1	2	3	4	5	6	$\bar{x}$	$\tilde{x}$	$s$
-	-	4%	11%	40%	45%	5.26	5	0.820

**Table 1: Sample item concerning the perceived helpfulness of the Concept Base coaching**

Moreover, the two items concerning the time effort indicate that, on average, the participants believed that the time spent for the coaching was well invested ( $\bar{x} = 4.57$ ,  $\tilde{x} = 5.0$ ,  $s = 0.99$ ), although there was more variation than in the scale ‘perceived helpfulness’.

*Results concerning the perceived benefit of the Concept Base by the coaching participants:* The coaching participants saw a greater benefit of the tool Concept Base after the coaching than before, in particular the benefit of the deep processing of mathematical concepts during the time consuming process of their creation (due to limited space details cannot be presented here).

*Results concerning the success in the exam:* The pass rate in the exam of the whole mathematics course ( $N = 815$ ) was 57%, which mirrors the pass rates in former years. The pass rate among the coaching participants ( $N = 48$ ) was significantly higher than of the rest: 81% versus 55% ( $p < 0.01$ ). These differences are not necessarily due to better initial mathematical qualification of the coaching participants because the final grades in mathematics at school did not differ significantly.

The comparison with the two comparison groups can be seen in Table 2. The differences between the coaching participants and the comparison groups are again significant ( $p < 0.01$ ).

	Participants of the coaching (N = 48)	Comparison group 1 (N = 91)	Comparison group 2 (N = 49)
Pass rate	81%	62%	55%

**Table 2: Pass rates in the final exam of the participants and the two comparison groups**

Assuming that students who did not take part in the coaching program but wanted to take part in the next semester (Comparison Group 1) are as similarly motivated as the current coaching participants, Table 2 suggests that the better performance of the current participants was not only due to higher motivation. The comparison with the students of the Comparison Group 2 (students who answered the question ‘*How often do you use the Concept Base*’ with 5 or 6 on a 6-point Likert-scale, but did not take part in the coaching), suggests that the coaching program and not just the tool ‘Concept Base’ were important.

*Results concerning the continuous use of the Concept Base:* The last important result is that most of the coaching participants continued using the Concept Base in the next semester (see Table 3). Hence, the coaching had a sustainable effect on the students’ study behavior.

	1	2	3	4	5	6	$\bar{x}$	$\tilde{x}$	s
Participants	-	-	8%	46%	8%	38%	4.77	4	1.09
Others	38%	19%	17%	17%	5%	4%	2.41	2	1.44

**Table 3: Comparison of the use frequency of the Concept Base of the coaching participants (N = 14) with the others (N = 343) in the following semester. Answers ranged from 1=‘never’ to 6=‘every week’**

Unfortunately, due to schedule difficulties, only 14 coaching participants took part in the mathematics course in the following semester. Hence, the result only yields a tendency; because the result is only based on one item, the interpretation also needs to be made cautiously.

## Summary and Discussion

The major finding of the research presented here is that the coaching program aiming to support the students in working with the Concept Base was helpful and important so that the students could become familiar with it, see its benefit (even despite the necessary time effort), and become more successful in the course. It furthermore indicates that, as a consequence, they tended to continue to use the tool on their own in the next semester (with the caveat of the small sample size of coaching participants taking part in the subsequent course).

Besides the problem of the small sample size of coaching participants in the next semester two other limitations of the research need to be mentioned that may be a starting point for future research:

- 1) The data cannot show in which way coaching program and the tool Concept Base itself helped the students to perform better in the exam exactly. It would be important to find out if the Concept Base really helped students to acquire a solid understanding of mathematical concepts.
- 2) Even if we tried to mediate the effect of motivation by choosing two comparison groups, of which we expected that they were also willing to invest time for their studies, we should keep in

mind that our coaching participants might nevertheless have been a group with special attributes. The results in the case of less motivated students may be different. Hence, scaling up this experiment on the whole course might be another important point for further research.

A last issue concerns the tool ‘Concept Base’. Although literature like Vollrath (1984) suggests that the categories of the Concept Base are crucial for understanding a mathematical concept, we did not investigate empirically how mathematicians in general concern themselves with these categories when trying to make sense of new mathematical concepts, which would be interesting for future research as well.

*Keywords: transition, bridging course, evaluation design.*

### **Description of the research topic**

This contribution documents an excerpt from a conducted research study concerning the integration of digital learning materials into a voluntary, attendance-based bridging course for freshmen majoring in different engineering subjects at the University of Paderborn, Germany. The focus of the study was to evaluate the acceptance of digital learning materials by the students during the lectures and self-regulated learning days of the four-week course. Based on the use of an audience response system (ARS), we developed an instrument to collect feedback from the students immediately after elements of blended learning – such as students' usage of interactive applets and digital, self-evaluating tasks with solutions and different elements using the ARS – were implemented during the lectures of this course to obtain students' reactions as instantaneous as possible.

The digital material was provided in form of the studiVEMINT-online course, which can be found on the website [www.studiport.de](http://www.studiport.de) as free-access material (only available in German yet). This learning material was designed and implemented by our research team during the years 2014 to 2016 and was created as an independent online course in mathematics that can be used for free by any person who wishes to prepare her- or himself for university mathematics (e.g., Biehler, Fleischmann, Gold, & Mai, 2017; Colberg, Mai, Wilms, & Biehler, 2014; studiVEMINT homepage: [go.upb.de/studivemint](http://go.upb.de/studivemint)).

Additionally, we prepared work assignments for this digital course that the students were asked to work on during the self-regulated learning days with the intention to support them in repetition and deepening their knowledge.

The study was conducted to answer (among others) the following research questions:

1. Do students appreciate the integration of digital learning materials in the lecture, i.e. do they experience it as a support for their learning process and do they find pleasure in using the materials?
2. How much time do the students invest to work with the provided learning materials on the self-regulated learning days?

### **Theoretical background and method**

ARSs can support feedback from learners and provide a means to collect data for research purposes. Ebner, Haintz, Pichler, and Schön (2014) suggest a distinction between front-channel (direct feedback during lectures) and back-channel (asynchronous feedback during and out of the lecture) of those

systems. They further distinguish these into qualitative and quantitative forms of feedback. The focus of the study is the evaluation of the presented teaching scenario in mathematics with its elements of blended learning (e.g., Bernard, Borokhovski, Abrami, Schmid & Tamim, 2014) via the ARS.

We used the ARS functionality regarding quantitative front channel feedback (Ebner et al., 2014) during the lectures to collect reactions to the use of the digital elements as instantaneous as possible. Furthermore, we asked the students how much time they spent working (as they were requested to do) with the digital learning material on the self-regulated learning days in each subsequent lecture. Supplementary data was collected by a pen and paper questionnaire issued at the first and the last day of the course.

## Results and discussion

The feedback concerning the integration of the digital learning materials into the lectures was largely positive. However, while looking at the results more closely, we found that more students appreciated the support of the digital materials for their learning processes than reported having pleasure while working with those materials. Another result was that the time students spent on their self-regulated learning days decreased dramatically during the four weeks of the course, even though students reported that the work on the tasks for these days was helpful for their individual learning and understanding. Further and more detailed results from the study have been presented at the conference.

### Introduction

During the past two decades, Inquiry Based Mathematics Education (IBME) has spread widely. It has been promoted by governments and international organizations through specific programs and curricula reforms, such as the PRIMAS and Fibonacci projects in Europe, or the Common Core State Standards in the United States. Artigue and Blomhøj (2013, p. 802) describe how different research frameworks offer “particular perspectives on the conceptualization and implementation of IBME”. Their analysis reveals that there exists shared principles such as the “authenticity” of questions and activities; their epistemological relevance; the progression of knowledge; the development of extra-mathematical questions and the role of mathematics as a modelling tool in inquiry processes. One of the problems emerging from this diversity of approaches is that the concretion of IBME in research experiences may only rely on these general principles, lacking a clear systematic methodology to design, manage and analyse the implemented experiences, and to provide specific research tools to develop these tasks.

Study and Research Paths (SRPs) are an inquiry-based teaching formats proposed by the Anthropological Theory of the Didactic (ATD) (Chevallard, 2015). They are initiated by a *generating question* ( $Q_0$ ) addressed by a community of study (a set of students  $X$  and a set of guides of the study  $Y$ ) that form a *didactic system*  $S(X, Y, Q_0)$ . The aim of the didactic system is to generate a final answer  $A^\heartsuit$  to question  $Q_0$ . The work of the community of study and the knowledge involved can be described as a concatenation of derived questions and their associated answers that will led to the development of  $A^\heartsuit$ . The inquiry process will combine moments of *study* of information available, with moments of *research* and creation of new questions and answers, including the adaptation of the information to the specific (initial and derived) questions addressed.

The goal of implementing an SRP is twofold. On the one hand, SRPs can be understood as a teaching device to promote a shift from the pedagogical paradigm of “visiting works” to the new paradigm of “questioning the world” (Bosch, Gascón, & Nicolás, 2018; Chevallard, 2015). On the other hand, SRPs can also be considered as a research tool to identify, modify and study *didactic phenomena*, that is, regular facts that take place in teaching and learning processes and that are specific to the content involved. The implementation of SRPs is an empirical tool to generate data to evaluate to what extent and how *didactic phenomena* can be modified and to work on the definition and design of alternative epistemological and didactic models in which the knowledge at the stake and its related teaching practices are questioned and newly organised.

The ATD framework has developed diverse subtheories enabling researchers to analyse study processes and SRPs in particular. Two of these tools are the Herbartian schema (Chevallard, 2008) (see Fig. 1) and the media-milieu dialectics. The first part of the schema represents the *didactic system*  $S(X; Y; Q_0)$  that faces the task to generate an answer to an open question  $Q_0$ . The second part of the schema describes the process of elaboration of an answer ( $A^\heartsuit$ ) of the community of study to the generating question  $Q_0$ . The hallmarked answers and works are preexisting knowledge developed in different institutions that the community of study will access in the *media*. This information obtained is then studied, deconstructed and adapted to the (sub)question addressed and incorporated to the *milieu*. This *media-milieu* dialectic that explicitly appears in the Herbartian schema allows researchers to question and analyse the external information (and its diversity) addressed by the community of study and how it is validated.

$$[S(X; Y; Q_0) \curvearrowright \{Q_1, Q_2, \dots, Q_m; A^{\diamond}_{m+1}, A^{\diamond}_{m+2}, \dots, A^{\diamond}_n; W_{n+1}, W_{n+2}, \dots, W_p\}] \curvearrowright A^\heartsuit$$

**Figure 1 Herbartian schema**

Following Artigue (2014), Barquero and Bosch (2015) have described four main phases in the design and research methodology related to Didactic Engineering: the identification of didactic phenomena; the design or a priori analysis of an SRP; the in vivo analysis of the SRP; and the evaluation or a posteriori analysis of the ecology and economy of the SRP. This is a crucial point of SRPs: including an explicit epistemological questioning differs heavily with other PBL approaches.

However, as Bosch (2018) and Florensa, Bosch and Gascón (2015) stated, this theoretical and methodological apparatus is difficult to be transposed to teacher and lecturers practice, especially when they are not at the same time familiar with the ATD framework. In fact, most of the experienced SRPs at university level have been led by researchers in the ATD or by lecturers working closely with them. In this paper, we present a retrospective analysis of previous SRP implementations at university level in order to identify the evolution of the used didactic tools. When examining this evolution, we intend to set up the foundations of a more systematic methodology for the design and managing of SRPs in university classrooms and for their viability.

## The experienced SRPs

Table 1 presents a brief account of the SRPs implemented during this past decade by the ATD research team based in Spain. Details of their design and implementation can be found in the references. Let us just point out that the integration of the SRPs has adopted different modalities to

be integrated in the traditional organization of the university courses. SRP1 and SRP2 ran as workshops in parallel to the regular course, as weekly 2-hour sessions for a total of 60 hours both, thus complementing the lectures and problem sessions. SRP3 consisted in an elective workshop that lasted about 9 sessions of 2 hours at the end of the course about forecasting the Facebook users' growth. SRP4 was fully organized as an SRP lasting a whole 6 ECTS subject (17 weeks, 4 hours per week). SRP5 was implemented after 8 weeks of lectures, labs and problem sessions, for the 7 last weeks of the course, thus covering a total of 21 h.

SRP	Subject	Level and degree	Period	References
1	Mathematics	Population dynamics 1 <sup>st</sup> year Chemical engineering (groups of 30-35 students)	2005-2009	Barquero, Bosch & Gascón (2011; 2013)

### **Dealing with knowledge in an SRP: the language of modelling**

The traditional “transmissive” way of knowledge dissemination at university level tends to sacralise the bodies of knowledge to be taught (Bosch, 2018). Therefore, tasks such as describing, organizing the work, collecting data, and searching well-established (and labelled) knowledge are not always part of the students' responsibility. And, when they are, they appear as non-problematic for the students, who only have to retake and at most summarize the accessed pieces of knowledge. In addition, the dominant pedagogical paradigm tends to hide the questions for which a specific knowledge is relevant, or at least leave them for the very end of the study process. These phenomena generate important constraints when implementing an SRP in a school institution. In the design and implementation of SRPs, the dialectics between the questions posed and the construction of answers is central, as well as the share of new responsibilities between teachers and students in the inquiry process. The development of tools enabling changes, especially those relating to the way “content” is described and managed, have appeared since the first implementations of SRPs.

Barquero, Bosch and Gascón (2013) present one of the first SRPs experienced at university level (SRP1). The SRP was implemented along the annual course of “Mathematical Foundations for Engineering” with students of Industrial Chemical Engineering, in the so-called “Workshop of

mathematical modelling” which was created only to develop the SRP and which ran in parallel of the regular course based on lectures and problem sessions. This three university teaching devices were easily coordinated because there was only one group of about 35 students and two lecturers, the one responsible of the theoretical sessions and the other (second author of this paper) who guided the problems sessions and the workshop. Although there was a study programme to accomplish, the lecturers-researchers had freedom to carry it out in the most convenient way. The generating question of the SRP was “How can we predict the long-term behaviour of a population size, given the size of a population over some previous periods of time? What assumptions should be made? How to forecast the population size’s evolution and how to test its validity?” The design and implementation of this SRP wanted to address the problem of teaching modelling at university level and to deal with the widespread didactic phenomena of reducing modelling activity to the simple “application” of some pre-established models and contents. Researchers designed the SRP paying special attention to the modelling process to be developed with students. The *a priori* design included a careful delimitation of the generating and derived questions that could be posed and of mathematical models and knowledge that would appear to provide answers.

One of the first necessities experienced by the lecturer guiding the modelling workshop was to share and institutionalise a new *discourse* to talk about the mathematical activity students were developing. In this occasion, most of the discourse needed was about modelling, which was quite new for the students. Introducing terms referring to systems and models, to the formulation of hypotheses, to the actions of validating the models or discussing the scope and limitations of the models, was a new *logos* for the students to describe, organise, justify and report their activities.

A second aspect highlighted by Barquero et al. (2013) is the necessity to create new didactic devices to transfer new responsibilities to the students who had “to produce their own answer [...] considering intermediate (sub)questions and write and defend a team report [...] with their temporary answers” (Barquero et al., 2013, p. 326). The main didactic devices to manage the implementation of the SRP and to institutionalize the modelling activities were the *weekly reports* that students developed and presented. From the second year on, these reports were based on an explicit fixed structure, including a description of the questions faced, the mathematical models built, the answers obtained, and the new questions proposed to follow with. Moreover, each team had to designate its own “secretary”, a student in charge of explaining and defending the team’s report at the beginning of each new workshop session. A whole class discussion followed these presentations, to state the main progress and to agree on how to continue with the inquiry. At the end of the SRP, each student individually had to write a *final report* of the entire study where she had to analyse the whole modelling process followed (Barquero et al., 2013, p. 327).

The implementation of SRP2 was initially done as a workshop that took place during the Mathematics course of a 1<sup>st</sup> year degree in Management. The workshop lasted for 5 weeks with two 2-hour sessions. The generating question of the SRP was: “A firm registers the term sales of its 7 main products during 3 years. What amount of sales can be forecasted for the next terms? Can we get a formula to estimate the forecasts? Which are its limitations and guarantees? How to explain them? What products sales are increasing more than 10% a term? Less than 12% a term?” It is important to highlight that the

lecturers established two kinds of sessions: one devoted to autonomous group work under the lecturers' supervision and another to share the results obtained and validate them by the big group.

### **From modelling to questions-answers maps**

SRP3 was initiated by the following question: “How can we model and fit real data about the evolution of the number of Facebook users to provide our forecasts about the short-term evolution of the users of this social network?” (Barquero et al. 2018). Its implementation took place in the academic years 2015-16 and 2016-17 with first-year students of a Business Administration and Innovation Management degree, at Pompeu Fabra University. It run as a teaching device created for its implementation called the “Modelling workshop” that was independent of the mathematics courses. Students voluntarily participated in the workshop, with the possibility of adding an extra point to their final mathematics grade. The responsible of guiding the workshop was the lecturer of the mathematics course who, for the first time, was not a researcher in the ATD. The workshop run for 2 hours every week for 9 weeks, although most of the modelling work was developed by students working in groups out of the class. This SRP combined online sessions and face-to-face sessions. The workshops sessions were devoted to students' presentations and to the debate about the questions posed, new questions to inquire and the models, tools and answers found out.

When designing the SRP, a group of researchers and the lecturer participated in it. In its design, the understanding of mathematics as a modelling tool was central, but the description of the “skeleton” of the SRP in terms of questions ( $Q$ ) and answers ( $A$ ) took the central role for many reasons. First, there was an intensive work in the designers' team to delimit the structure of the SRP in terms of  $Q$  and  $A$ , which define the epistemological models of reference upon which they started to plan and analyse the implementation—as proposed in other research works, Florensa, Bosch, & Gascón, 2018; Winsløw, Matheron, & Mercier, 2013).

Second, the weekly reports remained to be the main communication tool and were explicitly asked to be done in terms of questions and answers. To accomplish this, the virtual platform (called a c-book unit developed in the frame of the European project MCSquared) was extremely useful to provide students with dynamic tools to structure their reports (Barquero et al., 2018, p. 20-24).

Moreover, questions and answers maps were also used by the lecturer to analyse the development of each workshop session in collaboration with the researchers. It was then decided to start a *journal of implementation* as a tool facilitating the lecturer-researcher interaction and to report on the type of knowledge appearing in the inquiry process. As the authors describe, in this journal:

[...] the researchers indicated, before a workshop session, the questions they had to present, the way to organize student participation, some indications about the gestures and strategies they could follow, and so on. After each workshop session, the lecturers and researchers met to analyse the work of students, and compared it to the a priori design. (Barquero et al., 2018, p. 20)

SRP4 (Bartolomé et al., 2018) was implemented during the 2016/17 academic year in a “Strength of Materials” course of a Mechanical Engineering degree at Univ. Autònoma de Barcelona. The generating question of the SRP was: “You are working as an engineer in a company manufacturing slatted-beds. Your company supplies beds to an American client (a chain of motels). Recently, you

have been commissioned to provide them with single slatted-beds, capable of supporting the weight of a 120 kg person”. The SRP was implemented during the whole semester in all the sessions (17 weeks, two 2-hour sessions per week). In this work the management and description of knowledge was done using question-answer maps. This tool played an important role: it allowed both students and lecturers to communicate and they were also used to describe the final answer. An important difference between previous implementation was the explicit training of participants in the use and development of this tool. During this initial training session, the students were informed that the sessions would be structured in four phases. The first part of the session was devoted to check the status of the project using a common question-answer map followed by a brainstorming session to decide the next question(s)  $Q_i$  relevant to the problem. In the second phase the group was divided in different small groups each tackling a specific question. The third phase was devoted to team work developing an answer to the assigned question. The final phase consisted on each small group presenting a specific Q-A map describing their answer to the whole group. Figure 2 exemplifies the Q-A after the two first sessions. In addition, SRP4 also included the *media - milieu* dialectic as a managing tool. During the four phases of the sessions, students described not only their work in terms of answers and new subquestions but also, they had to incorporate the *media* they used to grasp information to generate the answer. In addition, the students had also to justify their answer presenting proofs or data in order to show to what extent the acquired data and its study and modification were adequate to generate an answer to the question tackled.

SRP5 was implemented in an “Elasticity” course in the same engineering degree than SRP4. In contrast, this SRP was implemented during the last 7 weeks of the semester, keeping the traditional structure along the 10 first weeks. In this implementation students were organized in small groups (3-4 students) and each group was in charge of designing and validating part of a machine (a bike for the first edition and a formula student car in the second edition). The assessment and management of the SRP was done using weekly reports in where Q-A maps become the main content. In contrast to the previous SRPs, the final report took the form of a technical report addressed to the company that commissioned the design work.

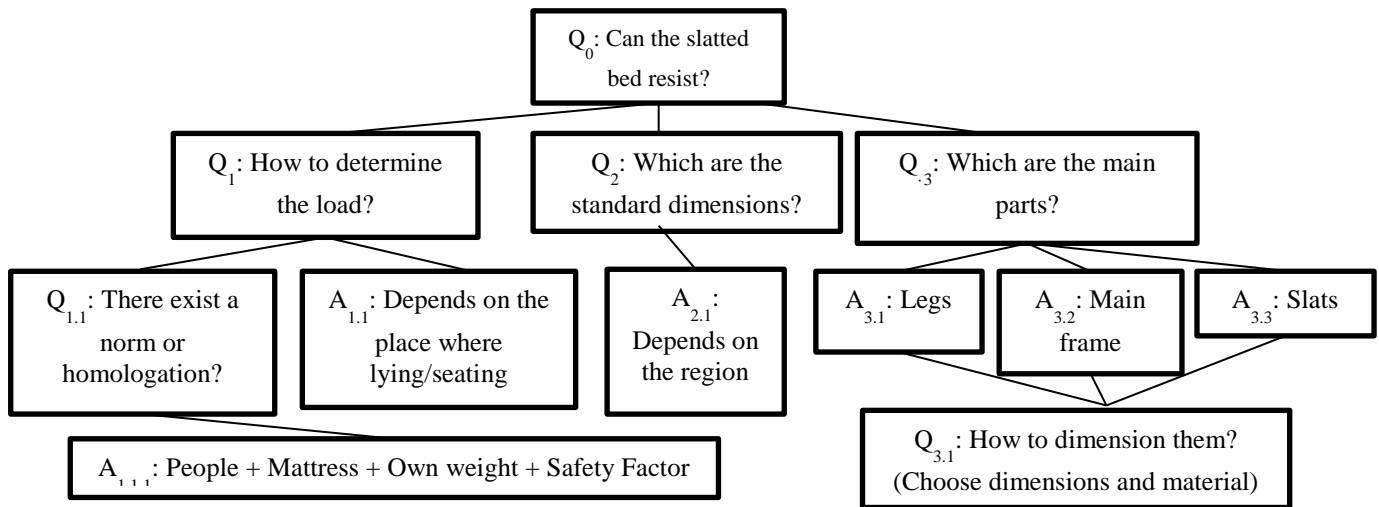

## Conclusions

The revision of different SRP implementations shows the evolutions that have occurred concerning the different didactic tools used in the design and managing of SRPs in university classrooms. We have focused on showing how, along the different investigations, these tools have been made available to the participants (students and lecturers) to deal with the knowledge and to organize the study processes. In addition, our retrospective study reveals that the tools needed by lecturers and students to manage and experience SRPs are diverse. We have identified aspects related to the language level: participants in SRP1 had to develop a specific terminology concerning modelling that was absent in the institution of study.

Another aspect relates to the need to describe and communicate how knowledge evolves during the inquiry process. Q-A maps have been satisfactorily adopted in different implementations helping teachers and lecturers to overcome this problem. Another useful aspect in one of the implementations is the transposition of the *media-milieu* dialectics—a research tool of ATD—to help teachers and

students organise their work. Making the search for information in the media and its confrontation with or integration into the milieu explicit helped to assign tasks.

**Figure 2: Initial Q-A maps generated during the SRP concerning the dimension of a slatted bed (Bartolomé et al., 2018)**

Another aspect that our study has identified is that the degree of explicitness of the implemented tools is increasing in each implementation. In the last editions of the SRPs, working with lecturers that were not researchers in didactics required a presentation of the ATD tools used. Finally, it is important to highlight that these tools (Q-A maps, media-milieu dialectics) come from the research and have been transposed to the community of study level for its use. We consider that these findings should encourage the community of researchers to more systematically use these tools in further SRP implementations. It seems to be a promising way to deal with some of the institutional constraints that have been found to hinder the dissemination of SRPs in university education, especially those related to the lack of epistemological terms to deal with inquiry processes.

### Introduction

Teaching and learning real numbers is not an easy topic, and it is probably for this reason that most secondary school curricula do not develop it, even if they are used. Several studies have been conducted on this subject, but often focusing on the double decimal representation of decimal numbers or on irrationality (Oktaç & Vivier, 2016) made a recension of researches on these theme). More recently, the emphasis has been placed on the completeness of  $\mathbf{R}$ , for the topology of the order, as one of the key characteristic properties to be achieved (e.g. Bergé, 2010; Durand-Guerrier, 2016). It has been hypothesized that these properties of  $\mathbf{R}$  are important for understanding real analysis. We are in line with this hypothesis with a positioning in favour of an algebraic approach, but how to develop the simultaneous study of algebraic and topological properties of  $\mathbf{R}$ ? In particular, we have built situations that may introduce the completeness of  $\mathbf{R}$ , on the basis of the algebraic properties of  $\mathbf{R}$ . In the two preliminary studies we present here, we analysed the students' mathematical work using the Mathematical Working Space theory – MWS- (Kuzniak, Tanguay, & Elia, 2016).

### Calculations with real numbers

This situation presents the basic algebraic operations in relation to the completeness of  $\mathbf{R}$ . In fact, the definitions of the sum and the product in  $\mathbf{R}$  are based on the completeness of  $\mathbf{R}$ . They are rarely worked at the secondary level, as if these definitions were trivial.

We asked the students to find the roots  $x_1, x_2, x_3$  of the polynomial  $P(x) = x^3 - 60x^2 + 980x - 4700$  using adjacent sequences of decimal numbers. At this educational level, it is only possible to calculate approximate values of these roots since exact values need more advanced mathematics (unless using an algebra calculator). We, then, asked them to calculate the results of the basic operations on the three real roots, such as  $x_1 + x_2 + x_3$ , that is actually 980 with the root properties of a polynomial. The visualization process is based on increasingly precise approximations (of the adjacent sequences) defining *small* nested intervals, and the signs (such as the tables of values), are used to support these processes. The main goal was to encourage work of visualization to conjecture the limits of each adjacent sequence, to recognize the polynomial coefficients.

This situation has been proposed to 6 grade 12 students by pairs, in France in 2018. The data are made on the student's dialogues and their written productions. Finally, the visualization of the limits did not take place, but this did not prevent elements of completeness from appearing spontaneously, as for the convergence and the intersection of the nested intervals, or from students confronting the epistemological obstacle of the potential infinite and the actual infinite.

## Functional equation of the real exponential

The fact that it is hard to distinguish the density and completeness of  $\mathbf{R}$  by graphical representation (especially in technological tools). In this sense, we propose to construct algebraically a function that allows a visualization of the discrepancy between density and completeness. This situation is attractive because it allows using and connecting of a wide range of academic knowledge.

The mathematical task consists in searching for the functions  $f$  defined on  $E$ , where  $E$  is the usual numbers sets  $\mathbf{N}$ ,  $\mathbf{Z}$ ,  $\mathbf{D}$  and/or  $\mathbf{Q}$  and  $\mathbf{R}$ , with values in  $\mathbf{R}$ , which satisfy the conditions: (a)  $f(1) = 2$  and (b)  $\forall x \forall y \text{ on } E, f(x+y) = f(x) \cdot f(y)$ . The first question proved that  $f > 0$  and that  $f(0) = 1$ . Then, there is a unique function (the exponential) in  $\mathbf{N}$ ,  $\mathbf{Z}$ ,  $\mathbf{D}$  and  $\mathbf{Q}$  but this is not the case in  $\mathbf{R}$ . More specifically, we ask for certain values and graphical representations. The functional equation is used as an artifact by calculating the values of  $f$  algebraically, and a graph is drawn for each set.

A first study in Chile with 6 students by pairs was conducted in 2017. The data are made of written students' answers and direct observation. For sets  $\mathbf{N}$  and  $\mathbf{Z}$ , there were some technical problems in using (b) to compute values and some students drew a continuous line but quickly realize that the context is discreet. For  $\mathbf{D}$  and  $\mathbf{Q}$ , the discussion is based on the line drawn and the density: do we represent a continuous line? Finally, a significant obstacle arose for  $\mathbf{R}$  because of the need of topological arguments. We think that asking more explicitly to build a function  $f$  on  $\mathbf{Q}$  and  $\mathbf{R}$  (additive subgroup of  $\mathbf{R}$  -  $1.a + \mathbf{Q}.b$ ;  $a \in \mathbf{Q}$ ,  $b \in \mathbf{Q}$ ) with  $f(1) = 1$  could help, and so do the use of a technological software like Geogebra.

## Conclusion and discussion

We presented two preliminary studies with these situations that have a great potential. Nevertheless, it seems that the introduction of an algebraic work allows to clearly show the topological jump made when "passing" from  $\mathbf{Q}$  (or  $\mathbf{D}$ ) to  $\mathbf{R}$ . Moreover,  $\mathbf{R}$  cannot be reduced to its sole property of completeness: the uniqueness of  $\mathbf{R}$  is based on several other properties, like its algebraic structure.

MWS theory has allowed us to design these situations and interpret the results obtained. Thus, the three dimensions of MWS has been activated: the work is done on the visualized signs (semiotic dimension), on the mathematical knowledge itself (discursive dimension) and on the technological tools to produce signs (instrumental dimension).

*We assess rhetorical aspects of the flow of proof, a notion that encapsulates various aspects of classroom presentation of proof, proposing Perelman's New Rhetoric (PNR) as a theoretical framework. We present findings from semi-structured interviews conducted with experienced mathematics lecturers, who were asked to reflect about general features and pedagogical considerations of mathematical proofs by relating to two proofs of the 'Two Pancakes theorem'. We focus on PNR's concept of audience and argue that lecturers generally address two types of audience, particular and universal, when teaching proofs and need to balance between the requirements of each audience. We conclude that PNR is suitable to capture this inherent tension in teaching proofs.*

*Keywords: Proof teaching, flow of proof, Perelman's New Rhetoric, mathematical argumentation*

### Reconnecting mathematics and rhetoric

The notion 'flow of a proof' has been used by Gabel and Dreyfus (2017) to examine different aspects of classroom presentation of proof: the way that the lecturer chooses to present the logical structure of the proof, to incorporate informal features into the presentation and to account for various mathematical and instructional contextual factors. The analysis of the informal and contextual features requires a theoretical lens that can account for rhetorical features of the presentation. However, traditionally, scholars perceive rhetoric and mathematics as antithetical disciplines (Reyes, 2014), two banks of a river. On one bank - mathematics, dealing with the establishment of unequivocal truths based on the rigorous laws of formal logic, and on the other bank - rhetoric, mostly related to the study of style, expression and ornamental aspects of discourse.

Yet, scholars have been gradually building bridges between the two banks by using rhetorical concepts to gain better understanding of mathematics and mathematical education. Davis and Hersh (1987), for example, challenged the then prevailing opinion that "mathematical truth is established by a unique mode of argumentation, which consists of passing from hypothesis to conclusion by means of a sequence of small logical steps, each of which is in principle mechanizable..." (pp. 59-60) and claimed that "mathematical proof has its rhetorical moments and its rhetorical elements" (p. 60). Ernest (1999) related to other scholars who share that approach and stated that in education this approach is less controversial than in mathematical and philosophical circles. Reyes (2014) adds that mathematics, as a practice of writing, thinking, and arguing, should be studied by rhetorical scholars, and that rhetorical scholars should explore mathematics discourse as its importance is constantly increasing. In this work, we analyse rhetorical features of mathematical proof presentation through the lens of an argumentation theory called 'The New Rhetoric' (PNR, Perelman and Olbrechts-Tyteca, 1969). PNR is a comprehensive theory that allows the considerations of a varied range of argument aspects within a single unifying theory and ties these different aspects to the adaptability to the audience for whom the argumentation is intended. Therefore, it enabled us to relate to different aspects of the flow as well as to the ways these aspects are intertwined.

## Perelman's new rhetoric (PNR)

PNR assumes a speaker addressing an audience and studies techniques that aim to increase audience adherence to the theses presented by the speaker. It concerns the effective use of informal reasoning, i.e. reasoning that promotes audience adherence. PNR was initially designed to complement formal logic and to show how choices, decisions, and actions can be justified on rational grounds; thus, it relates to dialectical, rhetorical and contextual features. It asserts that form is subordinated to content and to the effort to persuade, and that reducing an argument to its formal features undermines the rhetoric features that support its meaning. PNR offers a description of various aspects of argumentation: (i) *scope and organization*, which is a result of the lecturer's need to take into account a complicated, at times contradictory, set of considerations in the proof presentation; (ii) the constitution of a shared *basis of agreement* between the speaker and the audience (iii) the manner by which the lecturer uses rhetorical figures to endow elements with *presence* and to focus audience's attention on them; and (iv) different *argumentation techniques*. Moreover, PNR stresses that an effective argument must be adapted to the audience. In Gabel and Dreyfus (2017) we explained our adaptation of PNR for analysing mathematical proof teaching and how we use PNR to account for different aspects of the flow of a proof; we also discussed aspects (i) and (iii). In the current paper, we focus on PNR's notion of *audience* and examine its relation to inherent tensions in the teaching of mathematical proofs.

## The universal audience and the particular audience in Perelman's new rhetoric (PNR)

The audience plays a pivotal role in PNR. Perelman and Olbrechts-Tyteca (1969) make a distinction between argumentation aimed to persuade the *particular audience* addressed by the speaker, which is the actual, physical audience (and therefore the argumentation needs to be adjusted to particular knowledge, experiences, expectations, opinions and norms), and argumentation that transcends particularity and is aimed to convince what is called a *universal audience*. The universal audience is a mental construct of the speaker, composed of all normally reasonable and competent people, where competence is specific to a discipline or culture, and consists of a series of beliefs, agreements and language that are typical for this discipline, whether it is of scientific, juridical or other nature. Such agreements may be the result of certain conventions that characterize audiences, usually distinguishable by their use of a technical language of their own (van Eemeren et al., 2013). While every argument is directed to a specific individual or group, the speaker decides what information and approaches will be convincing according to the universal audience that s/he has in mind. Thus, some arguments appeal only to particular groups in a particular context and some arguments attempt to have a broader appeal. By addressing differences between universal and particular audiences, Perelman believes he can better distinguish between a merely effective argumentation that persuades a particular audience, and a genuinely valid argumentation that convinces the universal audience. In that sense, a universal audience may be used as a standard of relevance (Crosswhite, 1989).

## Rationale and goals

This work is situated within the growing research field concerned with different styles that mathematical lecturers employ (e.g., Hemmi; 2010) and the various pedagogical considerations they apply while teaching proof (e.g., Dawkins & Weber, 2017; Lai & Weber, 2014).

The goals of this paper are firstly to present different pedagogical dilemmas that mathematicians have when teaching proof at the undergraduate level and secondly to demonstrate how these dilemmas can be interpreted by using PNR's notion of two audiences. We show how the tension between the universal and particular audiences can explain decisions taken by mathematics lecturers and focus on conflicts that emerge during proof teaching between the lecturers' own views of mathematics and the characteristics of their students.

## Method

We present findings from interviews conducted with five experienced mathematics lecturers (10-40 years of experience), teaching a variety of tertiary level mathematics courses to diverse student populations (engineering students in college or university, mathematics students, prospective teachers, computer science students, high-school students). They volunteered to be interviewed and were asked about features of mathematical proofs and considerations for proof teaching by relating to the 'Two Pancakes theorem' and its two proofs (Davis and Hersh, 1983) outlined below:

**Theorem:** Given two arbitrary closed and bounded areas in the plane, A and B, there exists a line that simultaneously bisects the two areas.

*Proof 1* uses an arbitrary point O and a directed line  $\ell$  rotating through O (Figure 1); one defines functions  $p(\theta)$ ,  $q(\theta)$ : the coordinates on  $\ell$  of the lines perpendicular to  $\ell$  that bisect areas A, B. If  $r(\theta)=p(\theta)-q(\theta)$  is positive for some  $\theta$ , then it is negative for  $\theta+180^\circ$ . Hence, there exists  $\theta_0$  for which  $r(\theta_0)=0$ , i.e.  $p(\theta_0)=q(\theta_0)$ , according to the intermediate value theorem (IVT).

**Figure 1: Drawings for Proof 1 and Proof 2 (Case 3, Case 4)**

*Proof 2* is based on five successively more general cases. Cases 1-2 are trivial: If A and B are circles (concentric in Case 1, non-concentric in Case 2) then the line through their centres bisects both. Case 3 (Figure 1): A is a circle, B does not overlap A; when rotating the diameter of A, the part of the area of B that lies on one side of the diameter,  $p(\theta)$ , changes from 0 to 1; the existence of  $\theta_0$  for which  $p(\theta_0)=0.5$  follows from the IVT. Case 4 (Figure 1): A is a circle and B partially overlaps A; now  $p(0^\circ)+p(180^\circ)=1$ , and the claim follows from the IVT on  $0^\circ \leq \theta \leq 180^\circ$ . Case 5: Two arbitrary areas; the same argument as in Case 4 applies with the diameter of A replaced by a line that halves the area of A.

The interviews were semi-structured. Most questions related to features of mathematical proofs in general and pedagogical considerations for teaching proof. The interview began with questions relating to the proofs of the above theorem and proceeded to more general questions. The interviews

were audio-recorded, transcribed and analysed using principles of verbal analysis (Chi, 1997). The analysis was carried out in five steps: (1) Segmenting and reducing: Segmenting the transcriptions into modules that contain an answer to a specific question. Each module was reduced by selecting significant utterances; (2) Coding and organizing: Most categories were created naturally by the interview questions and some were created when reading the reduced data. The relevant utterances were summarized and placed in the appropriate category; (3) Operationalizing evidence: A collection of utterances that constitute evidence for each category was created; (4) Seeking for patterns in the organized data. When such patterns emerged, they were validated by looking for further evidence; (5) Repeating the procedure in order to verify the coding and alter it if necessary.

In this paper, we focus on the lecturer's answers to the following three questions:

1. Which of the two proofs would you use for teaching this theorem, and why?
2. What aspects of the proof do you emphasize when teaching a proof?
3. What language (formal/informal) do you use when teaching a proof?

## Findings

We start by presenting the interviewees' answers to the first question: which of the two proofs they would teach and why. Proof 1 was chosen by three interviewees: Sally, Dana and Max. Max claimed that Proof 1 is more correct and properly built: "[it] is built as a proof: you start at the beginning and reach the end. [In Proof 2] I am told: take a case and prove it... What would happen if there were 79 cases?! ... It's more elegant to find one proof that does not require the separation into cases"; he also stated that "students should learn the proper way to prove claims" and that the many cases of Proof 2 might "drive the student crazy". Dana stated that the division into cases makes "Proof 2 hard to remember" and Sally stated that it worries her: "...I am always concerned that a case is missing, it's stressful...". Proof 2 was chosen by Tara and Anne who stated that it is more intuitive and less 'tricky'. Tara said: "I relate better to the idea of halving the first domain and then the second one, than to the idea of the perpendicular lines". Anne said that "it enables to teach students how to 'play'" and that the gradual increase in complexity allows students to fully understand each case before proceeding.

The lecturers also suggested how to improve the proofs. Sally, Dana and Max preferred teaching Proof 1 but were aware of its difficulties, mainly the 'Deus ex Machina' nature of the function  $r(\theta)$ . Sally suggested to "divide the board, write down the stages and finally ... fill in the details. First the 'how' then ... the 'what'... define a-priori where [you are] heading", because "...completing the details is [only] half of the work...". Max suggested using Cases 1-2 of Proof 2 to increase students' intuition regarding the meaning of the claim. Dana suggested emphasizing one central idea: the construction of the distances. These lecturers chose Proof 1 because it agrees with their beliefs about what a "good, proper mathematical proof" is, but contemplated how to improve its communication to their students. Tara and Anne preferred teaching Proof 2; they felt its intuitive nature is better adapted to their students. The division into cases, a disadvantage for others, is an advantage for Anne, who believes that the gradual increase in complexity improves students' learning experience. Tara said that Proof 2 is more intuitive to her than the perpendicular lines of Proof 1; She said: "...I don't like it when proofs are based on an idea that I would not spontaneously think about... if it can be done... without 'tricks', I prefer it". Yet she suggested shortening the proof by omitting Cases 1-2.

Although these findings indicate different lecturer choices, there were noticeable commonalities in their answers. Firstly, Tara and Max chose different proofs, but were both bothered with the imprecise way of using the IVT and stated that one should explicitly define functions and justify their continuity before applying the IVT. For them, some standard of mathematical rigor is important. Secondly, several lecturers refer to meta-proof issues. For example, Sally refers to a proof plan, Anne to pre-proof activities ('play') and Max to the pedagogical value of using precise language. Thirdly, the lecturers address affective aspects, and subjectivity is demonstrated by the opposite attributes that different lecturers relate to the same proof feature. Whereas Sally and Max feel that the division into cases might disturb the students, Anne sees the gradual increase in complexity as giving students a sense of understanding and stability. Thus, the lecturers' choice of proof is highly influenced by their perception of the students attending the lesson. Moreover, earlier in the interview, when asked about their proof preference some lecturers stated that the choice mostly depends on the intended audience. Sally, for example, stated that Proof 1 is clearer in her opinion but that Proof 2 is better for her students. Then, when asked to choose which proof to teach she chose Proof 1 and described pedagogical ways to improve its presentation. The choice of proof appears to be an amalgam of mathematical and pedagogical considerations, personal preferences and convictions.

In the second question, the interviewees were asked what aspects they emphasize while teaching proofs. They all stated that their answer is population dependent. Table 1 summarizes their answers and reveals that lecturers invest a lot of effort in communicating the proof, and raising students' awareness of meta-proof and rhetorical aspects (e.g., aesthetics, and significance). Tara tries "...to look for... the significance, why this conclusion... [and] the way [it] was derived is important...". Anne focuses on pre-proof activities and states that she partly "... wants to teach them how to transform a 'game' into a proof...how to produce... the simplest example that still maintains the features of a problem, ... [how] to try to prove or refute when you still don't have a clue if the claim is true or false...". Max adds that his verbal explanations are what "really explains it to students".

Highlighted aspects	Suppressed aspects
<ol style="list-style-type: none"> <li>1. Ideas that are:               <ol style="list-style-type: none"> <li>(i) repeated in future proofs or</li> <li>(ii) related to the current content {A, S, D}</li> </ol> </li> <li>2. Sometimes – formality, if the proofs are trivial enough and the concepts have been thoroughly exercised {A}</li> </ol>

**Table 1: Proof features that are highlighted or suppressed while teaching**

In the third question, four were explicitly asked about their use of formal language (the fifth interviewee referred to the use of formal language throughout the interview). Sally used an analogy to explain the importance of using formal language: "... lawyers use words that have meaning only in the context of the law discipline. It's not the same meaning as their dictionary definition..." She says that similarly, students should master the proper way of writing proofs, using the necessary symbols and language. Tara and Anne demonstrate flexibility regarding the use of formality in places where it might obstruct student's learning. For example, Tara states: "in one classroom I might describe the concept of a limit very informally... as a sequence of values getting nearer some value; in a different classroom, I have to use the epsilon-delta definition with extreme formality". Anne admits that "...somewhat reducing the formality" might harm students' understanding but supports her choice by stating that otherwise students may "... lose their grasp of 'the whole'... they need to deal with parts... [and] sub-parts that are not well constructed yet..." Dana's approach marks the other end of the range, for she speaks of 'gluing' things in a non-formal way and clearly expresses her preference to emphasize central ideas rather than to dwell on technical steps. Dana advises students to concentrate on the main, less technical, proof ideas. Thus, the lecturers' answers to the third question reflect a range of attitudes: from a strict use of formal language, via compromises between formality and audience, to an entirely context dependent attitude. They balance between helping the students to be sufficiently acquainted with the customary mathematical language on one hand, and not getting lost in the rigidity and details of extreme formality on the other hand. At the same time, the proof presented to the students should reasonably satisfy some standard of the mathematical community, the same way a legal document should accept approval of law experts.

To summarize, the interviewees discussed a rich collection of proof features, constantly referring to pedagogical considerations. Two themes, subjectivity and context-dependent value of proof features, particularly the type of student population, were prominent throughout the interview.

### **Discussion of the findings within PNR framework**

The findings show that the interviewed lecturers have a clear vision of different mathematical ideas and features of the two proofs, combined with a rich collection of pedagogical considerations. These findings are consistent with the literature (e.g., Hemmi, 2010; Lai and Weber, 2014). However, we wish to focus on the manner in which the lecturers consider their students, i.e. the audience, while teaching proofs. Lai and Weber (2014) explored factors that mathematicians claim to consider when preparing a pedagogical proof and found that audience diversity influenced mathematicians in four aspects: (a) the assumed previous knowledge; (b) the actions that need to be taken to avoid potential student difficulties; (c) using techniques students find familiar or comfortable; (d) what mathematical ideas are emphasized by the proof. Indeed, most of these issues were also raised by our interviewees.

Our data show that when mathematicians teach proofs a tension between two poles arises: the first pole is the wish to present the proofs in a rigorous manner acceptable to professional mathematicians (as Max said "the proper way to prove"); the second pole is the wish to accommodate students' cognitive and affective needs so that they will gain adequate understanding and a rewarding learning experience. This tension is widely found in the literature (e.g., Dawkins and Weber, 2017; Lai and Weber, 2014). Dawkins and Weber (2017), for example, investigate values and norms of

mathematicians regarding proof and acknowledge that sometimes the needs of the mathematical community differ from those of the classroom community, which cannot perfectly mimic practices of professional mathematicians. They claim that expecting students to adopt mathematicians' proof norms without perceiving the underlining values might cause a dissonance between the mathematicians' and the students' communication culture. They also state that one outcome is that "researchers... have sensibly advocated loosening various norms for the purpose of encouraging students' genuine insights" (p. 133). Within PNR, this dilemma is an inherent feature of simultaneously addressing the universal and particular audiences. It is not about "compromising" but about adjusting the argument and creating a shared basis of agreement with the students while maintaining a proof presentation that would still be acceptable by professional mathematicians (possibly imagined as sitting at the back of the class). Moreover, PNR not only relates to the difference between the lecturer's and the students' norms and values but also to other rhetorical and informal features of the proof classroom presentation (Gabel and Dreyfus, 2017), as well as to other types of lecturer-student gaps in the argumentation and their sources.

This may also explain why during the interview, the lecturers frequently answered interview questions focused on mathematical proofs in general by raising pedagogical considerations related to the particular audience, constantly shifting between two perspectives: mathematician and teacher. We give three examples. Sally stated that as a mathematician, she prefers Proof 1, but Proof 2 better fits her students. Nevertheless, when asked to choose a proof to teach she chose Proof 1, suggesting pedagogical ways to improve its presentation. Sally also stressed the importance of formal language in class, but admitted skipping repetitive stages of proofs, and suppressing details that might currently be too difficult for her students. A similar tension can be found in the suggestion Max made regarding the improvement of Proof 1. Max declared the importance of proof formality and preciseness and chose Proof 1 both as his personal preference and as the better proof to teach. However, he suggested improving the presentation of Proof 1 by adding Cases 1–2 of Proof 2, in order to enhance students' intuition regarding the claim's meaning. A similar tension appeared when Anne, who chose to teach Proof 2 for the feeling of understanding it provides referred to formal language by saying that "...one can skip formality if one has the ability to reconstruct it ... but [students] don't know how to do that, so it's a kind of 'pretence' understanding".

Mathematics lecturers address two audiences when teaching proofs: particular and universal. The particular audience is the actual group of students attending the lesson, who bring with them their previous knowledge, attitudes, learning habits, beliefs and cultural conventions. The lecturer needs to address the needs of the particular audience, to maintain a shared basis of agreement with the students and persuade them that the claim was truly proved. In parallel, the lecturer needs to convince the universal audience, which is a mental construct of the lecturer; it may include professional mathematicians, experts of the taught material or admired lecturers. Convincing the universal audience requires different standards of formality, preciseness and rigor. Whenever mathematics lecturers teach proofs, they need to balance between the different requirements of both audiences. The need for this balance is demonstrated, for example, by Dana, who admits that in class she prefers to emphasize important ideas rather than to dwell on technical steps "in an attempt not to give up on classroom proving altogether because then understanding drops to a very low level".

Thus, PNR is a unifying and comprehensive theoretical framework that can be used to interpret a major challenge of proof teaching. Within PNR this challenge is considered an inherent tension that always exists between the need to present a proof that is convincing to the universal audience, in our context a complete, flawless proof accepted by expert mathematicians, and between the need to persuade the particular audience, in our context the students actually attending class. PNR also relates to other rhetorical and informal features of classroom presentation of proof, such as means to endow proof elements with presence (Gabel and Dreyfus, 2017) as well as to lecturer-student gaps in the argumentation and their sources. Therefore, PNR may be used not only to describe mathematicians' proof presentations but also to evaluate the presentations and to provide practical suggestions of how to improve them.

