roy experiences between how MICA courses are designed to engage students and how he perceives an ideal image of a learner in non-MICA courses. In Lab 10 of the course, students were asked to use their programs to explore the dynamical system based on the logistic function. When asked to reflect on his experience in the lab session, he noted:

The last class covered all of what I needed to start my project. This class didn't do much for me. This class should have been more about the assignment. I got some help with my project that I had almost finished but at times they refused to help since they were supposed to focus on the program we had to make to get 5% on the assignment. I understood the concept of a dynamical system but I never got why it was important. (L8–10, 10)

It is interesting to note that Roy did not take the opportunity to learn through inquiry. He struggles with the learning experience in the lab session because his ideal image informs him that, as a learner, the important thing is to complete the assignment and get a good grade.

### **Roy's self-efficacy**

Roy's self-efficacy in terms of accomplishment in the MICA I course is influenced by his perception of his mathematics and programming ability. In terms of mathematics ability, Roy seems to perceive himself as someone who is better than his peers: "I wouldn't ask my peers, normally..., [I'm] ahead of them" (A3, 5.3). This perception seems to show Roy's hesitance to work or collaborate with peers. In addition, Roy's perception of his ability in mathematics separates his ability in mathematics and his ability in programming when he encounters a difficulty in a 'progmatics' task. For example, he states:

The first two codes we had to do were easy, the third left out too much information. The lab was to help us understand RSA and by the end I still didn't have a strong understanding of it. I didn't like that we were told to get into groups to test out our program...The most challenging part was understanding the RSA encryption. When the math is broken into parts none of it was very challenging or hard to understand. It was the major concept I still didn't get at the end. (L5–7, 6)

The experience of mastery influences one's perception of one's ability, where success and/or failure on a task have a direct impact (Bandura, 1977). Roy's failure to deal with the third part of the lab due to the challenge it presented may influence his perception of his ability in programming. This part of Roy's self-efficacy in terms of accomplishment is also connected with his self-efficacy in terms of vicarious learning. On one hand, Roy perceives his mathematics ability as ahead of his peers, but on the other hand he perceives others' programming ability as more advanced than his own. In the interview, he said: No, it only worked...mine only works with numbers. Um, uh, the girl that I was sitting next to the previous one she did uh numbers she's like super advanced in computer science though (A2, 30). In other words, Roy's vicarious learning, a part of his self-efficacy, consists of him comparing his performance with others' and reflecting on his ability in mathematics and programming. Roy's self-efficacy in terms of emotional arousal could be seen in the choices that he made, the effort he expended, the perseverance he exerted in the face of

difficulties, and the thought patterns and emotional reactions he experienced in MICA I tasks. When he was asked about why he was not planning to take MICA II, Roy said:

I like the in-class learning about the RSA and how different number theories, chaos theory and that kind of stuff. I didn't like doing the programming. Whenever I got an assignment, I did not find it fun or engaging to do, which I found in my math class. I really like doing the equations in the programming or in chemistry. I like doing that stuff but in this I didn't have much enjoyment in doing the programming. Whenever I got a problem...it just didn't...it just sucks. (A4, 29)

When Roy was given the freedom to select the topic for a task in the final assignment, he displayed excitement and satisfaction, which in turn allowed him to invest himself emotionally with the learning goal of the task. When asked about the outcomes of his final project, Roy said: "Really awesome. It was cool that we actually got the same result [as the World Infant Mortality Rate], I thought."

### **Roy's environment**

One's environment is an essential element in building the identity of an individual as a member of the environment. Solomon, Croft and Duncan (2010) claim that peer-group relations play an important role in the educational success of the individual at the post-secondary mathematics level. As we have previously discussed, Roy seems to not like to ask his peers for help. This could be due to the fact that he views himself as "ahead" of others. Interestingly, Roy seems to be okay supporting others: "I did help another person with his conjecture by letting him see my code" (A1, 7). Also, he seemed to find it frustrating to work collaboratively with his partner in the final assignment. When asked about what was frustrating about working on his project, Roy answered:

Working with my partner, I guess. He wasn't a very independent partner, so he wanted us to sit beside each other while we do the project. I was busy doing other stuff, so I ended up doing the first part of the project but then he still wants to do the write up, which the write up only took two hours and I ended up doing the write up myself as well. (A4, 21)

Roy's relationship with faculty consisted of getting help from his professor and/or TA whenever he got stuck with a task.

### **Roy's four faces of learning mathematics**

Identity in terms of each of the four faces of leaning mathematics exists as a way in which one comes to understand their practices and membership within the community of mathematics learners (Anderson, 2007). Roy's enactment of identity in the MICA I course seems to be strongly influenced by his engagement. Anderson (2007) states; "much of what students know about learning mathematics comes from their engagement in mathematics classrooms" (p. 8). This enactment of Roy's identity in terms of the engagement face could be seen in the tension that Roy experienced in terms of the timing of when a task was assigned, which did not align with the timing of when some of the concepts needed to complete the task were taught in the class (even though they were eventually taught before the deadline): I had to do some research because in class we didn't, there was some of the stuff that were key concepts that we didn't actually, finish [before reading week] ... one of the last concepts before the due date, was then given it was very key. (A2,

2). It seems that Roy has developed this identity from his experience of engagement in many mathematics classrooms where assignments are normally given after the required concepts or skills are covered. Another way Roy's identity in terms of his engagement with the MICA I course could be seen is in his perception of the computer language used in the tasks:

The program language itself isn't very good. [Visual] Basic [is] pretty outdated—more or less obsolete. The only thing that [Visual] basic is used for is functions in Excel, like doing macros, which it's useful but it is not. It's getting outdated so I think the only part that was useful for me learning was the math that was taught in class and a little bit of how to implement that math into programming. But it's not going to be super useful in a job because I am not going to use [Visual] basic after I learn an entirely different programming language. (A4, 25)

This perception of the programming language seems to lead Roy to not identify with the MICA I environment and come to see himself as only marginally part of the MICA I community. In fact, when he was asked if he would take MICA II, he said no. Additionally, Roy's engagement with the programming language displays his identity in terms of his relativity/imagination face when he envisions how the computer language fits in with his future career goals. Further, when asked if he thought that doing mathematics in a programming setting was beneficial, Roy responded:

I think it would have to be more complex programming like when we were using Maple because that already has built-in functions, whereas this one, it just all, you have to do every bit of math yourself. When even today's time programming, you have to use other people's work to do more complex work. I think that eventually you would have to get to it. I think it's good for teachers but like for pure math students, that I don't think I got much out of it. (A4, 24)

This shows Roy's identity in terms of the alignment face of learning mathematics, where he chooses to align his energy toward a “progmatics” task that displays “more complex work” based on his perception of himself as a pure mathematics student. It is interesting to note that Roy's identity in terms of the nature face does not come forward in any of his interviews.

## Conclusion

This paper draws from research that addresses the need to better understand how post-secondary mathematics students come to appropriate programming as an instrument for mathematics investigations and applications. Papert (1980) proposes that every learner should program computers for personalizing learning and knowledge. He notes that at the heart of learning is ‘appropriation’ in the sense of making it ‘yours.’ This idea of taking the learning, and integrating it into one's way of being, thinking, and seeing necessitates an exploration of how one's identity plays a role in students' appropriation of programming (in the sense of transforming it as an instrument) for mathematics inquiry. This paper provides a beginning of this kind of exploration through a preliminary analysis of a case of one participant, Roy's enactment of identity in a first year MICA course. Roy came into MICA I with a perception of a learner in MICA I course based on his ideal image of a learner in traditional mathematics courses. Consequently, Roy's perception of this ideal image created a tension between the creative, inquiry-based expectations in MICA and his expectations of what the course should be. His perception of learning mathematics created a tension between his learning goals and the learning goals of MICA I—which are to learn to design,

program, and use interactive computer environments to investigate mathematics conjectures, concepts, theorems, or real-world applications. This paper highlights the idea that learning to program for mathematics investigation and modeling requires not just developing skills and knowledge, but also developing an identity of a learner who engages in the inquiry-based tasks (peripherally) as mathematicians would do.