*It is often said that understanding the complex teaching and learning issues at university level requires the networking of several theories. In this paper, we study how the Theory of Didactic Situations and the Anthropological Theory of the Didactic can be combined to address a developmental research issue at university level. We refer to criteria provided by Design-Based Research to compare and contrast the two theories. This preliminary study should allow us to design a teaching intervention related to Calculus at university.*

*Keywords: Calculus, hypothetical learning trajectory, Theory of Didactic Situations, Anthropological Theory of the Didactic, Design-Based Research.*

### **Delimitation of the project's context**

The final aim of our research is to design a teaching intervention in relation to real numbers and numerical sequences at university. At the entrance to university, real numbers and numerical sequences represent an important part of the real analysis curriculum in the mathematical sciences and pre-engineering in France and Tunisia where our experiment will take place. The goal of this chapter is to establish rigorously the properties of real numbers and their interpretation by means of numerical sequences, and its structure is generally founded (as requested by the curriculum) on the continuity principle of the set of real numbers: *Any non-empty subset bounded from above has a least upper bound*. This principle in conjunction with the ordered field properties achieves the implicit axiomatic construction of the theory of real numbers and other properties follow: Archimedean property, density of rational numbers and sequence's interpretation, sequence's interpretation of the continuity principle (monotone convergence theorem), adjacent sequences theorem, Bolzano-Weierstrass theorem and Cauchy completeness theorem. In line with Winsløw, Gueudet, Hochmut and Nardi's claim (2018) about the stability of the mathematical contents (including Calculus) at the first year of university, this chapter requires typical practices involving logical reasoning about the formal existence of real numbers or the aforementioned properties. Relying on different paradigms (e.g., cognitive, socio-cultural, semiotics), research on the secondary-tertiary Calculus transition has highlighted over the years students' difficulties to engage in these practices at the entrance to university and beyond (e.g., Bressoud, Ghedamsi, Martinez-Luaces & Törner, 2016; Winsløw et al., 2018). We decided to use a Design-Based Research approach (Anderson & Shattuck 2012) with the aim of designing a teaching intervention for learning real numbers and sequences that provides details about what is likely to happen and why. The DBR approach leaves an open choice concerning the theories involved in the design. Moreover, comparing and contrasting theories can contribute to improve these theories (Prediger, Bikner-Ahsbahr & Arzarello 2008). Here we have chosen to network the Theory of Didactic Situations (TDS, Brousseau 2008) and the Anthropological Theory of the Didactics (ATD, Chevallard 2015). TDS and ATD are indeed two neighboring theories with

strong epistemological concerns and with the same research program, so that: "[...] *each one reinterprets and reformulates the problems raised by the other.*" (Artigue, Bosch, Gascón & Lenfant 2010, p. 1535). In this paper, we firstly focus on basic variables for comparing and contrasting TDS and ATD by means of the DBR methodology. We secondly present our preliminary thoughts on the elaboration of the Hypothetical Learning Trajectory (HLT) of Calculus at the entrance to university (related to the interconnected properties of real numbers and sequences). The HLT is a fundamental component of DBR. It mainly contains mathematical learning goals, mathematical problems and specific learning and teaching assumptions in the context of these problems; it has a dynamic character and can change during the different phases of the research. The interaction between the HLT and the empirical results is the cornerstone element for developing the teaching intervention.

### **Design-Based Research as a methodological research**

Reports on what is DBR are numerous. In this paper we retain Anderson and Shattuck claim (2012): "Design-based research (DBR) evolved near the beginning of the 21st century and was heralded as a practical research methodology that could effectively bridge the chasm between research and practice in formal education." (p. 16). We focus our description of DBR on its main methodological components: 1) iterative cyclic process; 2) deciding on orienting theory and design guidelines framework; 3) HLT; and 4) selection of research instruments and techniques. The DBR methodology classically consists of intertwined cycles of three phases each: elaboration of the intervention (design); teaching experiments and analysis on the fly; and retrospective analysis. The collaboration between researchers and practitioners (teachers) is the key feature of the quality of the iterative adjustment and refinement of the intervention. This collaboration is carried out through prospective and reflective processes before, during and after each teaching experiment. The results of the retrospective analysis phase mostly supply a new cycle of three phases. Concretely, the research's aim (i.e. the development of an empirically and theoretically grounded teaching intervention for specific mathematics education aims) has to be firstly transformed into research questions and subquestions with the help of the orienting theory and of the design guidelines framework. The design guidelines framework is a theoretical construct describing how to design the intended learning and teaching environment. For an illustration of these choices, see for example the DBR project for statistics education of Bakker and Van Eerde (2015) where a semiotic approach is combined to the Realistic Mathematics Education framework. These theoretical frames guide the development of the HLT through the different phases of the research. In the first cycle, the design phase involves the reflection on what students should learn about the targeted mathematical topics and how this should be done. This first identification leads to the formulation of temporary mathematical learning goals which initiates the design of mathematical problems, identification of learning processes and teacher management of these processes. Informed by concrete mathematical tasks, the HLT is progressively shaped during this phase. An elaborated HLT contains: "[...] *mathematical learning goals, students' starting points with information on relevant pre-knowledge, mathematical problems and assumptions about students' potential learning processes and about how the teacher could support these processes.*" (Bakker & Van Eerde, 2015, p. 446). In the teaching experiment phase, the HLT is used by both teachers and researchers and could be adjusted or changed on the fly (i.e. during the lessons linked to one teaching experiment phase) sometimes by using additional theoretical considerations.

In the retrospective analysis phase, the evolving HLTs are the researcher's guideline to generate conjectures about students' learning and thus to create the teaching intervention. Reciprocally, the teaching intervention is progressively enriched by the evolving HLTs. The DBR methodology involves several instruments and techniques that connect theoretical concerns and concrete experiences in the form of testable hypothesis (potential HLT). For instance, task oriented analysis and longitudinal cyclic approach are useful to test and refine the HLT in the retrospective phase. Researchers who are familiar with TDS can quickly see similarities between Didactical Engineering (DE) as the research methodology of TDS (Artigue, 2000; Brousseau, 2008) and DBR methodology. The specialists of ATD may possibly connect DBR methodology with the theoretical construct of Study and Research Path (SRP) (Chevallard, 2015; Winsløw Barquero, De Vleeschouwer & Hardy 2014). Nevertheless, designing teaching experiments drawing on DE or SRP, specifically in the case of university mathematics education (UME), remains a challenging issue that requires further investigation. We claim that DBR can contribute to this investigation.

## **TDS and ATD from the DBR perspective**

### **Variables of the networking**

We draw here on the methodological components of DBR to generate appropriate variables for comparing and contrasting TDS and ATD. The selection of these variables is conducted with respect to the strategies that have been discussed and adopted by the researchers in the field of networking theories (e.g., Kidron et al., 2018). For the sake of clarity, we find helpful to firstly reorganize the whole DBR methodology through three stages according to the developmental process of HLTs: 1) the upstream stage; 2) the ongoing stage; 3) the downstream stage. In the following description of each stage, the role of both teachers and researchers and their potential collaboration, if any, are carefully stated. The instruments and techniques (questionnaires, interview, methods of analysis, etc.) used are a main issue that we cannot discuss here. The upstream stage is substantially linked to the chosen theoretical approach and leads to the formulation of the research question or problem by means of the epistemological and cognitive assumptions of this approach. At this stage, researchers need to carefully reflect on the (educational) aim of their project/intervention, by using two questions: V1: how to model the mathematics to be learnt and to be taught? V2: how to model mathematics learning and teaching processes? These questions represent the two first variables V1 and V2. The ongoing stage involves the development of series of HLTs and should be carried out by both the researchers and the teachers mainly at the experimental step. The potential variables are then: V3: the design guidelines; V4: the process of implementation. The downstream stage is related to the evolving HLTs and the improvement of the intervention, and it is supposed to be conducted by the researchers. The last two variables are: V5: the potency of the elaborated HLT and V6: transferability of the teaching intervention in other contexts.

### **Primary interpretations of the variables for TDS and ATD**

Starting from a concrete phenomenon or a set of data, the problem of the questions formulated by theories on them, was raised from the beginning by the researchers working on networking theories (Kidron et al., 2018). In the case of our project, the research question refers to the design and implementation of a replicable teaching intervention that focuses on transition issues and enhances

students' learning of Calculus at the beginning of the university. A more general question forms the basic goal of the *research program* of both TDS and ATD: 1) TDS's formulation: *"how to design, regulate and make controlled observations of experimental situations where mathematical content appear as the optimal way to address a mathematical problem?"* (González-Martin, Bloch, Durand-Guerrier & Maschietto, 2014, p. 120- slightly adapted); 2) ATD's formulation: *"how to design a didactic organization that places central questions at the starting point of mathematical activity, making mathematical content appear as models constructed to provide answers to these questions? And what is the ecology of these didactic organizations?"* (Winsløw et al., 2014, p. 106). In the case of our study, the refinement of our research question depends primarily and mostly on the values of each of the following variables.

**V1.** The ATD models mathematics through the construct of Epistemological Reference Model (ERM) which is formulated by taking into account all the institutions involved in the process of didactic transposition (i.e. the adaptation of mathematical scholarly objects to mathematical objects to be taught and learnt). The construct of Fundamental Situation (FS) models mathematics in the TDS approach. Its formulation takes into account the sources of the meanings of mathematical objects and defines the conditions for saving these meanings when they are concerned by didactic transposition.

**V2.** In TDS, the process of learning and teaching mathematics is modeled under the central construct of Situation: the system of relationships between the students, the teacher and a mathematical milieu (Ghedamsi, & Lecorre, 2018). Situation is defined by means of two levels: didactic (situation of institutionalization) and a-didactic (situation of action, situation of formulation, and situation of validation). In the didactic level, the use by the teacher of knowledge developed by the students in a-didactic level improves learning and its link to the teaching goal. In the case of ATD, this process is modeled into didactical organization (a set of didactical praxeologies modeling teaching and learning activities) which is strongly connected to the mathematical organization (a set of mathematical praxeologies) that this didactical organization aims to implement. The different didactical organizations are defined by means of the notion of moment of study: exploratory moment, technical moment and technological moment (Bosch & Gascón, 2001).

**V3.** In the case of TDS, the design guidelines are divided into two steps. In the preliminary step, the researchers conduct an epistemological, cognitive and didactical analysis in order to identify specific characteristics of the targeted mathematical objects, the complexity of the potential cognitive process for students and the actual teaching environment. These analyses aimed to identify the didactical variables (namely the parameters that influence students' learning of the targeted mathematical object(s)) that structure the whole design. In the second step, the construct of the milieu which structures the interactions between students, the teacher and the mathematical milieu in the a-didactic level is used to test several values of these variables. The researchers deploying ATD analyze all the steps in the didactic transposition process linked to the targeted mathematical objects or domain of objects: their origin, their relation with other objects, their integration in mathematical praxeologies, etc. in order to elaborate the related ERM and then to establish the generating question. This question should go over the school level (see the notion of scale of levels of determination (Bosch & Gascón 2006)) and be linked to specific subjects raised by the society. The study of this question will lead to new questions that make the study open and the learning goal not determined in advance. However,

in the rare case where the analysis must guarantee that students meet specific praxeologies, the learning goal should be clearly defined. Otherwise, it is the responsibility of students and teachers, during the study, to choose the trajectory which will determine the praxeologies they encounter.

**V4.** The implementation with ATD follows at least three criteria: a) the distribution of responsibility between teacher and students is continuously renegotiated, b) the access to intermediate answers is mediated by media (books, journals, TV, internet, etc.) and validated with regards to the didactical milieu, c) the final answer, if any, must include a learning goal. In the case of TDS, the improvement of the interactions among students is ensured by the teacher's enrichment of the mathematical milieu. Depending on the complexity of the mathematical objects, especially at the entrance to university, the teacher can manage the values of the didactical variables without minimizing students' responsibility in generating knowledge. The experimental situation evolves according to the rules of the didactic contract: *"the implicit set of expectations that teacher and students have of each other regarding mathematical knowledge and regarding the distribution of responsibilities during the teaching and learning processes."* (González-Martin et al., 2014). The teacher should support the change in the didactic contract by strengthening the link between the outcomes of the a-didactic level and the institutionalization level. Due to space constraints, we will not say more about the remaining variables. Figure 1 synthesizes the values of these variables for TDS and ATD.

	TDS	ATD
Global Vision	Socio-constructivist vision of learning and teaching mathematics.	Socio-cultural vision of learning and teaching mathematics.
V1	Fundamental situation of a mathematical object: Mathematical game (or problem). The problem should satisfy the same criteria as those developed in mathematical games theory. The object targeted by the problem should not be explicitly referenced and must provide an optimal method for solving it.	Epistemological Reference Model (ERM) related to mathematical object or domain of objects: Organization of local and regional mathematical praxeologies through sequences of connected praxeologies. Praxeologies (composed of two interrelated blocks: practical and theoretical) model human activity (including mathematical).
V2	Situation at two levels didactic and a-didactic	Didactical organization and moments of study
V3	Preliminary design	
	Researchers: Identification of didactical variables to determine global and local organizations of the design.	Researchers: Identification of a question with generating power for praxeologies and with significance in the context of students' life.
	A priori design	
	Researchers/Teachers: set the variables at certain values to achieve the learning goal.	Researchers/Teachers: the question is rarely accompanied by a learning goal.

V4	Teachers: a) more active role of teachers at the university (manage the values of didactical variables that are already decided), b) gradual change of didactic contract.	Teachers: a) distribution of responsibilities between teacher and students, b) dialectic media/milieu (Chevallard, 2008), c) final answer, if any, with a learning goal.
V5	Researchers: Testing the learning goal and the validity of the theoretical assumptions of TDS through the actual teaching and learning process	Researchers: Testing the actual teaching and learning process.
V6	Reproducibility and paradigmatic didactic contracts	Ecological issues (institutional conditions and constraints; scale of levels of determination)

**Figure 1: TDS and ATD from the DBR perspective**

This comparison enables the discussion on the potential of each theory by means of DBR methodology. In our case, this discussion will be developed through the project of elaborating a teaching intervention for real numbers and sequences at the entrance to the university. Among the DE studies on the transition towards university Calculus, Ghedamsi (2008) (see also González-Martin et al., 2014) discussed ways of designing a milieu that helps students deepening their understandings of the interrelated properties of real numbers and sequences at the entrance to the university. The epistemological hypothesis of the design is formulated as follows: numerical approximation methods connect the practical and theoretical existence of the mathematical objects stated in the interrelated properties of real numbers and sequences (see first section). These properties become the arguments to validate the used methods. The elaboration and the experimentation of the design have been undertaken through TDS constructs where the epistemological hypothesis has been cognitively formulated so that it can be verified or falsified. In the last section, we use the choices made in this DE as a filter to start a brief discussion on how to elaborate the HLT of the present research.

### **First steps towards the elaboration of the HLT**

This paper presents a theory networking study which is a preliminary step required to design the HLT. The succinct comparison above highlights the necessity to keep the coherence of the whole theoretical foundations when engaging in an intervention project. We retain three fundamental results from this study: 1) the two theories complement each other to address transition issues; 2) the implementation of the design in the context of university mathematics needs the planning of an ad-hoc didactical milieu; 3) the study of the replicability of the intervention necessitates the identification of paradigmatic university expectations about learning and teaching mathematics. We will not develop more the conclusion of this study; we have chosen to end this paper by presenting the first step towards the elaboration of the HLT. The process of modeling the mathematical contents related to the interconnected properties of real numbers and sequences is a fundamental step towards the elaboration of the HLT. The epistemological aspect constitutes the starting point for engaging the elaboration of the design for both theories i.e.: 1) the design of a collection of mathematical problem(s) where the interconnected properties of real numbers and sequences appear as providing the optimal solution, according to TDS; 2) the design of central questions where the interrelated properties of real numbers and sequences appear as models (mathematical praxeologies) constructed

to provide answers to these questions, from the ATD point of view. As claimed by TDS, the construction of mathematical problems, that create the need for these properties, requires firstly investigating the mathematical meaning of their relationship and its fundamental significance. This investigation should be done by using fundamental mathematical sources (i.e. the several theorizations of the set of real numbers) and by deepening insights on their historical growth. As researchers involved in TDS approach know, designing a collection of problems that connects rationally these properties remains a real challenge. The main reason seems to be that the didactical variables that may emerge must preserve the meaning of the relationship between these properties at the moment of their transformation into mathematics to be learned. For instance, the DE experimented by Ghedamsi (2008) shows that the mathematical organization related to the interconnected proprieties built upon the expectations of the curriculum (i.e. start with the self-evidence of the continuity principle) does not fit cognitive requirements. The fundamental reason was that during the teaching experiments, the students employed spontaneously the nested intervals theorem which is closely linked to the adjacent sequences theorem. However, the nested intervals theorem, in conjunction with the Archimedean property, generates all the targeted properties and leads to another foundation for real numbers theory. So, this theorem deserves more attention in the elaboration of the HLT. ATD materializes a mathematical organization by a set of connected mathematical praxeologies. In the case of the properties of real numbers and sequences, each set of praxeologies, including the one proposed by the official curriculum, is grounded on a specific theory of real numbers. Thus, the theoretical components of each set achieve a fundamental significance (in the terms of TDS) of the relationship between these properties. In the case of our project, the mathematical problems of the HLT must include in particular the theoretical aspects of the mathematics involved. At least two questions may guide the elaboration of these problems: what are the mathematical meanings produced by each set of praxeologies? How should several sets of praxeologies be combined to support learning? These comments provide some information to start thinking about the development of the HLT but to go further supplementary analysis is needed, in particular for formulating the learning goals.

*The notion of integral is usually first introduced to engineering students in their calculus courses before later being used in their professional engineering courses. In this paper we analyse the textbooks used as main references in two engineering courses: a calculus course and a mechanics of solids course. Specifically, we compare how each textbook presents the task of sketching the graph of an antiderivative in the context of kinematics. Our results indicate that the mechanics of solids course presents this task by emphasising the notion of area and basic geometric calculations, using different notation and rationale than in the calculus course. We discuss the possible impact of these differences on the training of engineers.*

*Keywords: Mathematics for engineers, teaching and learning of calculus, textbook analysis, anthropological theory of the didactic, antiderivative.*

## Introduction

The mathematical education of engineering students is a topic of increasing concern for mathematics education researchers, university mathematics teachers and professional associations (Bingolbali, Monaghan, & Roper, 2007, p. 764). In particular, calculus is considered an important component of basic engineering curriculum, providing notions, skills, and competences that are deemed necessary for the following professional courses. Nonetheless, the difficulties that calculus courses pose for students are not restricted to engineering programs (Rasmussen, Marrongelle, & Borba, 2014), and they may become a factor leading to the abandonment of STEM degrees (Ellis, Kelton, & Rasmussen, 2014).

In the case of engineering, there is still a lack of understanding about how calculus notions are used in professional engineering courses; and by better understanding this use, some changes could be made to the content of calculus programmes. For instance, our previous research (González-Martín & Hernandez Gomes, 2017, 2018) indicates that the notions of bending moment and first moment of an area (used in civil engineering) are used in tasks that are not present in calculus courses, despite these notions being defined as integrals. Nor does their use require techniques that are explicitly derived from practices introduced in calculus courses. In the case of the notion of bending moment (González-Martín & Hernandez Gomes, 2017), some professional engineering textbook tasks require students to sketch the graph of the antiderivative of a given function. For this reason, we are currently interested in the connections between functions and antiderivatives, as well as their graphic interpretation, in professional engineering courses.

Some difficulties that students encounter in interpreting the graph of a function and the graph of its derivative are well known. For instance, Borgen and Manu (2002) identified that some students may be able to perform the necessary calculations to find the stationary points of a function, but that the

same students would not see these points as a part of the graph. In addition, Ubuz (2007) identified several difficulties students encounter in sketching the graph of the derivative of a function by looking at the graph of this function. In the same vein, some studies point out students' difficulties relating the graphs of a function and its antiderivative. Swidan and Yerushalmy (2014) found that some students try to guess the shape of the antiderivative function based on the position of the function graph, instead of correlating the y-value of the function graph with the tangent slope value of the antiderivative function graph. Finally, Marrongelle (2004) investigated how undergraduate students in an integrated calculus and physics curriculum used physics to help them solve calculus problems. The circumstantial evidence exposed in this study "supports the view that students come to understand graphs, as well as other mathematical representations, by recalling or imagining physical events" (p. 271).

Because we are interested in the training of engineering students and how they use mathematics in their professional courses, we examine whether the ability to visualise and interpret graphs of antiderivatives is required in professional engineering courses (besides the notion of bending moment) and how this relates to practices taught in calculus courses. Our research program's first step is to analyse textbooks used in these courses. In the next sections, we present the theoretical tools we used in our study, as well as our methods and main results.

## Theoretical framework

To analyse the use of visualisation and the production of graphs in professional engineering textbooks, we use tools from the anthropological theory of the didactic (ATD – Chevallard, 1999). ATD considers human activities, as well as the production of knowledge, as institutionally situated; this means that knowledge about these activities and why they are important (or why we need to learn them) is also institutionally situated (Castela, 2016, p. 420).

One key element of ATD, essential in our analyses, is the notion of praxeology (in the case of the study of mathematical activity, mathematical organisation or mathematical praxeology – MO hereinafter). A praxeology  $[T/\tau/\theta/\Theta]$  is formed by four elements: a type of task  $T$  to perform, a technique  $\tau$  which allows the task to be completed, a rationale (technology)  $\theta$  that explains and justifies the technique, and a theory  $\Theta$  that includes the rationale. These elements are grouped in the practical block  $[T/\tau]$  (or know-how), and the knowledge block  $[\theta/\Theta]$  which describes, explains and justifies what is done. To describe mathematical knowledge (including its production, its use, and its learning), these two blocks permit an analysis of what needs to be done, how it is done, and the justifications for this. ATD distinguishes different types of MO: punctual, which are associated with a specific type of task; local, which integrate multiple punctual MOs that can be explained using the same technological rationale; and regional, which integrate local MOs that accept the same theoretical rationale (Barbé, Bosch, Espinoza, & Gascón, 2005).

Knowledge (and also praxeologies) can be used in institutions other than where it was created, which implies transpositional effects on the concerned praxeologies (Chevallard, 1999), causing some (or all) elements of the original praxeology to evolve. Although these changes may have little impact on experts, they may make it difficult for students to recognise "the same" knowledge used in another institution. Therefore, it is important to analyse the types of tasks and techniques as well

as the rationales employed (for instance, in different courses) to identify the challenges these transpositional effects pose for students. To that end, our research identifies specific local MOs present in professional courses; we analyse how calculus notions are used (practical block) and the explanations given (knowledge block) in relation to the way the notions are usually presented in calculus courses.

## Methodology

As we have noted, the study presented in this paper continues our previous work examining how calculus notions are used in professional engineering courses. Our latest work focuses on future engineers' use of integrals (first, to define shear forces and bending moments, and second, to define the first moment of an area – see, respectively, González-Martín & Hernandez Gomes, 2017, 2018), which is why we are pursuing the current study along these lines. As in all our studies concerning future engineers' use of calculus notions, we worked with teachers of professional engineering courses (all of them holding engineering degrees, some of them active engineers), who guided us in identifying key notions of engineering that are based on calculus notions and helped us grasp the important elements of these notions. Our current study focuses on two courses at a Brazilian university (although the textbooks we analysed are distributed internationally): Calculus (I and II), and Mechanics of Solids for Engineers. In the latter course, students need to work with functions, interpreting their graph and constructing their antiderivative graph to solve problems related to motion. At this stage of our research, we chose to work with the reference texts for each course. Guided by our collaborating engineering teachers, we examined the following books: *Calculus*, by Stewart (2012) and *Vector Mechanics for Engineers: Statics and Dynamics* (Beer, Johnston, Mazurek, & Cornwell, 2013), an international book used in the discipline of mechanics of solids. We consider the courses to be two different institutions, since practices vary greatly between them.

At this university, calculus is taught in the first year of the engineering program over two semesters, in two courses: Calculus I and Calculus II. Integrals appear towards the end of the first course and are the main topic in the second course (the second author of this paper has taught Calculus I for 15 years and Calculus II at this same university for two years). Both courses follow the structure of Stewart (2012) fairly closely, but it is worth mentioning that the Brazilian version of this textbook is divided in two volumes: volume 1 (Calculus I - chapters 1 to 6 of the international edition) and volume 2 (Calculus II - chapters 7 to 10 of the international edition). Mechanics of Solids is taught during the third semester of the program (second year), and, as stated above, the main reference for this course is Beer et al. (2013). We identified the pages in Stewart (2012) covering the introduction of integrals, and identified the pages in Beer et al. (2013) where content related to kinematics of particles in one dimension is taught. Within these pages, we then pinpointed tasks related to sketching the graph of an antiderivative and the proposed technique(s), paying attention to the use of given definitions and properties. We also identified each task's rationales (technologies) and whether they are implicit or explicit. Therefore, for each book, the identification of common rationales allowed us to recognize local MOs, which enabled us to propose an overall organisation for the content related to sketching the graphs of antiderivatives for each book. The next section provides specific details of our analysis.

## Data analysis and discussion

### Organisation of Stewart (2012)

The content concerning integrals in volume 1 of the Brazilian version of Stewart (2012) is distributed among chapter 5 (integrals), 6 (applications of integration), 7 (techniques of integration), and 8 (further applications of integration). In these chapters, content is basically structured using two local MOs. The first,  $MO_{M1}$ , presents notions and results justified by the definition of integral, the use of limits, and some theorems. It informally introduces Riemann sums to define definite integrals, interpreting them as areas, and leads to the Fundamental Theorem of Calculus (FTC) and the calculation of definite integrals using Barrow's rule; this then leads to some applications of the integral (area, volume, etc.). The tasks involve the use of the sigma notation, calculating integrals using series, calculating areas, proving some properties, and so on. The second,  $MO_{M2}$ , although it requires knowledge of the notion of integral, makes use of many algebraic properties of functions. It introduces techniques for calculating indefinite integrals (immediate integration to begin with, followed by various integration techniques). Many of the techniques used in  $MO_{M2}$  are derived from  $MO_{M1}$ .

The word antiderivative appears in the book for the first time in chapter 4 to introduce its definition: "A function  $F$  is called an antiderivative of  $f$  on an interval  $I$  if  $F'(x) = f(x)$  for all  $x$  in  $I$ ." (Stewart, 2012, p. 344). The connections between the graph of a function and its antiderivative are explained only in chapter 5, as a part of  $MO_{M1}$ , among other tasks of this MO. Section 5.3 presents the FTC, which is followed by an application to sketch the graph of the antiderivative of a function ( $g(x) = \int_0^x f(t)dt$ ) knowing the graph of  $f(x)$ . The technique consists of estimating the area under the curve up to certain points (based on the technology that an integral represents an area). For instance, for the graph of Figure 1a, the value of  $g(1)$  corresponds to the area of a triangle; the value of  $g(2)$  corresponds to the area of the triangle and the rectangle; for  $g(4)$  we can estimate that:  $g(4) = g(3) + \int_3^4 f(t)dt \approx 4.3 + (-1.3) = 3.0$  (Figure 1b). Students are given five exercises to practice this technique. A second technique to validate the sketch of the graph of  $g(x)$  is based on the fact that it is an antiderivative, and by estimating the slopes of tangents at different points we should get the graph of  $f(x)$  (Figure 1c). Note that this technique could be seen by students as coming from another  $MO_{M3}$  (developed in the chapters on derivatives – section 4.3. *How derivatives affect the shape of a graph* – and using the relation between the sign of the derivative and the shape of the graph as technology). Tasks involving the connection between the graph of a function and its antiderivative appear spread out until chapter 7, but in all these cases the technique calls for validation using notions from derivatives exclusively (increase, decrease, maxima, and minima). We find, for instance, arguments such as: "Notice that  $g(x)$  decreases when  $f(x)$  is negative and increases when  $f(x)$  is positive, and has its minimum value when  $f(x) = 0$ . So, it seems reasonable, from the graphical evidence, that  $g$  is an antiderivative of  $f$ " (Stewart, 2012, p. 409).

The number of exercises in which students are asked to relate the graphs of a function and its antiderivative is quite limited: seven exercises in section 5.3 (only five require students to sketch the graph of the antiderivative by hand), four exercises in section 5.5, five exercises in the summary of

chapter 5, four exercises in section 7.1, six exercises in section 7.2, and two exercises in section 7.4. None of them has a context of motion.

**Figure 1. Solved example showing how to sketch the graph of a antiderivative (Stewart, 2012, p. 387)**

### Organisation of Beer et al. (2013)

In Beer et al. (2013), chapters 1 to 10 are devoted to statics. The study of dynamics begins in chapter 11, where the graphic interpretation of antiderivatives appears. This chapter deals with particles in rectilinear motion; that is, the position, velocity, and acceleration of a particle. This chapter presents an MO<sub>E1</sub> with the main goal of studying kinematics problems. It uses several elements from MO<sub>M3</sub> to introduce the notions of average and instantaneous velocity and acceleration. The task of sketching graphic solutions is introduced at the end of the chapter, section 11.7 (pp. 632-634), as a complimentary technique to the analytical approach. We focus our analyses on this part, comparing with the approach to solve graphic tasks in Stewart (2012). A first graphic interpretation of these elements appears on page 606, relating the graphs of a particle's position ( $x = 6t^2 + t^3$ ), velocity, and acceleration (Figure 2). Note that the notation used in MO<sub>E1</sub> is different from that used in the calculus textbook, particularly the use of  $x$  as a dependent variable (compare Figures 1 and 2).

**Figure 2. Graphs of position, velocity, and acceleration (Beer et al., 2013, p. 606)**

On page 632 we find the type of tasks in which we are interested: the introduction of graphic techniques to solve problems involving rectilinear motion. The book states that both  $v = dx/dt$  and  $a = dv/dt$  have a geometrical significance and that  $v$  and  $a$  can be seen, respectively, as the slope of  $x$  and  $v$  (p. 632). This fact, sustained by elements from MO<sub>M3</sub>, leads to the introduction of the backwards process to sketch the  $x-t$  and  $v-t$  graphs given the  $a-t$  curve (Figure 3). This technique is based on elements from MO<sub>M1</sub>. We note, however, that in MO<sub>M1</sub>, elements related to this visual interpretation are rather marginal. There is also no physical interpretation, and different notation is used. In particular, after presenting cases where  $a$  is constant and linear, the following technique is given: “In general, if the acceleration is a polynomial of degree  $n$  in  $t$ , the velocity will be a polynomial of degree  $n + 1$  and the position coordinate a polynomial of degree  $n + 2$ ; these

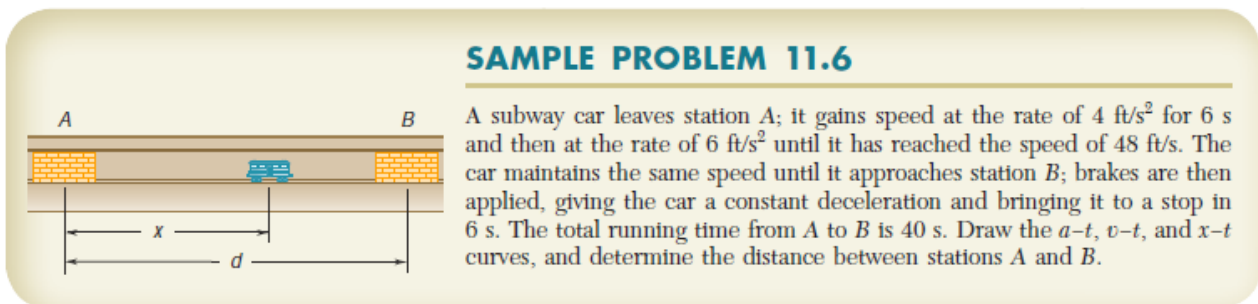

**Figure 3. Backwards process**  
(Beer et al., 2013, p. 632)

polynomials are represented by motion curves of a corresponding degree.” (Beer et al., 2013, pp. 632-633)

We note that this technique is introduced almost as a mnemotechnic rule, without any explicit connections to elements of  $MO_{M1}$  or  $MO_{M2}$  (where techniques of integration are studied). We also observe that it is written using terms from  $MO_{E1}$ , and not explicitly relating to the language used in calculus. These elements are used to solve problems such as the one in Figure 4. The application of the given technique, as well as basic geometric considerations, leads to the solution in Figure 5.

Two main observations can be made: 1) the sketching of the antiderivative is based mostly on explicit elements from  $MO_{E1}$ , which are implicitly related to elements of  $MO_{M1}$  and  $MO_{M3}$ ; 2) however, we note that the technique in  $MO_{E1}$  calls attention more directly to the analysis of the area under the curve and to geometric considerations, whereas the tasks of sketching an antiderivative graph introduced in  $MO_{M1}$  shift mostly to properties of the derivative

(from  $MO_{M3}$ ). Moreover, this section of the book groups together 28 exercises for students to practice this type of task. One factor that may hinder students’ appropriation of this type of task is that the technique presented relies more heavily on basic geometric considerations, does not make explicit connections with the rationale from the calculus book, uses many interpretations based on area and kinematic ideas, and uses sensibly different notation.

**Figure 4. A kinematic problem** (Beer et al., 2013, p. 634)

**Figure 5. Solution of sample problem 11.6** (Beer et al., 2013, p. 634)

## Final considerations

Our results indicate that there is an important rupture in the study of a similar task (sketching the graph of an antiderivative) as presented in two different textbooks used in two different courses. In the calculus book, the task is presented marginally, with a first technique practised in only five exercises and a second technique that emphasises properties of derivatives without taking into account students' known difficulties with the graphic interpretation of the derivative. On the other hand, the engineering book emphasises interpretations using the notions of area and kinematics, which seems to be a way of helping students better grasp antiderivatives graphs (Marrongelle, 2004). An important element to take into account is that the presentation of the task in the mechanics of solids book (through  $MO_{E1}$ ) does not make explicit connections to the content and techniques of the calculus book (mostly, through  $MO_{M1}$  and  $MO_{M3}$ ).

These findings are coherent with our earlier results concerning other engineering notions (González-Martín & Hernandez Gomes, 2017, 2018). Our previous research indicates that in professional engineering courses, although integrals are used to define certain engineering notions, tasks and techniques are presented without an explicit connection to the language and rationale of calculus, and the many techniques learned in calculus courses are not called upon to solve engineering tasks. We believe that an important element of students' difficulties in seeing the connection between calculus and their professional courses may be due to the following: although the "same" notions are used in both courses, they are used with different techniques and rationales, which may hinder students' ability to recognise these notions. Our results also indicate that a task such as the graphic sketching of an antiderivative (and its interpretation) is performed in at least two engineering courses: strength of materials (bending moments) and mechanics of solids (kinematics). More research is needed to identify whether this type of task is performed in other courses, which may justify spending more time on it in calculus courses.

Finally, we highlight the fact that the books analysed in our previous papers and in this one are of international distribution, so our analyses, although restricted to two different books, may be representative of a general situation in engineering programs. Moreover, the results regarding different topics seem to go in the same direction. We believe that more research is needed to better understand the real use of calculus notions in professional engineering courses, as well as teachers' practices and whether these practices reproduce what is presented in the reference books, to have a more precise idea of how these notions are actually introduced and used. Research on these issues will help advance an international discussion about the content traditionally taught in calculus courses and its adequacy in training engineers (especially in light of the fact many students abandon their programs due to their failing of calculus courses). Our research program intends to contribute to this discussion and our results will be the topic of future publications.

<sup>1</sup>Center of Research and Advanced Studies IPN, Mexico; arivera@cinvestav.mx

<sup>2</sup>Universidad Autónoma Metropolitana, Mexico; kaguirre@uam.mx

*In this paper, we examine the conditional reasoning of 14 undergraduate Mathematics students. The used instrument consisted of four questions in the context of the essential contents of Calculus. The analysis was based on the written answers given by students and five semi-structured interviews. We found two important logical flaws that prevailed among students' reasoning: 1) use of the invalid inference denial of the antecedent, and 2) incorrect use of negations of conjunctions involved in a structure of the type  $P \rightarrow Q$ .*

*Keywords: Calculus, advanced mathematical thinking, logical reasoning.*

### Introduction

In an undergraduate degree, a first course in Calculus is actually a course about its foundations. In this type of course, students are required to develop their mathematical and logical reasoning, specifically their conditional reasoning. Students' difficulties in conditional reasoning tasks have been demonstrated in several investigations (Hoyles & Küchemann, 2002). Some of them consisting of obtaining valid inferences from a rule given in the form  $P \rightarrow Q$ , and a minor premise, for example to assume  $Q$  or not  $P$  (Evans, Handley, Neilens, & Over, 2007; Inglis & Simpson, 2008). In general, given a statement  $P \rightarrow Q$  there are four commonly drawn types inference, two are valid and two are invalid. The valid inferences are modus ponens (MP) ( $P \rightarrow Q$ ) and modus tollens (MT) ( $\text{not } Q \rightarrow \text{not } P$ ); the invalid inferences are the denial of the antecedent (DA) ( $\text{not } P \rightarrow \text{not } Q$ ) and affirmation of the consequent (AC) ( $Q \rightarrow P$ ). There are three types of contexts where tasks of this kind can be made: verbal and mathematical contexts (Stylianides, Stylianides & Philippou, 2004), and abstract context (Evans et al., 2007; Inglis & Simpson, 2008; Attridge & Inglis, 2013). Specialized literature reported that verbal and mathematical contexts can influence when a logical inference is made (see, for instance, a study carried out by Stylianides (2004) on the use of MT inference in a verbal and mathematical contexts). In this paper, we use Toulmin's scheme to study the following question: can invalid inferences be identified from a conditional mathematical proposition by students who have completed a first course of university Calculus?

### Theoretical Framework

In this work we used the term difficulty as Gueudet (2008), that is: "the association of an inadequate mathematical production and of various levels of factors likely to have caused this production" (p. 239). On the other hand, we will understand conditional reasoning as

those inferences that can be made from a rule –major premise– of the form “ $P \rightarrow Q$ ” and a given minor premise, for example, suppose  $Q$  or not  $P$ . In general, the statement “ $P \rightarrow Q$ ” lead to four types of inferences summarized in Table 1.

Inference	Premise	Conclusion	Legitimacy
MP	$P$	$Q$	Valid
DA	Not $P$	Not $Q$	Not valid
AC	$Q$	$P$	Not valid
MT	Not $Q$	Not $P$	Valid

**Table 1: Model of logical inferences**

In our research we examined the performance of 14 students –who had successfully completed a first course in university Calculus– through a task that included DA inference in the context of Calculus. Two questions were proposed (P1 and P2) in which the students were to use fundamental concepts of Calculus already learned with in their previous course, and two auxiliary questions written in two versions (P1a and P1b) with the purpose of minimizing the possible influence of context on the students' reasoning.

We used Toulmin's argument pattern (TAP), to analyze arguments students provided to support their written answers. This scheme was designed to analyze arguments from different scientific and philosophical areas, and it has become an important instrument in mathematics education researches as a way to analyze arguments (Pedemonte, 2007; Simpson, 2015; Zazkis, Weber & Mejía, 2016). The scheme focuses on the content of the arguments and not on their logical structure. According to Simpson (2015), many authors adapt the Toulmin's scheme to their data and intentions for analysis. Toulmin identifies six elements in his model: Data (D), the available information which the claim is based; Conclusion (C) what is stated; Warranty (W) that justifies the transition of data to conclusion; the support (S) where warranty backs, for instance, a law, a theorem or a theory; a modal qualifier that assigns the degree of certainty in the conclusion, words such as probably, always, sometimes, never are examples of modal qualifiers; finally, Toulmin incorporates into his model the conditions of rebuttal (R) that show the possible invalidity of the conclusion (Toulmin, 2003; Simpson, 2015).

Toulmin's argument pattern and the logical inferences model were appropriate to analyze the students' written answers. By mean of the use of these two tools, we were able to specify and analyze both the structure and the content of the arguments.

## Methodology

The research instrument is composed of two questions (P1 and P2) that involved the use of fundamental concepts of Calculus studied in the first semester in Mathematics; and one auxiliary questions, written in two version (P1a and P1b), whose purpose were to minimize

the possible influence of the context in students' reasoning. Invalid DA inference has been considered within P1 and P2 answers options.

P1 (Weierstrass Theorem) If  $f$  is continuous in interval  $I$ , which is closed and bounded, then  $f$  is bounded and has a maximum in  $I$ . What would you say if interval  $I$  is not bounded? Indicate which of the following statements are true.

a) The theorem states that, if the three conditions are fulfilled, then  $f$  is bounded and has a maximum. Since  $I$  is not bounded, then  $f$  has not maximum; b) The theorem does not establish anything, if any of the hypothesis is not fulfilled; c) Since  $I$  is not bounded, then  $f$  is not bounded in  $I$ ; d) Although  $I$  is not bounded,  $f$  can be bounded and have a maximum.

P2. (Quotient Law of Convergent Sequences) Let  $(a_n)$  and  $(b_n)$  be two sequences of real numbers. If they fulfill: 1)  $\lim_{n \rightarrow \infty} a_n$  exists, 2)  $\lim_{n \rightarrow \infty} b_n$  exists, and 3)  $\lim_{n \rightarrow \infty} b_n \neq 0$ . Then,  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right)$  exists and  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right) = \frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ . Based on this theorem, indicate which options are true and which are false:

a) If  $\lim_{n \rightarrow \infty} b_n = 0$ , then  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  is not defined; b) Theorem states that if the three conditions are fulfilled, then  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right)$  exists. Therefore, if  $\lim_{n \rightarrow \infty} b_n = 0$ , we can affirm that necessarily  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right)$  does not exist; c) Theorem does not state anything if any of the hypotheses is not met; d) Even when  $\lim_{n \rightarrow \infty} b_n = 0$  occurs, the  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right)$  may exist.

In relation to the P2 question, we assumed that the prohibition on the division by zero would influence the inferences of the students (Tsamir & Sheffer, 2000; Kajander & Lovric, 2018). To minimize the impact of this prior knowledge, we opted to include an auxiliary question in our research instrument, which refers to the definition of the derivative of a function in its two versions:  $\lim_{h \rightarrow 0} \frac{f(x+h)-f(x)}{h}$  (P1a) and  $\lim_{x \rightarrow a} \frac{f(x)-f(a)}{x-a}$  (P1b). The purpose of considering two versions of the definition of the derivative of a function was to investigate if students would accept some quotients, whose denominator tends to zero for its popularity as consolidated topics in Mathematics, for example, P1a; or whether they actually apply the concept of limit. In addition, we considered both expressions thinking in the possibility of some students would know the definition of derivative in one or another version.

The research instrument was applied to 14 students who had completed their first university course in Calculus at the Facultad de Ciencias de la Universidad Nacional Autónoma de México (UNAM). Due to the incorporation of the auxiliary question (in its two versions), we decided to apply the research instrument in two sessions so that, it would not immediately influence the students' answers to P2. In the first session, students formed two groups: we applied (P1 and P1a) to one group and (P1 and P1b) to the other. After two days, the second session took place. Question P2 was applied to both groups at the same time. Experimentation

lasted 35 minutes. To deepen the arguments that students provided to support some of their answers, we carried out five semi-structured short interviews of 15 minutes.

Questions P1 and P2 have the same logic structure, see Figure 1.

**Figure 1: Logic structure of questions P1 and P2**

Question P1 has two correct answer options b) and d), the first makes clear the impossibility of decision of the theorem if any of the three hypotheses  $A$ ,  $B$  or  $C$  are not satisfied; and the second, i.e. d), alludes to the possibility that when hypothesis  $C$  is not satisfied, there are particular cases in which statements  $D$  and  $E$  are fulfilled. The answer options a) and c) are incorrect and contemplate the DA inference.

Question P2 has three correct answer choices: a) it is a distractor, b) it refers to the impossibility of deciding the theorem when one of the hypotheses is not satisfied; and option d) again opens the possibility that even when  $A \wedge B \wedge \neg C$  occurs,  $D$  and  $E$  can happen.

## Discussion and analysis of results

We provide the analysis and discussion for each question P1 and P2. Due to space restrictions, we will present only one TAP referring to P2, which reflect the general reasoning of most of the students.

### About Question P1

Only three of the fourteen students chose options b) or d), which are the correct answers. It should be noted that none of these 3 students chose b) and d) simultaneously. Most of the rest of the students chose c), they argued: “if it is a continuous function in an interval that is not bounded, then function is not bounded”; “all hypothesis must be met so we can say that a function is bounded in a closed interval  $I$ ”. In some cases, students that chose a), confused the maximum of a function with the maximum of the interval: “in order an interval has a maximum, it must be in the set, that is, it has to be closed and bounded”.

We highlight the logical flaw in the reasoning of these students; they think that the falsehood of the premise of a proposition necessarily implies the falsehood of what is stated in the conclusion (DA inference). Figure 2 shows the logical structure of the reasoning of most of them.

**Figure 2: Logical structure of students' reasoning in Question P1**

In terms of Gueudet (2008), this inadequate mathematical production was caused by factors of logical and mathematical type, that is, both the lack of knowledge of logical structures and the misuse of the concepts of Calculus, determined this inadequate production.

## About Question P2

The results reveal that 10 of the 14 students did not answer this question correctly. Before beginning the analysis of P2, we will briefly comment on what happened in the answers to the auxiliary question (P1a and P1b). Most students expressed that the existence of the limit in both P1a and P1b depended on the nature of the function. More precisely, in the case of P1a, most students identified this limit with the derivative of a function, and still two students stated that such a limit did not exist because the denominator tended to zero. In the case of P1b, although no student directly related it to the derivative, none said that this limit was indeterminate, even two students argued that this limit was equal to 1. Regarding P2, it might seem strange that most students failed in this question a few days after having faced a similar situation with the definition of derivative of a function, since the expressions in P1a and P1b, and  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  share the same structure of a quotient where the denominator tends to zero. However, the analysis of the students' responses and the interviews revealed the cause of this problem.

Figure 3 shows student A's TAP. The answer provided in the instrument by this student was incorrect and reflect the general reasoning of most of the students. However, the student identified the type of incorrect reasoning during the interview. As the initial data ( $D$ ), the student considered (Quotient Law of Convergent Sequences) and  $\lim_{n \rightarrow \infty} b_n = 0$ , and his conclusion ( $C$ ) was that the limit of the quotient  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  does not exist. The student chose the word “always” as the modal qualifier ( $Q$ ), and used as warrants ( $W$ ) the flawed reasoning “the negation of the premise implies the negation of the conclusion”, the prohibition of dividing by zero, the impossibility to calculate  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  and the equality  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right) = \frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ .

Notice that the warrants ( $W$ ) of student A were also justified by support ( $S$ ) that consisted of the properties of real numbers, the theory of limits, and the DA inference. The rebuttal conditions ( $R$ ) were considered during the interview with student. Student A was presented with some examples of quotients of sequences where the sequence in the denominator was convergent to zero.

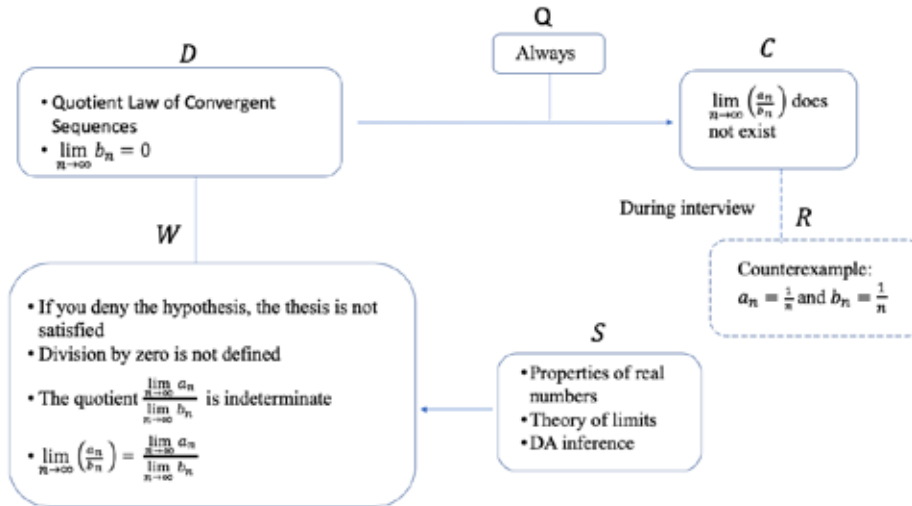

Figure 3: TAP of student A, who identified the incorrect type of reasoning

### The interview

During the interview, student A was asked to calculate  $\lim_{n \rightarrow \infty} \frac{a_n}{b_n}$ , where  $a_n = b_n = \frac{1}{n}$ .

Teacher: Please find the limit of the quotient.

Student A: But, that limit does not exist.

Teacher: Why do you think that the limit does not exist.

Student A: Well, mmm... because,  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  is indeterminate, and  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right) = \frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ .

At first, student A was reluctant to calculate the limit because he was convinced that the limit did not exist (C) and (Q).

Teacher: Please try to calculate it.

Student A: Ok! oh! the limit is 1! Is the theorem wrong? Let me see...

When the student finished the calculations, he was surprised to find the existence of this one (R) and, for a moment, questioned the validity of the theorem. After the interview, the student managed to modify his reasoning and obtained the correct answer.

The main obstacle to correct reasoning was the impossibility of calculating  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  when  $\lim_{n \rightarrow \infty} b_n = 0$ . That is, The student A could not distinguish between the existence of  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right)$  and the validity of the formula  $\lim_{n \rightarrow \infty} \left(\frac{a_n}{b_n}\right) = \frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ , because he considered these expressions as equivalents.

In general, the reasoning of the majority of the students was: since  $\lim_{n \rightarrow \infty} b_n = 0$ , necessarily the quotient  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  is not defined (which is correct), and therefore  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  does not exist, see Figure 4.

**Figure 4: Scheme of reasoning for P2**

There are two flaws that stand out in the logic used by these students:

- 1) Accept the DA inference in considering certain: if  $\lim_{n \rightarrow \infty} b_n = 0$ , then necessarily  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  does not exist.
- 2) They did not become aware that the conclusion of the theorem is a conjunction of two statements: one about the existence of  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right)$  and the other about equality  $\lim_{n \rightarrow \infty} \left( \frac{a_n}{b_n} \right) = \frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ . Both mistakes came from the impossibility to calculate  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$ , when  $\lim_{n \rightarrow \infty} b_n = 0$ , because students know that division by 0 is not allowed.

In terms of Gueudet (2008), the acceptance of DA inference, the impossibility to calculate the quotient  $\frac{\lim_{n \rightarrow \infty} a_n}{\lim_{n \rightarrow \infty} b_n}$  and the failure to identify that the conclusion of the theorem is a conjunction of two statements were the associated factors for an inadequate mathematical production.

## Final considerations

Our study suggests the importance of understanding the logical structure of mathematical statements; not being aware of it can cause additional difficulties for students, especially novice students who are barely getting involved in conceptual Calculus. Not knowing such structures can lead the student to false conclusions, for example, accepting invalid DA inference, or misapplying certain theorems, i.e., inadequate mathematical production.

The types of logical inferences (MP, MT, DA and AC) have been studied extensively, especially in abstract contexts, and are known to be difficult to assimilate. Our research focused solely on DA inference and revealed that this problem is further increased when conjunctions are involved in the premise and conclusion of a conditional-type structure in a mathematical context, particularly Calculus. Although the participants were students who had successfully completed their first course in Calculus of the Mathematics career and therefore already knew and had worked on the concept of derivative, the theorem of Weierstrass and the theorem of the limit of the quotient of sequences, even after all this, it is observed that these difficulties in the management of logical structures persist in a significant number of them.

Our study suggests that, in order to promote a better understanding of the students in the contents of Calculus, it would be very useful to pay special attention to the type of logical difficulties reported here, to insist on the structures of mathematical statements, to make them explicit and to point out their scope.

<sup>1</sup>Leibniz University Hannover, Germany <sup>2</sup>Technical University of Darmstadt, Germany <sup>3</sup>University of Paderborn, Germany; [hochmuth@idmp.uni-hannover.de](mailto:hochmuth@idmp.uni-hannover.de)

*VEMINT (Virtual Entrance Tutorial for the STEM subjects), a joint project by researchers from the universities of Darmstadt, Kassel, Paderborn and Hannover, has worked on material and course-designs for bridging courses for more than 15 years. In recent years, VEMINT has focused on the development of a psychometrically validated test to provide students with appropriate hints for the use of material and to evaluate the impact of teaching and learning activities. In this paper, we present elements of the test, which are based on ideas from Feldt-Caesar (2017), who combined cognitive activity and action control theoretical approaches in the development of a three-dimensional competence structure model, and on Anthropological Theory of Didactics, to explain content-related differences between dimensions of the model. Validating Rasch-analyses show that, in accordance with the design ideas, a three-dimensional Rasch-model fits with empirical data.*

### Introduction

The average dropout rates of mathematics and engineering programs in universities in Germany are 47% and 36%, respectively (Bildungsberichterstattung, 2014). These rates are higher than the overall average drop-out rate which is 33% for all study programs at German universities. In addition to the lack of acquisition of key competences such as the ability and willingness for self-reflection and self-motivation (Hilgert, 2016), the literature (e.g., Cramer & Walcher, 2010) highlights that the lack of prior mathematical school knowledge is one of the major reasons for the high proportion of dropouts.

As a measure to reduce the number of dropouts, most universities and higher education institutes have offered mathematical remedial activities in the form of bridging courses to support students' learning of university mathematics in recent years. The idea is to reduce the gap between school and university mathematics while maintaining the standards of the programs. One of the major challenges is to design remedial bridging courses that are sensitive to individual needs. For example, while some of the students need more support in simplifications of algebraic expressions, other students may need support in elementary calculus. It is also important for the students to know what prior knowledge is needed to take the courses at the university. To support students in deciding which of the modules of the bridging course to take, it is desirable to have an appropriate diagnostic tool available. Such tool should also measure the impact of bridging courses. A substantial content analysis is essential in order to provide detailed feedback to individual learners and advice to lecturers in choosing topics and in deciding how intensely topics should be taught in transition courses (Biehler & Hochmuth, 2017; Hochmuth, 2018). For more than 15 years, the universities of Darmstadt, and recently also Hannover, Kassel, and Paderborn, have been offering bridging courses in the cooperative project Virtual Entrance Tutorial for STEM subjects (VEMINT,

STEM in German is MINT) for students who wish to pursue mathematics-related programs (Bausch et al., 2014; Fischer, 2014). In recent years, the authors have also worked on developing a diagnostic test, the VEMINT-test, which is the focus of this paper.

The structure of the paper is as follows. After sketching the main goals of the VEMINT-test, we outline basic ideas of the competence structure model that underlies our test design and provide a briefpraxeological content analysis of tasks assigned to the dimensions of the model. Finally, we present results from a Rasch-Analysis empirically validating the three dimensions of the competence structure model.

## **The Development of the VEMINT-Test**

The development of the VEMINT-test follows two partly opposing, goals: While working as a diagnostic test to understand better students' prior knowledge and gaps, it should also help to evaluate the impact of bridging courses. In addition, the pre-test needs to give information in a short time so students can decide what modules they need to take in the bridging course. In recent years, the diagnostic test has been refined several times based on both empirical and theoretical findings. Thereby, our main aim was to develop a standardized diagnostic instrument in two essentially equivalent versions (Form A and Form B), which can be used every year at the beginning and at the end of a bridging course. An expert rating determined the particular content of the test, which focused on analysis and elementary algebra and took into account the German minimum standard requirements (see, Cooperation Schule Hochschule, 2014). The items were adjusted according to quality criteria for tests and technical possibilities (e.g., the use of the Moodle STACK plug-in, Sangwin, 2007).

The final test in two forms (A and B) was designed for 60 minutes and comprised 22 tasks from secondary levels I and II in German schools. The examined topics are algebraic terms, equations, functions and calculus (differentiation and integration). The test was developed using a three-dimensional competence structure model that will be described next. Afterwards we present results from a Rasch-Analysis, considering data that has been collected in the winter semester of 2017/2018. These results empirically reproduce the three-dimensional structure, thus validating our test-design in this respect.

## **A Competence Structure Model and its Dimensions**

The competence structure model is based on the idea of “Basic Mathematical Knowledge” (BMK), which has been introduced by Feldt-Caesar (2017) as follows:

Basic mathematical knowledge and skills refer to the mathematical knowledge, skills and abilities which are to be retrievable to all pupils at the end of the two secondary levels in the form of mathematical terms, theorems and procedures in the long term and independently of the situation, i.e. in particular without the use of aids. (Our translation, p. 182)

BMK serves “as a prerequisite for successful further learning, especially in a course of study” (our translation, p. 180), which requires that knowledge be sustainable and connected in the sense of “intelligent knowledge” (Feldt-Caesar, 2017; Weinert, 2000) and, furthermore, transferable and connectable with new content (Feldt-Caesar, 2017; Nitsch Bruder & Kelava, 2016). For related

diagnostic and feedback goals these ideas imply that items of a test should cover not only calculus-oriented tasks but should also aim at “intelligent knowledge” and “understanding oriented knowledge” where the latter is not the same as “understanding.” We agree with Skemp (1976) that no “understanding,” neither instrumental nor relational understanding, is validly testable without additional intersubjective interactions. On the other hand, “understanding oriented knowledge” including knowledge necessary for “relational understanding” beyond knowledge necessary for “instrumental knowledge” is an important basis for further learning (Bruder, Feldt-Caesar, Pallack, Pinkernell & Wynands, 2015; Skemp, 1976). These general underlying goals call for a sample of tasks which cover various qualitative facets of knowledge and associated mental activities. Moreover the sample should be helpful both in regards to diagnostic and evaluation goals as well as for providing appropriate feedback. To cover and operationalize the idea of such different qualitative facets we have developed a three-dimensional competence structure model on the basis of ideas from Feldt-Caesar (2017) and applied Anthropological Theory of Didactics (ATD, Chevallard, 1992)) for the content analysis of tasks.

In Feldt-Caesar (2017), cognitive, activity and action control theoretical approaches are combined to describe and analyze mental activities with respect to five conceptual levels. Within our context, the levels “elementary actions,” including identification and realization, and “basic actions,” including recognizing, describing, linking, applying and justifying, are important. In Feldt-Caesar (2017), both types of actions have been related to the so-called “content elements” that are conceptualized in terms, theorems, and procedures. In view of our focus on analyzing test tasks within the institutional context of the transition from school to university mathematics, it turned out that a praxeological view on “content elements” was probably more appropriate for the current project.

Accordingly, in the following we apply a few basic praxeological notions from ATD: The simplified [P, L]-model with P representing the praxeological block (i.e., the technical aspect(s) connected to a type of task and) with L representing the technological-theoretical block. The latter covers in particular: describing a technique, validating (e.g., proving or justifying how and that a technique works), knowledge about the efficiency and motives of a technique as well as knowledge about variants and simplifications, and finally, knowledge required or useful for controlling the application of a technique, which is particularly relevant for connecting practices and praxeologies. Our starting point for the identification of P and L lies in the single tasks of the test, curricula school books and in the VEMINT group consented experiences concerning the actual implementation and institutionalization of praxeologies and corresponding technical and technological aspects of school mathematics. There are, of course, further relations between above mentioned cognitive notions like “instrumental” and “relational understanding”: From the viewpoint of knowledge and meaning structures, they can be referred to qualitative differences in relationships between practical and technological-theoretical blocks of one or several praxeologies. A more detailed analysis of such issues, however, lies beyond the scope of this paper. Here, the praxeological notions mainly serve as a tool for describing and analyzing qualitative aspects of “content elements” with regard to the three dimensions of the competence structure model.

Dimension I (which is associated to instrumental understanding) is characterized by elementary

actions and cognitive operations such as identification and realization, and usually refer to a content element that does not have to be transferred to other content elements. The actions to be taken consist of a single step and are related to a “first elementary level” of mental activities in Feldt-Caesar (2017). Content-wise and in praxeological terms, Dimension I covers tasks from school that can be solved by techniques without especially taking into account technological aspects like supporting argumentations, proofs, or contextual embedding, etc. The techniques in Dimension I tasks are more or less extensively institutionalized in school mathematics, represent typical tasks of school examinations, and, at least partly, also appear in final exams (e.g., baccalaureates). A characteristic task in the test is the calculation of the derivative of  $\sqrt[6]{3 - x^2}$ . It can be calculated by algebraic operations that can be executed without referring to basic rules and notions. This kind of tasks, focusing on techniques without links to technologies and supporting mathematical organizations, seems to be dominant in school internationally (e.g., Barbé, Bosch, Espinoza & Gascón, 2005).

In Dimension II, the one-step approach is maintained but a linking to content elements of the same

A polynomial function  $f$  fulfils the following properties:  $f'$  is negative for  $x < 4$  and positive for  $x > 4$ . Which of the graphs belongs to  $f$ ?

**Figure 1: Example for a task of dimension II**

topic is necessary to solve the associated tasks. Such tasks are characterized by the main reference to one content element and possibly to other content elements, directly related to the main content element. Besides elementary actions, cognitive operations such as describing, linking, applying, and justifying are necessary in most cases. These tasks cannot be solved by simple calculations and are often unfamiliar to students (so that they need probably relational understanding). Content-wise, Dimension II covers tasks that relate to technological-theoretical blocks of praxeologies implying validation and justification. Students are not sufficiently trained in techniques of Dimension II tasks such that such technological aspects are superfluous for solving the tasks. Moreover, in the school context, this type of tasks typically demands verbal descriptions or even verbal justifications. A further common aspect of Dimension II tasks is that the technological aspects need no additional validation, for example by linking to technological aspects of praxeologies living in other domains; hence they are of a local nature. Figure 1 presents an example for a Dimension II task. It is expected that to solve this task students use relationships between verbal, graphical, and symbolic representations and switch across those representations. In order to solve the task, the second derivative is to be interpreted as the curvature of the function  $f$ . What is unusual about this task is that the values of the second derivative are given and, conversely, a function  $f$  must be reconstructed based on the given information.

Dimension III tasks are multi-step tasks, and characterized by several elementary actions and cognitive operations (associated to “intelligent knowledge”). The tasks refer to content elements

from at least two different content areas. Thus, solving of Dimension III tasks combines techniques from different praxeologies; the techniques involved are often more complex, or the technological aspects relevant for the combination of the techniques are either weakly established or combine aspects of different praxeologies. A task of this type, that combines techniques and is well-established in school, looks as follows (Feldt-Caesar, 2017): “The function  $f$  is given by  $f(x) = x^2 - 7$ . Determine the equation of the tangent  $t$ , which touches the graph of the function  $f$  at the point  $P(-2, 1)$ .” In this task, content elements of differential calculus must be linked and the results of the differential calculus must be used to establish a linear function (equation of a tangent). Thus, both content from secondary level I and secondary level II must be applied. Another task (item 13) of Dimension III is the following: “Simplify the following expression and collect the variables  $\frac{x^{k-n}}{y^{2n}} : \frac{x^{2k-n}}{y^{n-1}}$  ( $x, y \neq 0$ ).” In this task, the required combination of techniques from division of fractions and power calculations is nested; in addition, related technological aspects have to be combined in an appropriate way. This means that it is not enough to apply simple and local techniques from different domains. Content-wise, the main characteristic of Dimension III tasks is the link of different techniques and technologies, which is as such not well-institutionalized in school mathematics.<sup>1</sup>

## Rasch-Analysis

Roughly one half of 362 students from three German universities who participated in bridging-courses (29% female) filled out test-form A before and test-form B after the courses. The other half took the opposite order. No sequence effects were found. Each participant received each test-form only once, and, although pre- and posttest samples were related (both samples consisted of the same participants), the occurrence of test-effects is not plausible. Using pre- and posttest samples in one analysis reduces the probability of the occurrence (respectively the effect) of a possible limitation of variance, which can lead to a possible underestimation of all correlational measures and possibly limiting the information value of assertions regarding validity. Participants were tested before and after a bridging course and therefore were not on the same performance level at both times of measurement.

To scale the data, we first estimated two one-dimensional Rasch-models, one for each measurement point. A Rasch-model is a probabilistic psychometrical model for generating measurements from categorical data (e.g., right/wrong-answers in a performance test) as a function

**Figure 2: Scatterplot of the rank of difficulty**

<sup>1</sup> It should be noted that assigning tasks to a single of the dimensions is not always possible due to different possible solutions of a task. For the classification, several possible solutions were anticipated and the most probable one was used to determine the dimension. Analyses of some of our test tasks can be found in Feldt-Caesar (2017), which investigates validation issues.

of the relation between the ability of the respondents and the item difficulty (Rasch, 1980). EAP/PV-reliabilities were suitable,  $R = .868$  (resp.  $.865$  for Model 2), as well as the variances,  $V = 2.256$  (resp.  $1.967$  for Model 2). Figure 2 shows the

scatterplot of the rank of the difficulty parameters. Most importantly, the correlation of the difficulty parameters is high,  $R^2 = .95$ . For this reason, measurement invariance can be assumed.

Because of the high correlation between both measurement points, the approach of virtual cases could be applied (see Hartig & Kühnbach, 2005; Rost, 1996). If a participant took part at both measurement points, he or she represents two cases in the data. This approach has two advantages: Firstly, resulting scores are in a consistent metric and secondly, the appearance of the problem of constrained variance is less likely (see above). With this approach, a data set of 724 cases resulted. Again, a one-dimensional model was calculated but also a three-dimensional model consisting of the three performance levels described before. Results are shown in Table 1. Both models show good variances and EAP/PV-reliabilities as well as discrimination indices. The three-dimensional model shows significantly less deviance than the one-dimensional model ( $p < .001$ ), so it fits the data better.<sup>2</sup> Figure 3 shows the wright-map of the three-dimensional model. Thus, the Rasch-analysis empirically confirmed the three-dimensional structure of the test.

Dimensionality	One-dimensional	Three-dimensional		
Performance Level		I	II	III
Number of tasks	22	8	10	4

**Table 1: Results of the Rasch-Analysis**

The order of tasks within the dimensions could be understood as a consequence of how intensively and how often (regarding different classes, schools etc.) the tasks are practiced; the order could hardly be deduced by theoretical considerations alone. In accordance with our content analysis, Dimension II in fact includes tasks which need conversions between different representations of a function, even if these tasks are not unfamiliar. The task in Figure 1 is even rated as a rather difficult one within Dimension II in the Rasch model. Within Dimension III, besides the degree of institutionalization and the time of treatment of indicated techniques in school,

**Figure 3: Wright-map of the 3D**

<sup>2</sup> One item (Item 3) shows a weighted MNSQ larger than 1.2 (values should lie in the range of  $0.8 < \text{MNSQ} < 1.2$ ). This is not too problematic for all other indices perform very well.

the praxeological interconnectedness seems to be reflected in the order of tasks (items 3, 7, 10, 11, 12, 13, 15, 18, 20, 22). It is perhaps a little bit surprising that the complex term transformation task (item 13) turned out to be the most challenging task of Dimension III.

## Discussion

The main aim of bridging courses is to support students by providing learning materials and samples of tasks for their self-evaluation. From the design of material and courses as well as the point of view of teaching, specific test instruments are required for a possibly objective evaluation of the impact of support measures. The test instruments should be most sensitive for specific mathematical knowledge domains and should allow relating pre-post-comparisons to specifics of bridging courses in order to adopt courses in view of actual pre-test results. Our results show that our test takes into account qualitatively different knowledge dimensions and might be a valuable tool for reaching these goals, which, of course, needs further investigations.

*Previous research has shown that students' use of module resources strongly relates to the timing of the module's continuous assessment. In our case study of a large first-year mathematics module for Business students, Maths for Business, we examine this relationship and the resources relied on by students for completing their continuous assessment. In Maths for Business, students have the choice of using live lectures or online videos or a combination of both. We find that students who incorporate lectures into their approach engage consistently throughout each week with module resources, while others adopt a just-in-time approach for each weekly quiz. We also show that the introduction of remediation of quizzes can boost participation with resources, in particular feedback resources.*

*Keywords: Continuous assessment, student participation, remediation, undergraduate mathematics, service mathematics.*

## Introduction

Research shows that student engagement in a module is strongly related to the timing of assessment (Rust, 2002; Marriott & Lau, 2008; Holmes, 2018). In this study, we focus on this relationship in a service mathematics module, showing that through module design which includes frequent continuous assessment, students can be encouraged to consistently access resources both prior to, and post assessment (through feedback). While this relationship seems evident, we analyse electronic data to demonstrate it. To this effect, we analyse resource usage in a large first-year undergraduate module entitled *Maths for Business* (based on the 2015/16 student cohort). Continuous assessment is an integral component of *Maths for Business*, with 40% of the final module mark designated to a student's best eight (out of ten) weekly quizzes. We investigate which resources students access when preparing for the assessment; and when specific resources (lectures, online videos, worksheets, Maths Support Centre and quiz solutions) are accessed; and, whether the approach taken relates to a surface or a deep learning approach to learning (Rust, 2002).

While some research focuses on resource usage in preparation for continuous assessment (Holmes, 2018), we also wish to investigate the relationship specifically with feedback resources. In 2016/17, we introduced a 'remediation system' whereby students who did not receive the full five marks on their weekly quiz, had the opportunity to resubmit their quiz one week later with an explanation of their error(s) and corrections for one additional mark. We examine how the introduction of the remediation system increased students use of feedback resources. Subsequently our research questions are:

1. In *Maths for Business*, what is the relationship between the timing of continuous assessment and module resource usage?
2. In *Maths for Business*, what resources do students access when preparing for their continuous assessment?
3. Is there a relationship between students' choice of resource and their learning approach?
4. Through incentivising remediation, can students be encouraged to access module resources?

Unlike our prior work on *Maths for Business* (Howard, Meehan, & Parnell, 2018; Howard, Meehan, & Parnell, 2019), this study focuses on examining resource usage in the context of the timing of continuous assessment, rather than the reason behind students' choice of module content resources (Howard et al., 2018), or, whether the remediation system benefitted students based on their end-of-semester examination (Howard et al., 2019).

## **Theoretical Framework and Related Literature**

### **Engagement and participation**

In educational literature (Fredricks, Blumenfeld, & Paris, 2004), student engagement is considered under three sub-themes or constructs: behavioural, cognitive and emotional. Behavioural engagement (Fredricks et al., 2004) encompasses positive student conduct and participation or on-task behaviour for example effort, persistence, concentration, attention, asking questions, and contributing to class discussion. Fredricks et al. (2004) note there is a difference between active and passive behaviour. In this study, we refer to participation as the interaction students have with resources which is measured by log or attendance data. When we consider students' participation or resource usage, we are considering a narrow, limited definition or application of behavioural engagement.

### **Continuous assessment and engagement**

Holmes (2018) argues for the importance of student engagement owing to its relationship with student satisfaction and the quality of the student experience. Her research aims to improve the student experience by influencing the relationship between resource-use and assessment. Holmes (2018) shows that the introduction of frequent low-stakes assessment leads to a consistent increase in the use of online resources in a university geography module. This particularly benefits students with "weaker" prior knowledge in a module, as research suggests that they benefit more from participation with resources than their peers (Nordmann, Calder, Bishop, Irwin, & Comber, 2018). Marriott and Lau (2008), and the references within, argue that assessment is the main variable in accounting for how students approach their learning. Rust (2002) expands on this relationship, by noting that students will study the content or resources that they believe will be examined. Anastasakis (2018) uses activity theory to explore in detail engineering and mathematics undergraduates' resource-use. Anastasakis (2018) found that assessment rules were the main regulator of students' use of resources. Other, less significant factors included: students themselves including their learning preferences, degree and year of study; resources' usability; the level, nature and familiarity of the mathematics; and, lecturers and past members of students' community. In addition to encouraging pre-assessment resource usage, continuous assessment can also encourage engagement through the feedback provided for assessment.

Alternative to examining students' specific resource-use, one could consider whether students take a surface or deep learning approach to learning. A surface approach is often associated with rote learning and extrinsic motivation, whereas a deep approach is associated with learning for understanding and intrinsic motivation. Biggs, Kember, and Leung (2001) presents a survey to examine these approaches, the 'Revised Two Factor Study Process Questionnaire: R-SPQ-2F'. Trenholm et al. (2019) used the R-SPQ-2F to examine learning approaches in two mathematics modules where students had the option of attending lectures or/and viewing recorded lecture videos. Despite the modules being located in different universities, they found in both cases that a decrease in live lecture attendance combined with regular use of the recordings was associated with an increase in surface approaches to learning.

## Module Context

*Maths for Business* is a large first-year undergraduate module with approximately 500 business students enrolled annually. In *Maths for Business*, students have the choice of completing the module material by attending approximately 32 live lectures or watching 67 online videos or a combination of both. Each short video (average length of 7.5 minutes) was designed and created by the lecturer – second author of the paper. These videos were created using the *Explain Everything* app (<https://explaineverything.com/>), and consisted of the lecturer writing on “skeleton” slides while explaining the topic. Students also have access to the Maths Support Centres (the university drop-in centre and a dedicated module drop-in centre). All resources in *Maths for Business* – worksheets, lectures or online videos – list the specific learning outcomes which they address. The module is examined through an end-of-semester written 2-hour examination and ten weekly quizzes. These contribute 60% and 40% respectively towards a student's final mark. Students best eight (out of ten) quizzes contribute 5% each to the continuous assessment mark of 40%. From week three of the twelve-week teaching semester, all students sit the weekly quizzes on Tuesdays under the supervision of a teaching assistant. Further detail on the module can be found in Howard et al. (2018). Between 2015/16 and 2016/17, there were no changes to the learning outcomes of the module. While the content and aims remained the same, the quizzes were changed to ensure students did not copy from the prior year's quizzes.

Date	Oral feedback by TA for quiz	Quiz completed	Quiz returned	Remediated quiz submitted	Feedback resources made available
27 <sup>th</sup> of September	-	1	-	-	-
4 <sup>th</sup> of October	1	2	1	-	Quiz 1 pdf & video solutions
11 <sup>th</sup> of October	2	3	2	1	Quiz 2 pdf & video solutions

**Table 1: Example of the remediation timeframe**

In *Maths for Business* in 2016/17, a 'remediation system' was introduced (Howard et al., 2019). In the remediation system, any student who did not receive the full five marks on a quiz, had the

opportunity to resubmit their quiz with corrections and an explanation of their error(s) for one additional mark. Table 1 provides an example of the remediation time-frame. Both the pdf and video solutions highlighted relevant video resources for the quiz questions. Owing to the fortnightly remediation cycle, students only had the opportunity to remediate the first eight quizzes. Students were encouraged to use the Maths Support Centre for help with their remediation, particularly students who received a low score on their quiz.

## Data Collection and Analysis

We use a case study approach as we are not controlling the behavioural approaches of students and it allows for a mixed method approach. The case study approach allows for the examination of the real-life relationship between continuous assessment and resource usage in the context of *Maths for Business*. In accordance with our permission from the UCD Ethics Committee, for two years of *Maths for Business*, we collected students' lecture attendance, log data for online resources, Maths Support Centre attendance, Irish post-primary terminal mathematics examination grade (as an indicator of prior mathematics learning) and marks in the module. In total, there were 522 students in 2015/16 and 480 students in 2016/17. In addition, a survey that included the 'Revised Two Factor Study Process Questionnaire: R-SPQ-2F' (Biggs et al., 2001) was distributed to the 2015/16 cohort at the end of the teaching semester. We received 161 survey responses. For this paper, we are examining the results from the 'R-SPQ-2F' and one open-ended question from the survey, "How do you study for the weekly quiz, making specific reference to the resources you use (online videos, lecture slides, external sources, friends, worksheets, class notes, Monday drop-in session, Maths Support Centre)?" These survey results are beyond our prior research (Howard et al., 2018).

To examine the time dynamic between continuous assessment and resource usage, we use descriptive statistics in the form of graphs. We do not include resource usage data relating to the revision and examination period of the semester (prior to the end-of-semester examination) as the number of views increases substantially during this time as expected. To analyse the open-ended survey question on which resources are used in studying, we use thematic analysis (Braun & Clarke, 2006).

## Results

### RQ1: What is the relationship between continuous assessment and module resource usage?

Based on the 2015/16 cohort, analysis of the video views shows that students access videos prior to the weekly Tuesday continuous assessment (on Monday and Tuesday). Similarly, students mainly access the worksheets and Maths Support Centre prior to the weekly quiz. Alternatively, we could investigate the timing of resources based on a finer scale which considers students' main content resources. If we classify students according to their use of live lectures or online videos or combination of both (see Howard et al. (2018) for details of the classification by clustering analysis), we have four distinct groups: Dual-Users, Lecture-Users, Video-Users and Switchers. Switchers either start the semester predominantly using lectures and progress to predominantly using videos or choose between videos and lectures for content based on the timing of a lecture. Lecture-Users and Video-Users predominantly use lectures and videos respectively, while Dual-Users use both lectures and videos to review the same material. Figure 1 shows the standardised number of video accesses

for each cluster over the semester (views are divided by the number of students in each cluster). When examining video accesses in relation to the time in the semester for Dual-Users, Video-Users and Switchers, the distribution is of weekly peaks prior to the continuous assessment albeit with increasing peaks for Switchers as the semester progresses. However, for Lecture-Users, this pattern is not maintained initially. As the semester progresses, the limited number of videos seem to be accessed for assessment purposes. Dual-Users, and to a lesser extent Lecture-Users, use resources throughout the semester whereas Video-Users and Switchers use them on Mondays and Tuesdays. There are limited accesses of resources once their associated quiz has occurred.

## RQ2: What resources do students access when studying for their continuous assessment?

**Figure 1: *Maths for Business* video accesses for 2015/16. The number of accesses for each cluster has been divided by the number of students in each cluster to allow for comparisons**

Our findings from the first research question suggests a strong relationship between the time when students' access module resources and the date of the continuous assessment. After each quiz, students prepare for the next quiz rather than revising past quizzes. In order to understand the resources students use to study, towards the end of the 2015/16 semester, we asked students how they studied for the weekly quiz. From thematic analysis (Braun & Clarke, 2006) of the responses, a central and important theme identified is 'Order of Study'. Students often explained the order of their study approach using the word "then". For example, one response consisted of:

Firstly I go through all the videos and write out notes. Then I attempt the worksheet and highlight all the good examples and things that I need to remember. I then look back over the notes I took

and the completed worksheet. I went to the math support centre when I couldn't get the answer to a question.

Generally, students' study pattern for the weekly quiz fall into three stages:

Stage 1: Review the relevant module material - this is completed through videos or/and lectures. Students may also create their own notes at this stage.

Stage 2: Attempt/complete the worksheet, may refer to videos to help with the worksheet.

Stage 3: If stuck on the worksheet, seek assistance from friends and Maths Support Centre.

There are students who deviate from this, for example students who listed a single resource as their response such as worksheets or videos. Male students were more likely to list a single resource, whereas in contrast female students or Dual-Users were more likely to seek support as described in stage 3. Similarly to Figure 1, worksheets and Maths Support Centre were accessed in the days prior to the quiz. We have no data for when friends were consulted.

### **RQ3: Is there a relationship between student' choice of resource and their learning approach?**

Using Biggs et al.'s (2001) 'R-SPQ-2F', for the 2015/16 cohort, we examined students' approaches to learning, namely surface versus deep approach. The results from the five-point Likert scale questions were summed (as outlined in Biggs et al., 2001) to extract a numerical measure for students' surface and deep approach to learning. Surprisingly, using an analysis of variance approach, there was no statistical difference between the surface and deep approach of Lecture-Users, Dual-Users, Video-Users and Switchers. Following Trenholm et al.'s (2019) methodology, we also divided users into regular or low video users using the median number of videos accessed. Upon examination, there was no difference in the learning approach of these two groups. However, Trenholm et al. (2019) measured the learning approaches of students at two points in the semester whereas we measured the learning approach at one point, the end of the semester. They found an increase in the surface approach of students who regularly used lecture-capture videos combined with lower lecture attendance. The difference in results could possibly be caused by our lack of examining learning approaches at two time points or an innate difference between lecture-capture and short-designed videos for mathematics courses or possibly owing to a difference in survey respondents as our survey respondents were biased towards higher marks in comparison to our overall population.

### **RQ4: Can students be encouraged to consistently use module resources?**

In 2015/16 cohort, resources were accessed prior to the quizzes. In 2016/17, we introduced the remediation system where students could gain an extra mark out of five quiz marks if they resubmitted their quiz within one week of having it returned with an explanation of their error(s). While the primary motive of this was to encourage students to identify and learn from their errors in a timely manner (Howard et al., 2019), a potential side-effect was students engaging with quiz or/and feedback material post-quiz i.e. within a week after the quiz. The feedback resources provided included: the graded quizzes; oral tutor feedback; the lecturer providing a video entitled "Most Common Errors"; and, a pdf copy of the quiz solutions that also highlighted the most relevant online videos from the module. In addition, students could seek help from friends and the Maths Support Centre. We found (Howard et al., 2019) that the main resource students made use of was the pdf solutions, with limited

use of the videos and the Maths Support Centre. Upon further examination, with a focus on timing, students accessed the pdf solutions at the end of the remediation cycle i.e. prior to resubmission of their quiz. This just-in-time approach results in a similar distribution or pattern to the video accesses (Figure 1). This is in contrast to the prior year of 2015/16 as seen in Figure 2. For the teaching semester, the number of views for the pdf solutions doubled between the two cohorts (see Figure 2). Figure 2 indicates that students can be encouraged to positively participate with feedback resources.

**Figure 2: The number of pdf solution views for *Maths for Business* students by year and day.**

**Duplicate views by a student on a specific day have been removed**

## Discussion and Conclusion

In *Maths for Business*, we have examined resource-use in relation to its main influencer - continuous assessment. Continuous assessment is linked to students' resource use in two distinct forms: firstly, in preparation for the continuous assessment; and, secondly through students engaging with feedback on their assessment. Resources are accessed prior to the Tuesday quiz except for live lectures which are timetabled. Although the students are using a just-in-time approach, they are still accessing the resources weekly, and in that sense, consistently. The use of resources is divided into three stages or into the following order: module material review; practice questions; and, external help. While not all students will pursue each stage, females are more likely to seek external help from friends or the Maths Support Centres. For the 2016/17 cohort, a positive outcome of the remediation system was that students were encouraged to use feedback resources (pdf solutions). However, similar to preparing for the weekly quiz, a just-in-time approach was adopted for the feedback resources. As a limitation, we note that without qualitative data, we cannot confirm for what percentage of students this was the case. In comparison in 2015/16, there is no obvious distribution to viewing the pdf solutions (after the initial weeks). However, the number views are significantly lower.

In the broader context, continuous assessment can be used to encourage engagement by students and subsequently student satisfaction and the quality of the student experience (Holmes, 2018). Arguably, continuous assessment may lead to a 'study-to-the-test' approach. In Ireland, students' learning in the post-primary environment tends to be structured, leading to students struggling with the transition to becoming an independent learner at third level. *Maths for Business* is an entry-level module and the

continuous assessment within allows students to maintain some structure following the transition between education levels. Students' end-of-semester evaluations show an appreciation for the weekly quizzes and the opportunity to have module marks prior to the final examination through low-stakes assessments. This approach may not be applicable for specialist or higher-level mathematics modules. Currently, there is debate surrounding whether recorded lectures or specialised videos have a negative effect on students' learning when used as a replacement for the traditional lecture. In contrast to the current literature, we found no relationship between surface or deep learning approach and students' choice of resource. More research is needed to identify any influencing factors, for example the nature of the video, in this relationship.

# How to assess students' learning in mathematics literacy education: An attempt to use students' comments for assessment

Mitsuru Kawazoe

Osaka Prefecture University, Japan; [kawazoe@las.osakafu-u.ac.jp](mailto:kawazoe@las.osakafu-u.ac.jp)

*Keywords: mathematics education for non-specialists, student attitude, alternative assessment*

## Research objective and questions.

It is increasingly important for all students, regardless of educational level, to acquire mathematical skills for use in various contexts, especially in real-world situations. An education that fosters such skills is often referred to as *mathematical literacy education*, the aim of which often includes improving students' attitudes toward mathematics and deepening their interest in the subject. This raises the question, "How can we assess the success of such courses?" Accordingly, this study focused on students' text feedback, which is a rich resource that represents students' learning and attitudes (cf. Di Martino and Zan, 2010), and examined whether students' comments could be useful in assessing their mathematical literacy learning. With this aim, this study analyzed the students' reflection comments collected during one semester. Our research questions are as follows:

(RQ1) What categories are identified in students' reflection comments?

(RQ2) Do the students' responses stem from their actual learning? Or do they instead stem from their prior learning in high school or even from their attitudes at the beginning of the course?

## Two analyses on students' comments in mathematical literacy education.

A qualitative and quantitative analysis was conducted on students' comments collected during a mandatory one-semester mathematical literacy course for first-year students in social sciences and humanities majors. The course was designed as "learning mathematics through application," but the lecturer emphasized the nature of mathematical knowledge in each lesson. Students' reflections were collected over 14 weeks from an area reserved for comments on each lesson's worksheet. There were 68 first-year students in the class, and a total of 952 comments were collected. We distributed a questionnaire at the beginning of the course; before the students attended the class, we collected data on their courses in high school (science-oriented or humanities-oriented) as well as their attitude toward mathematics (good/bad at math, like/dislike math), using a five-point Likert scale.

The first analysis focused on RQ1, and an open coding method was used to determine a set of categories in order to understand how students described their learning. In the analysis, students' comments were segmented, and we assigned one code to each segment. The analysis was conducted with the help of the following three models: a three-dimensional model for attitudes toward mathematics by Di Martino and Zan (2010); the three phases of learning by Polya (1981, chapter 14); and the ICE model (Fostaty Young and Wilson, 2000), in which learning outcomes are distinguished in three levels. We found seven important categories that indicate learning progress or attitude improvement. We listed the categories with short explanations, and indicated the percentage of comments containing segments that were assigned with the codes: IA (expressing their Interest in Application, 17.1%), IM (expressing their Interest in Mathematics, 17.2%), MR (expressing their

Metacognitive Reflection, 7.9%), EL (expressing their Enjoyment of the Lesson, 7.9%), RQ (Raising Questions that extend their learning, 5.1%), MM (expressing their Motivation in using/learning Math, 8.5%), and RA (expressing their Reduced Awareness of being bad at math, 2.4%). IM and RA were regarded as being related to “vision of mathematics” and “perceived competence” in the model of Di Martino and Zan, respectively. MR was regarded as being related to a phase of “verbalization and concept” in Polya’s model and to a level of “connection” in the ICE model.

The second analysis focused on RQ2. Using statistical analysis, this study examined the codes IA, IM, and MR, and investigated whether the frequency of comments corresponding to each category per student depended on students’ courses in high school or on their attitude toward mathematics at the beginning of the course. For the second analysis, this study set the following groups based on the students’ answers for the aforementioned questionnaire: S+/S- (students who took science-oriented/humanities-oriented courses in high school), G+/G- (students who are good/bad at math), and L+/L- (students who like/dislike mathematics). The numbers of students in each group were 24 (S+), 43 (S-), 13 (G+), 38 (G-), 19 (L+), and 29 (L-). Next, the differences in the frequency of comments corresponding to each category per student between S+ and S-, between G+ and G-, and between L+ and L- were examined. A significant difference was found in the frequency of MR per student between L+ and L-. A Mann-Whitney test indicated that the frequency of comments containing descriptions corresponding to the rate of MR per student was greater for L- (Mdn=1) than for L+ (Mdn=0),  $U=371.5$ ,  $p=0.032$ . No significant difference was found for other codes, and no significant difference was found between the differences in students’ courses in high school.

## Discussion.

The first analysis showed that students’ comments collected from lessons in a mathematical literacy course contained multiple descriptions, including both their attitudinal change toward mathematics and their metacognitive reflections. An interesting result of the second analysis was that less-motivated students showed better results in terms of metacognitive reflection. The second analysis also suggested that students’ comments that showed their interest in mathematics or their metacognitive reflection did not stem from their prior learning in high school or their attitude toward mathematics before attending the course. These results seem to indicate that students’ comments are potentially useful to assess their mathematical literacy learning. However, more research is needed. One of future tasks is to analyze the changes in students’ comments over time.

# On tasks that lead to praxeologies' formation: a case in vector calculus

Margo Kondratieva

Memorial University, Canada; mkondra@mun.ca

*A praxeology comprises a type of task, a technique to accomplish it, a discourse (technology) explaining this technique and a theory supporting this discourse. We consider a situation where a praxeology was presented to students in a lecture, but they discovered an alternative one while working on a routine exercise. This exercise was then followed by a more challenging question related to immediate results obtained by the students. We analyzed this student experience in view of Chevallard's six steps of constructing a praxeology. We suggest that observing students' work on standard exercises may give some productive and innovative ideas for the design of tasks that help students deepen their understanding and encourage theoretical justifications of their solutions. We also comment about possible effects of the explicit requirement to search for the most efficient solution on the formation of praxeologies by students.*

*Keywords: Praxis, logos, task design, osculating plane, parametric curve.*

## Introduction

It has been observed that the majority of university mathematics classes are given in the format of lecture and largely employ the pedagogy of “massive scaffolding and direct telling” (Sfard, 2014, p. 202). This teaching approach has been criticized for its limited capacity to empower students in both critical reflection on given information and applying their knowledge in unfamiliar situations. In contrast, within the inquiry-based approach learners start with considering a problem, and then planning, developing and validating their own solutions (Polya, 1945). In this *adidactic* phase (Brousseau, 1997) learners construct their knowledge by working on a problem via thinking about it autonomously, studying related literature and talking to peers. In the didactic phase the teacher discusses the ideas produced by students, corrects them, validates and develops the subject further. However prolific it may sound, this approach is not fully applicable in teaching university mathematics due to the large amount of advanced material to be studied in a relatively short timeframe. Nevertheless, one can ask: to what extent is it possible to embed elements of inquiry in the lecture format courses? Where do we find questions that promote students' “intellectual needs” (Harel, 2012) for critically processing the information given in the lecture? What principles should guide the design of educational tasks that help students to progress from the direct application of given methods to the analysis and justification of them (Gravesen, Grønbaek & Winsløw, 2017)?

Perhaps the central requirement to these tasks is that they should help students to think about and reflect on their actions – what am I doing and why? – so that students can extract new knowledge directly from solving tasks. It is desirable that tasks have *adidactic* potential letting students to “find at least initial and partial answers” (Gravesen et al, 2017, p. 15). The same material can be taught with a different degree of initiative required from students. Typical examples illustrating general concepts and methods may be shown in class and then students can be assigned questions that are just a slight variation of already considered tasks. Such questions, known as *exercises*, contain little challenge but permit verifying students' initial grasp of the material, as students basically mimic

instructor's actions and adjust them according to his or her expectations. In contrast, *problems* require an adaptation or alternation of a given method or a combination of several previously discussed ideas and serve as a form of inquiry. A task that stimulates students to “construct new inferences between results or definitions, reformulate, generalize and instantiate them” is said to have a deepening potential (Gravesen et al, 2017, p. 13). Similarly, research potential of a task measures the possible degree of engagement with activities similar to ones of research mathematicians. However, even if a task is specifically designed, its potential may not be realized in a particular didactic situation. Thus, it is important to consider cases when students gain rich mathematical experience and to notice the circumstances that have a positive effect. This paper presents such a case confirming that even when a lecturer “tends to tell the learner what to do” and “rushes to present their own solutions” (Sfard, 2014, p. 200) it is possible and desirable to delegate to students some work that aims at the development of theoretical knowledge “while working on her own in the quiet of her room” (Sfard, 2014, p. 201).

### **Theoretical framework and research question**

We work under the assumption that “mathematics is a human activity of study of types of problems” (Barbé, Bosch, Espinoza, & Gascon, 2005, p. 236) and mathematical learning (even in a lecture based course) results from solving educational tasks (e.g. problems). Each task is a system of “given-required”, where “given” includes objects and relations between them, while “required” challenges the solver to derive new facts based on the “given” and their existing knowledge. A solution to a mathematical problem can be considered from two angles: “What is done?” and “Why does it work?”. In terms of the Anthropological Theory of Didactics (ADT) proposed by Chevallard (1999), the first question belongs to the domain of praxis, which includes techniques such as formulas, algorithms and methods, while the second - to the domain of logos, which provides corresponding theory, conditions of applicability, derivations and relations to general settings. The praxis consists of the types of tasks and corresponding techniques to solve them. The logos includes technology (explanations of the techniques, proofs of related theorems) and a broader theory within which the theorems are stated. Together praxis and logos components form a praxeology, described by Chevallard (2006, p. 23) as a “basic unit in which one can analyze human activity at large”. Praxeologies can occur at different levels of generality: punctual, local, regional or global. Punctual praxeologies address a unique type of task. Several punctual praxeologies can be integrated in different local mathematical organizations each of which provides a common technological discourse (e.g. algebraic). Local technologies can be further integrated into regional ones.

In the teaching of primary and secondary mathematics there is a tendency to focus on the praxis component with very minimal exposition of the students to the related logos. Even at the university level, there exists an artificial division of courses into e.g. Calculus and Analysis, assuming significant dis-balance towards the praxis in the former and leaving the theory until the latter (see Kondratieva & Winsløw, 2018). The lack of an explanation of why and when a technique works (i.e. lack of technology) leads to incomplete praxeologies; this is a disservice to learners at all levels as it kills natural learners' curiosity and reduces the flexibility of the technique. Even if technology is given by the teacher it may not necessarily lead to formation of a praxeology by students – to the practice when the use of a technique is informed by related technology. In this paper we look at a

case when students were engaged in the formation of a praxeology; the research question being: what are the instructional conditions making this possible at the undergraduate university level?

Our discussion will refer to the following six moments of creating a praxeology (Chevallard, 1999).

- 1) The moment of *first encounter* of a certain type of problem related to a praxeology;
- 2) The *exploratory* moment of finding and elaborating techniques suitable for the problem;
- 3) The *technical* moment of using and improving the technique;
- 4) The *technological-theoretical* moment in which alternative techniques are assessed;
- 5) The *institutionalization* moment, when one is aiming to identify the elaborated praxeology;
- 6) The *evaluation* moment, when one examines the value of the constructed praxeology.

Here the *adidactic* situation leads students to propose some techniques that need to be assessed and theorized. Students react on the situation in accordance with an existing *didactic contract* (Brousseau, 1997), that is, a set of responsibilities, rules and norms of schooling behavior. In our instructional setting we encountered a slightly modified sequence of events presented below.

## Instructional settings and observations

This section describes several episodes that occurred in a vector calculus course taught by the author of this paper in the Spring 2018 term at Memorial University (MUN) in Canada. The episodes had been selected in order to present the story of success. They describe a didactic contract, an error and its correction, made by students, leading to formation of a new praxeology.

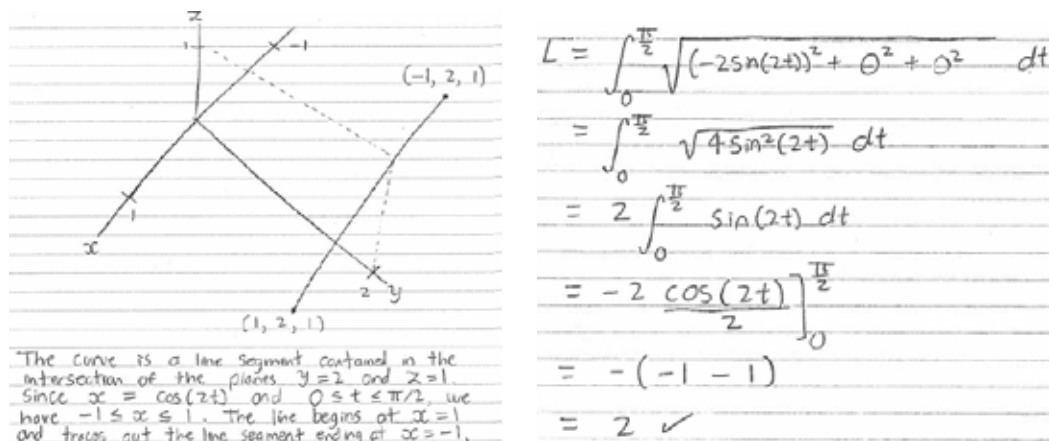

### The settings

The vector calculus course is the last course in the sequence of calculus courses offered by the department of Mathematics and Statistics at MUN. One-hour lectures are given three times a week for a twelve-week period (with regular homework assignments and a midterm exam) followed by a 3-hour written final exam. The course discusses such topics as parametric curves and surfaces, multiple integrals, Green's, Stokes' and the Divergence theorems with some motivations from physics. The course is usually taken by students majoring in either mathematics, physics, computer science or engineering. Similarly to preceding calculus courses it focuses mostly on computational techniques and obtaining numerical answers. Some sketches of proofs are discussed in lectures but they are not tested in exams. While the syllabus of the course is prescribed, the instructor has some freedom in composing questions for assignments and tests. In the considered case the homework assignments were marked by the instructor and consisted of the following types of questions: (1) short summary describing definitions, formulas, and conditions of their applicability as discussed in lectures; (2) exercises in direct application of formulas listed in (1); (3) problems that require minor alternations of formulas listed in (1); (4) bonus problems that may require additional reading and creative thought. Note that questions of types (1) and (4) were not typical in students' previous experience. Twenty students completed the course in Spring 2018.

### The observations and interventions

*Episode 1: Efficiency of solutions as a part of didactic contract.* This observation took place in the very beginning of the course. The students just learned how to find the curve length given a parametric description of a curve  $\mathbf{r}(t) = \{(x(t), y(t), z(t)), t \in [a, b]\}$ . Using the integration formula

$\int_a^b \sqrt{(x')^2 + (y')^2 + (z')^2} dt$  they were able to find the length of some exotic curves such as a part of a helix. However the assignment also included examples of parts of a straight line and a circle. Many students still used the general method to find the length of these curves even when they had recognized them correctly. It was then pointed out to students that they should aim at the most efficient way of finding their answers or at least mention that their calculations were consistent with the obvious answer. For example, the length of a straight line  $r(t) = \{(\cos(2t), 2, 1), t \in [0, \frac{\pi}{2}]\}$  connecting points  $(-1, 2, 1)$  and  $(1, 2, 1)$  (Figure 1, left) is obviously 2, which makes the calculation in (Figure 1, right) unnecessary. Similar situations appeared in other assignments. Some hints referred to efficiency in numerical calculations, such as

**Figure 1: Student's work on curve  $r(t) = \{(\cos(2t), 2, 1), t \in [0, \frac{\pi}{2}]\}$ . Description and length**

a suggestion to use the property  $\sqrt{(ka)^2 + (kb)^2} = k\sqrt{a^2 + b^2}$  ( $k \geq 0$ ), or warned that the simplification  $\sqrt{A+B} = \sqrt{A} + \sqrt{B}$  is not valid unless  $AB=0$ . All in all, such systematic instructional feedback shaped the didactic contract for this group of students.