# Using history of mathematics to inform the transition from school to university: Affective and mathematical dimensions

Seyda Uysal<sup>1</sup> and Kathleen M. Clark<sup>2</sup>

<sup>1</sup>Florida State University, Tallahassee, Florida, USA; [su17b@my.fsu.edu](mailto:su17b@my.fsu.edu)

<sup>2</sup>Florida State University, Tallahassee, Florida, USA; [kclark@fsu.edu](mailto:kclark@fsu.edu)

*In this paper, we briefly describe an intervention that addressed the transition from school mathematics to university mathematics by making students aware of concept changes in the history of geometry. We provide a description of the intervention (called the ÜberPro Seminar), the context and setting for the study, and the data sources that informed our work. Then, we focus on one particular data source and describe initial stages of our analysis and sample findings. In our findings, we share only a small glimpse into the affective experience students described when reflecting on the transition from school to university. We conclude with a discussion of some of the patterns that began to emerge from our analysis and we propose connections to current work on the transition from school to university mathematics and future direction for our research.*

*Keywords: Transition from school to university, emotions, affective dimensions, history of geometry.*

## Introduction

The transition from school mathematics to university mathematics has received increased attention in recent years in a variety of contexts (Clark & Lovric, 2009; Gueudet, 2008; Kosiol, Rach, & Ufer, 2018). On the one hand, several research efforts have focused on “the” transition; that is, examining undergraduate students taking courses at the moment they transition to university (see for example, Kosiol et al., 2018). Some studies focus on questions of whether or why students persist in either mathematics or other STEM-related fields (e.g., Di Martino & Gregorio, 2019) and others may approach the transition problem from a deficit model perspective. That is, there may be an emphasis on the lack of sufficient background knowledge on the part of students who move from secondary mathematics to tertiary mathematics. On the other hand, examples in the literature examine specific junctures that prove to be obstacles for students transitioning to university mathematics, such as students beginning coursework that focuses primarily on proof (e.g., courses in Analysis, Abstract Algebra, etc.). From either of these two perspectives, the transition may seem more discrete; that is, at one particularly time point – e.g., the change from the last mathematics course taken in high school to the first course at university, or, the change from courses to be considered more computational at university (e.g., Precalculus or Calculus) to more proof-oriented (such as Abstract Algebra). In our work, the transition problem, or, in German, *ÜbergangsProblematik*, is considered as a continuous phenomenon. That is, we do not consider the transition occurring at *one* particular moment in time. Instead, students may experience aspects of transition throughout their time at university. In this context, it may be more appropriate to consider *a* (as opposed to *the*) transition problem or multiple transition problems.

The research described in this paper originates from an experiment conducted in 2015, when we<sup>1</sup> began work on the design, development, and implementation of a seminar for undergraduate mathematics students who were preparing to teach mathematics. The theoretical foundation of the seminar included the hypothesis that:

The change from an empirical-object oriented to a formal-abstract belief system of mathematics constitutes a crucial obstacle for the transition from school to university. On epistemological grounds, similar changes regarding different natures of mathematics can be described for the history of mathematics (e.g., in the development of geometry). Student analysis of the historical belief change can support them on their individual transition from school to university and back to school again. (Witzke, Clark, Struve, & Stoffels, 2016)

In this paper, we share a very brief overview of research literature focused on transition from school mathematics to mathematics at university, describe the evolution of the seminar that began in 2015, and provide a description of a study conducted on the most recent implementation of it. Finally, we share selected findings for the research question: *In what ways do seminar students, when confronted with the historical development of mathematics, recognize their own transition?*

## **The study**

### **The seminar**

The seminar, “Addressing the Transition Problem from School to University Mathematics” (or, the ÜberPro (taken from the German term) Seminar), was first implemented as a three-day intensive seminar in Spring 2015. Readings and seminar activities were designed and piloted with 20 pre-service mathematics teachers at a medium-sized university in Western Germany. We used geometry as the topic of the seminar’s mathematical content and the seminar activities included engaging students in reading and discussing excerpts from student task transcripts, textbooks, learning standards documents, and historical resources, as well as working on various tasks prompted by historical sources and content. From its inception, the aim of the ÜberPro Seminar was to promote students’ awareness of the changes regarding the nature of mathematics from school to university as means to support their own transition from the changing mathematical and institutional context in high school to those at university. This was accomplished through the sequence of seminar sessions on examining beliefs about mathematics promoted in school and university mathematics textbooks, the nature of Euclidean Geometry (with an in-depth examination of proofs of the Pythagorean Theorem), the development of projective geometry, the failure of the parallel postulate (leading to the development of non-Euclidean geometry), and the formalism of Hilbert’s geometry. Additionally, students were reminded of the hypothesis (given above) during each session so that explicit connections between it and seminar content could be drawn. Gueudet and colleagues (2017), in literature focused on the transition from school to university mathematics contexts, have described certain boundary objects which may play a significant role in helping students to “make this

<sup>1</sup> The original research was conducted by the second author with colleagues Witzke, Struve, and Stoffels (see also Witzke, Clark, Struve, & Stoffels, 2018).

transition” (p. 108).<sup>2</sup> However, we share the same view as described by Gueudet, Bosch, diSessa, Kwon, and Verschaffel (2016), that the transition problem cannot be easily “smoothed out” and that it probably should not be smoothed out, because it gives the opportunity to reflect on one’s own beliefs, knowledge, and affect in mathematics during the transition. A unique attribute of the ÜberPro seminar course is in the potential of utilizing the case of the historical development of geometry to provide a means of support as students consider their own beliefs about mathematics in light of the changes in beliefs (e.g., nature) of mathematics that have occurred over time. The description of the first implementation of the ÜberPro Seminar (Spring 2015) has appeared elsewhere (Witzke et al., 2016), as well as the modifications to extend the initial intensive seminar into a semester-long seminar experience that was implemented in Summer 2016 (Witzke, Clark, Struve, & Stoffels, 2018). We propose that in light of the instructional materials (e.g., textbooks) that students face in school mathematics, they are more likely to acquire an empirical belief system. Yet, at university, students are likely to obtain a formalistic belief system based upon the instructional materials found there. Epistemologically, both of these experiences provide parallels to specific historical conceptions of mathematics, which we sought to highlight as the fundamental components for the design of our “transition problem” seminar for students. Yet, we wish to emphasize that we do not propose that the formal-abstract approach is exclusive to learning mathematics at university. Instead, the development of our hypothesis and the intervention we developed is based on survey and interview experience, as well as support from literature that there are certainly differences in the discourse, tasks, and nature of mathematics at university when compared to school, and this difference often materializes as empirical-object (school) versus formal-abstract (university).

### **Setting and context**

The research described here took place during the Summer 2017 semester at the same institution as the pilot seminar and the first semester-long version of the seminar. The seminar course was offered to pre-service mathematics teachers and these students also had the opportunity to take a similarly-designed seminar on probability (Stoffels, 2018).

### **Data sources and participants**

There are several data sources that informed our research on the Summer 2017 ÜberPro Seminar, including audio recordings and observer-participant notes from each seminar session (taken by the second author), all course materials used with seminar participants (designed by the instructor-researchers involved with each of the three implementations of the ÜberPro Seminar), and weekly submissions of reflection journals by the seminar participants. In this paper, we focus on the student participants’ reflection journals. Over the course of the 12-week semester, students were asked to respond to 59 reflection journal prompts. The reflection journal prompts were varied, with some focused purely on the transition from school to university mathematics and others focused on topics in geometry, on the historical development of geometry, or related to the participants’ future teaching

<sup>2</sup> It is important to note that we do not subscribe to the notion that such a transition can be “made.” That is, students experience a personal trajectory through the transition, and there are interventions (e.g., the ÜberPro Seminar) which may be enacted that aid in supporting students during this trajectory.

of mathematics. In summer 2017, 19 students participated in the ÜberPro Seminar. However, for this paper we consider the data for 14 of the 19, for whom we have responses to the reflection journal prompts. The mean age of these 14 students (8 male and 6 female) was 23 years and the mean semester at university was 6. It is also important to note that three of the students (1 male, 2 female) were considered as “expert” students because they had previously completed the ÜberPro Seminar on probability. In the reflection journal excerpts that follow, these students are identified with an “E” at the end of their code number.