*Episode 2: Accidental efficiency.* Another assignment included a problem of finding an osculating plane for the curve  $r(t) = (\cos t, \sin t, \cos t)$  at  $t = \pi/2$ . The instructor explained a method, which consisted of the following steps:

1. Find the unit tangent vector  $T = \frac{r'}{\|r'\|}$  to the curve at a given point.
2. Find the unit normal vector  $N = \frac{T'}{\|T'\|}$  to the curve at a given point.
3. Find the unit binormal vector  $B = T \times N$  to the curve at a given point.
4. An osculating plane by definition includes vectors  $T$  and  $N$  and therefore is orthogonal to vector  $B$ . Thus the equation of the plane is  $B \cdot (r - r_0) = 0$ , where  $r = (x, y, z)$  and  $r_0$  is the point on the curve where the plane is required.

An example considered in class in order to illustrate this method was helix of radius  $\alpha$ :  $r(t) = (\alpha \cos t, \alpha \sin t, t)$ . Note that in this case  $r'(t) = (-\alpha \sin t, \alpha \cos t, 1)$  and so  $\|r'\| = \sqrt{1 + \alpha^2}$  is  $t$ -independent. Consequently, the normal unit vector  $N = \frac{r''}{\|r''\|}$ . However, if  $\|r'\|$  is a function of  $t$ , this must be taken into consideration when calculating  $N$ . When working on the assignment described above, some students ignored this circumstance and used the formula  $\frac{r''}{\|r''\|}$  for  $N$  in step 2.

Nevertheless, they still got a correct answer for the proposed problem, the plane  $z = x$ . The mistake was pointed out by the instructor during a lecture, but the fact of accidental efficiency was surprising for students and caught their attention leading to an in-class discussion. Their first thought was that maybe the value of the parameter  $t = \pi/2$  was special, but the “wrong method” still gave a correct equation of the osculating plane for  $t = \pi/4$  and some other variations they tried. So, a bonus problem naturally emerged: to explain why and when the “wrong method” works.

*Episode 3: A praxeology given in the lecture.* The method of finding the osculating plane was not completely unexplained in the lecture. Prior to Episode 2 the students were presented with the statement that if a vector-function  $f(t)$  has a  $t$ -independent norm  $\|f\| \equiv \sqrt{f \cdot f} = \text{const}$  then the vector function  $f'(t)$  is orthogonal to  $f(t)$  for every  $t$ . Indeed, if we differentiate both sides of the equation  $f \cdot f = \text{const}$  we obtain  $f' \cdot f = 0$ . Now, the unit tangent vector has norm  $\|T\| = 1$ , therefore  $T'(t)$  is orthogonal to  $T(t)$  by the above statement. After normalization it gives the unit normal vector  $N(t)$ . The cross product of two unit vectors gives a unit vector orthogonal to both initial vectors. This way the binormal unit vector  $B(t)$  is obtained. These explanations presented a technology related to the praxis of finding an osculating plane. However, as it could be inferred from the error made by the students who were somehow misled by the example of helix in Episode 2, this praxeology, given by the instructor, remained external to them and the application of the method was not guided by the related theory. This revelation prompted the instructor to encourage students to develop their own explanations of the method that they had accidentally discovered.

*Episode 4: Towards a new praxeology construction by students.* Proving was not a well developed skill for many students, so their initial attempts naturally were flawed. We will follow the progress of a student called Sam (a pseudonym). Firstly, Sam arrived at the correct statement, but it was not very useful in the situation he needed: if  $r'(t) \perp r''(t)$  for  $t \in [a, b]$  then  $N = \frac{r''}{\|r''\|}$ . Indeed, the conclusion was desirable but the condition was not met in the problem they had. After some time Sam managed to prove algebraically that if  $r'(t_0) \perp r''(t_0)$  then  $N(t_0) = \frac{r''}{\|r''\|}$  (Figure 2, left). When this result was shared with others in class, it was noted by students that the statement is obvious from the geometrical point of view: if both vectors  $N$  and  $r''$  are orthogonal to  $r'$ , they must be proportional. In this way the case  $t = \pi/2$  was successfully explained. However, it was still unclear why the “wrong method” gave the correct equations of the osculating plane even in the case when  $N$  was not proportional to  $r''$  (see e.g. calculations for case  $t = \pi/4$  in Figure 2, right).

Left page (t =  $\pi/2$ ):

$$r' \cdot r'' = r' \cdot \frac{d}{dt} \left[ \sqrt{(x')^2 + (y')^2 + (z')^2} \right]$$

$$= \frac{r'}{2} \cdot \frac{2x'x'' + 2y'y'' + 2z'z''}{\sqrt{(x')^2 + (y')^2 + (z')^2}}$$

$$= \frac{r'}{\|r'\|} (r' \cdot r'') = T(r' \cdot r'')$$

$$\Rightarrow N = \frac{r'' \|r'\| - T(r' \cdot r'')}{\|r' \cdot r''\|}$$

If there exists a  $t_0 \in I$  such that  $r'(t_0) \cdot r''(t_0) = 0$ , then  $N(t_0) = \frac{r''(t_0)}{\|r''(t_0)\|}$

Right page (t =  $\pi/4$ ):

$$T'(\frac{\pi}{4}) = \frac{1}{\sqrt{2}} \cdot (-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}) = \frac{1}{2}(-1, -1, -1)$$

$$T(\frac{\pi}{4}) = \frac{1}{\sqrt{2}}(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}) = \frac{1}{2}(-1, 1, -1)$$

$$r''(\frac{\pi}{4}) = (-\cos t, -\sin t, -\cos t)(\frac{\pi}{4}) = (-1, -1, -1) \frac{1}{\sqrt{2}}$$

$$r'(\frac{\pi}{4}) = (-1, 1, -1) \frac{1}{\sqrt{2}}$$

$$T' \pm k r'' \text{ at } \frac{\pi}{4} \quad (1, 2, 1) + k(1, 1, 1)$$

$$\text{but } T' \times T = k(r'' \times r') \text{ at } \frac{\pi}{4}$$

$$(3, 0, -3) = \frac{2}{3}(2, 0, -2) \Rightarrow \text{sign for } \vec{N} \text{ different but for } \vec{B} \text{ the same!}$$

**Figure 2: Student’s work on a proof for the alternative technique: cases  $t = \frac{\pi}{2}$  (left) and  $t = \frac{\pi}{4}$  (right)**

*Episode 5: The new method explained.* After looking at several examples that produced a correct osculating plane by the “wrong method”, Sam started to realize that he should not try to prove that  $N$  is proportional to  $r''$  (which in general is not so) but instead he should try to prove that the span on vectors  $r'$  and  $r''$  forms exactly the same plane that the span of vectors  $T$  and  $N$  does. This shift of attention made Sam perceive a new property, which according to Mason (2008, p. 38) is feasible “when you are aware of a possible relationship and you are looking for elements to fit in”. Once he knew what he was looking for, a simple line sufficed: since  $r' = ||r'||T$ , by differentiation we obtain  $r'' = v'T + vT'$ , where  $v = ||r'||$  and  $v'$  are scalars. Thus, vector  $r''$  is a linear combination of vectors  $T$  and  $T'$ , or equivalently of vectors  $T$  and  $N$ . Therefore, whenever  $v \neq 0$ , vectors  $r'$  and  $r''$  can be used for finding the osculating plane initially defined by vectors  $T$  and  $N$ .

## Concluding discussion

In this paper we explored the possibility of imbedding an inquiry task, allowing students to construct technique-technological links and eventually to develop praxeologies by themselves, within a praxis-dominated lecture-based calculus course. Here we refer to the six moments of constructing a praxeology (listed in the Theoretical Framework section) in order to comment on two conditions that in our view had a positive effect on the successful outcome reported in Episode 5.

The first condition is the systematic attention paid by the instructor to the issue of the efficiency of students' work. This requirement for a solution of a problem is entwined with the inquiry-based methodology. In a situation when more than one approach is applicable to a problem in hand, one would naturally ask for the simplest answer, which is based on the insight about the nature of the situation and avoids unnecessary lengthy calculations. Indeed, “as mathematical thinking develops, it should become not only more powerful, but more simple” (Tall, 2013, p. 19) because “not only mathematics, but science as a whole progresses only if we understand things ... and explain [ideas] in simple terms” (interview with Sir M. Atiyah, as quoted in Tall, 2013). Episode 1 confirmed the observation that students in North America spend little time on planning their solution and jump into calculations right away (Schoenfeld, 1985). While the cognitive mechanisms for finding simple solutions in general are not clearly understood (see discussion in Koichu, 2010), it is important to establish the work habit of looking for legitimate simplifications whenever possible. Viewed as a part of didactic contract, the higher efficiency of the alternative method of finding the osculating plane prompted the students to keep trying to justify it. This efficiency gave the value to the praxeology being constructed (moment 6: evaluation).

The second condition is the fact that an additional new task emerged from the instructor's feedback on a mistake made by students while solving an exercise. Let us look at it a bit closer. The initial task in Episode 2 was to find an osculating plane for a curve at a point, which was defined in terms of the unit tangent and normal vectors -- the objects that were introduced to the students at the same time as was the osculating plane. The definitions prescribed the way of constructing all listed above objects. Thus, in the scenario of Episode 2 the first two moments (first encounter, exploration) were missing as such, and in this sense the task was an exercise in which a given technique was supposed to be used (a modified moment 3). On the other hand, the curve was chosen in such a way that it allowed a more intuitive approach in line with examples discussed in Episode 1. A “simple”, intuitive solution

was to notice that the curve belonged to the intersection of the cylinder  $x^2 + y^2 = 1$  and the plane  $z = x$ . Therefore the entire curve lied in the plane  $z = x$ , which thus was the osculating plane for any value of the parameter  $t$ . Finding this solution relied on explorations and noticing specific relations between components of the vector-function  $r(t)$  describing the curve. Indeed, several students had commented on this but only after they found the answer by a different method. Erroneously, they altered the method given to them attempting to (illegitimately) reduce the amount of calculations. The fact that the altered method provided an answer consistent with the “simple” intuitive approach led to a new task: to explain why it happened. It was the instructor’s role to formulate this task, but because the method appeared from the students’ own omission they claimed ownership of this task. Here the *adidactic* phase occurred later in the process and the development of praxeology by students basically started from moment 4, that is, from the assessment of the alternative technique. The successful outcome in Episode 5 was warranted by students’ reflection on the ideas related to the original praxeology with technology presented by the instructor in Episode 3, and modifying them accordingly. The institutionalization moment (5) was completed after Episode 5, when related physical motivation was also discussed in the lecture. Indeed, the observation that played the key role in the justification of the alternative method could be interpreted as follows: no matter how the object moves through the space the acceleration vector  $a = r''$  always belongs to the osculating plane:  $a = v'T + \kappa v^2 N$ , where  $\kappa = ||T'||/v$  is the curvature of the trajectory and  $v = ||r'||$  is the speed of motion. Vector  $T$  gives the direction of the motion and vector  $N$  points in the direction the object is turning. So  $T$  and  $N$  describe the (osculating) plane to which the trajectory of motion locally belongs. The expressions for the tangential and normal components of the acceleration vector make sense if we think of a passenger in a car making a turn (Stewart, 2003, p. 875).

Note that the praxeology developed by students in Episodes 2, 4 and 5 is punctual as it addresses just one particular problem of constructing an osculating plane. It is a refinement of the initial praxeology given in Episodes 2 and 3, and we conjecture that due to students’ involvement in its justification it will be more readily integrated in the future in local and regional types.

In sum, our case involved a routine exercise and a lot of “direct telling” as in a typical calculus course. This setup presumes that the two steps (first encounter, exploration) in the construction of a praxeology could be missing. Instead, through working on exercises using given information and techniques, the groundwork for developing alternative techniques and raising new questions is established. This situation gives us a clue about possible sources of questions that appeal to students and are perceived as important or meaningful, questions that help them to critically process given information and eventually develop praxeologies. We conclude that innovative ideas for task design can come from observing and analyzing students’ mistaken work with practice exercises. Sometimes the instructor can predict or even provoke those mistakes. Reshaping standard exercises so that they have multiple ways to solve them, like in our case above, may enrich the possibilities for the tasks that follow. If these tasks “aim directly to develop and refine knowledge in progress” (Gravesen *et al.*, 2017, p. 28), or explain certain puzzling phenomena, they will have the deepening potential and perhaps the research potential, helping students to work with new material in a meaningful way and gain richer experience of mathematical work. Because of their origin such tasks (compare to *a priori*

designed ones) may have a stronger and more personalized effect on learners when used in a didactic setting.

# What can be ‘annoying’ about mathematical conventions?

## Analysing post-exchanges of mathematically competent discursants

Igor’ Kontorovich

The University of Auckland, New Zealand; [i.kontorovich@auckland.ac.nz](mailto:i.kontorovich@auckland.ac.nz)

*The study reported in this paper is concerned with mathematical conventions, a discussion on which unfolded among mathematically competent discursants. The data came from a rich online thread, where practicing mathematicians, mathematics lecturers, graduate students and undergraduates at advanced stages of their studies were asked to share mathematical conventions “that are annoying, those that nobody likes but it’s too late to cancel”. Grounded in the commognitive framework, the study aims to delineate some rules that this discussion abided. Two discursive rules are presented herein: one rule calls for the use of the same symbols in different discourse communities to denote the same objects. The second rule appeals to a goodness-of-fit between mathematical objects and their conventional symbols. Some affordances that a discussion on conventions can bring to educational research and teaching practice are sketched.*

*Keywords: Conventions, commognition, mathematicians, mathematical symbols, online forums.*

### Introduction and background

Accepting established mathematical conventions – for instance, definitions of concepts, their names and symbols – is necessary for participating in a literate mathematical discourse (cf. Hewitt, 1999). However, research offers colorful instances of students and teachers grappling with some broadly accepted conventions. For example, in Kontorovich and Zazkis (2017), we asked pre-service teachers to propose arguments for denoting reciprocals and inverse functions with the same superscript ‘-1’. One of the teachers rejected the possibility that the two may have something in common beyond the symbol. After a comprehensive classroom discussion that revolved around the notion of closure under operation, the teacher amended his position and started using the terms “multiplicative inverse” and “inverse function”. Yet, he still refused to use “inverses” for referring to reciprocals and inverse functions together. The rest of the class, myself included, remained rather defeatist about the abstract algebra argument being not convincing enough for the teacher. These communicational clashes resonate with Sfard’s (2008) definition of a *discourse* as a type of communication “that draw[s] some individuals together while excluding some others” (p. 91); in the described episode, this feature could be ascribed to a *discourse on mathematical conventions* (DoMC).

At least two features distinguish DoMC from its mathematical congeners. First, it is substantially less deductive. While sequences of apodictic moves lead from a problem to a solution or from a theorem to a proof, the above episode illustrates that it might be difficult to justify a convention to a critical interlocutor (cf. Hewitt, 1999). Thus, familiar ways of mathematical communication might turn to be not transferable to DoMC. Second, DoMC mostly occurs among professional mathematicians (e.g., Kontorovich, 2016a; Knuth, 1992) and, in my experience, it rarely unfolds in regular mathematics lessons at school and university. Furthermore, a handful of studies show that teachers might intentionally avoid engaging in such a discourse with their students. Fukawa-Connelly (2015) reports on a lecturer in abstract algebra who wanted his students to engage in inquiry-based learning. He was

more successful, however, in delegating the responsibility for proving to the students – i.e. making conventional moves, rather than for developing definitions – i.e. introducing conventions. In Kontorovich (2016b), I show how thoroughly three mathematicians promoted particular conventions in their teaching, while being fully aware that they contradict the conventions promoted by their colleagues. Thus, little seems to be known about discursive practices that can be considered as characteristic of DoMC.

The study at hand is interested in drawing attention of the mathematics education community to DoMC as it unfolds in mathematics classrooms and professional mathematics communities. Research has repeatedly shown that a disciplinary inquiry into experts' thinking and doing can benefit the mathematics education community practically and theoretically (e.g., Poincaré, 1909/1952). This gives reason to believe that exploring the participation of mathematically competent discursants in DoMC might be insightful as well.

## Theoretical framework

This study is grounded in the *commognitive framework* (Sfard, 2008), whose usage in mathematics education in general and in university mathematics education in particular has been on the rise (e.g., Nardi, Ryve, Stadler & Viirman, 2014). Commognition posits that mathematical discourses are distinguishable through characteristic *words* (e.g., “reciprocal”, “inverse function”) and their use; *visual mediators* (e.g., the superscript ‘-1’ symbol) and their use; generally endorsed narratives (e.g., conventions); and *routines*, which are repetitive sets of metadiscursive rules (or *metarules*) that attest to actions and re-actions of the discursants. *Object-level rules*, in turn, “are narratives about regularities in the behavior of [usually mathematical] objects of the discourse” (Sfard, 2008, p. 201).

Sfard (2008) posits that “object-level rules of mathematics, [...] once formulated, remain more or less immutable” (p. 202), which might explain her main interest in discursant-centered metarules. The discourse of interest in this study revolves around mathematical conventions, a discourse the rules of which are said to be less known. Accordingly, the aim of this study is to discern some object-level rules that emerge from participation of mathematically competent discursants in DoMC.

The notion of object has an operational definition within the commognitive framework. Sfard (2008) argues that when communicating, we operate with perceptually accessible *signifiers* (e.g., words, symbols) that are realized into other signifiers. For instance, “inverse” can be realized into “ $\blacksquare^{-1}$ ”, which can be realized even further forming a *realization tree*. In this way, “[t]he discursive object signified by  $S$  in a given discourse on  $S$  is the realization tree of  $S$  within this discourse” (ibid, p. 166). This definition turns discursive objects into personalized and contextualized structures. However, our occasional success in coming up with mathematical narratives that are endorsed by our interlocutors show that there is room for expanding the notion beyond a particular person. In this study, some mathematical objects are ascribed to discourse communities in the sense that their object-names/symbols and corresponding realizations and narratives are shared by people who are recognized as community experts in mathematics.

## Method

This is exploratory research, the data for which comes from an online mathematical forum hosted on a popular social network. The forum communication occurs in Hebrew and it is far from sporadic. The forum has a clearly stated scope and descriptions of topics that are welcome for discussion. These include challenging theorems and problems in post-graduate mathematics, historical developments, and career paths in the discipline. Consequently, the forum brings together practicing mathematicians, university lecturers, graduate students, and undergraduates at the final stages of their studies. The forum activity is overviewed by a group of moderators who make sure that the posts are within the forum's scope. Posting in the forum requires registration, and the posts appear next to full and real names of their creators. This rather rigid frame of communication allows arguing that the forum discursants are committed to the ideas that they share in the forum at least to some degree.

As part of regular forum activity, one of the forum participants (FPs) raised the question, “*Which conventions do you know in mathematics that are annoying, those that nobody likes but it's too late to cancel?*” While this forum participant (FP1) did not elaborate any further on the meaning of the word ‘annoying’, the responses of FPs allowed to operationalize it as a tension between one's reconciliation with a particular mathematical convention and their awareness to its normative status in a broader mathematics community. The request for ‘annoying’ conventions was especially fortunate for this study, as it served as a methodological tool for illuminating discursive rules through breaching them (see Herbst & Chazan, 2011 for the use of breaching experiments in mathematics education).

FP1's call grew into a rich thread where 36 FPs enthusiastically engaged in a discussion on conventions and generated 132 telling posts. The thread constituted the data corpus for this study<sup>1</sup>. The sought discursive rules were inductively developed through an iterative analytical procedure (Glaser & Strauss, 1967). At the first stage, the posts were divided into mathematical conventions around which they revolved. Then, the conventions were grouped according to their similarities in the ‘annoyance’ that they raised for FPs. This categorization identified a potentially confusing use of words and symbols, which instigated me to engage reflexively with the commognitive framework in a search for the underlying tenets that these situations violated. This step yielded initial rules that were reapplied to the whole data corpus aiming to check whether the commognitive logic concurs with FPs' posts. Such systematic alternations between the framework and data resulted in four rules; two of them, the ones that accounted for the majority of discussed conventions, are presented next.

## Two discursive rules that ‘annoying’ conventions violate

### “Same object-symbol – same object” rule

To illustrate the first rule, let us consider Figure 1 for two narratives that FPs posted at FP1's request. Both narratives are concerned with conventional signifiers that feature in discourses that differ in their use of words and symbols, which results in conflicting narratives. In the first narrative, the ‘ $\subset$ ’-

---

<sup>1</sup>The study abided the recommendations of the University of Auckland Human Participants Ethics Committee for research with data collected from the public sphere.

symbol characteristic to set theory is used for signifying subsets by some and proper subsets by others. Figure 2 illustrates the second narrative with excerpts from popular textbooks that reflect discourses on vector decomposition in physics and mathematics. The same symbols  $\phi$  and  $\theta$  are used in both discourses, but their realizations are inverted: in the physics textbooks, we can see that  $\phi$  signifies the angle on the  $xy$ -plane and  $\theta$  denotes the angle with  $z$ -axis; in the mathematics textbooks,  $\phi$  signifies the angle with  $z$ -axis and  $\theta$  is used for the angle on the  $xy$ -plane.

### FP31

If  $A \subset B$  then the sets are necessarily different? (My approach: in the first two years of first degree yes, later no.)

### FP17

The immortal confusion between  $\phi$  and  $\theta$  in spherical coordinates among physicists and mathematicians. Not only what is signified how but also whether one of them is the angle with the plane  $xy$  or with  $z$ -axis.

**Figure 1: Example of the violation of the rule “same object-word/symbol – same object”**

The presented narratives exemplify a wider set of conventions that FPs shared, all violating the rule stating that in different communities of discourse, *the same object-symbol should stand for the same discursive object*. To put it more precisely (and more mathematically), I suggest determining the sameness of discursive objects  $S_1$  and  $S_2$  through an existence of a relation preserving one-to-one mapping between the realization trees of  $S_1$  and  $S_2$ . The presented examples illustrate that the mapping might require conversion of signifiers, which is what Sfard (2008) coins as discursive attuning – interlocutors reaching a consensus around their usage of particular words and symbols. Indeed, physicists and mathematicians do not disagree on how to decompose a vector, they disagree on how these components should be labeled.

Felder and Felder (2016, p. 232)

*Mathematical methods in engineering and physics*

Larson and Edwards (2010, p. 825)

*Multivariable calculus*

**Figure 2: Incommensurable approaches to spherical coordinates in physics and mathematics textbooks**

In turn, the sameness of object-symbols goes beyond their written and pronounced identity as it pertains to whether the signifiers are perceived as the same by the interlocutors. For instance, one FP shared that when studying probability and statistics, he often confused between visually similar symbols ‘ $\chi$ ’, ‘ $X$ ’ and ‘ $x$ ’, which led to multiple misunderstandings. When the difference between the symbols was clarified, many misunderstandings faded because the narratives that conflicted when assigned to the same object were distributed between different ones.

### “The goodness-of-fit” rule

The second discursive rule is concerned with a *goodness-of-fit between mathematical objects and their symbols*. In statistics, a goodness-of-fit is used for capturing the quality of a match between the factual data and the one that was predicted with some quantitative model. I discern a reflection of this idea among FPs, who were ‘annoyed’ when some key properties of a mathematical object were misrepresented in its conventional symbol. Figure 3 illustrates this rule violation with ‘|’ – a conventional symbol of divisibility.

#### FP26

[1]  $n|m$ ,  $n$  divides  $m$ . Who uses a symmetrical sign  $|$  for a non-symmetrical relation?!

#### FP24

[2] The sign of “divisible by” is asymmetrical. But the fact that there are two signs for “divides at” and “divisible by” just illustrates your claim.

[3] (In an internet search in English I haven't found evidence for existence of a sign for “divisible by”. But I know one. Very strange.)

#### FP26

[4] What is the sign for divisible by?

#### FP27

[5] Three dots that are written vertically is a standard sign for “divisible by”

#### FP24

[6] I am familiar with the diagonal, not vertical (and then it is asymmetrical). However the direction of a diagonal is not always consistent. Do you have a reference in Russian for this?

#### FP10

[7] And if we are already talking about this then why  $n$  is to the left of  $m$  and not to the right? If  $m$  is divisible by  $n$  then we get an integer when we divide  $m$  by  $n$ , and suddenly  $n$  jumps to the left side. So it is confusing. This is so annoying.

#### FP24

[8] You can just write  $n|m$ , and then it remains on the right 😊

#### FP10

[9] Correct but this is not accepted and I have never encountered such a sign in the context of numbers. [...]

#### FP10

[10] Besides the accepted signs  $m/n$  align with the accepted way to say that “ $m$  divided by  $n$ ” [...].

#### FP14

[11] Agree. The relation should be  $x/y$  for  $x$  “divisible” by  $y$ .

Figure 3: Example of violation of the goodness-of-fit rule

In the presented exchange, the discursive object of divisibility is separated from its conventional symbol ‘|’ and the attention is drawn to the mismatch between the two. In [1], FP26 addressed the mismatch in terms of symmetry: a visual symmetry that the symbol has and a symmetrical relation

that divisibility does not satisfy. In [7], FP10 focused on the inconsistency of equivalent realizations “ $m$  is divisible by  $n$ ”, “ $m/n=\text{integer}$ ” and “ $n|m$ ”: while in the two former realizations  $m$  appears to the left of  $n$ , the order is inversed in the third realization. The participants of the exchange seem to endorse the badness of the symbol’s fit since the exchange quickly refocuses on possible alternatives.

Figure 3 demonstrates two criteria of the goodness-of-fit that FPs recurrently praised in their narratives. The first criterion pertains to visual similarities between symbols of related objects. Indeed, FP14’s ‘//’-symbol in [11] is closely linked to ‘/’ – a conventional symbol of division. The second criterion suggests that the symbol should be accepted in some literate mathematics community, which can be shown through references (see [3] and [6]). More often than not, a promotion of unfamiliar symbols was criticized (see [8-9] as an example). Figure 3 also illustrates that it is not always easy to satisfy both criteria with the same symbol.

## Discussion

This study has been concerned with DoMC and the rules that this discourse abides. While the mathematics community tends to be explicit about object-level rules of discourses on well-defined mathematical objects (e.g., numbers, functions, triangles), this is not the case of DoMC. Metaphorically speaking, this discourse mostly unfolds in “corporate mathematical kitchens”, whose doors are firmly closed for outsiders. An online space though seems like a spectacular arena for observing how DoMC can unfold almost in the real-time (Kontorovich, 2016a). This being said, it seems worthwhile to highlight that the scarcity of our research knowledge on mathematicians’ communication about conventions should not tempt us to generalize discursive patterns emerging from a particular subcommunity to the mathematics community as a whole.

Two discursive rules were reported in this paper: same object-symbol – same object and goodness-of-fit between objects and their symbols. The first rule, stating that the same *objects* should be denoted with the same object-symbol in different discourse communities bears resemblance to the renowned intuitive rule “same A – same B” (e.g., Tirosh & Stavy, 1999). With “same A – same B”, Tirosh and Stavy refer to a reasoning principle, according to which the sameness in one property of two *objects* is often conceived as sufficient for deriving their sameness in another property. The FPs of this study would probably classify the resemblance between the discursive and intuitive rules as ‘annoying’ because the overlap of the italicized terms conceals the incommensurability of their epistemological origins. Building on the work of Fischbein and Piaget, Tirosh and Stavy concentrate on perceptual objects (e.g., geometrical figures) and their properties (e.g., length, perimeter). The study at hand, however, leveraged commognition for indicating regularities between discursive objects and their leading signifiers (i.e. names and symbols). Therefore, it would be more accurate to acknowledge that the intuitive and discursive rules agree on the “transition of sameness”, when the cognitive and commognitive foundations offer substantially different answers to “sameness of what?” and “transition to where?” Another similarity between the two rules is in the ways they are enacted. Tirosh and Stavy (1999) refer to their rule as “intuitive” since it is accepted as true without a need for any further justification. In a similar manner, the FPs of this study neither offered nor sought explanations for the nature of the ‘annoyance’ that they or their peers experienced when the

corresponding discursive rule was violated. This might suggest that the emotional disturbance was self-evident in these cases.

The goodness-of-fit rule emerged from the exchanges where FPs discussed how some key realizations of mathematical objects are poorly reflected in their symbols and what alternatives may ensure a better fit. Commognitively speaking, such a discussion requires a separation between a ‘root’ – conventional object-word or symbol – and the rest of the realization tree. This discursive move cannot be taken for granted. Sfard (2008) associates one’s understanding of a mathematical object with a particular form of talk, where mathematical intangibles are discussed in a manner that is similar to the physical congeners. Such a talk could not be possible without tightened connections between a leading signifier and the rest of the realization tree. In this way, the study shows that some mathematically competent discursants are capable of separating and contrasting between the two for judging the quality of the fit. Further research may explore the relations between this capability and one’s proficiency in a mathematical discourse.

### **Teaching-oriented remarks**

The interest in conventions that was identified in this study among mathematically competent discursants, begs us to consider the affordances that DoMC could offer to the educational research and the teaching practice. Three affordances are sketched next.

First, this study shows that mathematically competent discursants can be ‘annoyed’ with conventions featuring in a variety of mathematical areas. The nature of some of their ‘annoyances’ is not very different from the one identified in Kontorovich and Zazkis (2017) with pre-service teachers and some other studies with school and university students. This rare similarity between substantially different cohorts allows me to propose that the endorsement of some conventions requires exceptional discursive leaps. In other words, newcomers’ struggles with conventions might be interpreted in some cases as an expert-like sensitivity to a radical discursive change rather than a knowledge deficiency or a result of infelicitous teaching.

Second, all discursants in this study lamented over conventions that are often positioned as “well-established” and advocated for their less-celebrated alternatives (e.g., ‘|’ as a symbol of divisibility). In an educational context, this result delineates a barely explored teaching practice of *choosing* conventions for architecting classroom discourses (Kontorovich, 2016b). This conceptual delineation invites research on whether teachers are aware of the status of conventions in mathematics, how they choose between mathematically incommensurable alternatives, and how these choices impact discourses that students develop. I hope that the rules identified in this study will instigate teachers to make more informed and thought-through choices. Indeed, if mathematically competent discursants complain about same signifiers standing for different objects and the badness of symbols’ fit, then it seems reasonable to predict that students might struggle with such conventions as well.

Lastly, the discursants in this study transitioned between objects that are characteristic of different mathematical areas; they referred to definitions, symbols, and theorems; and they reasoned and communicated with each other. These desirable practices raise the question of whether students should also be given a space to actively participate in DoMC. The debate on this issue is ongoing (see Hewitt, 1999 and Kontorovich & Zazkis, 2017 for opposite views). I believe that opening this space

for students will also open a research space for articulating and challenging conventions that we, mathematics educators, hold about teaching and learning.

# Beliefs about learning attributed to recognized college mathematics instructors

Valentin A. B. Kuchle<sup>1</sup> and Shiv S. Karunakaran<sup>2</sup>

<sup>1</sup>Michigan State University, East Lansing, USA; [kuechlev@msu.edu](mailto:kuechlev@msu.edu)

<sup>2</sup>Michigan State University, East Lansing, USA; [karunak3@msu.edu](mailto:karunak3@msu.edu)

*Keywords: Beliefs, learning, teaching, college mathematics.*

The study of teachers' beliefs has a rich tradition (Calderhead, 1996), and several key categories of beliefs have been identified: teachers' beliefs about mathematics and the learning and teaching thereof (Ernest, 1989). Although the study of beliefs has largely focused on K–12 teachers, researchers have sought to extend this work to instructors of collegiate mathematics (e.g., Speer, 2008). Our study adds to this body of literature by focusing on a particular subset of college mathematics instructors, namely those who have been recognized with teaching awards. Although we do not equate winning a teaching award with teaching excellence, we note that recognized instructors are nominated by fellow colleagues and/or students, have had cause to reflect on their own teaching, and by winning the award have had their teaching explicitly commended by their department and college. Such an award adds weight to their voices in matters of teaching and makes them teaching role models. Thus, we seek to explore recognized instructors' beliefs about mathematics and the learning and teaching thereof.

Below, we present our study's preliminary findings from a series of interviews we conducted with recognized college mathematics instructors. We align with Ernest's (1989) conceptualization of beliefs and mirror his focus on beliefs about mathematics and the teaching and learning thereof. Furthermore, we espouse Speer's (2005) view that researchers attribute beliefs to participants and concur that interviews alone do not do justice to our participants' beliefs. Thus, we see our interviews as forming the first step of a larger study including detailed classroom observations.

## Method

At a large US institution, six mathematics instructors who had won at least one teaching award each were randomly chosen—from the set of thirteen mathematicians who had won a teaching award within the last five years—and individually interviewed for around one hour using a semi-structured interview protocol. Two of the participants were non-PhD mathematicians, the other four held PhDs in mathematics. One of the non-PhD mathematicians was male (Aleph), the other female (Beth), whereas the four PhD mathematicians were all male (Gimel, Dalet, Waw, and Zayn).

All interviews were transcribed and coded with the help of MAXQDA, a qualitative data analysis software. A coding scheme was iteratively developed by the two authors with four top-level domains (*Learning, Teaching, Mathematics, Miscellaneous*) and several subcodes allowing for more nuanced coding. Separately from this coding scheme, declarative statements were highlighted.

## Results

Thus far, we have identified three interesting findings. First, the interviews with the non-PhD and the PhD instructors took markedly different turns. For the non-PhD mathematicians, who had typically

taught incoming undergraduate students, students' motivation was perhaps the most dominant issue. Both Aleph and Beth agreed that students require intrinsic motivation for true learning, which their students lacked. As a result, both had embraced efficiency in their teaching, for instance via course handouts containing most of the lectures' content. For the PhD mathematicians, motivation was hardly a topic of concern: They took intrinsic motivation for granted—perhaps because they were teaching mainly upper-division courses.

Second, the beliefs of the PhD mathematicians varied widely: Beliefs ranged from learning is solitary to learning is collaborative. Whereas Gimel believed that learning happened when one was working alone on a problem, Dalet took a more moderate approach and stated that learning could be both a solitary and a social activity. In opposition to Gimel's belief, Waw asserted that learning is social. The last PhD mathematician, Zayn, noted that he did not want to impose his own learning experiences onto others and that there are as many ways of learning as there are students. Thus, even among this small number of PhD mathematicians, beliefs varied widely, and no dominant view emerged.

Last, PhD mathematicians' own learning experiences aligned with how they spoke about their teaching. Gimel, Dalet, and Waw all taught in a way that reflected how they themselves had learned. Even Zayn, aware of the possible differences between his and his students' learning, realized during the interview: “[The course] *is* made in my image, now that I think about it. I went through all that trouble of saying I don't want them to learn the way I learned, but now that you're making me say it ...” Thus, the PhD instructors' teaching mirrored their learning experiences.

## Discussion

Our results lead us to ponder several issues. First, we wonder whether college mathematics is too broad a term. Perhaps a more fine-grained view that distinguishes between lower- and upper-division courses might be beneficial for untangling college instructors' beliefs. Second, we note that instructors holding a wide variety of beliefs were able to win teaching awards at this institution. Lastly, the interview with Zayn demonstrated that one's teaching may be in-line with one's learning preferences even when one is aware of differences between one's own and others' learning experiences and wishes to be considerate of these differences.

*To support students at the often-times difficult transition from high school to university mathematics, some universities in Germany have introduced innovative lectures. The WiGeMath project evaluated to what extent these measures fulfill their self-set goals. During the evaluations, specific questionnaire items and lecture observations were applied to investigate which characteristics made these lectures different from traditional ones and in how far students valued these features in achieving the courses' learning objectives. The results show that students in the redesigned lectures value guidance and clarification rather than abstractions and that redesigned lectures include more social interactions and student engagement than traditional lectures.*

### Background and aim of the paper

Many students face difficulties at the transition from high school to university mathematics (Gueudet, 2008). Some universities give support by establishing redesigned lectures, by which we mean lectures that are usually held during the first semester and, unlike traditional lectures, do not focus on university mathematics content. They may, for instance, rather help students who have already failed certain tests to revise the necessary foundations for their further studies or they focus on study techniques like problem solving. Good experiences with lectures or courses that do not focus on the presentation of new theory have been documented in the UK with focus on problem-based learning of analysis (Alcock & Simpson, 2002) or problem solving activities (Tall & Yusof, 1998). Meanwhile, traditional lectures are still both widespread and criticized for neither promoting students' active learning nor exploiting their potential in drawing students into higher mathematical thinking (Pritchard, 2015). Promoting innovative support is the goal of the WiGeMath project (german for Effects and success conditions of mathematics learning support in the introductory study phase), which is a joint research project of the Universities of Hannover and Paderborn (Colberg et al., 2016). It evaluates diverse support measures including redesigned lectures. First, the project developed a taxonomy that serves to categorize features and goals of support measures (Liebendörfer et al., 2017; Kuklinski et al., 2018). This taxonomy was then used to lead guided interviews with the lecturers about the courses' goals. Previous research showed that redesigned lectures were successful in meeting at least some of their goals (Kuklinski et al., 2018). Students' mathematical self-concept and self-efficacy did not decline significantly in these lectures unlike in traditional lectures (Rach & Heinze, 2017), and toolbox beliefs decreased. Our research questions are (1) which course features named by lecturers did students find helpful in reaching learning goals and (2) which observable characteristics distinguish these courses from traditional ones.

## Method

With regard to research question (1), we will first report on a questionnaire survey and then, for research question (2), on lecture observations. After we had interviewed the lecturers about their concepts of the redesigned lectures, covering their envisioned teaching strategies, the learning goals they wanted students to achieve and which activities they hoped the students would engage in to reach the goals, we developed questionnaires that aimed at evaluating if attending students felt the lecturers succeeded in meeting their own goals. We applied a special concept for lecture course evaluations called the Bielefelder Lernzielorientierte Evaluation (BiLOE, Frank & Kaduk, 2017) which serves to investigate to what extent students feel they have reached certain learning objectives, which activities they found helpful in achieving those they feel confident they achieved and what reasons they see for not reaching the others. The items looked as displayed in Figure 1.

Question: To what extent have you achieved the following learning objectives?

	Achieved entirely	Rather achieved	Rather not achieved	Not achieved at all
I can handle various strategies for problem solving.	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
...	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Question: To what extent did you find the following activities helpful in achieving the learning objectives?  
→ Please fill this out only for those learning objectives that you achieved entirely or rather achieved.

		Learning objective 1: I can handle various strategies for problem solving.				Learning objective 2: ...			
	I did not do this.	Very helpful	Rather helpful	Less helpful	Not helpful at all	Very helpful	Rather helpful	Less helpful	Not helpful at all
I worked on problems of various types in the lecture.	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
...	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

**Figure 1: Example items of the BiLOE**

This questionnaire was given to the students towards the end of the term. The students were asked only to fill out the part of the helpful activities for those goals they felt they had reached or rather reached. An overview of our samples is given in table 1.

Cohort	Engineering students		Pre-service teachers			
Location	Kassel	Stuttgart	Kassel	Oldenburg	Paderborn	Würzburg
<i>n</i> (f/m)	13 (0/13)	55 (11/44)	12 (6/6)	102 (54/48)	45 (18/27)	41 (20/21)
Method	Paper-pencil		Online	Paper-pencil		

**Table 1: Overview of the sample size (*n*) and the numbers of female (*f*) and male (*m*) participants**

Moreover, we conducted lecture observations. We used the WiGeMath taxonomy to develop a guideline to observe the redesigned lectures and created an observation sheet where the observer has to mark different categories as they apply during five-minute-sections that we split the whole session into. The observation sheets for the non-participating observation contained a series of tables like in figure 2. As to the categories of jargon of mathematics and memorizing, these were coded if the lecturer explained the use of a mathematical formula/ character or named a character like  $\in$  or if he asked students to learn a definition, proof scheme or calculation rule by heart, respectively.

		Jargon of mathematics	Memorizing	Media	Form of interactions	Problem solving/ task solving
Time: 0.00 Min.- 5.00 Min.	Themes:	<input type="checkbox"/> Explanation:	<input type="checkbox"/> Definition:	<input type="checkbox"/> Board <input type="checkbox"/> OHP <input type="checkbox"/> Power-point	<input type="checkbox"/> Lecturer presenting, facing the board <input type="checkbox"/> Lecturer presenting, facing the students	<input type="checkbox"/> Students look for an answer <input type="checkbox"/> Lecturer helps during the solving process → kind of help:
Explicit reference to school		<input type="checkbox"/> Translation:	<input type="checkbox"/> Proof scheme:	<input type="checkbox"/> PC-Simulation <input type="checkbox"/> Work-sheet <input type="checkbox"/> Calculator <input type="checkbox"/> Tablet-PC	<input type="checkbox"/> Lecturer asks questions <input type="checkbox"/> Students answer <input type="checkbox"/> Student asks, lecturer responds <input type="checkbox"/> Student asks, student responds	<input type="checkbox"/> Students present their results <input type="checkbox"/> Lecturer presents the solution <input type="checkbox"/> Wrong approaches to the solution are discussed
Explicit reference to profession			<input type="checkbox"/> Calculation rule:		<input type="checkbox"/> Discussion <input type="checkbox"/> Individual work <input type="checkbox"/> Partner work <input type="checkbox"/> Group work	
Explicit reference to university						

Figure 2: Extract from the observation sheet

For each of the evaluated lecture courses, we employed two student assistants to observe the lecture course at three times during the semester, once in November, once in December and once in January (the semester lasts from October to January). The observers studied mathematics but were not regularly taking part in the lecture courses observed. They had been given the observation sheet and a manual including examples and they had been trained using a short video episode of a lecture to make sure they had understood the categories and their handling in the way we had intended them. The students were advised not to communicate so we would get independent results from them which led to a few disagreements in their codings but their overall assessments matched. To have a reference point as to the deviation that the evaluated lecture courses showed from traditional lecture courses, we also had two students evaluate a traditional linear algebra section and a traditional analysis section for first semester students.

## Results

We will first look at the results of the BiLOE and then analyze the lecture observations. For the BiLOE, the lecturers named some activities that they expected students to engage in, which did not seem to deviate from traditional lectures. These included attending the lecture sessions, working on homework alone or in groups or revising the lecture notes.

Yet, there were other activities that seemed to be of a more innovative and supportive kind. These activities very much appealed to the students as can be seen from the percentage of students that found them to be rather helpful or very helpful in achieving the lectures' learning objectives. Although the lecturers were free to name any activities they wanted without having been given categories or guidelines, the activities they named could be grouped into five different classes, namely reflection, testing oneself in a safe place, work with examples, work with prototypes and social interactions, see table 2.

With regard to research question (1), the categories of reflection and work with prototypes seemed to be the most helpful ones in the eyes of the students as more than 60% (for some of the activities a lot more than that) found them rather helpful or very helpful for all given learning objectives. All categories seem to reflect a learning atmosphere that is closer to school life than to university life. The categories of reflection, work with examples and work with prototypes all suggest that students hope for guidance and clarification rather than abstractions. Moreover, they do not like the feeling that they have to prove themselves, they rather want to work without pressure or in cooperation with others.

<b>Reflection</b>	Paying deeper attention to common mistakes	76% - 92%
	Reflecting on every step while solving problems	67% - 83%
	After solving a problem, reflecting which solution techniques were used	74% - 90%
	Reflecting the preconditions and the steps in every proof of the lecture	75% - 85%
	Looking for common patterns in proofs	67% - 96%
<b>Testing oneself in a safe place</b>	Writing mathematical texts myself	42% - 59%
	Doing smaller proofs myself	77% - 100%
	Working on difficult problems in an easier form at first	68% - 80%
<b>Work with examples</b>	Revising the examples from the lecture	40% - 77%
	Having the lecturer demonstrate how to prove	82% - 92%
	Having the lecturer explain different proof methods in detail	63% - 86%
<b>Work with prototypes</b>	Getting to know problems with many different facets	78% - 85%
	Working with very appealing proofs	60% - 100%
<b>Social interactions</b>	Asking the lecturer for help when I got stuck	59% - 79%
	Asking the lecturer for feedback even where my solutions were correct	54% - 72%
	Working on content together with others	40% - 88%

**Table 2: Activity categories and percentages of students who found the activity rather helpful or very helpful for all given learning objectives**

With question (2) in mind, we will now focus on the observation results. Although the predominant media used was limited to the blackboard almost exclusively, just as in traditional mathematics lectures, we found some interesting deviations in the social interactions that took place as well as in the way that students were engaged in problem and task solving processes. In all lectures, we observed various instances where the lecturer asked questions and students answered, indicating that interactions took place regularly. Besides, students also asked questions repeatedly. This suggests that the learning atmosphere in the lectures made students comfortable to openly express their comprehension difficulties. Yet, we did not encounter instances where a student asked a question and another then answered. In consequence, discussions did not take place and neither did typical teaching conversations. Although we observed a few phases of single, partner or group work, these stayed an exception which also indicates that the lecture atmosphere stayed distinct from a typical school classroom. Rather, the format of a lecture remained central and the two forms of interaction that were predominant in all courses were the lecturer talk facing the blackboard and the lecturer talk facing the students. But the fact that other forms of interactions did occur is enough to make the lectures distinct from traditional ones. In fact, phases where the students were actively engaged in problem or task solving processes did not occur in the traditional lectures we observed (Analysis I in Figure 3). In contrast, such phases were observed in all redesigned lectures and there was even one observation where students were active to this effect in 95% of the time (cf. Figure 3).

**Figure 3: Engagement of students in problem solving in some of the lectures**

As students rated the category of testing themselves in a safe place as helpful in the BiLOE, it seems like they profited from these periods of student task solving.

## Discussion

### Methodological discussion

To examine the features of redesigned lecture courses and in how far students find them helpful, we decided to make use of an established evaluation instrument called the BiLOE and to hire students who observed lecture sessions focusing on certain categories based on the WiGeMath taxonomy which we provided them with. To be precise, in applying the BiLOE we used an established evaluation method that we connected to the WiGeMath taxonomy and we developed an observation instrument that is easy to use with small training effort of the observers. Moreover, we did not rely on single observations but employed two raters.

The results of the BiLOE must be interpreted as personal estimates only. Though the students indicated how helpful they found the given activities to be in achieving the learning goals, we cannot say whether they actually did achieve these goals. Other indicators like exam results or homework assignments would have had to be examined to make a qualified statement in this respect. It would also be possible to use a pre- and post-test design to measure the students' understanding of the content. Moreover, the results we got from the BiLOE may be biased as we only surveyed those students that attended the lectures. Had we questioned all registered students of the course, results might have been different.

Concerning the observations, the two student observers did not always agree in their codings. However, we could not calculate inter-rater reliabilities due to unmatched timings by the observers. We recommend parallel timing for both observers in future research and maybe a more elaborate training. Yet, our results show that the use of simple methods can reveal important lecture features.

### Discussion of the results

The data show that successful, innovative lectures may benefit from the five elements of reflection, testing oneself in a safe place, work with examples, work with prototypes and social interactions. It is possible to implement such elements in traditional settings and students value these elements.

According to Slomson (2010) the format of lectures remains the dominant way of teaching for university mathematics students at the beginning of their studies and he claims that they have hardly changed for 40 years. Our results show, that changes are possible. They contradict the text of Wood

et al. (2007) referring to Gibbs et al. (1992) who claim that university lectures are more or less uninterrupted monologues by lecturers where student activity was limited to listening and note-taking. The innovative approach of the projects in WiGeMath is visible as in the traditional lectures we only encountered lecturer talk and no problem solving by the students during the lecture. In fact, Slomson (2010) gives four characteristics of lectures and one of them is that there is scarce interaction between the lecturer and his audience and the focus of the lecturer lies in transmitting a set amount of material. Moreover, Wainwright et al. (2004) also observed traditional mathematics lectures and did not encounter any instances where students collaborated or interacted with other students or the lecturer. Yet, students do seem to be interested in being more engaged during lectures just as we found in our research. In fact, Willcoxson (1998) found that students value teacher-student and student-student interactions in the lectures they attend and as Cavanagh (2011) makes clear lectures that engages students in more than just note-taking have positive effects in students' approaches to learning and their long-term understanding.

That students found social interactions and the work with examples helpful in achieving the learning goals goes hand in hand with the findings by Slomson (2010) that students prefer lectures with exactly these features and by Anthony (2000) that students believe that availability of support helps to lead to students' academic success. Moreover, Wood et al. (2007) explain the lasting percentage of students attending lectures where they could easily access the material online by the importance that these students must place on human contact in their university learning experience.

In another study that evaluated the success of so-called lectorials which blend traditional lecturing with more engaging activities where students learn cooperatively also found that most of the students valued these activities as they helped them in deeper understanding the content and in staying interested (Cavanagh, 2011).

While students in our surveys found the work with prototypes and examples helpful in achieving the learning goals, Anthony (2010) found that students did not allocate an important role to the practice with examples for achieving academic success. Yet, Anthony (2010) refers to the self-directed study of examples rather than the work with examples during lecture time. Conversely, Cavanagh (2011) found that students valued an abundance of examples in the lectorials he surveyed as they increased motivation and interest in the tasks.

An important question is, however, what caveats lecturers see in these innovative formats. A major concern might be the pressure they feel to cover all the contents (Johnson, Ellis, and Rasmussen, 2016). We should then discuss extending the time given for such lectures as well as the sustainability of students' learning.

### **Implications for research, policy and teaching**

Our results indicate that lecturers should consider restructuring their lectures so that students feel more secure to engage with the contents as well as with the lecturer and other students. Where possible, an abundance in examples might help students in understanding and then feeling more confident in the lecture content. So even though the traditional format of the lecture cannot be said to be useless in transmitting mathematical knowledge, our results indicate that students value social interactions and more lively formats which make the content illustrative by means of examples.