### **Data analysis**

In order to prepare the reflection journal prompt responses for coding, student responses were first translated from German into English through the assistance of Google Translate. Then, responses were revised for grammatical accuracy by the second author, who has some German language proficiency. Of the 59 reflection journal prompts, we focused on a subset of eight that provided us with student responses that reflected more affective dimensions of students’ experiences in the transition from school to university mathematics. Based on these criteria and for the purposes of this paper we narrowed the set of reflection journal prompts further from eight to two, as prompts of interest for this paper. In doing so, we ensured that sufficient data remained and we were able to pay attention to the principle of theoretical saturation (Merriam & Tisdell, 2016). Next, we reviewed all 14 students’ responses to the reflection journal prompts of interest and we approached the coding of students’ responses to the journal reflection prompts using aspects of Grounded Theory (Strauss & Corbin, 1990). We first completed line-by-line coding to determine aspects of recognition of their own transition from school to university mathematics (e.g., difficulties with content; differences in content, structure, or environment; reference to formal versus abstract belief systems). During line-by-line coding we also made analytical notes on each response, to assist with the next stage of coding in which we sought to determine themes. In the second stage of the data analysis, we focused on the two specific prompts (prompts 4.1 and 12.6, given in the “Initial findings” section) that explicitly asked student participants about the recognition and awareness of the transition problem during their undergraduate mathematics studies. We were most interested in coding words and expressions within students’ responses which might potentially reflect emotional aspects of the transition (e.g., emotionally-charged phrases and expressions) and these were noted by the two authors independently. We then met to discuss controversial interpretations for the purpose of establishing trustworthiness which contributes to the credibility of the study (Creswell, 2013; Lincoln & Guba, 1985). Ultimately, the purpose of the second stage of the data analysis was to identify and categorize repetitive and similar expressions and to highlight the themes in participants’ reflections.

### **Initial findings**

The focus for this paper was to highlight participants’ experience in the ÜberPro Seminar relative to their recognition – e.g., emotionally, mathematically – of their own positioning in transitioning from school to university mathematics. We purposefully selected the two reflection journal prompts because they asked for participants to explicitly reflect on their own transition early in the semester (prompt 4.1 from week 4) and at the end (prompt 12.6 from week 12). Thus, we were able to examine

the ways in which participants described aspects of the transition, both early in the seminar experience, and after having engaged with seminar content designed to make explicit the beliefs changes in students (over their mathematical trajectory) and in mathematics (using the example of the historical development of geometry). The two prompts are:

Q4.1: Think about your own transition from school to university and reflect this on the basis of the transition problem hypothesis presented in the seminar.

Q12.6: Explain the transition problem referring to the completed seminar. What consequences can be derived for university and school? Include what you have learned on your personal transition experience and how to deal with it in the future. You can also refer back to the seminar's underlying hypothesis on transition issues.

### **Investigating patterns: How do students recognize their transition?**

As described, 14 students' responses to the reflection prompts (prompts 4.1 and 12.6) were analyzed based on semester of enrollment, gender and age of the participants, and the general frequency of some expressions such as "change of viewpoint," "rapid," "difficulty," and "new ways of dealing with mathematics." For the purpose of this paper, we share only a brief collection of the type of affective experience students described when reflecting on the transition from school to university. In general, students felt confronted by the view of formal, abstract mathematics at university. Twelve of 14 students either implied or explicitly articulated that mathematics taught in school was a quite different experience from university mathematics, which refers to the gap between school and university mathematics. For example, Student 7360 described the following:

As part of my transition from school to college, I was confronted with a new way of dealing with mathematics: While I met mathematics in school mostly in the context of concrete computing tasks and applications, and only met a little proof, I was confronted with a definition-theorem-proof-example-mathematics, which was based on a strict formal approach and an axiomatic structure. The procedure was strictly axiomatic and I knew little until now. A special change was also in the now much higher value of proof. While there was hardly a lesson in school without examples (tasks) and hardly any lesson with proof, the picture was now the other way around: in the university, there was hardly a lecture with sample exercises and hardly a lecture without proof [...] (Response to journal reflection prompt 4.1)

Similar to Student 7360, other seminar students emphasized that more empirical examples were encountered in high school mathematics whereas university mathematics included more formal definitions and abstract proofs. Moreover, the students believed that they needed to change their view of mathematics to be able to comprehend formal abstract university mathematics. According to their responses, the ways in which students expressed their emotions toward this transition between school to university was fairly intense. Students who had or experienced an unpleasant transition frequently used descriptors such as "bumpy," "big hurdle," "very bad transition," "incredibly challenging," "struggling," "sudden" and "rapid change," and these terms capture the magnitude of the emotions that students associated with the transition from school to university. Some students mentioned the high drop-out rates of peers due to the change of view from empirical to formal mathematics as a

consequence of a difficult transition. One of the “expert” students (Student 1612E) expressed his experience as:

My own transition to university confirms the hypothesis of the seminar. It was a big hurdle and took some time to get used to the formalism and the level of abstraction of academic mathematics. I myself have finally mastered the transition; however, I know some who found the hurdle to be too high and have quit their studies. (Response to journal reflection prompt 4.1)

Another participant, Student 1609, identified the “rapid change” in views of mathematics as a defining feature of the transition, but he also compared the transition that students endure with the change in views that occurred in the development of geometry:

The rapid change from an empirical-object view or view of mathematics to a formal-abstract one is one of the most influential reasons that the transition problem is such an important issue today. I assert as well that every student must [go] through this phase of ignorance and acquire new knowledge, in order to first understand what is being conveyed in the lectures at university. In my opinion, there is a great deal in common between the transition from school to university and the historical development of geometry. This has developed from an empirical-objective conception to a formal-abstract one. As with the transition problem, there is added complexity in the evolution of geometry and it becomes more in-depth as time passes. (Response to journal reflection prompt 12.6)

In a similar way, Student 1905 drew upon the seminar content (i.e., the historical development of geometry) to situate her view of the transition problem, and to note a key difference for her experience at university (e.g., “a rigid conception is used”):

In the historical development of geometry, one finds mathematicians who represent an empirical-object view and mathematicians who represent a formal-abstract view. So, there are different views of geometry in the past. Here I see a difference [in views] to the transition from school to university. While [at university] only a rigid conception is used, in the history one finds a multiplicity of geometrical conceptions. I see a commonality in the transition. The conceptions that we find today between school and university can also be found in the development of geometry. (Response to journal reflection prompt 12.6)

As a final example, we present the characterization that Student 7536E (another “expert” student) offered in her response to journal reflection prompt 12.6:

The transition problem from school to university is clearly recognizable, especially in mathematics. Geometry also has a strong evolution behind it and is based on different views. The biggest difference is probably between Euclidean and non-Euclidean geometry, which also differentiates the school material and the university material. In these different views, the relationship to reality and truth always plays a decisive role.