The lecture courses we evaluated differ from traditional lecture courses in more respects than the ones we focused on in this paper. In the categorization of the WiGeMath taxonomy, their focus on revisions of content and on study techniques or mathematical working techniques rather than on mathematical content would be differences in the individual and system-related goals of the measures. Yet, the measures also show specificities in their frame conditions and their characteristics. For example, the measures for engineering students in Kassel and Stuttgart are set out with small groups where the students work in an atmosphere that resembles school lessons. The lecture courses in Kassel and Oldenburg, where we focused on the pre-service teachers, indeed address this group predominantly rather than traditional lecture courses which mathematics majors and pre-service teachers attend together. The lecture course in Paderborn uses two tests in the course of the semester to prepare the students for the final exam and the structure of university mathematics exams in general whereas the lecture course in Würzburg does not include any examination at all. In this text, we looked at some further aspects of the lecture courses' learning culture and didactical features but to evaluate in how far students find these other features helpful in their learning process might be an endeavor worth undertaking in the future.

# Students' work with a task about logical relations between various concepts of multidimensional differentiability

Elisa Lankeit and Rolf Biehler

Universität Paderborn, Germany; [elankeit@math.upb.de](mailto:elankeit@math.upb.de), [biehler@math.upb.de](mailto:biehler@math.upb.de)

*The purpose of this study is to identify student difficulties concerning the linkage of various concepts of differentiability in  $\mathbb{R}^n$ . For that reason, we designed a task where students are encouraged to explore the logical relations between these concepts and analyse how university students work with this task. Based on a detailed a priori analysis of the task building on TDS, we present results of an analysis of students' written work on the task, produced in tutorial group meetings. We identify different types of reasoning and compare difficulty levels of the different relations.*

*Keywords: College mathematics, multidimensional analysis, task design, tutorial groups.*

## Introduction and literature review

Differentiability and derivatives are essential topics in school and university mathematics and have been studied for many years (e.g., Orton, 1983; Zandieh, 1997). However, as Rasmussen, Marrongelle, and Borba (2014) point out, studies looking beyond first topics of calculus, for instance in multivariable calculus, are rare. From informal discussions with students and lecturers, and from our own teaching experience, we know that multivariable differentiation, an exciting and essential topic covered at the university level, is not an easy topic for many students. The transition from the one-dimensional into the multidimensional case is far from trivial, especially since there are inequivalent concepts of differentiability in  $\mathbb{R}^n$ . Nevertheless, the literature on the difficulties of students working with these different concepts and relating them to differentiability in the one-dimensional case is scarce. Martínez-Planell, Gaisman, and McGee (2015) studied students' understanding of the differential calculus of functions of two variables using APOS theory and found out that the geometric interpretation of functions in two variables and especially of their partial derivatives and total differential are problematic for students. However, they focused on the geometric understanding and did not define the total differential as a linear function and especially did not look at the students' understanding of the relationships of the different concepts. Since we could not find any literature concerning students' understanding of the relationship between the different concepts of differentiability in  $\mathbb{R}^n$  as such, we had to refer back to the one-dimensional case. Of course, there exists only one concept of differentiability (with different interpretations), and the concept of left- or right-hand differentiability usually plays no important role, whereas directional differentiability becomes an important notion in the multidimensional case. Students' knowledge and difficulties in linking differentiability, continuity and integrability in the one-dimensional case could provide helpful insights. Juter (2012) and Duru, Köklü, and Jakubowski (2010) found that many students believed continuity implied differentiability in the one-dimensional case. Additionally, students who found the correct relations between these concepts were often not able to give sufficient justifications. When looking at the relations between differentiability, continuity and integrability, success rates are even lower (Sevimli, 2018). In some

cases, students used the teaching sequence as an argument for the stated relations. Generalising from this, we expect even more difficulties in the multidimensional case, which may exacerbate, if the knowledge on the one-dimensional case is still fragile. A further challenge for the students is the linkage of the one-dimensional to the multidimensional case. This linkage requires that the students have acquired the interpretation of the derivative as the best linear approximation and not just the interpretation of it as a tangent line, as a local rate of change or as the limit of the difference quotient (for these different interpretations, see Greefrath et al., 2016).

In this article, we are especially interested in the way students work with different concepts of differentiability in  $\mathbb{R}^n$ . We designed a task asking to explore the logical relations between these. The task was given to students in their weekly tutorial group meetings in an Analysis II class (which is, from an international perspective, more on the level of upper-division proof-oriented Real Analysis courses in the US than typical lower-division Calculus courses). We will present the task and selected results from our study examining how students in their second or higher semester worked on the designed task, showing success rates for rating and justifying the validity of different relationships and selected ways of argumentation. Thereby we want to improve understanding of students' knowledge and learning of differentiability concepts and hopefully contribute to designing suitable learning environments regarding this subject area in the future.

## Theoretical framework

We base our task design and analysis on Brousseau's Theory of Didactical Situations (TDS) (Brousseau, 2006). A *situation* describes the circumstances in which students find themselves concerning their *milieu* (the set of objects on hand, available knowledge and interaction with others). The distinction between didactical and adidactical situations is essential. A situation is of adidactic nature if the teacher does not instruct, but students work autonomously and learn by adapting to the milieu whereas, in a didactical situation, acculturation happens through institutionalisation and devolution. For a more detailed description and a well-presented introduction of TDS, see for example Artigue, Haspekian, and Corblin-Lenfant (2014).

According to Gravesen, Grønbæk, and Winsløw (2016, p. 10), “exercises are the cores of situations of learning”. They developed a framework for task design and analysis, based on TDS and focusing on four specific “potentials” of tasks. The *adidactic potential* of a task describes the possibilities of a task to be used in an adidactical situation: Which possibilities does a student have to engage with the task and develop new knowledge independently without additional interactions with the teacher? A task's *research potential* is measured by the possibilities to engage with one or more research like activities formulated by Gravesen et al. (2016). *Linkage potential* represents the possibilities for students to connect “old” and “new” knowledge. At last, *deepening potential* means the task's potential to intensify and elaborate the students' knowledge regarding results, notations and methods.

## Research questions

We designed a task with adidactical, research, linkage and deepening potential and put the students into an adidactical situation of working on that task. We investigate how the students link the different concepts of differentiability in  $\mathbb{R}^n$  and want to identify students' difficulties in this subject

area. In this paper, we want to answer the following research questions: **RQ 1:** Which of the logical relations seem to be more difficult for the students? Is the order of difficulty levels the same for the decision of validity and the associated argumentation? **RQ 2:** What kind of reasoning do the students use when explaining the relationships? **RQ 3:** How is this reasoning related to the reasoning and identified problems that we anticipated in the a priori analysis? In this paper we focus on students' work on the two questions "Does partial differentiability imply differentiability?" and "Does continuity imply the existence of all directional derivatives?".

## Methodology and study design

The method of didactical engineering (Artigue, 1994), evolved from TDS, provides the link between the theoretical framework of TDS and the practical implementation in this study to answer our research questions. It is composed of a preliminary analysis of epistemological, cognitive and didactical dimensions of the mathematical knowledge that is to be learned in the situation. It includes the design of the situation including an a priori analysis with the students' expected behaviour based on the choice of the didactic variables, the experimentation (usually a classroom implementation of the situation) and an a posteriori analysis with evaluation and comparison of a priori and a posteriori analyses. Guided by these steps, we will now provide a short description of our approach.

**Step 1: Designing a task that supports our research interests.** We used the described method of didactical engineering and conducted a preliminary analysis at first (not shown here). For this, we analysed some broadly established Analysis II books used in German universities (e.g., Heuser, 1992) concerning the essence of the concept of multidimensional differentiability. When designing the task, we oriented ourselves by the four "potentials" according to Gravesen et al.'s framework. The task analysed in this article aims at supporting the students in gaining an overview of how the different concepts of differentiability are connected. After working on this task, students should be able to explain how the concepts are connected and to give counterexamples of functions having only some of the properties. The task discussed in this paper was preceded by a prompt to recapitulate which of the connections the lecture had already covered. The discussed task was given to the students after they completed this. In the task, students are asked to examine whether different implications (called "T1" to "T15") are valid or not. The diagram used in the task can be seen in Figure 1 together with the success rates. We created the visual representation of the logical relations (similar to a concept map) in order to support students' reasoning. In particular, the diagram is to support an abstract knowledge network, which students can use as an abstract reasoning tool that some implications are true / cannot be true because other logical relations have already been proven. We were interested in how the students would use this network vs try to proof or refute a particular implication by specific arguments.

**Step 2: Conducting an a priori analysis of the task.** The a priori analysis of two implications (T10 and T15) can be found in the next section. It was conducted before the implementation of the task.

**Step 3: Task milieu and data collection.** The situation of working on the task is characterized by the task itself and the milieu in which the students found themselves. The task, which was

coordinated with the teacher and teaching assistant, was given to the students of an Analysis II course in their weekly tutorial group meeting. Most of the students worked in pairs or small groups and discussed the task. They also used their lecture notes and could ask the tutor if they needed help. For this particular meeting, particular instructions for the tutors were developed: They were asked to only give strategic hints and mostly just let the students work on their own. The written work the students ( $n=31$ ) produced during the tutorial group meetings was collected anonymously, scanned and then handed back to the students (without comment or marking).

**Step 4: Analysis of data.** We analysed the students' written solutions concerning two aspects: the correctness of students' solutions and their ways of argumentation. At first, we used a normative approach by rating the solutions: For every implication arrow, there are two separate tasks: A. deciding whether the implication is true or false, and B. stating a correct justification which could be a counterexample or a proof. Two types of missing values are coded: If there are none of the boxes checked (A) or nothing was written down (B), but subsequent subtasks were worked on, we coded it as a "missing, but attempted", i. e. we believe the lack of written work was not due to time. If nothing is written down but none of the subsequent tasks was worked on, we coded it as "missing". For the last subtask, we decided to count as attempts every work where one of the boxes for T5 or T15 was checked, or anything was written down for B. The correct decision of A is rated one point if correct and 0 if wrong. B is rated as follows: a (nearly) right justification (i.e. correct with a minor formal error) is rated two points. We give one point for a meaningful attempt for a justification, including argumentations containing consequential errors or correct counterexamples without arguments why these are counterexamples. Wrong or incomprehensible justifications, including wrong counterexamples, are rated zero points. Two total solution rates for A and B were calculated. Here, we defined the success rate per task as the sum of the scores divided by the number of students who attempted the subtask multiplied by the maximum score (1 for A and 2 for B). For analysing the students' ways of argumentation, we used qualitative content analysis (Schreier, 2012) with categories deducted from the a priori analysis complemented with inductively found categories.

## A priori analyses

The a priori analysis is the first result and serves as a research tool in the data analysis as well since the results will be compared to our expectations.

### A priori analysis of "Does partial differentiability imply differentiability?" (T10)

Most students will probably state correctly that this implication is not true. A hint for this could be that if it were true, it would have probably been covered in the lecture when the other direction was discussed. Moreover, why should the lecturer introduce two different concepts if they turn out to be equivalent? We call these reasons "didactical-contract reasons". They are not mathematical reasons but based on assumptions on what constitutes the didactical contract (Brousseau 2006) of the lecture. For proof, there are several options. Since the students are in their second semester or higher and are used to using counterexamples, we expected that they would look for an example of a partially differentiable function that is not differentiable. The function used in the lecture to show that partial differentiability did not imply continuity (Example VII.1.5, see Figure 1) and stated in

part b) of this task, which is such an example, should come to mind quickly. Some students will probably only give the counterexample without explaining why it contradicts the implication. Others will explain why the function is not differentiable by calculating the error term  $\varphi$  and showing that  $\frac{\varphi(h)}{||h||}$  does not converge to 0 as  $h \rightarrow 0$ . Another possibility is that students will argue on the abstract level of logical relations and might take advantage of the argumentation that  $f$  is not continuous and therefore cannot be differentiable due to the contraposition of T3. However, it may also occur that students think the implication is true in the first place or that they have difficulties to construct own counterexamples. Based on this analysis, we expected that most students would solve task T10 successfully.

### A priori analysis of “Does continuity imply the existence of all directional derivatives?” (T15)

It is important to note that the lecturer defined directional derivatives as one-sided limits in this lecture. Students could have developed a general sense of what we may call “levels or degrees of smoothness” in  $\mathbb{R}^1$ . These students might quickly come to the conjecture that this implication is probably not true by making the courageous generalisation from  $\mathbb{R}^1$  that only continuity will not imply any differentiability whatsoever. A strategy may also be to check the meaning of this implication in  $\mathbb{R}^1$ . Students may know that  $\mathbb{R}^n$ -continuity for  $n = 1$  is the same as one-dimensional continuity. Moreover, the existence of directional derivatives for  $n = 1$  means that the function has a left- and a right-hand derivative (which need not be the same). With this clear picture, they remember that  $x \mapsto |x|$  is continuous and has both left- and right-hand derivatives, so the question is whether there is an  $\mathbb{R}^1$ -example that is continuous but has no left- and right-hand derivatives. Alternatively, students may initially think that  $x \mapsto |x|$  is a counterexample but then discover with a closer look that this is not the case. Some students might take this as a hint that the implication is, in fact, true, mainly because the only examples for continuous but non-differentiable functions coming to their minds might be jagged functions. Another example for a non-differentiable but continuous function that the students could know is the square root function  $\mathbb{R} \rightarrow \mathbb{R}, x \mapsto \sqrt{|x|}$  in 0, which will provide a valid counterexample for T15, having a “vertical tangent” in  $x = 0$ . If they do not know this example, it might be tough for them to construct a counterexample themselves. It could also happen that students look for counterexamples not in  $\mathbb{R}^1$  but in  $\mathbb{R}^2$  or higher dimensions, but we did not expect that they would be successful with that. Students might also try to use the logical network, but this will not be rewarding.

**Figure 1: The two success rates for each implication. The first number per arrow depicts the success rate for A (correctness of decision); the second number is the B success rate (correctness and quality of argumentation). We marked correct implications white, wrong implications dark grey. The implications without success rates had been covered in the lecture before.**

## Description of selected results

Our expectation that the implication T10 would be one of the most straightforward tasks was correct (see Figure 1). A success rate of 100% for A (decision what is correct) is notable and satisfying. We credited 72% of the attempts in T10B with 2 points, 10% got 1 point, 7% 0 points and 10% of the attempts did not contain any written work concerning this task. The success rates in A for the recognition of the correctness of the implication T15 are lower than we expected. We expected low success rates in B for the justification in T15, but the fact that the rates lower than the rate for T2 (where the counterexample is not intuitive at all) is somewhat surprising to us. None of the students received 2 points for their reasoning, 35% of the attempts got 1 point, whereas 26% of the attempts got 0 points and 39% was coded as missing but attempted.

## Results of the qualitative analysis of the written reasoning (B) in subtasks T10 and T15

For T10, we found the following categories from the a priori analysis and the data. We assigned two points for stating the function from Example VII.1.5 in the lecture as a counterexample and showing “by hand” that it is not differentiable by calculating the error term (coded “B1”) or the argumentation that it cannot be differentiable because it is not continuous (“B2”). Another argumentation assigned two points was working logically with the diagram saying that if T10 were true, together with T3, it would imply T6 which is wrong without stating a counterexample (“A”). A different correct counterexample with appropriate argumentation (“E1”) would be assigned two points as well. We assigned one point for stating the function from Example VII.1.5 as a counterexample without an explanation (“B0”). Giving a wrong counterexample (“E0”) resulted in 0 points. Typical examples for the two most common argumentations for T10, “A” and “B2”, can be found in Figure 2.

<p>“Partial differentiability does <u>not</u> imply differentiability Counterexample: <math>f</math> as in part b) is partially differentiable in <math>x_0 = 0</math>. If <math>f</math> were differentiable in <math>x_0 = 0</math>, continuity would be implied (<math>\dagger</math>) Thus, <math>f</math> is not differentiable in <math>x_0 = 0</math>”</p>	<p>“If partially differentiable and differentiable in <math>x_0</math> were equivalent, T6 would have to be true because T3 is valid. <math>\dagger \Rightarrow</math> T10 is not true.”</p>
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 2: Typical examples for “B2” (left) and “A” (right) (translated by the first author)**

Concerning T15, we assigned two points for stating a correct counterexample with appropriate reasoning. We expected the square root function as a counterexample, with different possible explanations: stating that it is continuous but not all directional derivatives exist (“W1”), this explanation with specifying the point of interest  $x = 0$  (“W2”) or a calculation that the directional derivatives in  $x = 0$  don't exist (“W3”). We gave one point for stating the square root function as a counterexample without an explanation (“W0”). The statement that the absolute value function is not a valid counterexample (“Bx”) was also rated one point. Additionally, some students gave explanations using the logical structure and wrong implications they thought were true in preceding tasks to argue without a counterexample, namely T12 and the fact that T4 is not true (“Z1”) or T13 and the fact that T5 is not true (“Z2”). Stating the absolute value function as a counterexample resulted in 0 points. For both implications, other argumentations were coded as “X”. The number of students who used these different kinds of argumentation can be found in Table 1 (T10) and Table 2 (T15). It can be seen that we could not assign some of the categories to any student, e.g., “B1” for T10.

Points (10 B)	Code	Number of students
2	B1	0
	B2	13
	A	8
	E1	0
1	B0	1
	X	2
0	E0	1
	X	1

Table 1: Student answers for T10

Points (15 B)	Code	Number of students
2	W1/W2/W3	0
1	W0	1
	Bx	1
	Z1	2
	Z2	1
	X	2
0	B	5
	X	1

Table 2: Student answers for T15

## Discussion of results

**RQ 1:** Most of the students were able to decide correctly for most of the implications whether they were true or not. The calculated success rates give hints concerning the level of difficulty of the implications. We can conclude that deciding whether an implication is true and stating the right reason are not the same, as illustrated by T15. It corroborates findings from studies reviewed in the introduction that students often cannot give correct justifications for relationships between different concepts in the one-dimensional case. However, students in our study were in general more successful than in some of the described studies. That could indicate that working with logical relations between new concepts becomes more accessible for students as they pursue their studies.

**RQ 2:** When they could, nearly all students used the logical structure of the diagram for answering whether a new implication is true, instead of constructing a new proof or a counterexample. In some cases, properties of examples were established by reference to the logical structure instead of verifying the property with calculations with the example itself (for example in T10). When they could, students traced the question back to one-dimensional cases and tried to find counterexamples there (which was possible for many of the implications and was our purpose in the design, utilising the task's linkage potential). The teaching sequence was not given as an argument (as was the case in Sevimli, 2018), which could be either because students knew from experience that this is not true, or because these concepts (except continuity) were introduced in a short period after another.

**RQ 3:** The a priori analysis was based mostly on our intuition because we could not find literature concerning didactics of multidimensional calculus, which is something we want to contribute to in the future. There were some lines of argument we did not anticipate, especially concerning incorrect reasoning. We found it surprising that a not negligible part of the students incorrectly considered the absolute value function as a counterexample in T15 although it was proven a week before that all directional derivatives of the absolute value function exist. There were some lines of argument we expected some of the students to use that were not used at all (like showing that the error term in T10 does not have the required property). This fact might, however, also be due to the rather small sample of only 31 students. Our estimates of the subtasks' difficulty were most often appropriate.

For further investigation, including what leads students to their decision, we additionally filmed eight pairs of students while working on the task. The analysis of these is expected to provide more

insights concerning the questions where the students got stuck and why. This analysis will be especially interesting because often students who made the wrong decision did not explain why they thought that (e.g., in T15). Our data will be analysed more thoroughly in the next months.

# Teaching of discontinuous functions of one or two variables: A didactic experience using problem posing and levels of cognitive demand

Uldarico Malaspina and Carlos Torres

Pontificia Universidad Católica del Perú, Lima, Perú; [umalasp@pucp.pe](mailto:umalasp@pucp.pe)

*This paper is a part of an ongoing research that seeks to propose sequences of problem-posing and problem-solving tasks that will help students to develop deeper comprehension of jump discontinuity of functions. We present a teaching experience focused on problem-posing in the context of discontinuous functions of one or two real variables, and analyze the cognitive demand that underlie the posed problems. We developed this experience in a real analysis course for in-service teachers. The teaching experience shows that it is possible to design a sequence of didactic tasks of problem-posing grounded in daily life situations, which facilitate the perception and intuitive comprehension of jump discontinuity of real functions. This experience suggests also to delve into the relationship between problem posing and cognitive demand.*

*Keywords: Problem solving, problem posing, discontinuous functions, cognitive demand, university mathematics.*

## Introduction

The concept of function has been considered for a long time as the most important in the whole development of mathematics. However, in mathematics education research, there are few publications related to discontinuity of functions at the university level. In one of them, Hitt (1994) claims that “when teachers came to construct functions they showed a marked tendency to think in terms of continuous functions. [...] Even if they had learned about discontinuous functions, the concept has not become an active element of their mathematical thinking” (p.19). Furthermore, Jayakody and Zazkis (2015) state that the type of definition that is used on continuity of functions is important for the teaching of this mathematical object. Thus, according to these researchers, students must face different definitions and representations, depending on the context. Based on our previous researches, we claim problem posing (PP) tasks help to deep into definitions and representations of a mathematical object previously chosen. Certainly, this innovation should be addressed by a teacher who should have the competence for analyzing his/her mathematical practices (didactic analysis competence) (Torres & Malaspina, 2018).

In our research, we are developing PP tasks with emphasis on the observation of the discontinuity of functions. Even more, with the purpose of contributing to the improvement of in-service teachers’ didactic analysis competence around this topic, we analyze the levels of cognitive demand (LCD) of the posed problems. With this feedback, the future similar sequences of tasks to be proposed could have more possibilities of adaptation to different groups of students. As Georgius (2013) says, “Teachers need to learn to differentiate between tasks of high and low cognitive demand and select tasks that require students to make deep mathematical connections.” (p. 9).

Our main research goals are: (i) To examine the cognitive demand of the problems posed by in-service teachers, from daily life situations, in the mathematical environment of the functions with jump

discontinuities; (ii) to propose a didactic sequence for the teaching of functions with jump discontinuities.

## **Theoretical framework**

### **Problem posing and mathematical teacher's competence**

It is worth mentioning that there are different positions in terms of what researchers understand by engaging in problem posing activities (Cai, Hwang, Jiang, & Silber, 2015). In this study, we adopt the proposal from Malaspina, Mallart and Font (2015), according to which problem posing is a process through which a new problem is obtained. If the new problem is obtained by modifying a given problem, it is said that the new problem was obtained by *variation*. If the new problem is obtained from a given situation or from a specific requirement, whether mathematical or didactic, it is said that the new problem was obtained by *elaboration*. These scholars also consider that problems have four fundamental elements: information, requirement, context (intra-mathematical or extra-mathematical) and mathematical environment; in that approach, problem posing by variation entails quantitative or qualitative modifications of one or more of these elements in a given problem; and problem posing by elaboration can be done specifying these four elements from the given situation.

Usually, in order to develop and assess students' mathematical knowledge and skills, instructional strategies mainly focus on problem solving. We consider that a teacher must not only have the ability to solve mathematical problems, but also choose, modify and pose problems with educational purposes, which means to facilitate or delve into his students' learning and stimulate their mathematical thinking (Tichá & Hošpesová, 2013; Torres & Malaspina, 2018). Moreover, we consider that the teachers' experiences, both in the problem posing and in the determination of their LCD, will contribute to the quality of the problem posing tasks when they design mathematical units of study, including the assessment of the learnings; i.e., such experiences will contribute to improving their didactic analysis competence.

### **Cognitive demand to discontinuous functions**

As one can imagine, conducting research regarding cognitive demand of mathematical problems is a wide endeavor. Most of the studies related to these topics apply quantitative research, which means to describe the LCD based on psychometrical methods. In our study, we want to go deep into cognitive demand from a qualitative perspective, because as Wilhelm (2014) claims "there is evidence suggesting that mathematical knowledge for teaching and conceptions of teaching and learning mathematics are likely to be related to the enactment of cognitively demanding tasks and that they might be interrelated in complex ways". In this sense, the cognitive demand of mathematical tasks as a research topic has been of interest for mathematics education researchers (Gutiérrez, Benedicto, Jaime, & Arbona, 2018; Smith & Stein, 1998).

The Cognitive Demand model proposed by Smith and Stein (1998), characterizes the mathematical tasks according to their *potential to engage students in high-level thinking*. It includes four levels of cognitive demand that assess the cognitive effort required from students to solve a mathematical task. Moreover, they argue the importance to examine the cognitive demand required by tasks because of their influence on student's learning.

Certainly, the proposal developed by Smith and Stein (1998) has been a seminal reference at this time. These researchers gave us a set of criteria to classify mathematical tasks or problems into four levels of cognitive demand corresponding to different grades of cognitive effort required to solve them. However, if we want to determine a LCD to the posed problems on discontinuous functions, we consider necessary to make adjustments to the characteristics of these LCD (Table 1). It is worth mentioning that there are already studies taking this approach. For example, Gutiérrez et al. (2018) made a particularization for pre-algebra problems.

Taking into account the importance of the LCD, expressed by mathematics education researchers, and considering cognitive demand as a characterization of the complexity of the reasoning required for solving a mathematical task, we think that having criteria and examples to assign levels of cognitive demand to problems on real discontinuous functions, will serve as a basis for assigning tasks on this mathematical object; even more, if the purpose is to work with non-routine problems, such as those proposed by the teachers themselves, based on situations from daily life.

We use the LCD proposed by Smith and Stein (1998) as a reference for our purposes. In Table 1 we describe these four LCD that we have adjusted to problems posed by variation or elaboration on discontinuous real functions. We take into account that in the given problem or in the given situation, a discontinuous function could be implicit or explicit. Each level is exemplified and some of the examples come from problems 1 to 7, which emerged in this didactic experience and are shown in the results and discussion section.

Levels of cognitive demand		Some characteristics of posed problems (by variation or by elaboration) on discontinuous functions
Low-level	Routine procedures (A)	Calculating values of a given function near, by left and right, to a point of jump discontinuity. (e. g. calculate $f(1.5)$ and $f(2.5)$ , where $f$ is the greatest integer function; See Problem 1)
	Procedures without connections to concepts or meaning (B)	Non evident values of an implicit discontinuous function of one or two variables in a given situation are calculated. (e.g., Suppose that for each kilo of rice you pay 3 dollars, but if you buy 4 kilos or more, you have a total discount of 10%. How much will you pay for 3.5 kilos of rice? And for 4 kilos of rice? See Problem 4 and Problem 6)
High-level	Procedures with connections to concepts and meaning (C)	Tasks focused on discovering the underlying contents and gaining mathematical understanding. (e.g. Make a graphic representation of the greatest integer function; See Problem 2 and Problem 5.)
	Doing mathematics (D)	Specify algebraically a discontinuous function of one or two variables, given implicitly in a situation. (e.g. Find the algebraic expression and its graphic of the pay function given as example in level B; See Problem 3 and Problem 7)

**Table 1: Characterization of the LCD to problems posed on discontinuous functions**

## The study methodology

This study is based on an experimental case study, exploratory and descriptive, taking as unit of analysis the problems posed by the teachers participating in the workshop. We use the LCD stated in Table 1 to analyze problems posed by the participants. They developed a sequence of tasks of PP aimed at guiding them in understanding the basic ideas related to functions with jump discontinuities. To determine the LCD of each problem, we examined the link between its information and its requirement, the solutions presented by the participants and the solutions we developed. Finally, we compared the characteristics found in our analysis with the characteristics given in Table 1.

## Sample and experimental setting

The sample for this study comprises of 22 in-service teachers who were enrolled in the *Analysis in the real line* course and *Analysis in several real variables* course from the Master's Program in Mathematics Education at Pontificia Universidad Católica del Perú. Most of them are in-service teachers, and some of them are engineers. None of them has had previous experience neither in PP whose objective is to facilitate learnings nor in studying discontinuous functions in daily life contexts.

We developed the experience in 6 phases: *Phase 1*: Become familiar with PP as part of the topics of the class; for example, given a daily life situation related to shopping in a convenience store, pose and solve a problem in the mathematical environment of affine functions. *Phase 2*: Choose a real situation corresponding to a single variable real function, discontinuous at points of integer abscissa, and ask for questions related to the given situation. *Phase 3*: Present the definition of continuous single variable real function at a point of accumulation of the domain of the function by using limits. Analyze the definition and jump discontinuity at a point using the questions and answers to Phase 2. *Phase 4*: Present a daily life situation and ask to use it to pose problems that illustrate cases of continuity and discontinuity of a single variable real function. *Phase 5*: Propose daily life situations favorable for graphic representations of subsets of the plane related to points of discontinuity of a two-variable real function. *Phase 6*: Use the results from the previous phase to formally define a two-real variable function with discontinuities. Analyze the definition and jump discontinuity at a point.

## Results and discussion

In this section, we analyze the results from the didactic experience, focusing on the LCD of the problems posed and solved by the participants, following the specifications given for each level in Table 1. We analyzed the cognitive demand of all the problems posed by the participants, but due to space limitations, we will show only some of them.

In Phase 1, we focused on what happened when students were asked to pose a problem based on the following situation: *A convenience store sells a specific brand of juice in one-liter bottles at 6 dollars each, and offers 3 bottles for the price of 2.* The problems posed were of different LCD, but due to space limitations we don't refer explicitly to them as we do for other phases, directly related to discontinuous functions with real variables.

We worked on Phase 2 with a common daily life situation, such as paying for a parking space. There are fees such as: *"4 dollars hourly or less"*. Students were asked to write problem-questions that could

be posed in the mathematical environment of real functions of a real variable. We chose some of the questions, considering the different LCD they entail:

Problem 1: *How much will you pay for parking for 1 hour and 15 minutes?*

Problem 2: *What is the graph like of the payment function for parking for  $x$  hours?*

Problem 3: *What is the algebraic expression of the payment function for parking for  $x$  hours?*

Students worked in pairs and some of them came to the correct graph of function  $P = P(x)$ : 'the payment of  $P(x)$  dollars for parking for  $x$  hours', as the one shown in Figure 1. After sharing this graph, we asked the following question: *If Mary says she parked her car for about 2 hours, can we know how much Mary paid for parking?*

**Figure 1: Graph of the payment for parking function**

With the graph (Figure 1) and the question, participants intervened saying expressions like 'discontinuity', 'left-hand limit' and 'right-hand limit'.

All of this we used for formally introducing the concept of continuity at a point of the domain of a real function of a real variable by using limits, when that point is a point of accumulation of its domain; that is, for developing Phase 3. We used the following definition: If  $f$  is a real function of a real variable,  $a$  is a point of domain and a point of accumulation of  $f$ ; then  $f$  is continuous for  $x = a$  if and only if  $\lim_{x \rightarrow a} f(x) = f(a)$ . We analyzed the meaning of this definition using the representations made by the participants.

We can see that Problem 1 requires a direct calculation, so we place it in Level A. Problem 2 explicitly requires the graph of a function, so we place it in Level C. Problem 3 requires complex and non-algorithmic thinking of the solver, so we place it in Level D.

**Figure 2: Graph of the payment function using the offer. Problem 2**

For Phase 4, we proposed the following: *Use the following situation to pose a problem whose solution shows cases of continuity and discontinuity of a function in the interval  $[0; 17]$ . In a convenience store there is a sign with the following offer: 6 kg bag of rice for 15 dollars. Price per kilogram: 3 dollars*

Most of the participants proposed using the situation to define a function and represent it graphic and algebraically, as shown in Figure 2.

For Phase 5, we proposed the following situation:

*At a market, rice and sugar are sold for 3 and 2.40 dollars per kilogram, respectively. Also, as a special offer, 3-kg-rice and 2-kg-sugar packages are sold for 10 dollars.*

The idea was to use the situation so that, assuming the quantities of rice and sugar bought can vary in intervals of real numbers, it is perceived that by taking the offer it is possible to find points near each other, whose corresponding payments are not near. Finding the function  $f$  of two variables, which expresses paying  $f(x; y)$  dollars for  $x$  kg of rice and  $y$  kg of sugar by taking the offer as long as it is possible, and assuming variables  $x, y$  can take every non-negative real number, it is a problem requiring high cognitive demand. We didactically consider it is important and necessary to pose problems

that facilitate the comprehension and solution of this problem; in other words, *pre-problems*, which is the term used in our PP approach (Malaspina, Mallart, & Font, 2015). The basic idea for such pre-problems was to identify points and regions of the plane where the convenience store's offer cannot be taken up on. Thus, we proposed participants to pose problems by using the given situation and different possibilities in relation to taking the convenience store's offer. Some of the problems were:

Problem 4. *How much should you pay if you take up on the offer for 4 kilos of rice and 3 kilos of sugar?*

Problem 5. *How much should you pay if you take up on the offer – when possible - for the following cases? 2.95 kilos of rice and 8 kilos of sugar; 3 kilos of rice and 8 of sugar; and 3.05 kilos of rice and 8 of sugar?*

Problem 6: *How much should you pay if you take up on the offer for 7 kilos of rice and 5 kilos of sugar?*

Problem 7: *When buying what quantities of rice and sugar is it not possible to use the offer?*

We invited the authors of problems 4, 5 and 6 to socialize their problems and solutions. Some doubts were clarified after a short discussion.

Due to the simplicity of these problems, we will stop at Problem 7, which is the one that implies the greatest cognitive demand. Its complexity requires restrictions and graphic representations of the corresponding regions. We asked all participants to solve it, telling them to use  $x$  as the variable representing kilograms of rice and  $y$  as the variable representing kilograms of sugar, both of which can take non-negative real numbers.

Something particularly important in this context is to consider strips of points where the offer cannot be taken up on since  $x < 3$  or  $y < 2$ . After examining this observation, participants stated that they understood the solution presented by their colleague A3 (Figure 3).

The problems posed by the participants and the solutions they analyzed – specially Problem 7 – created favorable conditions to go to Phase 6: define a function  $f$  whose variables  $x$  and  $y$  have the meanings already assigned, so that  $f(x; y)$  expresses the payment made to buy  $x$  kilos of rice and  $y$  kilos of sugar by taking the offer, as long as it is possible. To simplify, the purchase was restricted to 5 kilos of rice and 4 kilos of sugar maximum, and we asked to examine how much should one pay

**Figure 3: Solution of the Problem 7 presented by participant A3 (set L)**

for several  $(x; y)$  points in which the offer cannot be taken up on. After some rich mathematical and didactic discussion, it was agreed to name the given set as  $L$  in Figure 4, and the set of all possible purchases as  $A$ , considering the given restriction.

$A = [0; 5] \times [0; 4]$  and  $L = ([0; 3[ \times R) \cup (R \times [0; 2[)$ .  $A \cap L$  is shown in Figure 4.

Using these sets and calculating values such as  $f(3; 2)$ ;  $f(2.9; 1.8)$ ;  $f(2.9; 2.1)$ ;  $f(3.25; 3)$ ;  $f(2.9; 4)$ ;  $f(5; 1.9)$  we came to the following function:

$$f(x, y) = \begin{cases} 3x + 2.40y, & \text{if } (x; y) \in A \cap L \\ 10 + 3(x - 3) + 2.40(y - 2), & \text{if } (x; y) \in A - A \cap L \end{cases}$$

It became evident that  $f$  values for points near  $(3; 2)$  were not necessarily near  $f(3; 2)$ , and that is how the discontinuity of this function was perceived at point  $(3; 2)$ . It is worth mentioning that  $f$  is a discontinuous function not only at  $(3; 2)$  and that it was obtained by PP, considering an extra-mathematical context taken from a daily life situation. Following this discussion, the formal definition of continuous function at point  $a = (a_1; a_2)$  of its domain was given, when the function is real of two real variables and  $a$  is an accumulation point of its domain, similar to what was done for single variable functions in Phase 3.

**Figure 4:  $A \cap L$  shaded**

We placed problems 4 and 6 in Level B because they were basically calculations that were not straightforward. Problem 5, by proposing calculate values of the implicit function corresponding to points with non-whole abscise, and near to the point  $(3; 8)$ , contributed to the perception that the values of the function at a point of its domain are not necessarily near the value of the function near that point. Furthermore, that  $(3; 2)$  is not the only point with that characteristic (point of discontinuity), but there are many other points of discontinuity on the line with equation  $x = 3$ . Thus, we place it in Level C. Problem 7 is placed in Level D. It requires the perception of a subset of the plane that do not contain its boundary, precisely because at some boundary points the offer can be used.

## Final considerations

Based on the previous section, as well as on the results of the examination made at the end of the course, we consider that the didactic sequence, with the above described phases, to pose problems of different LCD, facilitate perception and intuitive comprehension of single and two-variable real functions, which have jump discontinuities at one or more points of their domains and which are related to daily life situations. Moreover, it allowed us to introduce and analyze definitions and representations of continuity and discontinuity of functions as Jayakody and Zazkis (2015) claimed to be helpful for understanding theses mathematical objects.

The adjustments that we propose of Smith and Stein's model of cognitive demand levels for analyzing problems on discontinuous functions and their examples emerged from the experience, give us elements for new proposals oriented to the improvement of teachers' didactic analysis competence. It could be useful as a starting point for similar experiences and deepening the research of teaching and learning single or two-variable discontinuous real functions, including LCD analysis. We consider it important that teacher educators and researchers of university mathematics education have examples

of problems about discontinuous functions created from daily life situations and characterized with specific LCD. It is also worth mentioning the students' positive comments about the tasks that they developed. Moreover, they value the links shown between daily life situations and the university mathematics, which are usually dealt only in intra-mathematical contexts. This experience, which links university mathematics, PP and cognitive demand, suggests research should be done to delve into these links that are not so present in the researches in these fields.

*As part of a large-scale study of algebra instruction at two-year post-secondary institutions in the United States, we have developed a qualitative video analysis framework, Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM). In this paper, we present two of twelve characteristics used to describe instruction (Instructors Making Sense of Procedures, and Student Mathematical Reasoning and Sense Making), which describe students and instructors engaging with mathematics so their ideas or ways of thinking are evident. We use examples taken from our corpus of videos to exemplify these two characteristics of instruction and how they contribute to its quality. We also offer suggestions for professional development activities.*

*Keywords: Instruction, College mathematics, Postsecondary education, Community colleges, Instructional quality.*

In the United States, 43% of all undergraduate students enroll in public post-secondary institutions that offer courses for the first two years of their undergraduate degree. These institutions, hereafter called community colleges, provide students with many options to further their educational goals, some of which include remediation, transfer to university undergraduate programs, vocational training, general education, continuing education, and workforce development (Blair, Kirkman, & Maxwell, 2018). Community colleges target diverse students who are mostly non-traditional (e.g., older, working, or with family responsibilities), offer flexible schedules, and charge very low tuition compared to universities. Because of the wider range of students who enroll, these colleges offer a broad range of mathematics courses, from developmental mathematics (designed to prepare students for collegiate level study of mathematics) to mathematics courses taught in the first two years of an undergraduate major. The failure rates in algebra courses at community colleges range from 30% to 70% (Bahr, 2010). Because algebra skills are of paramount importance for advancing into higher level mathematics, investigating algebra instruction at community colleges becomes important; however, community colleges are largely under-researched (Mesa, 2017).

In *Algebra Instruction at Community Colleges: An Exploration of its Relationship with Student Success (AI@CC*, Watkins et al., 2016), we seek to investigate the relationship between the quality of characteristics of algebra instruction and student learning as evidenced by student grade as a percent. In this paper, we exemplify two characteristics of algebra instruction at community colleges,

Instructors Making Sense of Procedures, and Student Mathematical Reasoning and Sense Making. We focus on observed instances that evidence mathematical sense-making<sup>1</sup>, to start addressing the wider question: What is the nature of sense-making evidenced in algebra instruction at the community college level of post-secondary mathematics education?

## Background and supporting literature

We used the instructional triangle to define algebra instruction as the interactions between instructors, students, and the content studied in community college environments (Figure 1, Cohen, Raudenbush, & Ball, 2003). To characterise algebra instruction, we drew on two frameworks that analyse the quality of instruction created for school-level mathematics education (Mathematical Quality of Instruction (MQI), Hill, 2014; Quality of Instructional Practices in Algebra (QIPA), Litke, 2015). These frameworks describe and code (with ratings from 1 to 5)

instructional practices from video-recorded class sessions by rating consecutive 7.5-minute segments. Although the two frameworks provided useful language to describe the characteristics of instruction, the actual descriptions were tied to elementary or high-school content and interactions that bore little resemblance to instructional practices at community colleges. We retained some of their characteristics, but modified the descriptions for our purposes, through multiple iterations that involved the use of video recordings of 15 class sessions in Fall 2016, ranging between 45 and 120 minutes (see Cawley et al., 2018). From this work we developed the video-coding framework called Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM). This paper includes two EQIPM characteristics, Instructors Making Sense of Procedures and Student Mathematical Reasoning and Sense Making, which emphasise ways in which instructors or students engage in algebraic sense-making in community colleges. Version 3.0 of EQIPM is presented in Figure 2<sup>2</sup>.

The definition of ambitious mathematics instruction (NGA, 2010) supports 11 of 12 characteristics of instruction in EQIPM. In ambitious instruction, the instructor engages students in challenging tasks, observing and listening while they work on those tasks providing an appropriate level of support to diverse learners. The instructional goal is to ensure that all students do high quality work instead of only expecting fast and correct execution of mathematical procedures. Classroom Environment emerged from our observations of community college lessons. This characteristic is informed by Danielson (2015) who advocated that in a respectful and open environment, student opinions are encouraged, and student contributions are validated in ways that make them feel safe.

**Figure 1: Instructional Triangle (Cohen, Raudenbush, & Ball, 2003)**

<sup>1</sup> We use the NCTM (2009) definition of sense-making which accounts for students discovering coherence across mathematical domains and seeing connections between new concepts and their existing knowledge.

<sup>2</sup> The development of EQIPM is ongoing. See Mesa et al. (2019) for the most recent changes in the code structure.

EQIPM: Evaluating Quality of Instruction in Postsecondary Mathematics			
Features of Segment	Quality of Student-Content Interaction	Quality of Instructor-Content Interaction	Quality of Instructor-Student Interaction
Mathematics is Focus of Segment	Student Mathematical Reasoning and Sense-Making	Instructors Making Sense of Procedures	Instructor-Student Continuum of Instruction
Procedure Taught	Connecting across Representations	Supporting Procedural Flexibility	Classroom Environment

**Figure 2: Dimensions and characteristics of instruction in EQIPM**

The American Mathematical Association of Two-Year Colleges' IMPACT<sup>3</sup> guide (2018) presents a vision to improve mathematics education in the first two years of college. The IMPACT guide concludes that for students to achieve proficiency in mathematics it is necessary

for them to, among other things, (1) know mathematics procedures and execute core computations fluently, (2) make sense of and solve problems, and (3) demonstrate evidence of mathematical understanding (AMATYC, 2018, p. 25). Research by Star (2005) provides additional evidence of the importance of linking conceptual understanding with procedural skills.

## Methods

The data for this paper were collected in the Fall of 2017. Trained observers video-recorded all class sessions on two of three topics from 40 instructors: linear, rational, or exponential equations and functions. The instructors, who volunteered to be observed, were at six diverse community colleges, which represent a range of institution size, degree of urbanicity, region (Southwest, Midwest, and Central in the U.S.), and student background. This round of data collection resulted in 131 class sessions, which ranged in duration between 45 and 150 minutes. Fifty-four percent of these sessions were solely in a lecture context and 85% included some elements of a lecture.

Starting in the Summer 2018, 17 trained coders used EQIPM to rate the characteristics of instruction that appeared in each segment<sup>4</sup> ( $n = 1,576$  coded segments of which 1,236 are full 7.5-minute segments) of every class session. For each segment, the quality of each characteristic was coded along the 12 characteristics using a rating from 1 to 5. The coders provided a justification for their rating, including the specific time stamp in which the coder noticed evidence that justified that rating, and a brief explanation of the quality of the characteristic based on specific guidelines of EQIPM. For the most part, a rating of 1 was reserved for "no evidence" except for the Mathematical Errors and Imprecisions in Content and Language in which the ratings are reversed. A rating of 3 was considered an acceptable quality, usually indicating a modal rating. A rating of 5 was reserved for exemplary cases; cases we interpreted as best examples of that characteristic against EQIPM. Ratings of 2 and 4 were reserved for 'in between' cases. When some features were present but they were of less quality

<sup>3</sup> Improving Mathematical Prowess and College Teaching (IMPACT)

<sup>4</sup> Hill et al. (2012) used a segment length of 7.5-minutes after several comparisons of coding using various lengths. All lessons were parsed into 7.5-minute segments; the last segments of the lessons were usually shorter than 7.5 minutes.

than what a rating of 3 would have been, a 2 was assigned. When the quality was better than a rating of 3, but not truly illustrative of an exemplary quality, a 4 was assigned.

Instructors Making Sense of Procedures refers to instructor work that fosters students' sense-making about how a procedure moves from one step to the other, rather than merely reproducing the steps of the procedure (Star, 2005). For this code, the coder is trained to assess the extent to which instructor practices of using mathematical definitions, symbols, properties, structures, examples, and interpretations of solutions motivate understanding of a mathematical procedure. Examples of such instructor practices include, but are not limited to attending to the type of solution generated by a procedure and its interpretation, using a series of examples of an abstract formula to extract key features, and clarifying symbols of definitions. For a 7.5-minute segment, an exemplary 5 rating of the characteristic is assigned in the event that the coder interprets that the practices identified motivate mathematical understanding and belong to either a range of instances or a sustained, prolonged instance with instructor practices for fostering student sense-making. A rating of a 5 only indicates that sense-making happened in an exemplary way, attending to elements of a procedure or the algebraic concepts in a procedure. Other codes in the framework will pick up additional elements of instruction that together may allow one to determine high-quality instruction.

Student Mathematical Reasoning and Sense Making entails the components of reasoning and sense-making for students. Mathematical reasoning includes student practices such as drawing logical conclusions from patterns identified, providing conjectures, offering counter-claims in response to a proposed mathematical idea, and mentioning the mathematical properties that underlie a procedure. Evidence for sense-making includes student practices such as asking mathematically motivated questions while requesting explanations, leveraging previous mathematical ideas while responding to a question, and interpreting the solution generated by a procedure. A 5 rating includes either a combination of instances that meet these criteria or a sustained instance that saturates the 7.5-minute segment with student reasoning or sense-making so that student ideas are evident and contribute to the development of the mathematics.

Coders adhered to three additional rules when coding: (a) assigning a higher rating rather than a lower rating when in doubt, (b) rating each segment in isolation from other segments within the same class session, and (c) focusing on evidence that was seen and said in the video, rather than what coders thought should be in the video. Following Hill (personal communication, September 2017), 10% of randomly selected class sessions were double-coded; the coders held calibration meetings to discuss discrepancies in ratings and agree upon final ratings. The data used for the analysis reported in this paper came from the coding of 903 segments.

## Findings

EQIPM offers a close and granular examination of the quality of algebra instruction at community colleges, but no element of EQIPM can stand alone to suggest high-quality instruction. Breaking down instruction into parts is a first important step towards efforts to understand the current status of instruction at community colleges, and a valuable activity that may help instructors develop their teaching skills. Qualities we interpreted as exemplary included cases of algebra instruction identified with a 5 rating. Only 89 out of 920 segments (10%) were identified as exemplary in at least one of

the 12 codes. There were 398 segments (43%) with a rating of 4 and 5. We identified 29 exemplary segments (5,3%) where instructors supported students in making sense of procedures and seven segments (1%) where students demonstrated exemplary mathematical reasoning and sense-making in class. Examining instances with a rating of 4 or 5, the cases increase to 95 (10%) and 37 (4%) respectively. In light of these percentages in the community college setting, we think that there is much room for improving instruction, and existing practices of exceptional quality can act as resources for improving instruction and student outcomes.

### **Instructors making sense of procedures**

In a lesson on rational expressions, Instructor 110 discussed with the students the procedure of finding domain restrictions. She started her lecture by asking what is  $\frac{0}{5}$  and why  $\frac{7}{0}$  is undefined, gradually moving student attention to rational expressions and the denominator of  $\frac{x+5}{x-7}$ . She asked students to find  $x$ -values for which the aforementioned rational expression is undefined, and students suggested  $x = 7$ . After the instructor made the calculations for the suggested value and confirmed that the outcome is  $\frac{12}{0}$ , which is undefined, she asked whether there were suggestions for other values for which the rational expression is undefined. She waited for 11 seconds for a response, and suggested  $x = -5$  for which the expression becomes  $\frac{0}{-12}$ . The students recalled this fraction equals zero so the rational expression is defined for  $x = -5$ . The instructor then gave the students time to find domain restrictions for a series of more complicated examples of rational expressions with denominators that are binomials, trinomials, and other polynomials (e.g.,  $\frac{x+4}{x^2-3x-10}$  and  $\frac{x^2-x-2}{x^2-25}$ ). The use of instructor practices was rated as an exemplary case for this characteristic, because the instructor attended to the type of solution (i.e., denominator equals zero) generated by the procedure of finding domain restrictions, first using integers, which the students are familiar with in this level of education, then interpreting increasingly complicated examples of rational expressions. The students successfully suggested -7 for  $\frac{12}{0}$  and related  $\frac{0}{-12}$  back to the information in the beginning of the lecture.

In a lesson on exponential functions, Instructor 102 discussed the reason behind the growth pattern of exponential functions. He created tables of values of a linear function, a quadratic function, and an exponential function in which the  $x$ -values started at 0 and increased by 1. He calculated the difference of consecutive  $y$ -values of each of the three functions, and found that for the linear function the difference was always 2, but for the quadratic function the difference each time increased by 2. He generalised the finding about the differences by saying for both functions that “It doesn’t matter it is a 2, it could be any constant.” He then found that for the exponential function the difference of consecutive  $y$ -values, even the difference of the difference of consecutive  $y$ -values, would never become constant or increase by a constant value; rather, the difference of consecutive  $y$ -values will repeat the growth of the exponential function. The instructor’s use of the structure of three kinds of functions—a linear, quadratic, and exponential—to clarify the meaning of exponential growth was rated as an exemplary case for this characteristic. In particular, he used various numerical  $y$ -values of the functions and their differences to find patterns and exemplify the exponential growth. Later in the lesson, all students went to the board to determine the type of growth of various types of functions and they were asked to classify the growth of functions as either exponential or linear.

## Student mathematical reasoning and sense making

In a lesson on rational expressions, Instructor 610 worked with the students on simplifying rational expressions. After the first half hour of the 150-minute lecture, the instructor asked students to tell her what simplifications she should carry out for the expression  $\frac{3y}{y^2+3y-10} - \frac{6}{y^2+3y-10}$ . A student correctly suggested the instructor to write  $\frac{3y-6}{y^2+3y-10}$ , to factor the polynomial in the numerator and denominator, and to simplify the rational expression. Another student correctly suggested for the expression  $\frac{5}{7} + \frac{4}{21}$  that the instructor could multiply both the numerator and the denominator of  $\frac{5}{7}$  by 3 and perform all calculations needed. A third student correctly suggested for the expression  $\frac{1}{5} - \frac{2}{3}$  that the instructor multiply the numerator and the denominator of  $\frac{1}{5}$  by 3, the numerator and denominator of  $\frac{2}{3}$  by 5, and perform all calculations needed. This instance where different students contributed to the lecture by leveraging the mathematical idea of Least Common Denominator (LCD) in various cases (e.g., the LCD is the same as or different from both of the denominators) while simplifying expressions lasts for about two of the 7.5 minutes of the segment. A follow-up instance in the same segment lasted for about four and a half minutes. It included a fourth student who orally provided the calculations he performed to find the LCD for the expression  $\frac{19x+5}{4x-12} + \frac{3}{2x^2-12x+18}$ . By factoring the latter expression, it becomes  $\frac{19x+5}{4(x-3)} + \frac{3}{2(x-3)^2}$ . The student reasoned the LCD was  $4(x-3)^2$  because the LCD included the highest exponent from all multiples of the factors of the denominators. Two other students found the LCD for each of two different rational expressions, using their fellow student's reasoning. The combination of two prolonged instances that saturate the segment with student reasoning and sense-making so that student inputs contributed to the development of the meaning of the LCD was rated as an exemplary case for this code.

A rule for deciding on the rating of Student Mathematical Reasoning and Sense Making was that there must be clear evidence of students engaging in mathematical reasoning or sense-making through verbal utterance(s) and/or through written work. A limitation for finding such evidence was that despite the premium quality of our audio-visual equipment, the recordings sometimes did not capture clearly student voices or written work. Although we found instances that saturated the 7.5-minute segments with student reasoning or sense-making, the audible or visible evidence found within a segment could not qualify for an exemplary case. That resulted into lowering the quantity of exemplary cases found for this characteristic of instruction in the community college classes.

## Discussion

This paper described two characteristics of instruction captured in EQIPM, Instructors Making Sense of Procedures and Student Mathematical Reasoning and Sense Making. The common theme in the three examples given can be summarized as 1) a sustained effort to provide sense-making behind procedures by use of a variety of examples in varying complexity while 2) prompting students to provide solutions to the examples with an explanation of their reasoning. The instructors' approach paved the way for students to develop proficiency in mathematical procedures; this is a new insight into community college instruction because educational research in this context is still rather limited. Rules were not given to simply be followed but ideas were presented with concrete examples to apply

sense-making. We currently work on improving the codes and ratings of EQIPM. In recent iterations for the development of EQIPM, we widened the mathematical content of the codes of the dimension Instructor-Content interaction. Instructor Making Sense of Procedures, for example, includes sense-making whether it occurred while supporting a procedure, a mathematical idea or ways of thinking.

In Instructors Making Sense of Procedures, instructor practices that motivated sense-making included the search for patterns, the use of integers or numerical y-values of functions which were familiar to students, and the careful selection of examples with increasing rigor. The latter can help students build their own understanding of rate of change, and later connect this idea to the concept of derivative in calculus. In Student Mathematical Reasoning and Sense Making, the instructor offered different students the opportunity to suggest how they would simplify rational expressions and to justify their choices, sometimes using their peers' language and reasoning. This practice also provides the instructor with the opportunity to overlay student discussion with more precise language and connect student ideas. Such video-recorded instances of exceptional qualities of algebra instruction at community colleges can be leverage points to discuss with instructors, compare, and build up the current instructional practices that are in place. EQIPM nevertheless is not intended to become a score system to evaluate teachers. It is created to understand what the characteristics are that constitute instruction at community colleges and what features make that instruction of high quality.

The AMATYC IMPACT guide provides a vision for mathematics instruction in the first two years of college and identifies key attributes that point to the importance of students making sense of mathematics and demonstrating evidence of mathematical understanding (AMATYC, 2018). The opportunities for students to develop these attributes, as evidenced by our video analysis, is not common practice at community colleges. Our findings indicate that exemplary implementation of Instructors Making Sense of Procedures, and Student Mathematical Reasoning and Sense Making occurred in only a small number of cases. Professional development using instances of exemplary practices that support high quality algebra instruction can help change the landscape of mathematics instruction at community colleges by helping instructors provide opportunities for their students to develop key attributes tied to mathematical proficiency. In the next phase, we will work to identify ways for instructors to support students to develop mathematical proficiency and to subsequently improve student performance and preparation for higher mathematics.

## Introduction

Little is known about the transition from being a university mathematics student to being a post-secondary teacher (e.g. Speer & Hald, 2008), particularly in cegep institutions (general and vocational colleges), the first step in postsecondary education in the province of Quebec, Canada. The program in those institutions covers, notably, calculus and linear algebra. Our goal is to explore that transition into being a teacher, while focusing on the (past and present) experiences of new teachers in relation to mathematics, and its teaching and learning. We do so by conducting a narrative inquiry with 5 new teachers with less than 5 years of experience, with whom we have met individually seven times over a semester. We *lived* alongside them and heard about their stories, their lives and their experiences.

In our work, we speak of “being a teacher” in the sense of *acting and thinking as a teacher*, rather than holding a teaching job. We see it as a “process of becoming” (Beisiegel, 2007, p. 23) that starts before the first teaching job and that will continue long after. It is supported by the idea that mathematics students receive implicit teacher training during their time as students, where their life experiences in a mathematics department shape their “views of the discipline and its teaching” (Beisiegel, 2009, p. 42). We see “being a mathematics teacher” as involving, among other things, thinking about mathematical concepts, with teaching and learning in mind, in a way that reminds us of Shulman’s (1986) pedagogical content knowledge. It also involves thinking, to various degrees, about the role of a teacher, presentation, assessment and the creation of material.

As we analyzed all the stories these 5 new teachers shared with us, we came to the realization that 4 out of the 5 participants were not “being teachers” during their studies in mathematics; for them, this “being a teacher” only happened when they actually held a teaching position, even if some of them were aiming for a teaching career. This triggered two reflections for us.

Firstly, we identified essential differences between what they need to emphasize to be successful students versus what they need to emphasize to be successful teachers. On a daily basis, to succeed as a mathematics student, they needed to create and validate proofs a professor deemed important, figure out what is expected from them to succeed in assessments and researching for proofs that may not even exist. To be teachers, instead, they would need to think about what is important for their students to learn while keeping it at a level that is adequate, what work would represent a passing grade in a particular course and choosing problems that would be interesting to solve, not for them, but for their students. The gap between these two needs suggests that there was no time or space during their studies in mathematics to “be a teacher.” This reflection shows us one way in which the

transition to post-secondary teaching could be different than the transition to school teaching since such time and space is probably not lacking in university teacher training.

Secondly, too often, mathematics faculty who focus on teaching are perceived by their colleagues as weak mathematicians who could not succeed as researchers; these “second-class” mathematicians are not good enough to participate in the very competitive mathematical community (Kline, 1977, cited in Beisiegel, 2009). Beisiegel (2009) showed the influence of this culture for graduate students, saying that “as [they] attended to the existing practices of the department, there were suggestions and rites of passage which revealed that only [...] becoming a mathematician, really counts” (p. 287). Also, Beisiegel (2007) states that “many dichotomies exist in mathematics and, in [the mathematics] community, you either are or you are not a mathematician” (p. 23); if you are a mathematics teacher, you are not a mathematician. Again, we can briefly underline how different this situation is from university teacher training, where students are not, most likely, torn between two different identities, as becoming a teacher is the goal of their education.

One of the participants in our study, however, seemed to have been successfully a mathematician and a mathematics teacher during her degree in mathematics. Indeed, as a student, while keeping up with the highest standard of performance in her classes, she would constantly look at how the class was presented, thinking how she would do it when she would get to stand in front of a classroom, collecting great explanations of things as models and always asked herself, “why?” and “what if?” specifically so that she would be more prepared to teach certain pieces of mathematics. We believe that those two differences put her in a similar position than a student in a teacher training program (Lee & Shallert, 2016). Our research explores why it is that she was “being a teacher,” according to our definition above, in the midst of a mathematician’s training, while the others did not.

This research goes into detail of some stories shared by the participants about their transition from mathematics student to teacher. Because we found that it is possible to do both, “be a mathematician” and “be a teacher,” during a mathematicians’ training, we ask how we can help mathematics students to “be teachers” while in their mathematics training and to help them use this time to their advantage.

*Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM) is a video coding instrument that provides indicators of the quality of instruction in community college algebra lessons (AI@CC Research Group, 2017)<sup>1</sup>. It grew out of two instruments that assess the quality of instruction in K-12 settings—the Mathematical Quality of Instruction (MQI) instrument (Hill, 2014) and the Quality of Instructional Practices in Algebra (QIPA) instrument (Litke, 2015). We present a revision of EQIPM prompted by results of factor analyses performed with preliminary data, then discuss next steps and research implications.*

*Keywords: Algebra, instruction, video coding, community colleges.*

Various reports have established an indirect connection between students leaving science, technology, engineering, and mathematics (STEM) majors because of their poor experiences in their STEM classes (Herzig, 2004; Rasmussen & Ellis, 2013). Most of these reports, however, are based on participants' descriptions of their experiences in the classes, rather than on evidence collected from large scale observations of classroom teaching (Seymour & Hewitt, 1997). When such observations have been made, they usually focus on superficial aspects of the interaction (e.g., how many questions instructors ask, how many students participate, or who is called to respond, Mesa, 2010) or their organization (e.g., time devoted to problems on the board, or lecturing, Hora & Ferrare, 2013; Mesa, Celis, & Lande, 2014). Undeniably, these are important aspects of instruction, yet these elements are insufficient to provide a characterization of such a complex activity as instruction.

A key concern in post-secondary mathematics education is the lack of preparation that mathematics instructors receive in their graduate education (Ellis, 2015; Grubb, 1999). We argue that the lack of a reliable and valid method to fully describe how instruction occurs hinders our understanding of the complexity of instructors' work in post-secondary settings and therefore limits the richness of preparation and professional development opportunities focused on the faculty-student-content interactions (Bryk, Gomez, Grunow, & LeMahieu, 2015). As part of a larger project that investigates

the connection between the quality of instruction and student learning in community college algebra courses, we have developed an instrument, EQIPM (Evaluating Quality of Instruction in Postsecondary Mathematics), that seeks to characterize instruction. This paper focuses on the instrument and its validation, and to this effect we present the fourth revision prompted after results from exploratory and confirmatory factor analyses and a discussion with our advisory board suggesting several areas that needed refinement.

## Theoretical Perspective

We assume that teaching and learning are phenomena that occur among people enacting different roles—those of instructor or student—aided by resources of different types (e.g., classroom environment, technology, knowledge) and constrained by specific institutional requirements (e.g., covering preset mathematical content, having instructional periods of 50 minutes, see Chazan, Herbst, & Clark, 2016; Cohen, Raudenbush, & Ball, 2003). We focus on instruction, one of many activities that can be encompassed within teaching (Chazan et al., 2016) and define instruction as the interactions that occur between instructors and students with the mathematical content (Cohen et al., 2003). These interactions are influenced by the environment where they happen and can change over time. Empirical evidence from K-5 classrooms (5-11 year olds) indicates that ambitious instruction (Boston, 2012) is positively correlated with student performance on standardized tests (Hill, Rowan, & Ball, 2005). Understanding mathematics instruction requires attention to the disciplinary content and the mathematical knowledge for teaching and learning. Therefore, we assume, first, that quality instruction is illustrated through the experiences of instructors and students while interacting with mathematical content that have a significant impact on what students are ultimately able to demonstrate in terms of knowledge and understanding, and second, that it is possible to identify latent constructs that might account for the observed quality of instruction. We seek to corroborate findings from Hill et al. (2005) in the community college context.

Instruction is central to EQIPM. EQIPM (see Figure 1) was designed to assess the three main interactions that Cohen and colleagues (2003) used to define instruction: (1) Quality of Instructor-Student interaction, (2) Quality of Instructor-Content Interaction, and (3) Quality of Student-Content Interaction, which are hypothesized by our framework for instruction (Cohen et al., 2003, see Figure 1). An additional aspect, *Mathematical Errors and Imprecisions in Content and Language*, is also hypothesized to be an indicator of the quality underlying all the interactions (Hill, personal communication, 2017). The *Mathematical Errors and Imprecisions in Content and Language* code is intended to capture all *uncorrected* errors or imprecisions that may occur within a segment; including those advanced by students. This code is the only code that attends to errors and imprecisions within the segment. Within each quality construct we propose codes adapted from existing rubrics (Hill, 2014; Litke, 2015) in order to capture specific observable behaviors that can be used as a proxy for the construct. Thus, the *Student Mathematical Reasoning and Sense-Making* code is a proxy for the quality of student interaction with content as it seeks to describe and qualify instances in which students make their thinking evident. Likewise, the codes *Connecting Across Representations* and *Situating the Mathematics* provide evidence for such interaction (Leinwand, 2014). In a similar way we chose four codes under the instructor content interaction, *Instructors*

EQIPM: Evaluating Quality of Instruction in Postsecondary Mathematics

		Supporting Procedural Flexibility	Remediation of Student Errors and Difficulties
		Organization in the Presentation	
		Mathematical Explanations	
	Mathematical Errors and Imprecisions in Content and Language		

**Figure 1: Dimensions and codes for the EQIPM 4.0 instrument**

*Making Sense of Mathematics* a code that seeks to assess the extent to which instructors assist students in making sense of the mathematics they are teaching. This code is related, but different from, *Mathematical Explanations*, which attends primarily to the quality of the mathematical argumentation and justifications that instructors provide for any particular mathematical process or idea. While sense making might use informal language or everyday contexts, explanations require in

addition that definitions or proofs be used in sound mathematical arguments. *Supporting Procedural Flexibility* was included in order to account for the quality of the teaching of procedures, an important component of the teaching of algebra (Litke, 2015; Star, 2005; Star & Newton, 2009). The last code in this dimension, *Organization in the Presentation*, originally from Litke's (2015) instrument, was included because there is evidence that such organization contributes to student performance (Cabrera, Colbeck, & Terenzini, 2001). Finally, the codes under the third dimension seek to capture the way in which instructors and students negotiate the work in the classroom, the extent to which their contributions are taken up to shape the direction of the lesson (*Continuum of Instruction*), how instructors respond to and seek to understand student misconceptions (*Remediation of Student Errors and Imprecisions*), and how the interactions produce a class environment that is conducive to learning (*Classroom Environment*). These codes directly reveal the quality of the student and instructor interactions. The codes under Features of Segment help characterize the activity in the segment without qualification (e.g., *Nature of math*: procedures, applications, etc.; *Modes of instruction*: lecture, group work, etc.; *Technology use*: graphing calculators, etc.). These codes are not assessed on quality, only on presence and are used to describe the lessons.

## Understanding how the instrument works

In the Fall 2017 semester, we video-recorded 131 lessons in intermediate and college algebra classes from six different community colleges in three different states. These lessons ranged in duration between 45 and 150 minutes, and were taught by 40 different instructors (44 different unique courses video-recorded; 4 instructors taught 2 sections of a course). The majority of the lessons covered one of three topics: linear equations/functions, rational equations/functions, or exponential equations/functions. These topics were chosen because they offered opportunities to observe instruction on key mathematical concepts (e.g., transformations of functions, algebra of functions) and to attend to key ways of thinking about equations and functions (e.g., preservation of solutions after transformations, covariational reasoning), which are foundational algebraic ideas that support more advanced mathematical understanding (Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). The development of EQIPM was iterative process similar to that used by Hill and colleagues (2008) and by Litke (2015). Their instruments subdivided video-taped lessons into 7.5-minute segments, after testing the efficacy of 3 to 15-minute segments,

they found that 7.5-minutes provided coders with a segment long enough to capture mathematical practices and events in a cohesive way when rating all segments within a lesson without compromising quality of coding that is experienced in long segments. In the Spring 2018 semester, our iterative process produced the EQIPM version 3a which was used in the first round of coding (AI@CC Research Group, 2017). Coders were given up to four consecutive 7.5-minute segments to reduce bias due to familiarity with the previous work. Coders recorded their ratings and justifications in a spreadsheet developed for this purpose after watching each segment. Each segment was rated on each of the codes on a 1 to 5 scale (see Mali et al., 2019 for more information on rating and exemplification of codes). Ten percent of segments were randomly chosen for double-coding. Each pair of coders held calibration meetings to discuss codes with ratings with a discrepancy greater than one point; the pairs reconciled their new rating by consensus.

Following an exploratory factor analysis [EFA] using 169 segments (Mesa, Duranczyk, Bardelli, & AI@CC Research Group, 2018) we identified a three-factor structure that corresponded to our hypothesized dimensions (see Figure 2a). This analysis also identified two problematic codes (*Remediation of Student Errors and Imprecisions* and *Mathematical Errors and Imprecisions in Content and Language*). A subsequent confirmatory factor analysis [CFA] with 306 coded segments, suggested instead a two-factor structure (Instructor-Content interaction and Student-Instructor interaction) and four problematic codes (one had poor loading, *Connecting Across Representations*, and three could not be used in the analysis, *Mathematical Errors and Imprecisions in Content and*

Exploratory Factor Analysis			
Codes	Factor 1	Factor 2	Factor 3

Mathematical Explanations		<b>0.561*</b>
Situating the Mathematics		<b>0.480*</b>
Supporting Procedural Flexibility		<b>0.409*</b>
Conn. across Representations		<b>0.289*</b>

The two-factor solution had a good fit to the data: RMSEA = 0.061, 90% CI = [0.039, 0.083], CFI = 0.958, TLI = 0.942, SRMR = 0.065. These two factors are weakly and positively correlated: corr Factor 1-Factor 2 = 0.351 ( $p < 0.001$ ) indicating that the two factors are correlated, but significantly distinguishable. \* Significant loadings at the 95% level. In CFA loadings are only estimated for the hypothesized factors. Factor 1: Quality of Instructor-Student Interaction; Factor 2: Quality of Instructor-Content Interaction.

(b)

**Figure 2: (a) Loadings for the EFA 3-factor solution; (b) Loadings for the CFA 2-factor solution**

*Language, Organization in the Presentation of the Procedure, and Classroom Environment*, see Figure 2b). In addition, in both analyses, some codes did not load into the hypothesized dimensions (e.g., *Situating the Mathematics*, *Connecting Across Representations*, *Student Mathematical Reasoning and Sense Making*). We called a meeting with our advisory board to discuss the conflicting results. Their review of the instrument and the findings helped us identify two issues that required

substantial revision of the instrument (EQIPM 4.0, see Appendix for the revised definitions of the codes) to better describe the ratings and de-confound: 1) quality with quantifiable elements and 2) low quality with absence. We discuss these next.

### **Confounding quality with quantifiable elements**

For some of the codes we had assigned low or high ratings depending on either the time span in which the behavior was observed (or not observed) or other visible quantifiable aspects of the observed behavior. For example, for the code *Student Mathematical Reasoning and Sense Making* we were assigning a high rating to cases in which the work was “sustained” over the duration of the segment; if an instance was observed but it was “not sustained” or “not the focus” of instruction in the segment, the instrument directed coders to lower the rating. In another case, in the *Connecting Across Representations* code we accounted for number of representations that were visible in the segment in addition to the quality of the connections made; a high rating would be assigned only to lessons in which the instructor used 3 or more representations. Such approach resulted in lower ratings for segments in which instructors made really good connections but only used two representations; these segments were rated as a 3. We believe that this attending to number of representations possibly over quality of the connection might explain why this particular code had low loadings in both factor analyses. In EQIPM 4.0 we have eliminated language across all codes that refers to quantity or duration, and instead focused strictly on quality.

### **Confounding low quality with absence**

The rating system that we chose, a 1 through 5 scale, was adopted following prior work by Hill (2008) and Litke (2015). Our instrument included similar language in describing a rating of 1 which was assigned to two scenarios. For example, a 1 rating for *Mathematical Explanations* read as follows: “No mathematical explanations provided by instructor or student. **OR** Explanations do not include mathematical reasoning or justification; instructor or students provide only steps of a procedure.” This way of defining a 1 was problematic, because in some codes a rating of 1 meant not present (e.g., *Situating the Mathematics*), in others (e.g., *Classroom Environment*) it represented the lowest quality, and yet in others it meant both (e.g., *Mathematical Explanations*, the example above). Our advisory board pointed out that the ambiguity makes it difficult to interpret what a low score in a scale would represent. In EQIPM 4.0, the revision of the meaning of a rating of 1 also required a decision about the scale for assessing quality. We had followed Litke’s practice of using a rating of 3 to be “modal practice,” meaning practices that could be expected in many instances or that would not be extraordinary (in terms of both high and low quality). Ratings of 2 and 4 were defined as “in between” levels, less than or better than 3, without being the extremes. Defining the scale in this way was problematic for several codes, especially for those in which 1 could mean not present. In those codes the change from 1 to 2 was not commensurable to a change from 2 to 3, 3 to 4, or 4 to 5 on our rating scale. The recommendation was to use a four-point scale in order to force the coders into differentiating four levels of quality, with 1 being the lowest and 4 being the highest. We assigned a rating of 0 for “not present” which will facilitate their exclusion as needed.

## The revised EQIPM 4.0 instrument

The current version of EQIPM is presented in Figure 1. Once the data are recoded we will run a split sample EFA/CFA to understand the revised instrument's factor structure. The preliminary analyses with the previous instrument lend support to the structure underlying the instrument. One issue we face is the high number of segments in which lecture is the main mode of instruction (75%, 688 of 920 segments coded as of this writing had lecture combined with other modes of instruction, e.g., group work, and 487 of those used only lecture). We believe that with the revised instrument we will be able to differentiate interactions that are solely led by the student. If there are enough segments in which students lead the interactions, we will run an analysis to see whether the three-factor structure holds.

As we move forward we will account for (1) the multi-level structure of our data, specifically, segments within lessons, lessons within instructors, and instructors within colleges, which will address the possible non-independence of some of these codes, (2) lesson duration (e.g., in some lessons, student work individually at the end) and (3) coder bias. We anticipate that the structure will be stable in these cases as well and that as lecture diminishes as consequence of exposure to professional development, we may see that data will fit with three distinct factors as student interaction with content increases.

## Acknowledgment

Funding for this work was provided by the National Science Foundation award EHR #1561436. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation. We thank Emanuele Bardelli and Inah Ko for analytical assistance and Saba Gerami for comments to earlier versions of the proposal. We thank the faculty who participated in the project. Without them this work would not have been possible.

#### Appendix: Revised Definition of the Codes

Code	Revised Definition: The following codes assess...
<b>Student Mathematical Reasoning and Sense-Making:</b>	student utterances that showcase reasoning and sense-making about mathematical ideas (e.g. drawing logical conclusions, providing conjectures, counter-claims, reasoning and engaging cognitively in problem solving)
<b>Connecting Across Representations:</b>	the connections that instructors or students make between and across representations of the same mathematical problems, ideas, and concepts
<b>Situating the Mathematics:</b>	how instructors or students make connections to other aspects of the algebra curriculum, related topics, or the broader domain of mathematics, situating and motivating the current area under study within a broader context.
<b>Instructors Making Sense of Mathematics:</b>	how instructors attend to specific aspects of mathematics (e.g., solution, symbols, conditions) to clarify their nature
<b>Mathematical Explanations:</b>	how mathematical reasons and justification for why something is done are provided
<b>Supporting Procedural Flexibility:</b>	how instructors identify what procedure can be applied, and when and where to apply them, or makes connections across procedures
<b>Organization in the Presentation:</b>	how complete, detailed, and organized the instructor's or students' presentation (either verbal or written) of content is when outlining or describing the mathematics at hand.
<b>Instructor-Student Continuum of Instruction:</b>	how the investment that students make in their own learning and development of mathematical understanding by expressing thoughtful ideas that advance their learning.
<b>Classroom Environment:</b>	how instructor and students create a respectful and open environment in their classroom conducive to learning; high quality mathematical work is the norm.
<b>Inquiry / Exploration:</b>	the amount of exploration and inquiry of the mathematics that students do in the classroom
<b>Remediation of Student Errors and Difficulties:</b>	how remediation in which student misconceptions and difficulties with the content are addressed
<b>Mathematical Errors and Imprecisions in Content or Language:</b>	mathematically incorrect or problematic use of mathematical ideas, language, or notation.

# University Student Use of Dynamic Textbooks: An Exploratory Analysis

Vilma Mesa<sup>1</sup>, Angeliki Mali<sup>2</sup> and Elena Castro-Rodríguez<sup>3</sup>

<sup>3</sup>Universidad de Granada, Granada, Spain; [elenacastro@ugr.es](mailto:elenacastro@ugr.es)

*Keywords:* Textbook research, instruction, educational resources, didactical tetrahedron, linear algebra

Within the array of resources for teaching and learning, the textbook continues to be the most prevalent one for instructors and students. Textbook formats have been changing from paper to digital, open source formats, including sophisticated tools such as computing cells, annotation tools, and powerful search engines, easing access at relatively low cost. Importantly, open source textbooks never expire or go out of print and can be distributed at no cost to students, making them practically fully accessible. The main study seeks to describe how instructors and students use two open-source, technologically enhanced textbooks (linear algebra and abstract algebra for math majors). We use Rezat and Strässer's (2012) didactical tetrahedron to investigate how resources support instruction (Cohen, Raudenbush, & Ball, 2003). The tetrahedron suggests a relationship between textbooks, students, instructors, and the content at stake and suggests that instructors, and the nature of linear algebra, can influence the interactions between the students and their textbooks. We investigate the use of the textbook by the students (student-textbook interaction, arrow *a* in Figure 1) and how linear algebra chapters of the textbook and instructor planning influence such use of the textbook by the students (arrows *b* and *c*, respectively, in Figure 1.)

**Figure 1: Relationships studied in the didactical tetrahedron (adapted from Rezat & Strässer, 2012, p. 241)**

We analyzed bi-weekly log<sup>1</sup> data from 102 students from four instructors in four different states who were using a dynamic linear algebra textbook (Beezer, 2017). The textbook can be accessed on any device with any commonly available browser. It is online, free, open-source, enhanced with computational cells.<sup>2</sup> It includes standard linear algebra chapters (e.g., systems of linear equations, matrices, vector spaces, etc.) and is written in a definition-theorem-proof format, with exercises and some solutions towards the end of each chapter. The textbooks used in the project have a tracking system that allows to identify which sections of the textbook are being viewed and for how long.

<sup>1</sup> A log was an online survey that contained between four and seven questions about the use of the textbook during the past two weeks. We used thematic analysis to group log responses regarding student use of the textbooks.

<sup>2</sup> Students did not use the open-source feature, and infrequently used computational cells.

The analysis of the viewing data revealed, unsurprisingly, that viewing tended to occur during the days when the classes were offered (mostly during class sessions), close to exams days, or when homework was due. The students mainly used solutions of exercises—in 17,405 viewings, 81% of the viewing time was for solutions of exercises, 15% for examples, and 5% for all the other elements. In the log responses students reported that they checked the textbook the day before class or the last day of their break; they also used it to study for the upcoming class, or when they were stuck, missed class, or had not understood their instructor's explanation. Students reported using mainly problems, exercises, and examples as they were preparing for class. When asked about their use of theorems, definitions, and examples, students said those were mainly used when producing notes for later use because they wanted to make sure they were connecting ideas and knew the basic definitions. In addition, students created class notes, homework documents or solutions, and textbook notes in order to improve their understanding, for practice, and reminders or memorization, and used many other resources (classmates, Internet, Google, YouTube, Chegg, Khan Academy, and class lecture videos).

We have been tracing how the various uses students reported relate to the specific content covered in the courses and to decisions instructors had made about the course. We noticed that students did not use features that were not required by their instructors; in general, the students (and their instructors) seemed reluctant to take full advantage of novel features (such as the programming cells). We speculated that by itself, the design of the textbooks was insufficient for pushing users into adopting different ways of using these textbooks in teaching and learning linear algebra. Instructors might need training, perhaps in the form of conversations with designers and authors or in authorship that takes advantage of the open nature of the textbooks, so that they can envision new ways in which these textbooks can be used for teaching and learning. Textbook production is expensive, and thus, research that documents how open access textbooks can be made widely available is important. Yet, without knowing how to best take advantage of the new technologies, we might not realize their potential within mathematics classrooms.

# An exploratory study of calculus students' understanding of multivariable optimization problems

Thembinkosi P. Mkhathshwa

Miami University, USA; [mkhatstp@miamioh.edu](mailto:mkhatstp@miamioh.edu)

*Contributing to the growing body of research on students' quantitative reasoning at the undergraduate level, this study reports on students' reasoning about a multivariable optimization problem that involves finding the dimensions of the largest volume bag a passenger can carry on an American Airlines flight. Analysis of verbal responses and work written by 11 students when solving the problem revealed that finding the required dimensions was easy for nearly all the students. However, showing that these are the dimensions of the largest volume bag was problematic for a majority of the students. Implications for instruction and directions for future research are discussed.*

*Keywords: Optimization problems, quantitative reasoning, problem solving, calculus education.*

## Introduction

Optimization problems form an essential part of the study of differential calculus at the undergraduate level in the United States. Findings of a comprehensive review of literature on students' understanding of various topics in university calculus by Speer and Kung (2016) indicate that research on students' reasoning about optimization problems is lacking. A growing body of research (e.g., Borgen & Manu, 2002; Dominguez, 2010; LaRue & Infante, 2015) has examined students' reasoning about univariate optimization problems (UOPs). We define UOPs as optimization problems where the objective function, that is, the function whose minimum/maximum value(s) is to be found is a real-valued function of a single variable. Only one study (Heid, 1988) has reported on students' understanding of multivariable optimization problems (MOPs), that is, optimization problems where the objective function is a real-valued function of two variables. Heid found that determining minimum/maximum values of objective functions when solving MOPs where algebraic forms of the objective functions were given was problematic for a majority of the 135 students who participated in her study. We remark that the focus of Heid's study was more on the impact of resequencing skills and concepts on students' understanding of fundamental concepts in calculus, and less on students' understanding of MOPs.

While Heid's study has provided beneficial information about how students calculate minimum/maximum values when solving MOPs, there is still much to be explored about how students set up and solve MOPs in situations where an algebraic form of the objective function is not given, which is the motivation for this study. Thus, to build on Heid's study, we intend to explicitly examine students' understanding of the key steps (e.g., setting up the objective function, finding critical points of the objective function, and using the critical points to find the minimum/maximum value(s) of the objective function) that are generally involved in the process of solving MOPs algebraically.

## Research on students' understanding of UOPs

While the focus of this study is on students' understanding of MOPs, it is important to discuss the research literature on students' understanding of UOPs for comparison. Specifically, we use the

literature base on students' understanding of UOPs to identify trends in students' reasoning about UOPs that may be comparable to the results found in this study. There are three themes that emerge from the research that has looked at students' understanding of UOPs: (1) students' difficulties with setting up the objective function, (2) students' difficulties with determining and interpreting critical numbers and/or extrema, and (3) students' difficulties with justifying/verifying extrema (the minimum/maximum value(s) of the objective function). Following is a brief discussion of each of the aforementioned themes.

In the first theme, several researchers have found that setting up the objective function is problematic for high school and undergraduate students (e.g., LaRue & Infante, 2015; Swanagan, 2012). Swanagan (2012) reported on a high school student who used the equation of the parabola,  $y = x^2$ , as the objective function in a task about finding a point on the parabola closest to the point (1,0). In the same study, another high school student used the perimeter function as the objective function in a task about minimizing the cost of fencing a rectangular plot of land. LaRue and Infante (2015) found that formulating the objective function when solving contextualized optimization problems is problematic for undergraduate students even if the objective function is simple and the context of the problem is familiar to the students.

In the second theme, evidence from research (e.g., Dominguez, 2010; Mkhathshwa, 2018; Swanagan, 2012) shows that determining and interpreting critical numbers and/or extrema when solving optimization problems that have real-world contexts is problematic for high school and undergraduate students. Two of the five high school students in Swanagan's (2012) study occasionally relied on guesswork to determine extrema in a cost minimization context. Interpreting extrema in a profit maximization context was problematic for a majority of the 94 undergraduate calculus students who participated in Dominguez's (2010) study. In another profit maximization context, Mkhathshwa (2018) reported on three undergraduate business calculus students who conflated extrema (maximum profit) with a critical number (profit maximizing quantity).

In the third theme, research by Borgen and Manu (2002) and Mkhathshwa (2018) shows that justifying/verifying extrema is problematic for undergraduate students. Borgen and Manu (2002) reported on a student who presented a perfect solution to the problem of finding the minimum value of the function  $y = 2x^2 - x + 1$ . However, when asked for a justification on why the function has a minimum value and not a maximum value, the student incorrectly claimed that since the coefficient of the linear term of the function is negative, the function must have a minimum value. Mkhathshwa (2018) found that 16 of the 24 students who participated in his study had difficulty verifying extrema (maximum profit) while reasoning about a profit maximization task.

## **Relationship between UOPs and MOPs**

Solving MOPs algebraically may be more difficult for students than solving UOPs for several reasons. First, setting up the objective function for a MOP is more difficult than for a UOP. Part of the difficulty stems from the fact that in the case of a MOP the objective function is a real-valued function of two variables, whereas in the case of a UOP the objective function is a real-valued function of a single variable. Second, the algebra involved when solving a MOP may be more challenging than the algebra involved when solving a UOP. In particular, to find a critical point(s) for a MOP, students

have to simultaneously solve a system of equations, where as in the case of a UPO, they only have to solve a single equation (the derivative of the objective function) to find a critical number(s). Third, algebraic procedures such as the Second Derivative Test (Stewart, 2016) for verifying extrema when solving a MOP are much more complex than algebraic procedures for verifying extrema in the case of a UOP. Thus, one can expect the aforementioned students' difficulties with UOPs to carry over to MOPs.

## Theoretical perspective

This study draws on the theory of quantitative reasoning (Thompson, 1993; Thompson, 1994b; Thompson, 2011). Quantitative reasoning (hereafter, QR) is the act of analyzing a problem situation in terms of the quantities and relationships among the quantities involved in the situation (Thompson, 1993). In this study, QR refers to how students: (1) constructed formulas for quantities, (2) how they evaluated these formulas to determine numeric measures for quantities, (3) how they interpreted quantities, and (4) and how they reasoned about relationships between or among quantities while solving a MOP situated in a volume maximization context. Thompson (2011) identified several tenets that are central to the theory of QR. We describe three of those tenets that are related to the study reported in this paper. These tenets are: a quantity, a quantitative operation, and quantification. A quantity is a measurable attribute of an object. Examples of quantities (i.e., measurable attributes) in this study include the volume, length, width, and height of the carry-on bag (i.e., the object) mentioned in the task that appears in the methods section. Thompson (1993) distinguished between a quantity and a numerical value: A quantity has a unit of measurement but a numerical value does not.

A quantitative operation is the process of creating a new quantity from other quantities (Thompson, 1994b). The task used in this study provided a number of opportunities for students to create new quantities (partial derivatives) through the process of differentiation, that is, to perform quantitative operations. More precisely, one way students could use to solve this task successfully is to find a model (algebraic formula) that relates the quantities in the task. In this task, an appropriate model would be the formula for calculating the volume of the carry-on bag (hereafter, bag), i.e.,  $V = lwh$  where  $V$  is the volume of the bag,  $l$  is the length of the bag,  $w$  is the width of the bag, and  $h$  is the height of the bag. Multiplying the length, width, and height of the bag would result in the creation of a formula for the quantity of volume for the bag. In addition, differentiating this model (preferably, after first writing it as a function of two variables by taking into consideration the constraint on the dimensions of the bag given in the task) partially with respect to two of the dimensions (e.g., width and height) of the bag will result in the creation of new quantities (partial derivatives). Quantification is the process of assigning numerical values to quantities (Thompson, 2011). The task used in this study provided several opportunities for students to engage in the process of quantification. For example, evaluating the formula for the quantity of volume,  $V = lwh$ , after the dimensions of the length, width, and height that will maximize the volume of the bag have been found would lead to the determination of a numerical value for the quantity  $V$ . Our study was guided by the following research question: How can we interpret the theory of quantitative reasoning in the context of students solving MOPs?

## Methods

This qualitative study used task-based interviews (Goldin, 2000) with 11 students. The interviews lasted for about 34 minutes, on average, and contained two tasks. In this paper, we report on how the students reasoned quantitatively about one of the tasks:

American Airlines requires that the total outside dimensions (*length + width + height*) of a carry-on bag not exceed 45 inches. What are the dimensions of the largest volume bag that a passenger can carry on an American Airlines flight?

The students worked through the task while the interviewer asked clarifying questions about their work. After the student concluded their work on the task, the interviewer asked the following questions about the task and the content of their solutions: (a) Have you seen a problem like this before? (b) What did you do to solve the problem? (c) What does your answer tell you? (d) What does each quantity you used throughout your solution mean? (e) What are the units of each quantity that you used in your solution? (f) What was the easiest part when solving this problem? (g) What was the challenging part when solving this problem? Eight students acknowledged having seen or even solved a similar task prior to participating in this study.

### Setting, participants, and data collection

The study participants were undergraduate students at a research university in the United States. These students represented most of the high-performing students who were enrolled in two sections of a traditional calculus III course taught in the spring semester of 2018. The students were chosen based on their willingness to participate in the study, and on their ability to explain their thinking when engaged in problem solving. In addition, drawing on my my past experience with inviting students to participate in research studies similar to the one reported in this paper, high-performing students are more likely to accept the invitation than average or low-performing students. The students were familiar with formal techniques (e.g., the Lagrange multiplier method) that can be used to solve the problem posed in the task from course lectures and the course textbook (Stewart, 2016). We state as a remark that the students in this study had limited exposure to optimization problems that are situated in real-world contexts through classroom instruction and/or homework assignments. At the time of the study, four students were mathematics majors, another four students were engineering majors, two students were physics majors, and one student was an economics major. We note that this is a required course for mathematics, engineering, and physics majors, and that students outside the aforementioned disciplines rarely take this course as an elective. Eight students were freshmen, and the other three students were sophomores. Data for the study consisted of transcriptions of audio-recordings of the task-based interviews and work written by the 11 students during each task-based interview session.

### Data analysis

Data analysis was done in two stages. In the first stage, we used a priori codes that consisted of the themes on students' difficulties when solving UOPs discussed earlier. Specifically, we carefully read through each interview transcript and coded: (1) instances where students reasoned about the objective function, (2) instances where students reasoned about finding and interpreting critical points

and/or extrema, and (3) instances where students reasoned about justifying/verifying extrema. In the second stage of the analysis, we looked for patterns in each of the codes identified in the first stage of the analysis. These patterns included trends in the students' understandings, or difficulties they had in connection with each of the a priori codes identified in the first stage. The common understandings or difficulties in students' reasoning found in the second stage of our analysis provided answers to our research question.

## Results

There are three main findings from this study. First, setting up the objective function was easy for nearly all the students. Second, most of the students successfully determined and correctly interpreted critical points and extrema. Third, verifying extrema was problematic for a majority of the students.

### Setting up the objective function

Ten students were successful in setting up the objective function (i.e., the volume function) for the problem posed in the task. These students performed a quantitative operation by conceptualizing a measure of the quantity of volume as a quantitative product, i.e., volume as the product of the length, width, and height of the bag. The following excerpt illustrates how Sally, whose reasoning is representative of these students, thought about the objective function and constraint function.

Researcher: What was the first thing you did when solving the problem?

Sally: I wrote down the equations for the volume [ $V = lwh$ ], which is what we are trying to solve for and maximize, and our constraint [ $l + w + h = 45$ ] that we have, in terms of the variables we have, which is length, width, and height of the carry-on bag.

Researcher: What are the units of the  $l$ ,  $w$ , and  $h$ ?

Sally: They will be in inches.

Researcher: How about the units of  $V$ ?

Sally: Cubic inches.

After reading the problem statement, Sally recognized that the volume of the bag is the product of the length, width, and height of the bag, and that to maximize the volume of the bag, the sum of the dimensions of the bag will have to be 45 inches. She quickly turned these recognitions to algebraic equations for the objective function and constraint function. Sally also recognized the volume, length, width, and height of the bag as quantities (and not as unit-less variables) when she assigned units of measure to the variables  $l$ ,  $w$ ,  $h$ , and  $V$ . Only one student, Andy, had difficulty setting up the objective function. This student conflated the objective function with the constraint on the dimensions of the bag given in the task. Consequently, he incorrectly claimed that the volume function would be  $f(x) = xyz = 45$ , where  $f(x)$  represents “the volume of the bag” and  $x$ ,  $y$ , and  $z$  represents the length, width, and height of the bag respectively. Andy's notation for the volume function suggest that this student either did not know how to write the correct function notation for a real-valued function of three variables or that he treated the variables  $y$  and  $z$  as constants.

### Determining and interpreting critical points and/or extrema

Eight students correctly determined the critical point of the objective function using algebraic methods. The following excerpt illustrates how Ronda, who is representative of how six of these students used the Lagrange multiplier method (hereafter, LMM) to find the critical point of the objective function.

Researcher: What did you do next [after finding the objective function and constraint function]?

Ronda: I found the partial derivatives for the volume equation [ $f(x, y, z) = xyz$  in Figure 1], and I did the same thing for the other equation [ $g(x, y, z) = x + y + z$  in Figure 1]. From there, I tried solving. I used the Lagrange multipliers [method] but I don't know if that is what I was supposed to do but that's what I ended up doing. I ended up getting that the length, the width, and the height will equal each other, and I got  $45/3$  or 15 inches for all of those [length, width, and height].

Handwritten work showing the solution to a Lagrange multiplier problem. The student defines  $V = lwh$  and  $g(x, y, z) = x + y + z = 45$ . They compute partial derivatives  $f_x = yz$ ,  $f_y = xz$ ,  $f_z = xy$  and  $g_x = 1$ ,  $g_y = 1$ ,  $g_z = 1$ . They set up equations  $yz = 1$ ,  $xz = 1$ ,  $xy = 1$ , and  $x + y + z = 45$ . They solve for  $x$ ,  $y$ , and  $z$ , finding  $x = y = z = 15$ . Finally, they calculate  $V = 15 \cdot 15 \cdot 15 = 3375$ .

Figure 1: Ronda's solution

Ronda correctly used the LMM as presented during classroom instruction and in the course textbook to find the critical point of the objective function. When asked about the meaning and units of the quantities she used in her solution, Ronda stated that the variables  $V$ ,  $x$ ,  $y$ , and  $z$  represent the volume, length, width, and height of the bag respectively and that the units of the variable  $V$  are "inches cubed" while those of  $x$ ,  $y$ , and  $z$  are "inches." In the process of using the LMM to find the critical point of the objective function, Ronda created new quantities (i.e., performed quantitative operations). Three of the quantities she created are the partial derivatives  $f_x = yz$ ,  $f_y = xz$ , and  $f_z = xy$ . When asked about the meaning of the partial derivative  $f_x = yz$ , Ronda said, "that would be saying like the width and the height would both be constant, so they wouldn't be changing at all,  $x$  is the only variable." While Ronda's interpretation of the partial derivative  $f_x$  shows that she clearly understood that only  $x$  is allowed to vary while  $y$  and  $z$  are held constant, it does not show that she understood the partial derivative to be a "rate" quantity. She stated that the units of the partial derivative  $f_x = yz$  would be "inches cubed," suggesting that she conflated a "rate" quantity with an "amount" quantity, i.e., volume. Ronda gave similar interpretations and units for the other two partial derivatives, namely  $f_y$  and  $f_z$ . Ronda and three other students (Sally, Austin, and Tim) went on to engage in quantification by evaluating the volume function at the critical point they found (i.e., 15 inches for the length, width, and height respectively) to determine the volume of the bag.

Two other students (Noel and Paul) used another algebraic method to find the critical point of the objective function. Because of space limitations, we will not show student work that illustrates the method used by these students. Two other students (Tom and Austin) drew on their prior experiences with calculating volumes of rectangular prisms and correctly determined the critical point of the objective function. Another student (Andy) incorrectly assumed that the length, width, and height of the bag will each be  $\sqrt[3]{45}$  inches long.

### **Verifying extrema**

Eight students had difficulty verifying that the dimensions of the bag they found would result in a bag of largest volume. For example, when asked how they can convince someone that the dimensions of the bag they found are the dimensions of the largest volume bag a passenger can carry on an American Airlines flight, Ronda commented, “honestly, I am not sure” while Garry said “I would probably google Lagrange multipliers to refresh myself. Lagrange multipliers would sort of be my proof.” In response to the same question, one of the students who gave an acceptable response, stated that he could use a numerical approach that involves randomly trying other numeric values for the quantities of length, width, and volume besides 15 inches and showing that these values would result in a smaller volume than when each side of the bag is 15 inches long. He also stated that the Second Derivative Test, discussed during classroom instruction and in the course textbook, could be used. The student correctly explained how this test could be used, in addition to using it correctly to verify extrema in another task not reported in this paper.

### **Discussion and conclusions**

Although previous research (e.g., LaRue & Infante, 2015) has reported on students’ difficulties with setting up the objective function when solving UOPs, this was not the case for most of the students in this study. To some extent, findings of this study suggest that students’ difficulties when solving MOPs are similar to students’ difficulties when solving UOPs. In particular, verifying that the dimensions of the bag the students found (correct or incorrect) were the dimensions of the largest volume bag a passenger can carry on an American Airlines flight was problematic for eight of the 11 students who participated in this study. Similar results have been reported among students when solving UOPs (Borgen & Manu, 2002; Mkhathshwa, 2018). One student (Ronda) interpreted a “rate” quantity represented by a partial derivative as an “amount” quantity with units of volume (i.e., inches cubed). Similar results have been reported in other studies that have examined students’ reasoning about “rate” and “amount” quantities in real-world contexts (e.g., Mkhathshwa & Doerr, 2018). As noted earlier, the students in this study had limited exposure to solving MOPs that have real-world contexts. The presentation of optimization problems during course lectures closely followed the presentation of optimization problems in the course textbook. In particular, verifying extrema using informal and formal techniques such as the Second Derivative Test received minimal attention during course lectures. Hence, we argue that the students’ difficulties with verifying that the dimensions they found would result in a bag of largest volume may be directly related to the limited opportunities they had to verify extrema via examples that were given during course lectures. Calculus instructors may have to supplement examples given in course textbooks in order to maximize students’ opportunity to learn about MOPs. Future research might examine whether or not there are gaps in students’ prior

knowledge that impact them in understanding MOPs and the use of technology (especially graphs and spreadsheets) during classroom instruction to help students understand MOPs.

# **Towards a better understanding of engineering students' use and orchestration of resources: Actual Student Study Paths**

Birgit Pepin and Zeger-Jan Kock

Eindhoven University of Technology, Eindhoven School of Education, The Netherlands;

[b.e.u.pepin@tue.nl](mailto:b.e.u.pepin@tue.nl), [z.d.q.p.kock@tue.nl](mailto:z.d.q.p.kock@tue.nl)

*In this study we explore (1) which kinds of 'resources' engineering students use in selected first year university mathematics courses (Calculus, Linear Algebra); and (2) how they use/orchestrate them for their study of mathematics. Using a case study and mixed methods approach, we found that in the large Calculus course students followed various study paths. Moreover, it appeared that in such courses students used/included human and social resources extensively. In the smaller Linear Algebra course students could follow the study path established by the lecturer/course designer, with all resources provided for students to pass their examinations. At the theoretical level, we coined the term Actual Student Study Path to describe their self-reported ways of how they identified and orchestrated their chosen resources for their study of the mathematics.*

*Keywords: Student use of resources, university mathematics education, actual student study path/s.*

## **Introduction**

In most western (engineering) universities students now have access to a plethora of resources, both digital/online resources and 'traditional' curriculum resources, such as textbooks, readers (course textbook/set of materials prepared by the lecturer), worksheets, provided by the university and by lecturers. In particular in large first year courses (e.g., Calculus), students are typically expected to use and blend the available resources according to their individual needs, to support their learning. The rationale for our study is that, in times where students have access to almost limitless learning resources online, it becomes increasingly important to understand which resources are preferably (and beneficially) used by students from the ones on offer, and how they orchestrate them for their study of mathematics. This, in turn, is likely to inform the designers and teachers/lecturers of mathematics courses in their efforts to enhance their courses.