## Discussion

Gueudet (2008) observed that “[u]niversity is seen as a new world, or at least a new country, with a new language and new laws that make the novice student feel like a foreigner” (pp. 242–243). Indeed,

ÜberPro Seminar students' responses revealed that they experienced palpable difficulty in dealing with a new way of mathematical thinking, which might be analogous to learning a new language. The expression of "change of viewpoint" was referred to either explicitly or implicitly by the seminar students, which we found interesting in our analysis. The change in students' viewpoint also gives us cues concerning historically different views in mathematics. On the other hand, the repetitive use of expressions regarding the change of viewpoint from empirical to formal validates the inconsistency between secondary and university mathematics, which makes it harder to initiate a schema (Rumelhart, 1980) to make cognitive connections between prior knowledge and abstract/theoretical mathematics. Failing to adjust to the change of viewpoint is most likely to affect students' dispositions toward formal mathematics in terms of attitude, emotion and belief, which is examined as "affective factors" by Di Martino and Gregorio (2019). Therefore, the severe difficulties which potentially lead to dropout of students from STEM-related undergraduate programs without obtaining a degree seem to be problematic due to their connection to psychological strain from an individual standpoint (Di Martino & Gregorio, 2019). In our future work we plan to design interventions for our local context (Florida State University), in which we will continue to use the context of history of mathematics as a means to bridge the gap between secondary and university mathematics. Additionally, we will explicitly address student dispositions and emotional response to the transition to investigate whether such supporting features assist students in avoiding the most severe aspects of the transition. We believe that from the educational perspective, keeping the impact of affective factors in mind could contribute to students' weathering of transition problems (particularly in STEM-related fields) and hence, positively impact student achievement. Therefore, in our continuing open-ended analysis, we seek to investigate additional methods of data collection and analysis that will enable us to further contribute the growing body of research on students' transition from school to university mathematics in ways that highlight and honor the emotional and affective aspects of transition, and ways in which they may be mediated and remedied by interventions such as the ÜberPro Seminar.

## Conclusion

We determined that a need to address and reflect on students' emotional dispositions emerged when students were prompted to articulate how they recognized their own transition during the ÜberPro Seminar. Furthermore, this intervention may have contributed to the promotion of metacognitive thinking about students' own transition and gave them agency in partially managing the remainder of their transition process.

## Epistemological characteristics influencing didactic choices in course planning – the cases of Basic Topology and Differential Geometry

Olov Viirman<sup>1</sup> and Magnus Jacobsson<sup>2</sup>

<sup>1</sup>University of Gävle, Sweden; [olov.viirman@hig.se](mailto:olov.viirman@hig.se)

<sup>2</sup>Uppsala University, Sweden; [magnus.jacobsson@math.uu.se](mailto:magnus.jacobsson@math.uu.se)

*There are many factors influencing the didactical choices made by university mathematics lecturers in course design. We focus on one of these: the inherent structure of the mathematical domain to be taught. Adopting an institutional perspective, the Anthropological Theory of the Didactic, we conduct an epistemological analysis of two courses aimed at second and third year mathematics students, Basic Topology (BT) and Differential Geometry (DG), showing how their different epistemological characters affect these didactical choices. We argue that the main differences stem from their aims and objects of study: where BT aims to develop the theory of topological spaces, and providing a categorization of them, DG aims at producing tools for analyzing geometrical properties of surfaces. In other words, where BT is theory-driven, DG is praxis-driven. We show how this and other differences relate to the course design, and argue this as a case of domain influencing pedagogy.*

*Keywords: University mathematics, course design, epistemological analysis, mathematical and didactic praxeologies, didactic co-determination.*

### What influences university mathematics teachers' didactical choices?

University mathematics education (UME) research is increasingly engaged with questions concerning teaching, and university mathematics teachers' (UMTs) teaching practices, as seen, for instance, in the growing amount of research investigating factors influencing UMTs' didactical choices when planning and preparing courses or individual lectures. Some of these factors are individual, depending upon the UMT's own educational background, research practice, and beliefs about mathematics and students (e.g. Hernandez-Gomes & González-Martín, 2016; Tabchi, 2018). Some concern more general pedagogical issues, such as the specialisms of different student groups (Bingolbali & Ozmantar, 2009), available textbooks and other educational resources (Mesa & Griffiths, 2012), or the choice to adhere to particular instructional design principles (Andrade-Aréchiga, López & López-Morteo, 2012). Others again are institutional, such as imposed reform initiatives (Stieha, Shadle & Paterson, 2016) or the dominant epistemology of the institution (Barquero, Bosch & Gascon, 2013). Here, however, we will consider a different factor that we believe deserves further study: the inherent structure of the particular mathematical domain covered by the course. This paper grew out of conversations between the first author, a UME researcher, and the second author, a research mathematician at a large Swedish university. His research is in topology and geometry and he has been teaching university mathematics for twenty years, at all levels from beginning undergraduate to doctoral courses. While planning and conducting two different courses, Basic Topology (BT) and Differential Geometry (DG), both aimed at second or third year mathematics majors, he was struck by the extent to which the character of the two topics influenced the way he chose to design and teach the courses. To study the particularities of this

influence, we adopt an institutional perspective, the Anthropological Theory of the Didactic (ATD) (e.g. Bosch, 2015). In what follows, we will present an epistemological analysis of the topics, aimed at describing how their different epistemological characters affected the didactical choices made during course design. First, however, we introduce the aspects of the ATD pertinent to the analyses in this paper.

## A praxeological perspective on mathematics teaching

ATD “offers a general epistemological model of mathematical knowledge where mathematics is seen as a human activity of study of types of problems” (Barbé, Bosch, Espinoza & Gascon, 2005, p. 236). This activity consists of, on the one hand, the *practical block* (or *praxis*) of *tasks* to be solved and *techniques* for solving them and, on the other hand, the *knowledge block* (or *logos*) providing “the mathematical discourse necessary to justify and interpret the practical block” (ibid, p. 237). This block consists of *technologies* referring directly to the techniques used and *theory* justifying the technology and organizing the discourse. An example of a task could be finding the instantaneous rate of change of a certain function at a given point. This task can be solved using different techniques, for instance, calculating the slope of the tangent line to the function at the point. This technique can be justified, for instance, using the definition of the derivative using difference quotients, a technology in turn part of a theory of differential calculus. Together the tasks, techniques, technologies and theories form *mathematical praxeological organisations* (MO's) or simply *praxeologies*. In fact, ATD “considers that the notion of praxeological organisation can be applied to any form of human activity, and not only to mathematics” (ibid, p. 239). Hence, the practice of teaching (and learning, for that matter) can be described using *didactic praxeological organisations* (DO's). The teacher's didactic praxeology is used to help students engage with a particular MO. As any praxeology, it consists of a *practical block* composed of types of *didactic tasks* and *didactic techniques*, and a *knowledge block* formed by “a *didactic technological-theoretical* environment” (ibid, p. 239). Praxeologies develop within *institutions*. Indeed, it is a basic tenet of ATD that “human practices and human knowledge are entities arising in institutional settings. (...) As institutions are made of people, institutional praxeologies evolve because of the changes introduced by their subjects” (Bosch, 2015, p. 52). Such evolution is subject to *conditions* that enable or facilitate the development of a certain praxeology in a given institutional environment, and *constraints* hindering or impeding its development. “The notions of *condition* and *constraint* are relative to the position assumed by a person in a given institution. A *condition* becomes a *constraint* when it cannot be modified by the person in this position, at least not in the short run.” (Barquero, Bosch & Gascón, 2013, p. 313) These conditions and constraints occur at different *levels of didactic co-determination* (ibid, p. 314):

Civilisation	Society	School	Pedagogy	Discipline	Domain	Sector	Theme	Question
--------------	---------	--------	----------	------------	--------	--------	-------	----------

The levels from Discipline to Question concern the particularities of the specific discipline and the way it is structured, while the levels from Pedagogy to Civilisation concern how societies organise the study of disciplines (ibid.). Barbé et al (2005) use the case of the teaching of limits of functions in Spanish high schools to show how teachers' practices are conditioned by various restrictions, both mathematical and didactical. At the university level, Bosch, Gascón and Nicolas (2016) use the

case of the teaching of Group Theory “to illustrate two different ways of questioning the mathematical content to be taught: a first one based leaving the global structuring of the content untouched; and a second one requiring a complete deconstruction and reconstruction of the knowledge to be taught” (ibid, p. 256). In light of the above, we aim to investigate possible relationships between the Mathematical Organisations and the development of the Didactic Organisations in the courses Basic Topology and Differential Geometry. Before presenting an epistemological analysis of the two domains, we will briefly describe the context in which the study took place.

## **Epistemological analysis and didactical considerations**

Both the BT and the DG courses are included in a mathematics program, typically attracting about 30 students each year. Additionally, the courses also attract some students from other programs, for instance, engineering and physics. Prerequisites for both courses include Introductory Algebra, Calculus in one and several variables, and Linear Algebra. When planning the courses, the second author worked with already determined syllabi, although he had control over the choice of textbook (Munkres (2000) for BT, and Do Carmo (2016) for DG). At the department where he works, the more advanced courses are usually taught in a Definition-Theorem-Proof (DTP) format (Weber, 2004), and although this is not enforced, there are few institutional incentives for radical changes in the teaching format. Hence, the courses discussed here were also taught in this format. The analysis that follows developed through conversations between the authors, and hence reflects the way the second author thinks about and chose to teach the courses. Still, this largely corresponds with how the courses are typically taught, as suggested for instance by the fact that already established syllabi were used.

The main object of study in BT is the class of topological spaces and continuous maps. The course introduces the notions of point-set topology, for instance, compactness, connectedness, and separation properties, in a systematic axiomatic fashion. The main object of study in DG, on the other hand, is the (mostly local) geometry of (curves and) surfaces. It starts with the geometry of surfaces in 3-space and proceeds via the fundamental forms and Gauss' Theorema Egregium (Gauss curvature is preserved under isometric transformations) to the notion of abstract surface geometry with examples such as the flat torus and the hyperbolic plane, which have no isometric embeddings into 3-space. The aim of BT is to structure the class of topological spaces, which is vast and mostly unknown to the students beforehand, into tractable subcategories introducing a comprehensive (and traditional) set of definitions. In contrast, DG concerns itself largely with the production of tools for the analysis of geometric properties of the intuitively relatively accessible collection of all surfaces, building on the students' knowledge of curves and surfaces (in 3-space) from previous courses in the calculus of several variables. DG thus works its way from a concrete setting towards the beginning of a more abstract theory, while BT may be said to go in the other direction. Definitions serve largely different purposes in the two courses. In BT, their main purpose is to establish a vocabulary for the class of topological spaces, which allows for effectively breaking it down into more tractable subclasses. Compactness, separation properties, connectedness and countability properties are all definitions of this type. Few interesting things can be said about all topological spaces. The notions above allow for the study of subclasses (e.g. locally compact Hausdorff spaces)

about which interesting theorems can be proved. In DG, on the other hand, definitions establish the tools to make precise distinctions in a setting where the object of study is well known. The first and second fundamental forms, various curvatures and the Gauss map are all examples of this; with their help, it becomes possible to analyse the geometric properties of the surface quantitatively. The particularities of definitions in the BT course have consequences for the use of examples as well. The first role of examples in BT is to show how the few topological spaces that the student has already encountered in earlier courses fit into the general framework that the course provides. For instance,  $\mathbb{R}^n$  is an example of a Hausdorff space. The second role is to expand the known collection of topological spaces, and in particular, to show that new definitions are not empty. For instance,  $\mathbb{C}^n$  equipped with the Zariski topology is an example of a  $T_1$ -space which is not Hausdorff. It is unlikely that the student has heard of the Zariski topology before. Moreover, in the context of the BT course its relevance in other mathematical domains (e.g. algebraic geometry) cannot be properly discussed. Instead, its presence in the course serves to motivate the definition. In this context, the role of the concept is primary and the example secondary. In fact, one might say that the topic of the BT course is as much the established ways of rendering the category of topological spaces understandable, as it is the topological spaces themselves. On the contrary, in the DG course the role of the examples is mainly to illustrate the different mathematical techniques involved. Hence, examples mostly consist of concrete calculations, much as in earlier calculus courses (e.g. explicitly computing geodesics on a surface of revolution by solving the appropriate differential equation). With a slight exaggeration, one might say that in DG the examples precede the definitions, which are there for the sake of understanding the examples, whereas in BT the definitions precede the examples, which serve the purpose of understanding the definitions. The aim of the BT course, that is, structuring the class of topological spaces and developing a vocabulary for this purpose, has implications also for the type of theorems the course contains. In a sense, most of the theorems are of a technical nature; clarifying the definitions and the properties of the spaces that satisfy them. At least in the beginning of the course they are very elementary, and could easily be given as exercises to students, even at this level. Indeed, we are aware of at least one textbook where the theory is developed with most proofs given as exercises for the reader (Viro, Ivanov, Netsvetayev & Kharlamov, 2008). Most of the course is introductory and the theorems proved are thus reasonably easy for the students to follow, with a few exceptions, which (unsurprisingly) occur in the more structured areas, notably in the part concerning metric spaces. The DG course, on the other hand, with its aim of analyzing the geometric properties of surfaces, contains more complex theorems requiring more advanced proof techniques from analysis (relying on relatively advanced theorems, e.g. the implicit function theorem). Where the BT course has mostly technical theorems, The DG course has at least two central, historically and philosophically significant theorems which can provide structure for the course to be built around – the Theorema Egregium and the Gauss-Bonnet Theorem (which connects the curvature of a compact surface with its Euler characteristic). The above differences have direct consequences for the way the material is presented to the students. BT is presented in a strictly axiomatic fashion. The whole course unfolds deductively from the definition of topological space. This is a consequence of the extreme generality of this notion and the fact that very few examples are known beforehand. The course requires no prerequisites apart from basic set theory, although a certain degree of mathematical maturity is necessary, due to the

degree of abstraction involved. Proofs consist of set theoretical arguments to show that a certain class of spaces or maps has certain properties, while examples consist of the same, but for specific spaces or maps. As mentioned above, the vocabulary is as much an object of study as the particular examples of spaces the course includes. In fact, one reason for developing this vast general theory without much prior knowledge of the objects it describes is that this vocabulary in itself is so useful, that once mastered (even if only through toy examples of little independent value) it is applicable as soon as the student happens upon a topological space in their later studies.

DG, in contrast, admits a looser structure, since it is possible to rely on students' previous knowledge and intuition in the presentation of the material and since the course is about closer analysis of a known class of objects. Indeed, it has clear prerequisites of Calculus of several variables and Linear Algebra, which are both necessary and sufficient. This implies that the rich collection of tools of infinitesimal calculus and linear algebra are available for use. Hence, the arguments used in proofs have a very different flavour from those in BT, more akin to standard basic calculus. In DG, definitions are typically motivated by conceptual arguments, relying to a large extent on the student's preconceptions and intuitions. The conceptual meaning of the central definitions can usually be (and often is) explained even without concrete examples, relying on the students' grasp of earlier courses. For instance, the relevance of the geodesic concept can be argued by the wish to generalize the meaning of 'straight line' (or motion with zero resultant force). Similarly, just by sketching some pictures the ideas behind principal curvatures or the Gauss map can be conveyed. In contrast, the explanation of definitions in BT cannot rely very much on pre-established intuition, since there are very few examples that the students are familiar with beforehand. Instead, the definitions in BT are presented as a fixed vocabulary to be digested and understood. The point of many of the definitions is seen only in hindsight, when they prove themselves useful in proving theorems. For example, few students immediately understand the definition of first countability of spaces. The relevance becomes clearer when the connection with sequences in the space is explored in more detail. In praxeological terms, the MO underlying the DG course takes its starting point in the praxis, in tasks aimed at understanding the behaviour of surfaces, as objects already familiar to the students, and in techniques used to carry out these tasks. The course develops technology justifying the techniques but the idea of a general theory of abstract Riemannian manifolds is presented only toward the end of the course and is not extensively developed. From a didactical perspective, the fact that students are already familiar with the objects and techniques of the course enables the lecturer to build on this familiarity when presenting arguments and explanations. The MO underlying BT, on the other hand, is structured much more around the logos. A theory of topological spaces, with an elaborate set of technologies, is developed around one main task, namely, classifying topological spaces, and using techniques mostly taken from set theory. In a sense, the BT course is all about logos. The tasks of the taught MO are to a large extent "toy examples", developed in order to support the learning of the theory, rather than being of interest in their own right. Indeed, the BT course is largely about developing technologies that can then be applied elsewhere, to justify techniques for dealing with topological spaces in other settings. In conclusion, we suggest characterizing the DG course as praxis-driven, whereas the BT course is logos-driven.