The use of particular curriculum resources by teachers and students in higher education mathematics has been subject of current research. In a recent review study (Biza, Giraldo, Hochmuth, Khakbaz, & Rasmussen, 2016), the opportunities afforded by introductory university mathematics textbooks and the actual use made of these curriculum materials by students are described. Anastasakis, Robinson, and Lerman (2017) investigated the different types of tools ('external' to the university, and 'internally' provided resources) that a cohort of second year engineering undergraduates used. Their results showed that although to some extent students used resources external to their university, their practices were dominated by tools that their institution provided. The students in their sample chose certain tools mainly because these enabled them to pursue their examination-driven goals. Specifically, the use of visual resources (e.g. online lectures) has been studied by Inglis, Palipana, and Ward (2011). Using the Documentational Approach to Didactics, Gueudet (2017) investigated mathematics teachers' interactions with resources at university, and Gueudet and Pepin (2018) explored how Brousseau's (1986) Didactic Contract can be seen through the lens of the use of

curriculum resources. Whilst the learning of Calculus (CS) has been studied extensively (e.g. Bressoud, Mesa, & Rassmussen 2015), Linear Algebra (LA) learning has had less attention (e.g. Grenier-Boley 2014).

However, we note here that relatively little research is available on the broad range of resources available to first year university students to learn the mathematics, and moreover how students actually orchestrate the resources in order to study mathematics. Typically, studies include the curriculum resources made available or recommended as part of mathematics courses (e.g., textbooks), but there are also *social resources* (e.g. lecturers, tutors, peers) that students tap into, and digital and other resources mobilized by students themselves. Inglis et al. (2011) suggest that students might need explicit guidance on how to combine the use of various resources into an effective learning strategy. Before this guidance can be given, more in-depth information on students' actual use of resources is needed. Hence, we ask the following research question:

*How do first year engineering students identify and use the available resources for their study of Calculus and Linear Algebra in their first year at university, and what kinds of paths do students describe?*

## **Theoretical frames/literature review**

### **The lens of resources**

Leaning on the Documentational Approach to Didactics (e.g. Trouche, Gueudet, & Pepin, 2018), in this study we use the notion of *re-source/s* that students have access to and interact with in and for their learning. We assume that the ways university students learn the mathematics is influenced/shaped by their use of the various resources at their disposal. By *use of resources* we denote, for example, which resources students choose (amongst the many on offer) and for what purpose (e.g. revision); the ways they align and orchestrate them (e.g. first lecture then checking the textbook); which ones seem central to achieve particular learning goals (e.g. for weekly course work, for examinations, for their engineering topic area). However, we do not address the specific learning of CS and LA, that is how students interact with particular (e.g. cognitive) resources to learn particular topic areas in CS and/or in LA.

Gueudet and Pepin (2018) have coined student resources as anything likely to re-source (“to source again or differently”) students' mathematical practice, leaning on Adler's (2000) definition of mathematics re-sources, in Adler's case used by teachers. In this study, following Pepin and Gueudet (2018), we distinguish between (1) material/traditional text/curriculum resource (including digital resources); and (2) human/social resources. As to (1) material/traditional text/curriculum resources: a further distinction has been made between (a) curriculum resources (those resources proposed to students and aligned with the course curriculum), and (b) general resources (which students might find/access randomly on the web). Curriculum resources are developed, proposed by teachers and used by students for the learning of the course mathematics, inside and outside the classroom. They may include text resources, such as textbooks, readers, websites and computer software, to name but a few. General resources are the non-curricular material resources mobilized by students, such as general websites (e.g. Wikipedia, YouTube). (2) In terms of social resources, we refer to formal or casual human interactions, such as conversations with friends, peers or tutors/lecturers.

## Actual student study paths

The research literature in mathematics and science education shows many different terms and concepts linking to student study paths, often associated with instructional theory and curriculum design, such as Hypothetical Learning Trajectory (HLT) (Simon, 1995); Learning Trajectories/Progressions (Lobato & Walters, 2017); or, Learning Trajectories in mathematics education (Weber, Walkington, & Mc Galiard, 2015). Whereas some of the approaches focus primarily on learners (e.g. Lobator & Walters, 2017), Simon's (1995) HLT approach includes instructional supports for learning and was originally conceived as part of a model of teachers' decision making. Simon and Tzur (2004) later highlighted the importance of and principles for selecting tasks that promote students' development of more sophisticated mathematical concepts. Building on this work, Clements and Sarama (2004) define learning trajectories as

descriptions of children's thinking and learning in a specific mathematical domain and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking, created with the intent of supporting children's achievement of specific goals in that mathematical domain. (p. 83)

Whilst recognizing this important work, it is clear that we have to define what we mean by student study paths for our purpose: first, when using the lens of resources to investigate students' study paths, we look at the alignment and orchestration of resources, and not at the actual tasks or activities and how students develop understandings of mathematical concepts; second, we view this from the students' perspective, how they actually orchestrate and align the resources for their own learning, and how they give meaning to these self-reported paths. We call these *Actual Student Study Paths*.

## The study

Using a case study approach, we explored two first year mathematics courses in a Dutch engineering university: Calculus (CS) and Linear Algebra (LA), as our cases.

LA was taught to one group of approximately 130 students, mainly mathematics and physics students. The LA course was organized with four hours of lectures per week, and four hours of tutorials (in groups of approximately 30 students). The learning aims were described as the acquisition of mathematical skills, and to help students develop the skills and appreciate the importance of correct mathematical communication, including writing formal proofs. Completing a mathematical writing assignment was part of the course requirements to reach this aim. According to lecturers, the purpose of LA was to prepare students for higher mathematics (used in the mathematics and physics courses).

CS was taught as an obligatory subject to approximately 2000 students, in 6-7 groups of 300 students each (all types of engineering). The CS course was organized with six hours of lectures and one hour of tutorials (in small groups of approximately eight students). It was also differentiated at three levels (A, B, and C), according to perceived level of difficulty and with varying level of emphasis on formal aspects of mathematics (e.g. proof). The aim of the CS course (according to lecturers) was to provide students with a basic set of mathematical/computational tools they could subsequently use in their engineering studies and in their future work as engineers.

In terms of participants, in total 24 students participated in the study; all of them ‘opted in’ after a general mail to all CS and LA students: 18 CS students, involved in nine different engineering programs and all taking the B level CS course; 1 CS student who dropped out of university; 5 LA students, all studying for the applied mathematics engineering course. In terms of background, of the interviewed CS students 15 came from secondary schools in the Netherlands, three came from other educational systems.

For this paper we used data from the following data collection strategies:

- Individual and focus group interviews with students (24): 19 CS + 5 LA. The CS students were interviewed in four focus groups, and one individual interview. The LA students were interviewed in two groups of two, and one individual interview.
- CS students’ drawings (see example Figure 1): students were asked to draw Schematic Representation of Resource System (SRRS - see Pepin, Xu, Trouche, & Wang, 2017) during the interviews, to illustrate the particular resources each student used, and how. During the interviews students were asked to explain their resource use based on their SRRSs. The SRRSs were a methodological tool, to help the researchers better understand student use of resources.
- Interviews with course designers/lecturers and tutors (of the CS and LA courses): 3CS + 2LA.
- Selected observations of CS and LA lectures and tutorials, and examination of documents/curriculum materials provided by the university for the students, such as syllabi, textbook/s, reader/s, and lecture videos (mainly to understand the context in which students were working).

In terms of analysis, the interviews were first transcribed and interview quotes were coded using ATLAS-ti software. The codes were based on our knowledge from the literature (e.g. concerning the different curriculum resources and their use) and on our knowledge about student approaches to learning mathematics. Second, student drawings were compared with their explanations (within case comparison): how they explained their identification of (for them) suitable resources and the orchestration of these resources; this resulted in self-reported study paths. Third, these self-reported study paths were compared (across case comparison), and this resulted in particular types of study paths. In another step, the findings from CS and LA were compared, also taking into account our knowledge of the context and course organization.

## Results

Overall, students used different/additional resources in the two courses, and they used the available resources differently for LA than for CS: (1) Basically, all LA curriculum resources offered/provided were used, and students worked with them according to the lecturer’s guidance. (2) The CS resources seemed to be a large bag of ‘tools’, a ‘pile of bricks’, that the students could pick from (according to their needs) and use for their learning. However, how students could orchestrate and align the resources for the learning of CS was not clear. These differences appeared to be related to (a) the size and student audience of the courses (130 students in LA; 2000 in calculus), and this, in turn, was connected to different organizations of the courses (4 hours lecture and 3 hours tutorials in LA; 6 hours lecture and 1 hour of tutorial in calculus); and (b) the organization and alignment of the resources with the assessment/tests. For example, there was a clear intended (by the lecturer) learning

trajectory in LA, with exercises aligned with the examinations. Students mentioned that if they worked according to/with the reader and did “all exercises in the reader”, and the obligatory weekly assignments, they could expect to pass the examination. In the CS course, many support tools were proposed (e.g. on the web, in print), with many exercises and tasks that, according to the students, were not always clearly aligned with the examinations. Students said that it was not possible to do all exercises, read all materials provided, and they often had considerable difficulties choosing from the immensity of resources provided.

From the interviews based on students’ drawings of their resource system, we could identify several study paths, which were the paths students perceived/drew when we asked them which resources they used, the importance of those resources (their role with respect to their perceived study paths), and how they orchestrated them for their learning. The study path of the LA course appeared to be relatively traditional and most students followed it: students could identify core resources (e.g. the lecture, the reader, past examinations, weekly tests), and a particular blending of the different resources was recommended by the lecturer. This would help students to understand the weekly coursework and to pass the final examinations. In addition, students had time to work together (in tutorials), and they also used human resources (e.g. peers, tutor/s, lecturer) during that time. In this course the number of tutorials was balanced as compared to the number of lectures (4 + 4).

In contrast, the students on the CS course outlined several study paths, based on their individual preferences and experiences, and for each path different resources came into play, and different core resources were described. For example, in the interviews based on their drawings, only two students put the lecture as a center point for their learning. For others, it appeared that the lecture was for information only of what students had to learn: “If I hear them talk about it, it’s easier for me to revise/practice when I’ve already seen it, heard about it” (see Joanna’s<sup>1</sup> drawing in Figure 1).

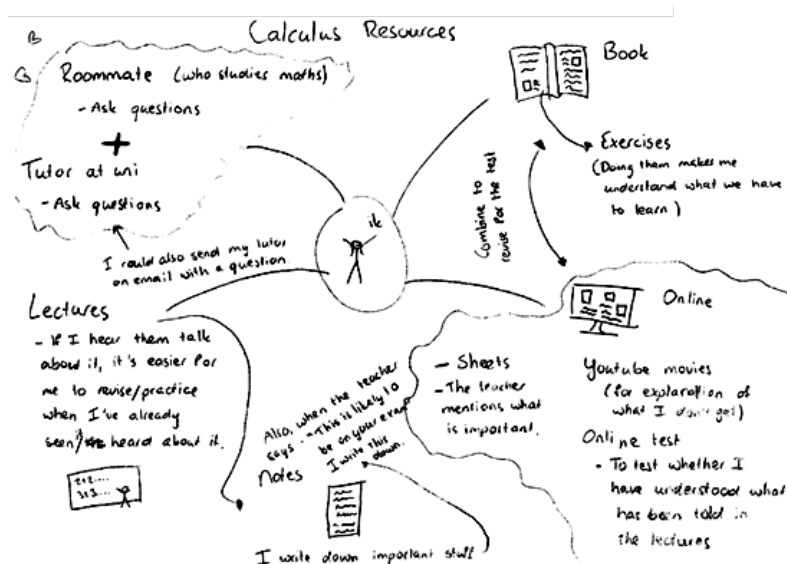

Figure 1: Joanna’s drawing of her resource system

<sup>1</sup> All names are pseudonyms

At the same time, either the lecture or lecture notes were mentioned by all students as a supporting resource for their learning of CS. Interestingly, a large number of students pointed to human resources, in particular their friends and peers, and the tutor, as resources they often used. As perhaps expected, books and tests/quizzes/exercises were mentioned as a huge help, and the digital resources (e.g. YouTube; Khan Academy) seemed to gain importance compared to high school. Altogether, the CS study paths showed a complex picture of students using a mixture and ever-increasing number of external resources, in particular of human and digital nature. Due to the interviews based on the SRRSs, we could identify a small number of (for students) ‘productive’ study paths that students self-reported upon. What made a study path ‘productive’ was that it allowed the students to orchestrate the different resources around a particular focus, in such a way that the students felt the demands of the course could be met.

The study paths we present here had different foci: (1) tests and examinations, weekly homework; (2) lecture; (3) friends and social media; and (4) understanding.

- (1) For most students the *weekly homework, tests and examinations* were the focal point, hence they described the resources that helped them to solve the associated tasks (e.g. “last resort professor”). Some students described a real trajectory of how they prepared for solving particular tasks or homework, and for passing tests and examinations.
- (2) Selected students chose the *lecture* as focus:

Dirk’s path: from lecture → tests → tutor hour & old exams → YouTube/Khan academy → homework (“reading text” & “do it”)

Naomi’s path: from lecture (every week) → tutor time → homework every week → on-course extra questions & weekly quiz → discussion with friends → “my own comments” /writings to prepare for exam.

- (3) Example of *human resources and social media* as focus:

Rebecca’s path: from “human resources” (at center) - first friends & summary chapters (book)/exercises & weekly homework → lecture “for orientation & overview, not in depth” (video lecture “only if I missed an essential”) → Matlab “own curiosity & personal interest” → Tutor hour (falling asleep).

Jop’s path: social media at the center

- (4) Example of students who differentiated between resources used for different kinds of learning:  
Melissa’s path: she made a distinction between (a) procedural understanding: solving exercises/passing exams (resource/s: e.g. tutor, weekly quiz, online practice test), and (b) conceptual understanding: “if you do not understand underlying thought/concept” (resource: YouTube).

## Conclusions

From our findings, it can be seen that students’ use and orchestration of resources were largely shaped by the course organizations. In one case (LA), the lecturer/course designer provided a ‘home-made’ reader (no other textbook was needed) which provided all necessary and important information in

terms of the mathematics (e.g. concept explanation) and the most relevant exercises. All other curriculum resources were aligned with the reader, and in line with the learning objectives/course aims (as described in the course guide booklet). In addition, the lecture and tutor hours afforded opportunities to discuss problems and ask for help from the lecturer/tutors, or indeed from peers. In the case of CS (at the B level), a commercially produced textbook was used, and several lecturers and tutors were involved. Moreover, in terms of opportunities for learning, the lectures were foregrounded (6 hours), with only one hour of tutor support. In addition, several resources had been prepared and were provided within the course web environment, as a support for students. However, it appeared that in this environment students looked for their own ways to use the affordances of the resources on offer (e.g. opportunities offered by textbooks and other resources, see Biza et al., 2016). They sometimes had difficulties navigating their ways around the different resources, benefitting from the quality of the resources on offer, with little (time and) guidance from the tutors. There were many (and new) resources to choose from, and the “didactic contract” (Gueudet & Pepin, 2018) was not clear to them; hence, students created their own actual study paths.

Based on our results we claim that it is not sufficient to provide a plethora of curriculum resources, may they be digital, traditional text or human resources, but that serious consideration should be given to how students might work with these resources, and orchestrate them into productive *Actual Student Study Paths*. In addition, it is advisable to help, perhaps even to train students how to develop such study paths, and these might be different from one subject to another (even from one mathematics course to another). This, we claim, is the responsibility of the lecturer/teacher/course designer. Such course design would involve purposeful design, including the development of particular (intended) study paths, and the design of particular resources supporting such paths. Simply providing access to curriculum resources does not seem to help students to orchestrate the resources on offer, neither to develop their individual study or learning strategies, but may rather confuse and overwhelm them (due to the immensity of resources on offer), and drive them towards “learning for the test”. As Anastasakis et al. (2017) claim, under such conditions “students use the most popular resources [and] they aim mostly for exam-related goals” and use “certain tools because these enable them to pursue their exam-driven goals” (p. 67).

# Conceptualising knowledge of mathematical concepts or procedures for diagnostic and supporting measures at university entry level

Guido Pinkernell

University of Education Heidelberg, Germany; pinkernell@ph-heidelberg.de

*At the 10<sup>th</sup> CERME in Dublin, Pinkernell, Düsi and Vogel (2017) introduced a model of proficiency in elementary algebra that serves as a frame of reference for analysing and constructing material for diagnostic and supporting measures for students at the entry level of university. One basis of this model was a systematic analysis of the mathematical concepts and procedures of elementary algebra with regard to five aspects of understanding mathematics. This paper introduces this framework in detail, thus contributing to a genuine mathematics educational conceptualisation of content oriented knowledge for STEM subjects at university entry.*

*Keywords: STEM Education, Secondary Education, Assessment, Knowledge, Understanding.*

## Conceptualisations of knowledge at university level

The recent years have shown a growing interest of mathematics educators for the transition from secondary to tertiary phase, which is mainly being characterised as a gap between mathematical levels and institutional cultures. In her analysis Gueudet (2008) describes differences with regard to modes of conceptualising mathematical objects, also different levels of rigour in communication or reasoning, and institutional differences, e.g. concerning the didactics of teaching and learning mathematics. Thomas, de Freitas Druck, Huillet, Ju, Nardi, Rasmussen and Xie (2015) come to similar findings when they analyse the transition from four different theoretical perspectives. One aspect that adds to these cognitive, didactical and institutional differences, however, is the content orientation that appears to dominate discussions about the demands and deficits of students in STEM subjects at university entry. This becomes manifest, for example, in catalogues of minimum mathematical requirements (e.g. cosh, 2014) or in a large-scale delphi study with mathematics teachers in the tertiary sector (Neumann, Pigge, & Heinze, 2017). Yet when it comes to devising diagnostic and supporting measures, what students need to know can only be made clear when there is a notion of what knowing means.

Among the frameworks for conceptualising knowledge that are familiar at university level is the so-called Bloom taxonomy, which in a revised version by Anderson and Krathwohl (2001) differs between various categories of knowledge about subject matter content as well as various forms of cognitive activities on that subject matter content. According to Krathwohl (2002) the reasons for revision were to update to new psychological models of knowledge as well as to meet with terminology use among teachers or educators. This resulted, e. g., in formulating four categories of knowledge, which are factual, procedural, conceptual and metacognitive knowledge. This framework had been designed for trans-disciplinary purposes (Krathwohl, 2002), which is seen as an advantage since it seems suitable for interdisciplinary use (Maier, Kleinknecht, Metz, & Bohl, 2010). While the procedural-conceptual dichotomy is not only part of many models of general knowledge but of mathematical knowledge as well (e.g. Hiebert & LeFevre, 1986; de Jong & Ferguson-Hessler, 1996; Rittle-Johnson & Alibali, 1999), it appears that for analysing mathematical content knowledge, the

four categories do not quite fit to how the knowledge of mathematical concepts or procedures is seen from within mathematics education. Firstly, Star and Stylianides (2013) have shown that while psychologists see procedural and conceptual knowledge as merely two different types of knowledge, in mathematics education these two are regarded as of different quality. For many school teachers, conceptual knowledge is preferable over procedural knowledge which is seen as simply recalling facts or applying algorithms “without significant thought.” (Star & Stylianides, 2013, p. 178) Secondly, this again seems to be in contrast to how many university teachers view procedural knowledge. They see procedural proficiency as a necessary basis for following or performing symbolic mathematical reasoning. In fact, since the process of learning abstract mathematical concepts can be described as a progression from procedures to concepts (Tall, 1991; Sfard, 1994), the procedural-conceptual dichotomy does not quite grasp the nature of knowledge in mathematics where concepts and processes are seen as part of the very same knowledge entities (see also Kieran, 2013). In fact, Star and Stylianides (2013) suggest “abandon[ing] the conceptual/procedural framework entirely and select new words or phrases to describe knowledge outcomes of interest.” (p. 179)

This paper proposes a genuine mathematics educational approach to conceptualising mathematical knowledge at the transition from the secondary to the tertiary level. While procedural and conceptual knowledge is still implicitly present, it addresses specific forms of accessing or understanding a mathematical object, thus acknowledging the content orientation and other characteristics of mathematical knowledge as it is seen at university level.

### **Content orientation from perspective of mathematics education**

The following ideas are rooted in the German Stoffdidaktik (subject-matter didactics) tradition. It shares the conviction that student oriented approaches to abstract mathematical objects are possible without compromising on the mathematical validity. At the centre of didactical efforts of Stoffdidaktik is a thorough analysis of the mathematical concept. In the past this took on the form of mathematical rigour that seemed unsuitable for the use in learning situations (Hußmann, Rezat & Sträßer, 2016). While subject of an ongoing dispute, the ideas of Stoffdidaktik are still present in German mathematics education. Prediger and Hußmann (2016) for example plead for a combination of a thorough content analysis and empirical evaluation, for which they describe four phases: 1. a formal analysis of mathematical conceptualisations of the teaching object, 2. a semantic analysis of meaningful interpretations of the teaching object, 3. a structural orchestration of the findings in the form of a teaching unit, and 4. constant empirical evaluation and subsequent modifications of steps 2 and 3 to adapt to students' needs. Especially the first two phases indicate that formal conceptualisations and meaningful interpretations of mathematical objects can be part of one didactical framework, which seems suitable for purposes at the transition from school to university where formal and educational perspectives meet.

### **The WiGORA frame of reference**

Before going into details, this section starts with an outline of necessary a priori settings that reflect the area where the framework is being used, which is the transition from secondary to tertiary maths: First, it is a concise and summative view on what facets of knowledge of a given mathematical object a student needs to have at his or her disposal once it has been taught, not a formative view on how

knowledge should be developed during school-time. Further, the facets of knowledge are considered normative, that is they are meant to cover mathematically sound ways of accessing a mathematical object which include, e.g. explanatory models or visualizations that are structurally equivalent to the object. Moreover, considering the formal level at which mathematics is being taught at university (Gueudet, 2008; Thomas et al., 2015), a correct use of terminology and definition based access to mathematical objects will be addressed explicitly. Simultaneously, since formal and abstract nature of mathematical objects requires a flexible use of representations (Duval, 1999), this aspect will be addressed explicitly, too. And last, this framework is for conceptualising an “intelligent content knowledge base” (Klieme et al., 2007) for developing higher level competencies, it is not a framework for higher level competencies itself.

The acronym WiGORA derives from the German labels for the five facets of knowledge that make up the frame of reference. In the following each facet will be introduced and illustrated by tasks that address the concept of integral.

- Declarative knowledge (“Wissen”) refers to the ability to recall or identify correct definitions, rules or characteristic properties of a mathematical concept or procedure as well as the necessary terminology associated with it. Declarative knowledge basically is knowledge about facts and information (Anderson, 1976). It seems rather less present in conceptualisations of mathematical knowledge as compared to procedural or conceptual knowledge. While in its strictest sense it does not allow for weighting knowledge regarding significance, declarative knowledge here also comprises prototypical knowledge that characterises, but not necessarily defines, the object (Rosch, 1983; Tall & Bakar, 1992; Weigand, 2004). The following task asks for prototypical knowledge that differs between definite and indefinite integrals.

Which of the four statements are correct?

$$\int_a^b f(x)dx \text{ is a number. } \int_a^b f(x)dx \text{ is a function.}$$

$$\int f(x)dx \text{ is a number. } \int f(x)dx \text{ is a function.}$$

- Explanatory models (“Grundvorstellungen” or GV for short) refers to the ability to recall or identify conceptualisations of a mathematical object that “make sense” (vom Hofe & Blum, 2016; Greefrath et al., 2016; Weber, 2017). The concept of GV is one of the key concepts of German Stoffdidaktik, which “should be able to, on the one hand, accurately fit to the cognitive qualifications of students and, on the other hand, also capture the substance of the mathematical content at hand” (vom Hofe & Blum, 2016, p. 227). In international context, GV are also being referred to as “basic ideas”, “basic notions” or “conceptual metaphors” (Soto-Andrade & Reyes-Santander, 2011). In its broadest sense, GV comprise normative, descriptive and constructive aspects. Here, at the transition from school to university, the notion of GV is restricted to its normative aspect. As such, a GV could result from a semantic analysis of a mathematical object (Hußmann & Prediger, 2016). For example, “reconstruction” of rates or speed is one of the GV for the concept of the definite integral (Greefrath et al., 2016) and is subject of the following task.

The graph shows for any point of time the current fuel consumption for each of two vehicles A and B.

Which of the vehicles has a higher consumption overall over the period shown?

- Operational flexibility (“Operationale Flexibilität”) refers to the ability to apply, adapt and modify mathematical procedures for situational needs. Going beyond simply reproducing step-by-step instructions this facet refers to the cognitive construct of operations in the sense of Piaget and Aebli. Characterised for example by reversibility or transitivity of the mental operations involved (Fricke, 1970), corresponding tasks would require reversing procedures or selecting efficient over routine procedures (“strategic flexibility”: Rittle-Johnson & Star, 2007). Here, procedures are not restricted to algorithms for calculating numbers or transforming algebraic expressions. A procedure can be any method for solving a mathematical task, which e.g. could also involve switching representation forms. The following example shows a reverse task which can be answered by mentally visualising a graph and/or recalling prototypical information about the periodicity of trigonometric functions.

Specify as many  $a \neq b$  as you can find  
such that  $\int_a^b \sin(x) dx = 0$ .

- Representational flexibility (“Repräsentationale Flexibilität”) refers to the ability to switch within and between representational forms or registers of a mathematical object. Following Duval (1999), this ability is specific to understanding higher level mathematics since a mathematical concept, being essentially abstract, can not be addressed otherwise: “From a didactical point of view, only students who can perform register change do not confuse a mathematical object with its representation.” (Duval, 1999, p. 318). As to the many possible forms in which a mathematical object can be represented, this framework is restricted to those that are conventionally used in mathematics such as numerical, algebraical, geometrical representations, or verbal paraphrasing.

Order by value:

$$\int_a^a f(t) dt, \int_a^c f(t) dt, \int_a^d f(t) dt, 0, \int_c^d f(t) dt$$

by H. Körner (in Pinkernell et al. 2015)

- Knowledge application (“Anwendung”) refers to the ability to identify a mathematical concept or procedure as suitable for solving a problem. Here, the given concept or procedure

is considered as a potential model for mathematising situations within or outside mathematics (“Mathematisierungsmuster”: Tietze, Förster, Klika & Wolpers, 2000). This facet, as all five facets do, focusses on meaning and use of a given mathematical object. It does not refer to the modelling process or parts of it, but it addresses the content knowledge base of modelling. The following example asks for the average of values of a continuous function over an interval  $\frac{1}{b-a} \int_a^b f(x) dx$  which here is determined by graphical estimation.

## Discussion

With WiGORA, this paper proposes a framework for conceptualising mathematical knowledge at the university entry level. With focussing on single concepts or procedures WiGORA follows a similar approach as the familiar taxonomies of Bloom or Anderson and Krauthwohl, yet with a genuine theoretical base from mathematics education. When compared with Anderson and Krauthwohl (2001), the most significant difference is that the well-known dichotomy of procedural and conceptual knowledge has been abandoned. It has been replaced by facets of knowledge that take specific aspects of objects from formal mathematics into account, which roughly can be characterised as being abstract “by definition”. The facet “Grundvorstellungen” (GV) asks for the activation of explanatory models for the abstract mathematical object at hand. Such models can be hands-on activities on real or virtual material or situational interpretations within or outside mathematics. Equally, the facet “Repräsentationale Flexibilität” reflects the abstract nature of mathematical objects by asking for a flexible use of representations of this object. Also, the facet “Operationale Flexibilität” derives from the cognitive nature of mental operations as being abstractions from step-by-step procedures when it asks for heuristic flexibility in adapting mathematical procedures to situational needs. Among these facets, procedural and conceptual aspects of knowledge are still present though not explicitly. From the two other facets, “Wissen” corresponds to the category “factual knowledge” from Anderson and Krauthwohl (2001).

The five facets of the WiGORA framework all stand for viewing the same mathematical concept or procedure from different perspectives. Although the perspectives are different, the tasks that result from operationalisations following the framework are not necessarily disjunct. In fact, the very same task could address several facets. E.g., among the five examples above, three require representation change. And since GV are often associated with actions and concepts from everyday life, they identify

obvious applications for the mathematical objects. For example, the GV “average value” (Greefrath et al., 2016) points to applying the integral for measuring the average of a continuous function, as shown in the fifth task. Hence, WiGORA has its main use for analysing or devising test material that is based on a list of given concepts or procedures. It is meant to serve as a model of reference for checking whether the five facets are being covered in a diagnostic tool.

With focussing on single objects, WiGORA does not allow for analysing a whole network of knowledge of a mathematical field, which from an educational perspective is characterised by a meaningful use of the specific language or the mastery of key concepts from that field. In the field of elementary algebra, these would be various aspects of knowledge specific to the structuring, transforming and interpreting of algebraic expressions (Pinkernell et al., 2017), as e.g. aspects of giving meaning to expressions (structure sense: Hoch & Dreyfus, 2006; systemic vs. surface structure: Kieran, 1989), or aspects of interpreting the equation sign (operational vs. relational meaning: Baroody & Ginsburg, 1983). Hence, the object related facets of knowledge from WiGORA would need to be integrated into a larger educational conceptualisation of the knowledge of that area. Presently, as part of the German optes+ project (Mechelke-Schwede, Wörler, Hübl, Küstermann, & Weigand, 2018), this is being done for the areas secondary arithmetic, functions and geometry.

# Formative assessment of proof comprehension in undergraduate mathematics: Affordances of iterative lecturer feedback

Alon Pinto and Jason Cooper

Weizmann Institute of Science, Israel; [alon.pinto@weizmann.ac.il](mailto:alon.pinto@weizmann.ac.il); [jasonc2107@gmail.com](mailto:jasonc2107@gmail.com)

*Research shows that lecturer feedback on students' proofs is crucial for developing proof-comprehension in advanced mathematics courses, yet students often fail to comprehend lecturer feedback, and only rarely receive further feedback on their revisions. In this study we investigate the affordance of a novel formative-assessment scheme, designed and enacted by a mathematics professor, which employed multiple rounds of lecturer-feedback / student-revision. We analyze one such round, focusing on various facets of proof comprehension that underlie the lecturer's feedback and the student's subsequent revisions. On the basis of this analysis we discuss various ways in which lecturers can leverage feedback/revision cycles, not only for gaining insight into students' comprehension, but also for fostering meta-level ideas, and affording opportunities for students to develop agency and holistic proof comprehension.*

**Keywords:** Undergraduate mathematics education, proof comprehension, formative assessment.

## Introduction

One of the most prominent learning activities in advanced mathematical courses is proof reading. Students listen to their professors as they present proofs in lectures, and are expected to continue studying these proofs extensively after class, using their lecture notes or the course textbook (Weber, 2012). However, reading, validating and comprehending mathematical proofs are not easy tasks. It involves not only strategic knowledge in specific content areas, but also knowledge and norms specific to proof and reasoning (Knapp, 2005). In a study of students' proof validation practices, Alcock and Weber (2005) found that students focused on superficial features of proofs, while failing to develop a holistic view of the proof and neglecting arguments' explicit or implicit warrants. In spite of these difficulties, instructors rarely attend directly to proof reading in their teaching, presumably because knowledge related to proof reading strategies is largely tacit (Weber, 2012). Weber (2012) concludes that the mathematicians he interviewed provided "little guidance to students on how to engage in the complicated process of reading and comprehension of proofs and, by their own admission, lacked adequate methods for assessing students' understanding of a proof" (p. 478).

Lecturer feedback is an important aspect of assessment practice. Moore (2016) has argued that lecturer feedback is instrumental not only for proof comprehension, but also for developing the notion of proof and the ability to write proofs. Yet, relatively little empirical research has been conducted on how proofs are assessed in undergraduate mathematics courses, particularly in relation to lecturer feedback. Moore, Byrne, Hanusch, and Fukawa-Connelly (2016) have investigated students' comprehension of written lecturer feedback, and found that students "were generally quite capable of writing revised proofs that remediated the issues indicated by the professor's marks and comments, even when they could not fully explain the rationale for the comments" (p. 320). Consequently, students' written proofs were found to be insufficient for distinguishing between different levels of comprehension. These findings highlight that when students do not resubmit their revised proofs,

neither the students nor the lecturers have a way of knowing whether students have interpreted the feedback and respond to it in ways that promote proof comprehension.

One way to address this limitation is by having students' work iteratively critiqued and resubmitted until deemed acceptable by the lecturer. Our research goal is to investigate how multiple rounds of lecturer feedback and student revision can be used effectively for formative assessment of proof comprehension. We use the term *formative* for assessment that is integrated with teaching to contribute, through feedback, to student learning. Mejia-Ramos, Fuller, Weber, Rhoads, and Samkoff (2012) have proposed a conceptual framework for proof comprehension based on an extensive literature review and on interviews with mathematicians. Based on this framework, they have proposed an assessment model that comprises questions for probing various facets of proof comprehension. They suggest that this model can be used by researchers "to examine how proof comprehension develops in students and to evaluate different means of improving it" (p. 4), and by lecturers to "inform what specific aspects of a given proof students understand and what aspects they do not understand" (p. 4). In this study we draw on Mejia-Ramos et al.'s work in order to scrutinize the affordances for formative assessment of proof comprehension of a novel assessment scheme that includes cycles of feedback/revision, which was designed and enacted by a mathematics professor.

## Setting

The assessment scheme examined in this paper was used in a proof-oriented Real-Analysis course at a large public research university in the United States. The key aspect of the assessment scheme was the instructor's decision to replace the "traditional" problem sets (weekly homework assignments; exams) with a term-paper assignment: Students were required to produce and submit weekly 'lecture notes' that would present selected proofs taught in the lecture in the students' own words. The instructor, whom we will call Mike, is a research mathematician who had been teaching proof-oriented courses for more than two decades. In the term under investigation he invested a great deal of time and effort in this novel assessment scheme, planning his lectures accordingly, redesigning the assignments for the course, and providing extensive written feedback on student submissions. Assessment of the students' proofs proceeded in cycles of feedback and revision until the instructor was satisfied. These submissions were a passing requirement for the course.

Prior research of Mike's goals and expectations for the term-paper assignment revealed that it was meant to promote students' proof comprehension by scaffolding their independent proof reading (Pinto & Karsenty, 2018). Thus, the term paper assignment can be seen as part of a formative assessment scheme for proof comprehension. Though this assessment scheme was not designed by educational researchers, it nevertheless seemed to address some of the key limitations for formative assessment of traditional assessment practices (e.g., Moore et al., 2016). Many of the students' initial submissions contained numerous flaws. Mike's assessment scheme gave him more flexibility when facing feedback related challenges, for example:

- Prioritizing comments: Indicating all of the deficiencies in a proof can be overwhelming for students, while selective feedback may be misconstrued as endorsement of unmarked errors.
- Diagnosing student (mis)comprehension: Deficiencies in a proof can be linked to different kinds of miscomprehension. Has the instructor correctly diagnosed them?

- Providing effective feedback: What will students learn or mis-learn from the instructor's comments? Will they be able to leverage the feedback to produce a satisfactory proof?

In this paper we describe how Mike addressed these challenges in one feedback/revision cycle and present an in-depth analysis of its affordances for formative assessment, thus shedding light on ways lecturer and students can leverage feedback/revision cycles to promote proof comprehension.

## Methodology

The main source of data for our analysis is iterations of students' proofs, along with Mike's comments on each iteration. Additional background data include: video-documentation of lectures; field notes; informal discussions; and two 90-minute interviews with Mike, one conducted at the beginning of the course and the other after its conclusion. The interviews focused on the course design and aimed at eliciting Mike's goals and expectations (for further detail, see Pinto & Karsenty, 2017).

For the study reported herein we chose to analyze a particularly long cycle: six submissions of a student, whom we will call Ben, for a proof of the theorem, *a non-empty subset of the real numbers bounded above has a least upper bound*. The 6th submission was accepted without comment. Mike defined the real numbers as the set of all decimals and proved the theorem in class by constructing the least upper bound, digit after digit in an infinite iterative process. In his first submission, Ben tried a different approach for proving the theorem. This submission had numerous deficiencies, including a structural flaw, as Ben relied on a corollary of the theorem he was attempting to prove. The number of iterations and the variety of flaws in Ben's first submission, which intensify the dilemmas discussed in the previous section, made this cycle particularly suitable for our investigation.

We view students' submission of a proof "in their own words" as an opportunity for assessing their comprehension of the proof presented during the lecture. Such assessment is formative when the instructor, in his feedback, invites students to reflect on and develop their comprehension of the proof. We characterize opportunities for formative assessment through analysis of the instructor's feedback (i.e., which aspects of proof-comprehension he stresses) and of the students' subsequent revisions (i.e., how they attend to the feedback). For this analysis we draw on the seven facets of proof comprehension proposed by Mejia-Ramos et al. (2012, see Figure 1), which were grouped into *local* – discerned by studying a few related statements within the proof – and *holistic* – ascertained by inferring the ideas or methods that motivate a major part of the proof or the proof in its entirety.

These seven facets were operationalized in terms of 19 assessment items (pp. 5–6). In coding Mike's feedback, we asked ourselves: "to which of the 19 assessment items is Mike implicitly asking students to attend?" For example, the feedback "one can only prove a statement, not a bound" (Figure 1) was coded as *meaning of terms and statements*, because Mike appears to want Ben to notice that the statement should have been "to prove *the existence of* an upper bound," and therefore his feedback could have been rephrased as "explain the meaning of the term *prove a bound*." In coding Ben's submissions, we listed all the deficiencies that we found in his proof, and for each we asked ourselves: "Which of the 19 assessment items can we conclude that Ben has responded to inadequately?" For example, if a statement was correct but did not serve a logical purpose in the proof sequence, we coded for *logical status*, because Ben would apparently not have had an adequate response to the implicit question "identify the purpose of the sentence."

Local Facets ( <i>example</i> )	Holistic Facets ( <i>example</i> )
<ul style="list-style-type: none"> <li>Meaning of terms and statements (<i>state the definition of a term</i>)</li> <li>Logical status of statements and proof framework (<i>identify the purpose of a sentence</i>)</li> <li>Justification of claims (<i>identify the specific data supporting a given claim</i>)</li> </ul>	<ul style="list-style-type: none"> <li>(Summary of) high level ideas (<i>provide a good summary of the proof</i>)</li> <li>Transferring general ideas or methods to another context (<i>appreciate the scope of the method</i>)</li> <li>Modular structure (<i>identify the logical relation between modules of a proof</i>)</li> <li>Illustrate with examples (<i>illustrate a sequence of inferences with a specific example</i>)</li> </ul>

**Figure 1: Seven facets of local and holistic proof comprehension (Mejia-Ramos et al., 2012)**

The coding was conducted in three stages. In the first stage, each author individually coded local facets of each of Ben's submissions, as a backdrop against which to consider the instructor's feedback. We refrained from coding holistic facets, which would have been highly speculative. In the second stage, each author individually coded Mike's feedback on Ben's submissions. Some feedback addressing normative mathematical writing (e.g., inadequate notation) did not align with the framework, and was excluded from the analysis. Disagreements in coding were discussed and resolved. In the third stage, we located Ben's responses to Mike's comments, and coded them according to the deficiencies that they did or did not address. Our analysis of the coding had three foci: 1. Ben's initial submission, reflecting the range of issues from which Mike could choose what to attend to; 2. Subsequent interplay of feedback and revision; 3. Ben's final submission and overall appraisal of the assessment process.

## Analysis

**1. Ben's first submission:** In Ben's first submission (see Figure 2, only the highlighted text was added in the second submission) we recognized substantial flaws: Ben relied on a corollary of the theorem he was attempting to prove; this is a case of cyclic reasoning, which we coded as *logical status of statements and proof framework*, because we assume he might have responded inadequately to the question "identify the purpose of the sentence within the proof framework." Furthermore, the proof of this corollary that was presented in the lecture relied on properties of the construction of  $\mathbb{R}$ ,

**Theorem 4.1:** A non-empty set  $E \subset \mathbb{R}$  bounded above has the least upper bound (denoted  $\sup E$ ). Why? It might be clear to you, but not to me. To prove an upper bound? One can only prove a statement, not a bound.

**Proof 4.1:** Let  $A$  be the set of real numbers as follows:  $\alpha \in A$  if and only if there is some  $x \in E$  such that  $\alpha < x$ . We denote  $B$  as the set of all real numbers not in  $A$ . It is clear that no member of  $A$  is an upper bound of  $E$ , and it is also clear that every member of  $B$  is an upper bound of  $E$ . Thus, to prove a least upper bound of  $E$ , it must be proved that  $B$  contains a smallest number. It must be verified that  $A$  and  $B$  satisfy the following hypotheses:

(a) Every real number is either in  $A$  or in  $B$ . I've already voiced my objections to this argument last time. If you don't understand my comments, you should ask. The reason why it cannot be correct is because you never use the definition of real numbers, and so the argument applies verbatim for rational numbers. But in this case the statement is false: in  $\mathbb{Q}$ , the set  $E$  of rational numbers  $x$  with  $x^2 < 2$  do not have the least upper bound.

(b) No real number is in  $A$  and in  $B$

(c) Neither  $A$  nor  $B$  is empty:

(d) If  $\alpha \in A$  and  $\beta \in B$ , then  $\alpha < \beta$ :

Given these hypotheses are true, then there is one and only one real number  $\gamma$  such that  $\alpha \leq \gamma$  for all  $\alpha \in A$  and  $\gamma \leq \beta$  for all  $\beta \in B$ .

(a) and (b) hold by contradiction. Suppose there are two numbers:  $\gamma_1$  and  $\gamma_2$ , and  $\gamma_1 < \gamma_2$ . Choose  $\gamma_3$  such that  $\gamma_1 < \gamma_3 < \gamma_2$ . Then,  $\gamma_3 < \gamma_2$  means  $\gamma_3$  must lie in  $A$ , but  $\gamma_1 < \gamma_3$  implied  $\gamma_3$  must lie in  $B$ . Thus, there is only one such  $\gamma$  that lies in either  $A$  or  $B$ . (c) must hold because since  $E$  is not empty, there is some  $\alpha < x$ , so  $A$  is not empty. Since  $E$  is bounded above by  $B$ , there is a  $y$  such that  $x \leq y$  for  $x \in E$ , thus there is a  $y \in B$  so  $B$  is not empty. (d) must hold since it has been shown that  $\alpha < x$ . If there is some  $\beta \in B$ ,  $x \leq \beta$ . Then,  $\alpha < \beta$ . Counterexample in  $\mathbb{Q}$ : Let  $A$  and  $B$  be rationals respectively smaller and greater than  $\sqrt{2}$ .

There exists a corollary such that if the above 4 hypotheses are satisfied, then either  $A$  contains some largest number or  $B$  contains some smallest number. But,  $A$  cannot contain some largest number: let us choose an  $\alpha'$  such that  $\alpha < \alpha' < x$ . Then,  $\alpha' \in x$  and  $\alpha$  cannot be the largest number of  $A$ .

**Figure 2: Ben's 2<sup>nd</sup> submission; revisions of the 1<sup>st</sup> submission are highlighted; Mike's feedback appears in red**

a crucial point that Ben did not mention in the proof. We coded this oversight as *justification of claims*, because Ben would presumably have failed to answer the question “make explicit an implicit warrant in the proof.” We coded Ben’s use of the phrase “it is clear that” as another case of *justification of claims*, because in our judgment what followed required elaboration, suggesting that Ben had not appreciated how subtle the justification of this claim might be. The phrase “it must be proved that” was coded as *logical status of statements*, because in fact it is not *necessary* to prove the claim that followed, but rather it is *sufficient*.

2. Interplay of feedback/revisions: Mike’s feedback on the 1<sup>st</sup> submission referred only to the holistic structure of the proof, without explicitly drawing attention to the issue of cyclic reasoning: “Your argument cannot be correct because you are not using the definition of real numbers and therefore your argument equally applies to rational numbers [where] the statement [...] is false.” We note that the course definition of the real numbers had a central role in the lecture proof of the existence of least upper bounds in the domain of real numbers. Thus, Mike’s feedback underlined a key idea that was absent in Ben’s 1<sup>st</sup> submission, and was therefore coded *Holistic: High-level ideas*. In response to this feedback, in his 2<sup>nd</sup> submission, Ben made two changes (Figure 2, highlighted text): he added the full statement of the corollary that he was relying on (*Local: Meaning of statements*) and he added justifications as to why the corollary’s conditions are satisfied (*Local: Justification of statements*). The remainder of the proof was unchanged. Therefore, there is a discrepancy between Mike’s holistic feedback and Ben’s local revisions. Seeing that the structural flaw was not resolved, Mike reiterated his criticism in his feedback on Ben’s 2<sup>nd</sup> submission: “I’ve already voiced my objection to this argument last time...” (*Holistic: high-level ideas*) and added an example of how the corollary does not hold for rational numbers (*Holistic: illustrate with examples*). Mike also commented on local issues that were already present in Ben’s 1<sup>st</sup> submission, criticizing Ben’s use of the phrase “it is clear that...” (*Local: Justification of claims*) and drawing attention to his misuse of the word “prove” (*Local: Meaning of terms*). There were several additional indicators of possible comprehension issues that we identified in Ben’s 2<sup>nd</sup> submission that Mike did not comment on. For example, it is *sufficient* and not *necessary* to verify the conditions of the corollary (*Local: Logical status of statements*).

Synopsis of submissions 3-6: In his 3<sup>rd</sup> submission, Ben reverted to the proof that had been presented in a lecture, though it is not clear to what extent he appreciated the structural problem in his initial approach. In his 3<sup>rd</sup> feedback, Mike implicitly endorsed Ben’s new approach, and his feedback addressed issues of local comprehension as well as providing structural hints (e.g., “Now prove that  $b^*$  is an upper bound, and is smaller than any other upper bound,” *Local: proof framework*). The 4<sup>th</sup> feedback included a mix of local and holistic comments; the 5<sup>th</sup> and final feedback was strictly local. In both the 4<sup>th</sup> and 5<sup>th</sup> feedbacks, Mike focused on notational issues. Our analysis—comparing successive submissions—highlighted improvements in Ben’s proofs, yet Mike did not comment on this, limiting his feedback to errors and deficiencies. Our analysis also highlighted that in many cases, Ben’s revisions, while attending to Mike’s feedback, introduced new local issues, some of which were commented on and subsequently revised.

3. Ben’s final submission: While most of Mike’s comments were resolved by the 6<sup>th</sup> submission, our analysis reveals some unresolved issues. Nevertheless, it was implicitly endorsed when accepted without comment.

In spite of several apparent *local* issues in Ben's 1<sup>st</sup> submission, Mike chose to focus his first feedback on big ideas, attending to them in a *holistic* manner, stressing that as long as there is no use of properties of real numbers the proof cannot be correct, because it would apply to rational numbers where the claim does not hold. He illustrated this through a counter-example: The set of rational numbers less than  $\sqrt{2}$  does not have a rational least upper bound. Ben's revisions generally attended to Mike's comments, yet he did not always attend to them immediately. For example, in his 4<sup>th</sup> feedback, Mike criticized local aspects of Ben's definition of a sequence of nested sets: "here there needs to be a condition on  $a$ ." Ben's 5<sup>th</sup> submission did not address this problem, so Mike commented again in his 5<sup>th</sup> feedback, and Ben eventually addressed it in his 6<sup>th</sup> and final submission.

## Discussion

Our analysis highlights potential affordances of multiple cycles of feedback and revision for formative assessment of proof comprehension, which we now turn to discuss while keeping in mind the three feedback-related challenges discussed in the Setting section: prioritizing comments, diagnosing student (mis)comprehension, and providing effective feedback.

Our analysis of Ben's 1<sup>st</sup> submission highlighted various deficiencies. In a traditional assessment model, providing only one opportunity to provide feedback, Mike might have responded to Ben's 1<sup>st</sup> submission by commenting on all deficiencies, which could have been overwhelming for Ben. Alternatively, Mike could have picked one or two issues that he considers most crucial. He would need to be quite explicit in his feedback, because he would not have the opportunity to clarify subtle points that Ben could not make sense of on his own. Instead, in the cycle we have analyzed, Mike's feedback began with holistic structural issues, later moving to local issues of notation, terms, and logical status and justification of claims. Mike did not need to be exhaustive in his feedback, knowing he would have opportunities to return to unattended issues later on. This transition suggests lecturers can leverage multiple cycles of feedback for prioritizing feedback according to a didactic agenda. Postponing feedback related to local issues until resolving issues related to structure and big ideas of a proof does not only support students' development of proof comprehension, but also signals which aspects of comprehension are most valued. For example, in his feedback to Ben's first two submissions, Mike highlighted a meta-level idea related to proof and proving—does the proof make use of all the assumed conditions, and how would it fail without them? This is a central theme in university mathematics, where the domain of a result is of interest, and reflects a "mathematical habits of mind" of *tinkering* (Cuoco, Goldenberg, & Mark, 1997).

In the cycle we examined, there were deficiencies that Mike highlighted in his feedback that were not resolved in Ben's next submission, and deficiencies that emerged during the revision process. While an analysis of Ben's proof comprehension is beyond the scope of this paper, we note that these additional data provide valuable insights into Ben's comprehension that were not salient in the 1<sup>st</sup> submission, which suggests that multiple rounds of feedback and revision could support lecturers' diagnosis of their students' proof comprehension. In addition, we found discrepancies between the facets of proof comprehension that Mike and Ben addressed in their respective feedback and revision. In particular, we found that in some cases Ben responded to holistic-oriented feedback with local-oriented revisions, and responded holistically only after Mike reiterated his comment. Thus, our

analysis indicates that multiple rounds of feedback and revision could support lecturers in providing feedback that students could leverage to produce a proof that the lecturers would find acceptable.