## Conclusions and discussion

In this paper, we have analyzed the epistemological characteristics of two university courses aimed at second and third year mathematics students: Basic Topology and Differential Geometry. We have shown how the different theoretical starting points of the courses, with BT being logos-driven and DG praxis-driven, had consequences for the design of the courses. Here, however, a caveat is needed. We are aware that the MO's that we have described above to some extent are mixtures of the scholarly MO's underlying the courses and the transposed MO's actually taught in the classroom. However, preserving a strict separation is difficult, and we believe that the mixture does not significantly alter the gist of our argument. In fact, the difficulty of adequately separating the two might go some way towards explaining the observation made by Florensa, Bosch, Cuadros and Gascón (2018), that when university lecturers reflect upon their own practice, content-related didactic considerations often seem to be lacking. We see this paper as a small step towards such content-related didactic reflection. In terms of didactic co-determination, we have presented an example of how the domain, and thus the discipline, influences pedagogy. If content of the type included in the BT course is to be presented to students, this poses constraints on the type of pedagogy available. It makes it more difficult, for instance, to make use of students' previous experience and knowledge, and to provide motivation through showing applications of the theory. On the other hand, the mostly self-contained nature of the material, its axiomatic structure, and the relative accessibility of the proof techniques employed, makes a course such as BT suitable for a form of teaching that inducts students into the practices of formal proof. Through use of the DTP format, the lecturer can model this part of mathematical practice (see for instance Viirman, 2014) and can provide students with tasks that lets them engage in such practice in a manageable setting. A course such as DG is less suitable for this, since the proof techniques required are much more complex. However, the way it takes its starting point in relatively accessible, practical problems invites an inquiry-oriented approach, where these problems serve as starting points for the handling of content. This approach appears to be less suitable for the BT course, although one might conceive of a course taking as its starting point the overall question of how to categorize topological spaces. Still, even from this starting point, the course would probably enfold in much the same manner as the course discussed in the present paper. Moreover, we wish to emphasize that the differences in the MO's underlying the two courses should not be seen as mainly influencing the temporal organisation of the material. One could imagine another instance of DG, consistent with the course syllabus but maybe not didactically ideal for the intended students, where the starting point is an abstract definition of Riemannian surface and the extrinsic geometry of surfaces in 3-space would appear as embedding theory. However, the course would still be praxis-driven, focused mainly on developing the technology for justifying techniques used for solving geometrical problems. Similarly, BT could be set in the opposite order, starting with several examples of topological and metric spaces arising in natural contexts, and only then introducing suitable notions to understand their similarities and differences. This would be an interesting but likely somewhat ineffective way of teaching the same material, consistent with the course syllabus. Still, the course would be logos-driven in that the main purpose of the examples would be the development of the theory. In other words, the temporal order of definitions and examples could be inverted, but this does not alter their different epistemological status in the courses.

The analysis we have presented here should be seen only as a first step. For instance, one might ask whether other mathematics courses taught at university fit within the two patterns described here. One example of a type of course that does not seem to do so is the Calculus of Variations course at the second author's department. Roughly speaking, it consists of showing how a single central technique (the variational principle) can be applied in a large variety of settings in different areas of mathematics and the applied sciences. At first glance, it would seem as if the logos block would play a very different role in such a course compared to the ones under scrutiny in this paper, and it might be enlightening to examine this case further. Moreover, a more detailed analysis of the interplay between the DO and the scholarly and taught MO in a particular course would require data analysis that we did not engage with in the writing of this paper. This could involve, for instance, an examination of the role of textbooks and other didactic resources on the development of the DO as well as analysis of tasks given to students and of the potentially constraining role played by established assessment practices. Moreover, a deeper understanding of the DO would require empirical data on the teacher's and students' practices. The work presented in this paper is not intended as the type of more radical rethinking of the organization of content suggested, for instance, by Bosch, Gascón and Nicolas (2016). We have done some thinking on alternative ways of course design, cutting "against the grain", so to speak, of the established structuring practices according to mathematical domain. One might consider, for instance, a course on "classification", looking at various ways of structuring classes of mathematical objects in different domains. However, any such radical rethinking would risk encountering major difficulties because of institutional constraints, particularly in early courses taken by students from many different programs, and would thus, at least at first, probably only be possible in relatively high-level courses aimed at future research mathematicians. Still, just thinking about such alternative ways of organizing content may aid in the content-related didactical reflection requested by Florensa et al (2018), by forcing us to question established ways of structuring content, and how this structuring might influence the ways in which we can teach.

*Calculus is often an essential milestone during a students' time at university and can be especially impactful for students wishing to pursue a math or science field. Given its relative importance, the ways in which calculus courses are delivered can have a lasting impact on a student's trajectory and relationship with mathematics. In this study we document the ways in which three calculus course variations at the same university operate to promote different mathematics identities for students. Drawing on the framework of figured worlds (Holland et al., 1998), we showcase the ways in which these course variations act as if they are different calculus worlds that constitute socially organized and produced realms of being. We highlight the ways in which these figured worlds position or fail to position students with the opportunity to refigure themselves and others.*

*Keywords: Calculus, mathematical identity, figured worlds, course variations.*

In the United States (US) there is a need to increase the number of students in science, technology, engineering, and mathematics (STEM) to address the nearly 1 million additional STEM degrees needed to support the nation's growing research and technology economy (PCAST, 2012). To address this need, the PCAST report recommended the adoption of empirically validated teaching practices, replacing standard lab courses with discovery-based research courses, addressing the mathematics-preparation gap, and diversify pathways to STEM degrees. Additionally, any efforts to improve the quality of undergraduate STEM education must also attend to fostering an environment that promotes diversity and inclusion in STEM classrooms (NASEM, 2017).

The vision and enactment of creating an equitable robust STEM education is a complex and multifaceted endeavor that will require continued research; however, one such approach in undergraduate mathematics in the US is the tailoring of calculus courses to meet the needs of individual students, which we refer to as course variations. Course variations have the potential for addressing the recommendations from the PCAST report since they can specifically address the preparation gap for students by incorporating prerequisite material in courses, by stretching out the course content, or by infusing labs and standard based teaching in courses tailored for science majors<sup>1</sup>. Such course variations can even provide diverse pathways into STEM for those that have taken a non-traditional math background through transition courses. Rasmussen et al. (in press) documented how these variations to the standard course across the US have been associated with greater rates of passing calculus and put forth a call for future research to examine the ways that these courses may help promote a sense of community and identity development among students in the different course variations. We take up this call for future research by addressing the following

<sup>1</sup> Major refers to the academic discipline or program of study to which an undergraduate student formally commits

research question: *How do the structures and activities of three different calculus courses at one university impact the types of possible mathematical identities that emerge for students from those contexts?*

## **Theoretical Background and Literature Review**

Mathematical identity is a powerful concept in the analysis of mathematical learning, in part due to the recent social and political turn in education (Adiredja & Andrews-Larson, 2017). Identity frameworks in math education have drawn largely from sociocultural perspectives that link identity and learning to one another and arise from social practices. Additionally, this research often utilizes positioning theory to account for identity as constructed through social interactions to construct storylines about who a person is in relation to others in a social context (Langer-Osuna & Esmonde, 2017). Holland, Lachicotte Jr., Skinner, and Cain (1998) demonstrate how the sociocultural theory of identity and self, known as figured worlds, is a useful perspective for studying identity production in education, and how the context of education allows or does not allow the emergence of certain identities. Figured worlds are “socially and culturally constructed realms of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (Holland et al., 1998, p. 52). Figured worlds are dynamic. They are constantly formed and re-formed in relation to the everyday activities and events that occur within the realm of possible “as if” worlds. Figured worlds are thus situated in a social context and time period and represent a reflexive relationship and negotiation of the possible identities that can be constructed and affirmed in the figured world.

Boaler and Greeno (2000) utilize the perspective of figured worlds to illustrate how two different types of secondary school classrooms afforded students different identities and storylines as mathematical learners. One such figured world drew on what they referred to as “received knowing”, which promoted the belief of doing mathematics as memorization and being able to quickly recall information. In contrast, the other figured world promoted “connected knowing”, which emphasized the belief of doing mathematics as making sense of mathematical concepts and procedures and a sense of agency among the learners. This study highlights how the context of education setting and approach to teaching can impact students’ identity production as learners and doers of mathematics, which can impact their decision to continue (or not) in a STEM program.

In related work, Solomon, Croft and Lawson (2010) examined how mathematics support centres, which were intended to support skill development for engineering students, were dynamically co-opted by the students to support the development of group learning strategies which promoted a strong community identity among the participants. This study highlights the way this STEM community of practice, which can often be highly competitive and individualistic, can refigure itself by reflecting on the positional identities that can be challenged in that space by drawing on the physical resources and artifacts to disrupt the available storylines. For instance, the physical space of the tutoring center, allowed students to refigure their relational identity to mathematics as a social endeavor of helping each other succeed.

## Methods

The analysis presented draws on student focus group data from one University, which we refer to as Tree Line University (TLU). TLU offers three different calculus courses. In addition to the standard offering, TLU has a coordinated calculus-physics course for advanced students and a life science course, which includes a focus on biology. For each of the calculus offerings (standard, honors studio physics, life sciences), we conducted a single focus group during week 13 of 16 with three to five students currently enrolled in each of the respective courses. We used student focus groups (as opposed to individual interviews) since they offer opportunities to understand the nature of students' socially constructed figured worlds. Students for the focus group were sent an email invitation as well as recruiting efforts done in-person during the course. As such the students who participated represent a self-selected sample of students willing to participate in the focus group, and while this may not be representative of the entire course they highlight the realm of possible mathematical identities afforded in each of the courses. The focus group conversations centered on topics such as who they are, their experiences in the course, how and why they chose this particular course, what happens during a typical class period, how they relate to others in this course as well as to students in different calculus courses. Each of the focus groups utilized the same interview protocol but the extent to which each topic was discussed was driven by the engagement and discussion of the participants.

All focus group interviews were audio recorded and transcribed for subsequent, thematic analysis (Braun & Clarke, 2006). Guided by our theoretical framing of figured worlds, we developed narrative accounts in a collaborative endeavor among the researchers by first producing a descriptive account of the focus group and then using within and cross-case comparison to develop themes related to the research focus. These narrative accounts centered around the themes of students' emerging mathematical identities, sense of community or belonging, and positional relationship to calculus as (ir)relevant to their major and career goals. We present how these themes are enacted as figured worlds in the three calculus courses along with illustrative quotations from the narrative accounts.

## Results

### **Calculus for Life Sciences: A refiguring of productive mathematical identities**

Calculus for Life Sciences at TLU functions as a combined differential and integral calculus course without topics in trigonometry. The course was originally designed at the request of the college of life sciences and agriculture for students majoring in the life sciences. The content remains fairly similar to the standard calculus course but has what faculty described as a "lighter approach" that emphasizes concepts and some application of topics. Our focus group in this course included five students enrolled with the same instructor (Dr. B) for the lecture session but who had different teaching assistants for the twice weekly recitation sections.

Students in the focus group conveyed that prior to enrolling in this course they had identities as poor performers in mathematics, which made them anxious to take a university calculus course. One student shared that they had taken precalculus and had gotten a C- in the course, and stated that it, "was the lowest grade I had ever gotten for a college class," and as a result was worried about how well they would do in this class. All of the students in the focus group concurred with this

sentiment, with one student stating, “I did so poorly in that class, and I just thought like I am not meant to pass calculus.” Other students discussed how the gap between their last math course in secondary school and taking this calculus course made them less prepared, and that they were “nervous going into calculus.” Students in the focus group had a personal social history (history-in-person) that positioned them outside of the world of learners and doers of mathematics. For example, one student stated that they were, “someone who is not naturally inclined to math,” while another stated, “I am not meant to pass calculus.” However, as we will show, the students conveyed that through their experiences in this course, they were able to refigure their identities as productive mathematical learners largely as a result from positive interactions with their instructor.

Students in the focus group conveyed that as a result of this course they now viewed themselves as someone who was capable of learning and doing mathematics. One student said that “I feel like I'm not completely hopeless at all in math anymore.” This sentiment was supported by two other students who recognized a shift from their prior conceptions and experience in mathematics. For example, one student said, “I can actually do this, rather than like, in many past courses where I really have no idea what's going on.” Students discussed how they were really “understanding” what they were doing rather than memorizing formulas, which aligned with the goal and vision of the course from the faculty perspective. As a result, students were able to refigure their positionality towards learning mathematics, as exemplified in the following quotes: “I’ll be able to succeed in other math heavy courses” and it “boosts my confidence in that regard.”

One of the contributing factors that helped students refigure their mathematical identities was their relationship with the instructor. “I can't say enough about our professor, this is probably the only math class that's really felt like it made sense in my life.” Students described instructional practice that contributed to their positive experience such as the teacher breaking down concepts in a way that made sense, using anonymous polling to see how they were feeling about course concepts, and providing prerequisite information such as the quadratic formula without assuming the students had memorized this information. These practices seemed to convey to the students that the instructor cared about them and their learning, allowing for them to acknowledge their past mathematical identity while being supported in the negotiation of productive mathematical identities. The impact of the individual instructor versus other features cannot be isolated in this study; however, the instructor through pedagogical techniques such as group work and anonymous polling (both on content and affective issues) allowed for the enactment of a figured world that aligned with the goals of the course to have students focus on understanding and connected knowing.

There were also ways in which the enactment of the course variation positioned the students outside the world of mathematics learners. For instance, while one of the students mentioned that they were unaware of the difference between calculus for life sciences and the standard calculus course, three of the students mentioned the ways in which it was “low base calculus” or “more basic algebra” compared to “real calculus.” One student even described how their friend who was studying physics teased them saying, “you're not taking calculus, calc for life sciences is just like classical math.” Additionally, all but one of the students felt that the stated goal of the course to serve life sciences students was too broad. This resulted in students feeling that the course was not tailored to their specific discipline identities, “I'm either getting pushed aside or pushed under the rug with

everybody else by just saying, “Oh well, you're in the life sciences major, you got to do this.” In this figured world of calculus for life sciences, students were maintaining a strong discipline identity (equine science, zoology) which they viewed as not needing calculus.

### **Honors Calculus: A collaborative community of academically-minded students**

Honors calculus at TLU is a unique course that it is designed to integrate topics in physics and calculus and takes a theoretical approach to the material. It is a two-course sequence that is co-taught in a studio laboratory by a math instructor and a physics instructor. The math instructor for this course was teaching it for the second time. Our focus group consisted of three students majoring in mathematics. Students emphasized the difficulty of this course by the fact that they often have to rely on one another to finish the homework and study for exams. For example, an agreed upon sentiment is that “Collaboration is actually one of the strengths of the class...you know everyone in the class, you feel like you can trust that they're going to put in the effort, and you're going to put in the effort, and you're going to come together if you need to.” The word “trust” was often used by the students in this focus group interview. They felt that there was a need to trust each other in order to do well. It is important to note that the objective for these students was clear; it was not to just pass the class, but to do well in the course together.

All of the students in this focus group entered with AP calculus credit<sup>2</sup>. They entered into a world where they viewed their peers as equals who enjoyed learning and doing mathematics as much as they did. From the start they described a course that positioned them in the figured world of calculus where they felt accepted and academically challenged. This is reflected by the students' frequent reference to being surrounded by people who are the “same.” One student in the focus group reinforced this idea as follows: “In my calculus class, we have students who are all STEM. They are students who have the same mindset”. These students are in a space where they are comfortable to acknowledge that they are joined by, “intelligent people who have the same common objective”. This highlights how mathematical identity of high-ability and like-mindedness is socially formed and reproduced (Holland et al., 1998).

Students were able to relate to each other and work together based on the fact that they are all coming in with similar interests, similar class objectives and career goals. During lecture, they were required to work in groups, which was a point of contention at the beginning of the semester. There was reluctance from some students to work with one another because they wanted to “motor through” the activities. However, they came to view group work positively once they created a world where they were able to openly share their ideas. As one focus group member put it, “I get to share my perspective, I get to hear their perspective,” which they felt created a class that was more enjoyable. The figured world of honors calculus that the students created for themselves allowed them to grow and form a mathematical identity that centers around succeeding, understanding the material, and supporting others.

<sup>2</sup> AP Calculus is a first course in differential calculus offered through the advanced placement system, which is a program in the US and Canada that offers university level curricula and examinations to secondary school students.

The students in the focus group also reported having an extremely strong sense of community that was supported through the development of their figured world, full of high achieving STEM majors. One student explained how close knit they are as follows: “If I have a concern about anything really, I feel like I can go and find someone from the class and talk to them about it and ask them what they think. And, you know, that’s something that I think might be more exclusive to the [Honors Calculus].” There was something special about this particular experience compared to their other honors classes. The figured world that they created for themselves, with the help of their instructors, strengthened their identities as capable mathematicians. These high achieving students created a space where they are comfortable to admit when they need help and trust that their peers can support them in their learning process.

### **Standard Calculus: A realm of disconnected knowing and isolation**

The standard calculus sequence at TLU is primarily a service course for engineering majors. The two-course sequence is taught on a rotating basis by experienced instructors. The focus group consisted of three men, with majors in ocean engineering, mechanical engineering, and chemical engineering. The students in the focus group had varied secondary school mathematics experiences where one student took a non-AP calculus course, one took an AP calculus course, and the third student did not take calculus in secondary school.

Although each of the students entered with different levels of math preparation, they each expressed a similar experience in the course – it was fast-paced and disconnected. The one student who had not taken calculus in secondary school described Calculus 1 as fast-paced and not well-organized. He also expressed some personal disconnect with the material when he said, “I didn't know what a derivative, like what is the definition of a derivative, till like two weeks after we had started them.” The other two students who had taken calculus in secondary school also felt that the course was fast-paced but were less concerned with the material. In general, the three students positioned themselves as external to calculus, where calculus was something they had to do, as opposed to something that they were excited about learning. For example, one student said, “it's a class and I have to do work for it. That's just normal college stuff” and another student said calculus was a course “they had to take.” Thus, upon entering calculus as first year students, none of the three positioned themselves as particularly excited about mathematics or very interested in mathematics. As they progressed from Calculus 1 to Calculus 2, this feeling of being disconnected from mathematics was *not* refigured, but rather seemed to become entrenched and reified.

In both Calculus 1 and 2, the three students had similar experiences in the lecture portion of the course. One student explained that he felt so disconnected that he stopped going to his assigned lecture and attended a different lecture instead. He recounted that in class he felt, “nobody knows what's going on because you're just up there writing, and you won't answer the questions. So, this is very frustrating.” Another student chimed in that “Everything that he just said that happens this semester, happened for me last semester.” The feeling of being personally disconnected from their instructors and the course content was amplified in Calculus 2. In contrast to Calculus 1 where they felt the material was more applicable and useful, their experiences in Calculus 2 was on memorization. For example, one student contrasted his experience in Calculus 1 and 2 as follows: “The expectation [in Calculus 1] was that there would be understanding. The latter [Calculus 2] is

memorization without any expectation of understanding.” This was a common sentiment for all three students. In fact, one student explained that he was told that Calculus 2 is “really advanced math” and so there they are not expected to “understand what we are doing.” Even his teaching assistant (TA) positioned the content as something that was not within their reach for understanding. “And like my TA has dropped a line similar to just saying like, ‘You don’t need to know further, this is what you need in order to do this. So, this is what you’re given.’” Thus, their experience in calculus at TLU resonates with the figured world of “received knowing” described by Boaler and Greeno (2000).

TLU’s no calculator policy seemed to further figure calculus as something that is disconnected from their interests and previous experiences. For example, one student explained that in secondary school their exams had calculator and no calculator parts and he liked the calculator part because “you could actually like finish the problem.” The no calculator policy in calculus stood in contrast to how he imagined his future self in the workplace as an engineer. “You’re not going to be working in a laboratory somewhere and they’re just having you do calculations of derivatives and integrals like, in your head. Like you’re going to have a calculator. Especially if you want to do real-world problems.” They also contrasted their calculator experience in calculus with that in physics and chemistry, where calculators are used all the time. This positioned mathematics for them as outside the realm of connection with other disciplines.

When asked about the extent to which they felt they had formed bonds or connections with their classmates, the three students agreed that any relationships they formed were *not* the result of how class was structured or due to any effort on the part of their instructors. Instead, those that they do homework with are either friends or live in the same residence hall. Their ability to work with a wide range of students from different lectures was made possible because TLU has tightly coordinated curriculum, homework, and assessments. As these three students explained, “there’s a lot of behind the scenes learning from kids explaining, or students explaining stuff to one another” and “there’s a lot of, frankly, bonding over freaking out.” Thus, at a system level, the course coordination allowed for considerable peer to peer bonding that otherwise might not have happened and allowed these three students to refigure their relational identities as helping residence hallmates survive calculus.

## Discussion

Given the exploratory nature of this work we did not posit any hypothesis regarding how the different course variations would impact student mathematical identities, and instead our aim was to capture the salient features described by the students and how those related to their beliefs about knowing and doing mathematics. The enactment of these figured worlds considers the totality of the lived experience such as the role of the instructor, calculator policies, discipline-based problems, and the structures surrounding entry and pathways into the courses. These elements cannot be separated since they are fundamental to the construction of the figured world. For instance, instructors for the calculus for life sciences are selected knowing the course should emphasize mathematical understanding and are aware that most of the students have had negative experiences with mathematics prior to starting the course. This results in assigning instructors who often are more student-centered in their teaching approach. The selection of instructors for the standard

calculus is less intentional, but not random. Experienced instructors with good teaching reputations are typically tapped to teach this course because it is a core requirement for all STEM majors.

We also want to stress that the three different figured worlds are not consequences of the course variations themselves, but rather lie in the possibilities that the different course variations offer for how it is enacted and experienced. For example, the role of the instructor to either express care for their learning, to encourage peer collaboration, or to lecture the material at a quick pace was a paramount factor in how the students described their beliefs about being able to learn and do mathematics. The way the instructors approached teaching we speculate is tied with the programmatic features of the course variation. Whereby the standard course is content heavy and puts pressure on instructors to cover the material through lecture, the honors course has more contact hours and was designed with collaborative labs, and the life science course focus on understanding and less on computation which promotes instructor inquiry into student thinking.