This case study also illustrates that it may be necessary to support students in harnessing lecturer feedback to develop their holistic proof comprehension. Research indicates that it is difficult for students to develop holistic comprehension of proofs even when instructors' explicitly highlight holistic aspects of proofs in their lectures (Lew, Fukawa-Connelly, Mejía-Ramos, & Weber, 2016). Cycles of feedback and revision may offer affordances for holistic comprehension. Mike's first feedback on Ben's alternate proof scheme was not prescriptive—he did not tell Ben how to correct his proof. Providing open questions as feedback is a risky move in a traditional single-round assessment, as students may fail to answer these questions and revise the proof, as Ben's second submission illustrates. However, because Mike was able to monitor Ben's revisions and provide further feedback, he was able to provide Ben the opportunity not only to reflect on the inadequacies of his own submissions, but also on the ways in which they are addressed in the lecture-proof that he eventually reproduced (e.g., the role of the definition of real numbers in the proof). The discrepancies between Mike's holistic feedback and Ben's local revisions, along with Mike's comments on these discrepancies, highlighted gaps in instructor-student communication that were likely to remain hidden in a traditional single-round assessment of Ben's first submission.

We now turn to discuss a potential affordance of multiple cycles of feedback and revision from the student perspective. In his first submission, Ben attempted a proof scheme different from the one presented in class. In his re-submissions, Ben postponed attending to some feedback, splitting his responses to Mike's 4<sup>th</sup> feedback over his 5<sup>th</sup> and 6<sup>th</sup> submissions. While we can only speculate on Ben's considerations, we recognize in his readiness to submit an original proof and to prioritize his revisions an indication of agency that in our experience is not common in undergraduate mathematics courses, particularly in relation to proof writing. A consequence of instructors' tendency to grade proofs by reducing points for deficiencies rather than assigning points for merit is that students might avoid taking risks and constructing original arguments that expose their thinking and (mis)comprehensions. In contrast, if students know they will have the opportunity to resubmit their work, and that their work will be graded on the quality of their final submission, then they have little to lose and something to gain from constructing an original argument. Thus, students can leverage multiple cycles of feedback and revisions as an invitation to explore and take risks in their proving.

## **Concluding thoughts**

We have discussed various potential affordances of an assessment scheme that include multiple rounds of feedback/revision for formative assessment of students' comprehension of mathematical proof. We note an advantage of such a scheme in relation to the scheme proposed by Mejia-Ramos et al. (2012); whereas Mejia-Ramos et al. propose designing sets of questions to probe various facets of student comprehension, multiple rounds of feedback and revision seem more compatible with traditional practices of assessment grounded in proof validation, and thus may be more accessible and appealing for some instructors. We acknowledge that multiple rounds of feedback and revision are demanding for both instructors and students, because each new homework assignment entails reviewing/revising any number of prior assignments. Furthermore, it is not clear when the process

should end. Ben's 6<sup>th</sup> and final submission included several substantial deficiencies. Did Mike deem it "pedagogically acceptable"? Did he decide that in spite of its flaws, his time and effort would be better spent commenting on Ben's submissions of more recent assignments? Or did he simply tire of the process? Cutting the feedback process short could have serious consequences, because refraining from comment on a student's proof could be misconstrued as implicit endorsement of its correctness. It is also important to recognize that although multiple iterations of feedback and revision may provide invaluable opportunities to engage students with the various facets of proof comprehension, lecturers and students will not necessarily capitalize on these opportunities. Mike noted, in retrospect, that in some cases students ended up copying proofs from the textbook. In the final interview, he mentioned several examples where students' revisions of their proofs, in light of his comments, revealed that "they did not understand what they were talking about."

Thus, there is still much we need to learn about enacting assessment schemes based on multiple rounds of feedback and revision effectively. We call for further research that will develop and validate various formative assessment schemes, towards promoting student proof comprehension.

## Relations between academic knowledge and knowledge taught in secondary education: Klein's second discontinuity in the case of the integral

Gaëtan Planchon

IMAG –Université de Montpellier, France; [gaetan.planchon@umontpellier.fr](mailto:gaetan.planchon@umontpellier.fr)

*Keywords: Klein double discontinuity, teacher training, integrals in mathematics, Anthropological Theory of the Didactics*

Felix Klein (1872) put forward a double *discontinuity*: in addition to the secondary-tertiary transition, a second discontinuity occurs at the end of university studies when a student who obtains a teaching position is appointed to teach mathematics in high-school. This discontinuity is observed through the difficulties faced by postgraduate students in France to perceive the links between the knowledge of mathematics learned at university and the knowledge acquired in high school (for example between the integral as a measurement of an area and the Lebesgue integral, even with the Riemann Integral). These postgraduate students are therefore often reluctant to work on advanced mathematics (e.g. upper division undergraduate courses) as part of their teacher training.

Winsløw and Grønbaek (2014) formalized this double discontinuity in the language of the Anthropological Theory of The Didactics (ATD), using the notion of personal relationship  $R$  to an object of knowledge within an institution, introduced by Chevallard (2007). Let us consider: the institution, which here will be either high school ( $L$ ) or university ( $U$ ); an individual  $x$  who occupies different kinds of positions in his path through the institutions: first as a student in high school ( $s$ ), then as a student at university ( $\sigma$ ) and then back again in high school as school teacher ( $t$ ); an object of knowledge, that lives in the institutions and noted  $o$  in high school and  $\omega$  when considered at university level. Klein's double discontinuity may be expressed as the following diagram:

$$R_L(s, o) \longrightarrow R_U(\sigma, \omega) \longrightarrow R_L(t, o)$$

The purpose of my research project (PhD thesis) is to study the second transition between  $R_U(\sigma, \omega)$  and  $R_L(t, o)$  by choosing an object of knowledge from the field of analysis: the integral. Students meet integrals in different institutions and in different theories (Newton Integral in high school, Riemann and Lebesgue integrals, and Measure Theory at university). So a first research question is: *how does a math teacher in high school mobilize his knowledge of university mathematics to teach integrals in high school?* To study this question, we formulate sub-questions: *What links are put forward by the institutions between the different integration theories? Conversely, which gaps can be observed in the curricula? How are the continuities and discontinuities perceived by teacher students? What training courses may be proposed to help students draw connections?* The poster presents the overall methodology of my study and some preliminary results obtained so far.

The methods used are of a qualitative nature. *Epistemological Models of Reference* (EMR; Florensa, Bosch, & Gascón, 2016) are built in order to describe the relationships to knowledge, beginning with  $R_U(\sigma, \omega)$  and  $R_L(s, o)$ . The EMR is a tool for the researcher who operates a reconstruction of knowledge. The elaboration of the EMR is based on epistemological analyses related to historical

epistemology (supplemented if necessary by a study of contemporary epistemology by means of interviews with mathematicians) and the analysis of official syllabi and curricula, teaching materials and textbooks. This model is constructed both to analyze continuities, discontinuities and gaps in the path of the learner through institutions and to identify possible entry points for the design of a didactic engineering.

A first study (conducted in the context of my Master's degree thesis) consisted of comparing EMRs between the logos block of praxeologies related to the Riemann integral at university and the integral in high school. The main results and their consequences for learning (in the form of hypotheses for further research) are as follows: on the one hand, the praxeologies related to the measurement of areas at high school contain an implicit logos that a teacher student will probably have difficulties to relate to academic knowledge on the integral (a substantial mathematical work would be necessary to link the notion of area from high school with Measure Theory, taught as a highly abstract subject at university); on the other hand, the academic praxeologies involving Riemann's integral focus on computational techniques for antiderivatives rather than working on the corresponding logos, apart from abstract questions on integrability (probably out of reach for a majority of students). As a result, it is likely that students will draw little connections between the block of the logos of Riemann praxeologies and the methods for approximate computation of integrals at high school since they will not grasp the conceptual scope of Riemann sums.

In order to study Klein's second transition and to propose training courses for future teachers, didactic praxeologies of the teacher need to be investigated: indeed, the tasks of the teacher are not limited to solving problems, but also to elaborate problems that promote adequate conceptualization and learning, make pertinent choices of didactic variables, and provide adequate feedback to students. The development of a model to describe these praxeologies will be based on observations of classroom practices and teacher interviews, in order to determine the role and then explore the possibility of strengthening the use of academic knowledge in didactic organizations of the teacher.

## Theorizing coordination and the role of course coordinators

Chris Rasmussen<sup>1</sup>, Jessica E. Hagman<sup>2</sup> and Naneh Apkarian<sup>3</sup>

<sup>3</sup>Western Michigan University, USA; [naneh.apkarian@gmail.com](mailto:naneh.apkarian@gmail.com)

*Keywords: Coordination, calculus, community of practice.*

In the United States (US) improvement efforts at the school level have a long history of bringing teachers together to plan lessons, discuss issues of student learning, create assessments, etc. For example, lesson study has been implemented across American schools as one way to create community among teachers and improve teaching and learning (e.g., Lewis & Takahashi, 2013). Professional learning communities are another way of building community among teachers to improve instruction. At the university level, coordination of high enrolment introductory courses provides a similar opportunity for bringing faculty at the same institution together to improve student success. Coordination systems are particularly popular as a response to the large numbers of students enrolled in calculus courses and the wide range of instructors teaching them. Robust coordination systems, led by one or more coordinators (who are typically ladder rank faculty) consist of two major elements: uniform course elements (e.g., common text; exams) and regular instructor meetings. Regular meetings convened by course coordinators are important because they provide opportunities to bring faculty together to discuss issues of learning, assessment, pacing, etc. Robust coordination systems can, therefore, have the effect of turning calculus instruction into a joint enterprise, engendering a community of practice (Rasmussen & Ellis, 2015).

While coordination systems are widely used in the US, such systems are under-theorized. In this report, we draw on case study data from five universities to begin theorizing about coordination systems more broadly and the role of the coordinator in particular. More specifically, we address the following research goal: *How might we characterize coordination systems and the role of coordinators in these systems?* A better theoretical understanding of these phenomena will contribute to pragmatic efforts aimed at improving the teaching and learning of high enrolment, coordinated, undergraduate mathematics courses. The 2-3 day case study site visits we conducted were part of a larger national study of successful calculus programs in the US (Bressoud, Mesa, & Rasmussen, 2015). We employed thematic analysis (Braun & Clarke, 2006) of the data corpus, which included interviews with faculty, administrators, classroom observations, and student focus groups.

Our theoretical framing of coordination systems and coordinators draws on work in behavioral economics, thus bringing a novel point of view to university mathematics instructional systems. In particular, we draw on the work of Thaler and Sunstein (2008), who offer an insightful perspective on how libertarian views of free choice can be profitably combined with paternalistic structuring of choices for others in the marketplace. A central construct in their thesis of libertarian-paternalism is that of *choice architect*. A choice architect is someone who is responsible for organizing the context in which people make decisions. For example, the person responsible for arranging the way in which school cafeteria food is displayed has the potential to influence the food choices that kids make. What

should be placed at eye level, cookies or green beans? The power of a choice architect lies in focusing peoples' attention in a certain direction, and "nudging" them to make particular choices, rather than making the choice for them. Similarly, we argue, this is what effective course coordinators can do.

In our analysis of the five case studies, we came to see the coordination systems more broadly as an example of *coordinated independence*. The notion of coordinated independence, much like that of libertarian-paternalism, embraces the oxymoron that individuals can be part of a system that directs their choices, but maintains a certain level of autonomy. Our retrospective search of the literature for use of the term coordinated independence revealed the original coining of this phrase to describe the premier jazz drummer "Cozy" Cole in the late 30's. Cozy Cole was renowned for the way in which his hands and feet acted independently yet produced a harmonious sound that was highly coordinated. In a similar way, we theorize that effective course coordinators allow for instructor independence yet result in a harmonious calculus instructional system.

Drilling down into the particulars of what the course coordinator does to promote this culture of coordinated independence, we posit that the coordinator functions much like a choice architect as described by Thaler and Sunstein (2008). In our analysis we identified the following overlaps in the roles of a choice architect in the market place and the various roles of the coordinator in an educational setting: makes life easier by setting default options; provides feedback to users; makes mappings easy to understand; and provides information about what others are doing. For example, Thaler and Sunstein describe how a computer manufacturer functions as a choice architect by making life easier for users by pre-setting screen-saver default settings. A user can change the default options but doing so takes time and requires taking some action. We found that the calculus coordinator similarly sets a number of "default" options for instructors, including homework problems, exams, class activities, syllabus, and rubrics for exam grading. In our interviews with instructors we learned that the vast majority of instructors very much appreciated the coordinator taking care of these decisions, while still allowing for pedagogical autonomy and some choice within these default setting. Our poster presentation gives illustrative examples of this and other roles of coordinator as choice architect.

[woerler@mathematik.uni-wuerzburg.de](mailto:woerler@mathematik.uni-wuerzburg.de)

*Keywords: Bridging course, engineers, competencies.*

## Introduction

Many students perceive the transition from school to university mathematics as problematic. Existing studies not only discuss difficulties broadly but promise that so-called bridging courses can help to reduce the gap between school and higher education. Also for students studying science, technology, or engineering (STE), mathematics is an important prerequisite for successful studies. For them, mathematics is mainly used as a tool for other subjects. We focus on these STE-students, who have a high heterogeneity with regard to their mathematical knowledge before entering university. Taking this phenomenon into account, creating a bridging course in mathematics especially for this group of students is important in order to build a common level of mathematical knowledge, which professors can take for granted and rely upon when students enter university.

## The OPTES+-project – optimizing the self-study phase

OPTES+ is a project funded by the BMBF (Ministry of Education and Research) that includes several universities in Germany working together to reduce the drop-out rate in STE-related subjects. The heart of the project is an online mathematics course, similar to a traditional mathematics book, but enriched with additional interactive elements. The whole course is implemented in the open source learning management system ILIAS. All the material offered by OPTES+ will be accessible for universities and other educational institutions in the future. The contents of the course are based on the experience of the involved lecturers and the cosh-catalogue (Cosh group, 2014), a catalogue written by representatives of schools and universities to list the minimum requirements in mathematics that students should have when starting their studies in economy or a STE-related subject at university. Moreover, as engineering per se often requires the application of mathematics, not only mathematical knowledge is important, but also the development of mathematical competencies. Weinert defines mathematical competencies as an individual's available or learnable cognitive abilities and skills to solve certain exercises, as well as the connected willingness and ability to use the solutions in variable situations in a successful and responsible way (Weinert, 2001). For that reason, apart from the mathematical contents, the bridging course should also concentrate on mathematical competencies, which leads to the following questions.

## Research Questions

(Q1) Which model can be used to describe the learners' mathematical competencies and simultaneously provide a basis for differentiation within the course?

(Q2) How can the chosen competency model be implemented into the online course?

(Q3) How could, after the construction and implementation of the model, an evaluation and reflection of it take place as a step of design-based research?

## The Ability Matrix

We decided to take the HarmoS-model (Huber, Späni, Schmellentin, & Criblez, 2006; Schweizerische Konferenz der kantonalen Erziehungsdirektoren [EDK], 2011) as foundation for constructing our own model – the so-called Ability Matrix (AM), as the aspects of action used in the HarmoS-model seem to fit well the competencies the future engineer students should acquire. Figure 1 illustrates the AM.

content fields	LOC 1: arithmetic					
	LOC 2: equations/inequalities					
	LOC 3: powers/roots/logarithms					
	LOC 4: functions					
	LOC 5: geometry					
	LOC 6: trigonometry					
		knowing and describing	operating and calculating	using representations	mathematizing	reasoning
		aspects of action				

Figure 1: The Ability Matrix

## Outlook

While (Q1) and (Q2) concentrate on theoretical considerations that are answered by the construction and usage of the Ability Matrix, we plan to run a pilot study in January and February 2019 to answer (Q3) and to investigate if the chosen competency model and its implementation are suitable for our setting. To do so, we will compare the measured competencies before and after the course to see if the attendance of the course (including the feedback the students get by the visualization of the Ability Matrix) brings any improvement of the students' competencies. Based on the results of this pilot study we will evaluate the used competency model and reflect on possibilities of adjusting it.

# The connectivity in resources for student-engineers: the case of resources for teaching sequences

Hussein Sabra<sup>1</sup>

<sup>1</sup>University of Reims Champagne-Ardenne, Cérep EA4692, France

*This paper concerns the teaching of mathematics for student-engineers. We focus on the theme of sequences in the first year of engineering education. We claim that teaching sequences in the first year of engineering education requires different kinds of connections: connecting different topic areas, different concepts, and different registers. We use here the concept of connectivity, to analyze resources in the case of an engineering school in France. We provide elements from interviews showing that the teachers can strengthen some forms of connections during their use of resources.*

*Keywords: connectivity, resources in engineering education, mathematics for engineers, sequences.*

## Context of the research

The present paper concerns the teaching of mathematics in the context of engineering. We present an analysis of resources collectively designed by teachers in a French Engineering School (undergraduate education). We address the issue of the connections made in mathematics for student-engineers. We focus on the theme “sequences”.

The textbook is a crucial artifact for university teachers (González-Martín, Nardi, & Biza, 2018). However, the appropriateness of the content offered by textbooks in some academic paths remains a controversial issue; Randahl (2016) shows that student-engineers do not perceive the mathematics offered by the textbook as relevant for the engineering context. She considers that the issue of how the textbook is combined with the context of lectures and task solving sessions might “provide learning opportunities with meaningful use of the textbook” (Randahl, 2016, p.67).

Research literature highlights the gap between the mathematics taught in mathematics courses and the use of them in engineering courses (Biehler, Kortemeyer, & Schaper, 2015). Minding this gap supposes to understand the reasons behind it. Research evidences also the necessity of making explicit connections between theory and practice to make the mathematical content in engineering education relevant to students (Flegg, Mallet, & Lupton, 2012). According to Gueudet and Quéré (2018), engineers in the workplace identify missing links in the mathematics taught during their studies: links between mathematics and the real world, and between different mathematical contents.

All these sources suggest that the teaching of mathematics in engineering education should propose specific “connections”. The main question we address here is: what type of connections is present in the resources used and in teaching practices regarding mathematics for engineering students?

## Connectivity in resources: topic areas, concepts and semiotic representations

“Connections” can be related with (at least) three issues that could influence the teaching of mathematics; some of them are specific to the context of engineering education.

(1) Within mathematics, the networking between mathematical objects and their representations (Hiebert & Carpenter, 1992), identified as essential for the understanding of mathematical facts.

(2) The need to build links between mathematics courses and engineering courses.

(3) The modifications of learning processes in the digital era prompted Siemens (2005) to introduce the concept of *connectivism*. He considers learning as an “actionable knowledge” that can reside outside ourselves. The learning in this case depends on the ability to build a network of connections between, and across, the available resources (or databases) and users of these resources.

Based on these works, we have proposed the concept of *connectivity* (Gueudet, Pepin, Restrepo, Sabra, & Trouche, 2018) developed in the frame of e-textbooks analysis. This connectivity has two components: “macro-level connectivity” that refers to the potential of linking to and between users and resources outside the textbook (practical aspect); and “micro-level connectivity”, where the focus is on a particular mathematical topic within the e-textbook to look for connections in, between, and across individuals’ cognitive/learning tasks and activities. We define therefore *connectivity* in a set of resources for teaching a mathematical theme as a linking potential for a given user (student or teacher) both practically as well as cognitively. We only use here micro-level connectivity. We indeed consider, in the case of sequences, the connections present in resources between different topic areas or mathematics fields, between different concepts, and between different semiotic representations.

For Duval (2006), semiotic representations are productions constituted by the use of signs belonging to the same “register” (natural language, formalism, algebraic formula, graph, figure, etc.). A register of semiotic representation allows the following activities: to represent a concept; to treat representations within the same register; to convert representations from a given register into another. According to Duval (2006), the conceptual acquisition of a mathematical object necessarily passes through the acquisition of one or several semiotic representations. However, the connection between different representations, seems absent in engineering programs. Quéré (2017) interviewed French engineers about their mathematical needs in the workplace. They declared that the teaching of mathematics they received during their studies “did not make enough connections” particularly connections between different mathematical contents and between different representations.

From the institutional point of view, the mathematics taught are shaped by the institution where they are taught (Chevallard, 2003; González-Martín et al., 2018). We consider, as Quéré (2017), that in engineering education, mathematics courses constitute an institution different from engineering courses. Different institutions could shape the teaching of mathematical topics in different ways. Moreover, teachers’ *personal relationship* with those topics, which results from their experiences in different institutions (Chevallard, 2003; González-Martín et al., 2018), could shape the mathematics taught. Indeed, the teaching actually implemented by a teacher using a given resource can offer more connections than this resource. Teachers might develop an “unexpected” connectivity in practice, by their discourse, examples produced “on-the-spot”, and how they show proofs, etc. Here, there is the issue of the combination between *potential connectivity* and *effective connectivity* developed in use, which could be also related to the teacher’s perception of students’ needs and difficulties.

Our aim here is to consider the connectivity in the case of teaching sequences in the first-year in a French Engineering School. Therefore, we reformulate our general question as follow:

Q1: Which connections concerning sequences appear in resources for a mathematical engineering course?

Q2: Which is the effective connectivity of the curriculum implemented by different teachers using these resources?

## **Sequences in the French curriculum and in the engineering education**

Our choice of to focus on sequences is related to its importance in some engineering paths. Within mathematics courses, sequences constitute an entry for other concepts (single and double integrals, series, etc.). They are also essential for studying Fourier series. In engineering courses, sequences are needed in a different way: in the study of some processes of discretization (transferring of continuous models into discrete models), in numerical analysis (numerical resolution of differential equations or heat equations, etc.), and in the “signal processing” course.

In France, the first encounter of students with sequences happens in grade 11. The curriculum recommends that the teaching of sequences in grade 11 goes through the modelling of real-life situations. Connections in terms of registers are recommended. For instance, the curriculum requests using the spreadsheet (numerical representation) or the calculator (algorithms) to compare the evolution of arithmetic and geometric sequences, as well as to represent the term of a sequence graphically. According to the curriculum, in grade 12 the concept of “limit of a sequence” should be studied in order to prepare the introduction of “limit of a function”.

In different engineering education paths, the introduction of sequences usually appears in the calculus courses. Randahl (2016) notices that calculus is part of the basic mathematics courses for engineering students, and it has many formal aspects. Compared to the secondary level, more time is dedicated for mathematical reasoning and the use of formal representations. Research literature on the teaching and learning of sequences acknowledges the existence of strong links between both concepts “limit” and “sequences” (Alcock & Simpson, 2004; Roh, 2008). Regarding the concept of “convergence”, studies highlight the importance of the graphical representation to make sense of it, as well as to facilitate the appropriation of its formal representation (Alcock & Simpson, 2004).

## **Context of the study and methodology**

The context of our study is a French Engineering School. It is one of the three technological universities in France. Mathematics teachers in this Engineering School have different statuses (teacher-researcher, full-time teacher, etc.) and various specialties (mathematicians, engineers, physicists, etc.). Four semesters structure the first and second academic years, where there are “basic science courses”, including mathematics, physics and chemistry. There are four mathematics courses. Each of them followed in consecutive semesters. Sequences are introduced in the first chapter of the mathematics course of the second semester. In this context, our methodology consists in two parts: 1) collection and analysis of resources on sequences; 2) interviews with 3 teachers and their analysis.

The resources collected are collectively designed and used by teachers. They contain the textbook’s lesson distributed to students; the slideshow projected during the lecture sessions; the tutorial that contains tasks to solve and problems; and the Practical Work tutorial (PW) composed of online exercises on a moodle platform.

To analyze the resources, in terms of micro-level connectivity, we used the grid developed by Gueudet et al. (2018). We adapted it to our case, according to the definition of connectivity we

discussed above. We then analyzed the resources following four steps. In the first step, we identified concepts used in the resources, we mentioned the connected concepts and the way they are connected by definitions, propositions, theorems, examples, and/or exercises. Within this step, we studied the connections that concern “progression” chosen by the designers (connections with previous knowledge and further knowledge). In the second step, for each concept (or connected concepts), we characterized the different moments of their appropriation (lesson, examples, exercises, problem solving, or practical tasks); we considered also the context of this appropriation (different topic areas within mathematics, different disciplines, real-life situations, etc.). In the third step, for each concept (or connected concepts), we identified the registers of semiotic representation used or that can be used in solving tasks; we characterized them in terms of the three cognitive activities “to represent”, “to treat”, or “to convert” (Duval, 2006). In this step, we determine, where appropriate, the connections made with particular tools (software, calculator, etc.). The fourth step concerns particularly the exercises; we determined the different strategies to solve them, and the variations of the same exercises. The fourth step allowed us to understand the connections that the designers emphasize between concepts, registers and mathematics topic areas.

We also conducted interviews with three teachers. We chose teachers with contrasting profiles in terms of their specialties and academic education, and in terms of their status. T1 is a physicist, he has a PhD in theoretical physics and modeling, he teaches mathematics, modeling and physics; T2 is an engineer, he has a PhD in Engineering, he teaches mathematics and engineering courses; T3 is a mathematics teacher, he has an “agrégation” in mathematics (French competitive examination that must be passed to teach at university). We hypothesize that the contrasted profiles can inform us on different forms of connectivity developed in implementation of mathematics resources.

The interview grid covers four axes, according to which we analyzed the teachers’ declarations. The first concerns the connections to make across the different mathematics topic areas, across different disciplines, or with real-life problems. The second axis concerns the teachers’ point of view on students’ difficulties, which influences the connectivity they could emphasize in their use of resources. The third axis concerns the place of the examples they add, which allows to make connections between concepts or to use the registers of semiotic representation. The fourth axis concerns the place of mathematics proofs in engineering education, and their role in enhancing connectivity. We aim by the analysis of the interviews to identify elements on the effective connectivity of the curriculum implemented by different teachers using the same resources. Nevertheless, we are limited here to what teachers declare about the use of resources.

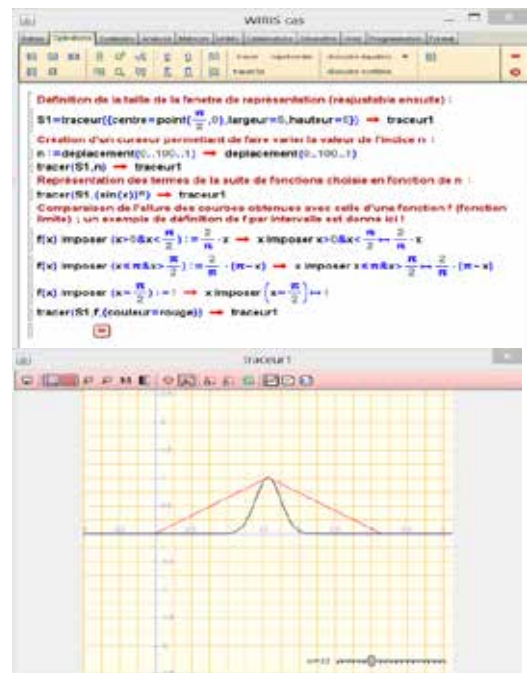

### **Potential connectivity in resources for teaching sequences**

We identified in the resources for teaching sequences: 7 definitions, 10 theorems, 29 exercises, and 9 examples. The PW contains three exercises, where the use of Wiris CAS calculator is requested.

In terms of previous knowledge, some basic concepts from secondary school are reintroduced but in a formal register (convergence and limit of sequences). We note that continuity and limits of functions are taught in the first semester. We also note that the sequential definition of limits of functions is not taught. The order used to teach the concepts of “limit of sequences” and “limit of functions” is different from the choice made in the curriculum of secondary school (see above).

The connections between both concepts “limit of sequences” and “convergence” are emphasized. The resources also emphasize, in the properties and exercises, the connections between “convergence”, “variation of sequences” and “bounded sequences”. For instance, there is in the tutorial an exercise with nine different sequences; students are asked to study the convergence of sequences and calculate their limits when it is possible. The sequences given need different strategies to solve the proposed tasks (a sequence bounded by another one that tends to 0; a decreasing sequence and bounded from below by 0; a task that needs the use of properties about the quotient of convergent sequences; etc.). Recursive sequences are particularly emphasized in the different components of the resources. The exercises related to recursive sequences allow students to establish connections with “upper bound”, “lower bound” and functions.

There is no connection between different topic areas within mathematics. In terms of different semiotic representations, the resources contain particularly one semiotic representation, the formal representation. In general, the treatment of tasks remains within the same representation. The resources contain rarely tasks where students are asked to represent mathematical objects in a given register. The PW constitutes an opportunity to make new connections between mathematics topic areas as well as between semiotic representations. Nevertheless, it is restricted to three exercises. The connections between semiotic representations are strengthened; there are, for example, tasks that need the graphical study of the given sequences. Besides, the algorithmic topic area changes to study the behavior of recursive sequences by dynamic representations (Figure 1). The use of Wiris CAS software offers the potential to make connections between algorithms and the graphical register.

**Figure 1. It is required to act on the cursor “n” to relate the two dynamic representations (Wiris CAS).**

In the analyzed resources, sequences constitute a theme where the mathematical materials are mainly limited to the calculus topic area. This is very similar to the content presented to mathematics majors. There are strong connections between concepts (convergence/divergence, limit of a sequence, function, upper/lower bound, recursive sequences). The tasks and activities propose mainly treatments within the formal register. In addition, there are no authentic situations, real life problems, or problems referring to other disciplines. All the examples, exercises and applications are intra-mathematical, which could strengthen a possible gap with the institution of engineering courses.

### **Analysis of interviews: towards effective connectivity in the enacted curriculum**

Concerning the characteristics of a mathematics teaching well suited to engineering education, we identify three different trends in the answers of the interviewed teachers: T1 emphasizes the need for “contextualization”; T2 perceives his profile as interesting for teaching mathematics in engineering

education; T3 perceives himself as a teacher who applies the mathematics as are “recognized in the university institution”. T1 notices that teachers who are mathematicians have a reluctance to integrate problems referring to other disciplines. He supposes that they need some support in the design and the implementation of this kind of problems. T2 states he has “ability” to make connections between contents to ensure a continuum of learning between mathematics courses and engineering courses. He sees himself as a “specialist in mathematics for engineers”. He says:

T2: Specialist of mathematics no, I am not a mathematician. Otherwise, am I a specialist in mathematics for engineers? I think I have a lot of experience to know how math tools are used in the workplace. [Our translation]

He presents mathematics content as tools that have utility in the workplace of engineers:

T2: We try often to remind students that later on they will need mathematical tools and they have to build them. They have to be able to manipulate them properly. [Our translation]

T3 only considers the mathematics courses in terms of utility within mathematics.

In their answers about students’ difficulties, the teachers referred to: 1) reasoning (T1, T2, T3); 2) treatment of tasks within the formal representation (T2, T3); 3) the capacity of abstraction (T1, T3). It seems that the emphasis on formal representations in resources accentuates these difficulties.

According to their declarations in the interviews, the examples they add during the classroom sessions appear as revealing their will to support connectivity in different ways. Each teacher, in his preparation of the course, designs his own examples. T1 says that the examples he designs should enhance the meaning of the concepts at stake. He presents examples referring to other disciplines. T2 says that he gives examples particularly during the introduction of concepts, “intra and extra-mathematical examples”. According to T1 and T2, examples referring to other disciplines of real life situations are opportunities to make sense of the contents. T3 says that he gives examples after having stated a theorem. He uses examples to illustrate the “operability of the theorem”.

Concerning proofs, all interviewed teachers stated that they do not do, in the classroom sessions, all the proofs given in the resources. The reasons they gave could be interpreted in terms of personal relationship with calculus [our translation]:

T1: the proofs I like are usually the useful proofs. I do not like for instance the “trapping” proofs for which if you do not have the right intuition, you cannot start.

T2: When you look at the theorem and the proof does not come to your mind right away, and you finally find out that the proof is based on tricks, I think this proof should be replaced by examples.

T3: If the proof requires little effort and seems important to me, I do it. I do not do it if I think we can understand the theorem without the proof, sometimes the proofs help to understand.

T1 and T2 show in class the proofs that can support the learning of a form of reasoning, which is, according to them, essential for future engineers. T3 shows the proofs that can help to understand theorems and properties, even if they sometimes require fastidious techniques. However, the interviews allowed us to identify criteria the teachers consider for choosing the proofs to do in the

mathematics courses in engineering education: they can help improve the understanding of theorems; they allow highlighting the importance of a given theorem; they can help – during the proof – implement a mathematical reasoning. Each of these criteria could promote a specific form of connection between concepts.

The additional resources that the teachers design individually can strengthen specific connectivity in their teaching. T2, for instance, prepares examples to motivate the introduction of a given concept or to replace “tricky” proofs. T1 designs resources to show situations from other disciplines. T3 designs additional resources (exercises and examples) to strengthen links between mathematics concepts.

## Discussion and conclusion

We present in this paper the issue of connectivity concerning a mathematics course in engineering education. We analyze the potential connectivity of resources, collectively designed, for teaching sequences theme. We highlight elements on effective connectivity that teachers, as users of these resources, could develop in their implementation.

The potential connectivity in resources for teaching sequences appears as restricted to the calculus topic area. The register of formal representation occupies an important space. According to two of the interviewed teachers (T1 and T2), making connections with engineering contexts, real-life problems or other disciplines “remains a dimension to enhance”.

It appears by the interviews that the way the teachers use resources is likely to lead to an effective connectivity different from the potential connectivity, and this could be related to their personal relationship with the topic at stake. The teachers stated that students struggle with making sense of formal properties. Hence they attempt to support students by designing additional resources. They add examples and select separately the proofs to show in lectures sessions. These individual teachers’ choices could strengthen some forms of connections. The physicist (T1) tries to enhance the connections in terms of other disciplines; the engineer (T2) constructs mathematical tools and tries to make connections with the engineering courses; the mathematics teacher (T3) tries to maintain connections within mathematics.

The analysis of the interviews draws our attention to the need to take into consideration the macro-level connectivity (Gueudet et al. 2018), especially connectivity across disciplines, in terms of teachers’ own resources, as well as in terms of teachers’ and students’ joint work. Besides, based on the analysis of the interviews, we highlight the necessity to observe how the teachers select and implement proofs in their sessions, which could tell us more about the effective connectivity built.

The issue of connectivity in resources and the connectivity developed by their use seems to be relevant in the context of engineering education, where the connectivity between theory and practice is crucial. Each of these elements requires further study with a larger sample of teachers, considering different mathematical topics and articulating the analysis of resources and classroom observations.

### Introduction

At CERME11 two groups addressed mathematics education research concerning technology. TWG15 focused on issues related to teaching, teacher education and professional development, whereas TWG16 focused on students' learning with technologies, alongside software and task design issues (see Introduction to TWG16 in this volume).

The TWG15 work was stimulated by contributions in the form of 12 research papers and 8 posters that had responded to the call that had highlighted the following themes:

- The specific knowledge, skills and attributes required for efficient/effective/equitable mathematics teaching with generic and mathematics-specific technologies and resources.
- The design and evaluation of initial teacher education and teacher professional development programmes (to include MOOCs) that embed the above knowledge, skills and attributes.
- Theoretical and methodological approaches to describe the identification/evolution of teachers' practices (and of 'best' practices) in the design and use of technology and resources.
- Theory and practice relating to the formative/summative assessment of mathematical knowledge in technological environments.

The work of TWG15 drew upon research from 13 countries: Austria, Brazil, Denmark, England, France, Iceland, Israel, Germany, Greece, Norway, Portugal, Sweden and Turkey.

### Organisation of the TWG15 at the conference

During the conference the TWG15 convenors piloted a new format for the 30-minute paper presentations. Two weeks in advance of the conference, each lead paper author was paired with another participant in the group, their *partner*, and it was this partner who was invited to present the paper. She or he was asked to share their presentation slides, which were required to include some questions to the author. In reality, this led to email exchanges, online calls and face-to-face meetings, most of them before the conference, and some during the early days of the conference. The resulting presentations enabled the ideas in the submitted papers to be explored in much more depth than at previous CERMEs - often requiring the author(s) to show examples of tasks, resources and functionalities from within their selected technologies. Alongside this, the TWG15 poster submissions were thematically aligned with the TWG session programme and the poster authors were

invited to give a brief overview of their research. Following these paper and poster presentations, small group discussions were instigated within the TWG that focused on understanding the presented work in its cultural context. In particular, we probed the terminologies and contexts within the reported research that related to technological, pedagogical, mathematical, theoretical and methodological ideas. The TWG leaders supported the analytic and synthetic processes of the group by capturing the comments and questions made by participants as an ongoing process. We reflect on participants' perspectives of this approach later in the TWG15 introduction.

## **The emergence of TWG15 sub-themes**

During the final two TWG sessions, the group spent time to discuss and agree the emergent sub-themes, which were: teachers' uses of students' (digital) productions; sorting and organising digital content such as: simulations, applets, Open Educational Resources (OERs); the teaching of computing/programming in, and through, mathematics; teachers' choices and beliefs concerning technology use; and the group's ongoing grappling with theory. The TWG sub-divided into smaller groups, each of which then contributed text to the summaries that follow.

### **Teachers' uses of students' productions**

A number of papers and posters described research that featured teachers' practices when using students' work as a basis for discussion in the mathematics classroom. In these projects different technologies were employed, e.g. *c-book* units (Diamantidis, Kynigos & Papadopoulos), videos (Kristinsdóttir, Hreinsdóttir & Lavicza; Fidje & Erfjord), connected classroom technologies (Fahlgren & Brunström), and mini-whiteboards (Eidissen, Hreinsdóttir & Lavicza). These technologies served to both make students' thinking visible and to stimulate classroom discussions based on students' own work/solutions, which are known to be important formative assessment practices (Black & Wiliam 1996).

However, orchestrating class discussion based on students' contributions was reported to be challenging for teachers for which the selection, deliberate grouping and sequencing of student productions are useful strategies. When it comes to sequencing, the role of teacher preparation was considered important, however sometimes students' responses opened opportunities for discussion that could not have been realistically predicted by the teacher. Such opportunities can contribute to the classroom discussion, if the teacher has both the flexibility to take it up and it aligns with the teacher's goals for the lesson. As such, this relates to the existing framework of instrumental orchestration (Trouche, 2004) within the socio-mathematical norms where students' various personal meanings of concepts are valued and 'up for discussion' as a crucial factor to foster classroom discourse. The TWG group agreed that the aforementioned technologies might aid teachers in this endeavour.

The use of students' productions in education was exploited by Diamantidis et al., who focused on the role of students as co-designers - with teachers - of digital resources for learning mathematics. Their project design involves collaboration between students and teachers, who used digital tools for mathematics education for the design and production of *c-books*, a set of narrative units blended with digital artefacts. The research, which was framed by the *documentational approach* (Gueudet & Trouche, 2010), aims to research the design phase as a learning process for the students as they search

for new mathematical meanings that emerge around the concept of co-variation (in the sense of Thompson, 2002).

Kristindóttir et al. presented a poster on the use of silent videos to the whole class in Iceland, with the possibility for the students to view them as often as they want. The students, divided in pairs, were asked to plan and to record their voice-over for the video. The role of the teacher is of facilitator, encouraging students in many ways, for example by reminding them that their voice-overs might help their classroom peers to gain access to the mathematics shown in the video. The research is highlighting how the use of silent video in this way is particularly helpful to teachers as a form of formative assessment, because data about students' knowledge can be collected in an indirect way.

Fidje and Erfjord's research also focused on videos produced by students, this time in Norway, which are used to stimulate discussions that are coordinated by the teacher. Their project *Digital Interactive Mathematics Teaching*, explores the use of digital tools in three lower secondary mathematics classes. The student-produced videos are presented as a tool for the students to show strategies related to inquiry-based tasks given by the teacher (in this case, relating to similar triangles). The idea emerged from the teachers as they wanted to explore different uses of videos in teaching, both teacher- and student-produced. The three-part lesson sequence used in the analysed lesson was developed by both teachers and researchers in a workshop. The aim for both teachers and researchers was to develop an approach for eliciting student talk in full-class mathematics discussions. The results show that the teachers adopt different 'teacher moves' to steer the discussion towards both didactical and mathematical goals.

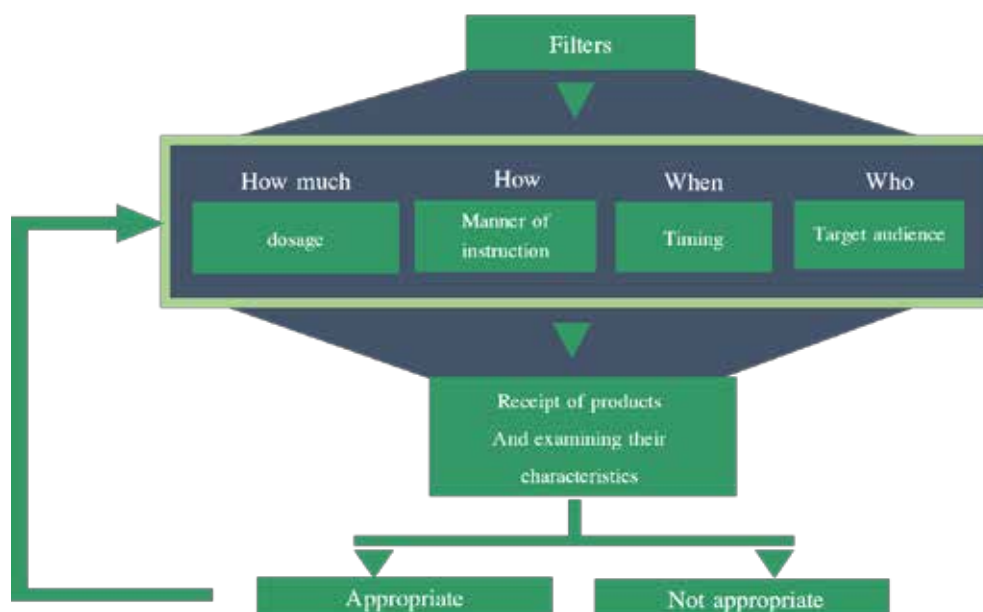

The final two research studies that relate to this sub-theme are those of Fahlgren and Brunström and Eidissen et al.. Both sets of authors presented posters of work in progress. Fahlgren and Brunström's study concerns research into the impact of *connected classroom technology*, a networked system of personal computers or handheld devices specifically designed to be used in a classroom for interactive teaching and learning, through a design-based study with Swedish mathematics teachers to establish design principles for its use for formative assessment purposes. The contribution by Eidissen et al., notable by its absence of digital technology, proved to be a significant one for the TWG as it challenged the group to consider how theories such as instrumental genesis and orchestration (Trouche 2004, and Drijvers' plenary paper in this volume) might be applied for classroom practices involving non-digital resources.

### **Sorting, organising, and increasing quality of mathematical digital content**

The current diversity, complexity and potential of mathematical digital content demands research studies to support better understanding and communication of the main characteristics, constraints, didactical value, and quality. The abundance of digital resources for the teaching and learning of mathematics highlights the need to provide teachers with guidance and support to make discerning choices. In the previous CERME, a paper was addressed specifically on discerning quality issues of web materials useful for teaching mathematics with technologies (Kimeswenger, 2017). In this CERME, TWG15 included several contributions that had adopted both empirical and theory-driven research approaches to address the challenges to sort, organise and make judgments about the quality of mathematical digital content.

Wörler focused on finding central features of digital simulations for learning mathematics, and articulate the underlying traits that can be derived within the context of mathematical modelling. The resulting research question concerned how these features and traits might enable an a priori classifications of mathematical simulations. This question, and the results of the study give some order within the field of modelling and simulation for teaching mathematics and enable comparisons between the products used in different countries and contexts. Considering the importance of variation in the field of simulation, the author introduced a classification based on the kind of variation, number and possibilities of varying elements in a simulation model, and kind of representation used. In this way, different simulation applications are classified with a quantitative scale based on different levels of manipulation, and the classification is useful to both researchers and teachers.

Alongside simulations, applets are also widely (and increasingly) available for the teaching and learning of mathematics and it is widely evidenced that teachers find it challenging to select which ones to use, highlighting a need for some related quality criteria (Nakash-Stern & Cohen). The authors reported research that concluded teachers' choices, which were classified by the intended mathematical learning goals, the role of the applet in the planned lesson and the nature of its planned use. Nakash-Stern and Cohen's research aims to support teachers to cope with the propensity of such OER by offering a methodological tool (a meta-data map, as shown in Figure 1) to link a teacher's pedagogical-content considerations with the didactical aims.

**Figure 1. A Map for applets integration in teaching sequence (Nakash-Stern & Cohen)**

The specific case of gamification within mathematics is addressed by Russo, whose research has reviewed the features of existing gamification platforms for mathematical learning to develop a framework for the evaluation of their motivational aspects. This is to be used to inform the development of a gamification editing platform that will be explicitly designed for teachers' uses.

Braukmüller, Bikner-Ahsbahs and Wenderoth offer a publisher's perspective to the same challenge in their consideration of teachers' needs whilst developing a digital tool for learning algebra in the German *multimodal algebra learning* (MAL) project. They argue that, as textbooks are the dominant media in mathematics teaching, research with textbook authors is necessary to derive principles for integrating the MAL digital tool within textbook authoring.

These different approaches all address the aim to facilitate teachers' choices, uses and evaluation of all manner of digital tools in classroom practice. The collaborative work of the TWG resulted in new ideas for future research focusing on some aspects that are considered useful when evaluating a tool, for instance motivational features, authoring systems, types of use and levels of interaction/activity. Basically, two different approaches arose: platforms that suggest some tools according to teacher needs (using filters) and the provision of frameworks to evaluate a specific tool for a special use case.

### **Teaching computing/programming in and through mathematics**

Discussions in the group revealed that several of the represented countries are now implementing computing curriculum in schools (England) and/or mandating compulsory technology usage (Denmark, Sweden). The legacy of Seymour Papert (1980) and his seminal work that resulted in the computer programming language LOGO stimulated the TWG discussions on this sub-theme.

The ScratchMaths project (Clark-Wilson, Noss, Hoyles, Saunders & Benton), a large-scale evaluation project in English primary schools focused on making the mathematics explicit by focusing on an explicit pedagogical framework, the *5 Es* (Explore, Explain, Envisage, Exchange, bridgeE). The research reports the important methodological considerations in relation to the teachers' adoption and adaptation of the pedagogical ideas as a means to assess the fidelity of classroom implementations of the computing curriculum.

In Norway, Munthe is undertaking design-based research with upper secondary students on an elected science and mathematics pathway in which they are presented with mathematical problems to investigate how the use of programming can facilitate their learning of mathematics in the classroom. His poster is a good example of how the mathematics explored was explicit, within the problem of solving quadratic functions with no real roots.

This idea is researched from the teachers' perspective in the paper by Misfeldt, Szabo and Helenius, in Sweden, where teachers' perceptions of the relationship between mathematics and programming is explored within the context where teachers are expected to integrate compulsory programming within the mathematics curriculum, without deep thought about its value.

There is a diversity in the perspectives of the different papers in relation to both the definition and positioning of computational thinking within the school mathematics curriculum, which lead to differing approaches to curriculum and teacher development. Critical to this were the questions, *where is the mathematics?* and *how is the mathematics transformed (in terms of syntax, representation and meaning) through the use of different programming tools?* - and the implications of these approaches on teachers' roles and actions.

## Teachers' choices, beliefs and practices with technology

A number of TWG15 contributions addressed issues related to mathematics teachers' attitudes to, and uptake of, digital technological tools. The paper by Thurm and Barzel adopts a quantitative approach to explore the link between teachers' self-efficacy and their use of *mathematical analysis software* (MAS). They adopt Bandura's definition of *self-efficacy*, 'a judgement of one's ability to organize and execute the courses of action required to produce given attainments' (1997, p. 3), to develop and validate a scale that concludes that teachers with high self-efficacy tend to use MAS more frequently. Furthermore, high teacher self-efficacy is less well-correlated with the teachers' level of experience with technology. A different methodological approach to explore teachers' perceptions of their technology use is evident in the work of Bang et al., who use a stimulated interview task to research how Danish teachers are integrating computer algebra software (CAS) into their teaching.

In his presentation of ongoing doctoral work, Dreyøe declares the integration of digital tools by teachers of mathematics to be a *wicked problem*, a phrase first coined by Rittel and Webber for problems with many interdependent factors making them seem impossible to solve (Rittel & Webber, 1973). Dreyøe's study explores the impact of participatory design with mathematics teachers as a means to create shared understanding of their declared intentions and practices with digital tools.

Focusing more on mathematics teachers' particular practices with digital tools, research by Rocha and Yemen-Karpuzcu & Isiksal-Bostan adopt a micro approach with respect to particular mathematical content. Rocha's study explores Portuguese teachers' representational fluency when teaching functions at high school level and the impact of their choices of representations within their practice, concluding hierarchies in algebraic, graphical and tabular forms. Yemen-Karpuzcu & Isiksal-Bostan research Turkish teachers' mathematical practices as they taught a sequence of lessons addressing the concept of slope that used both concrete and technology-based resources. Their findings highlight the nuances of teachers' practices, which vary by: the mathematical construct, their own understanding of it; and their knowledge of their students' understandings of the same construct.

## The use and application of theories within TWG15

Over the years, and especially this year, the TWG15 papers have shown a strong appreciation of theory, which is used to inform hypotheses, research questions and research methodologies. During TWG15, this work continued as we discussed theories in relation to: individual papers; by making links with other papers in the group; the CERME plenaries; or other papers in the literature. One theory that continues to be present has been *instrumental genesis*, with its origins in French cognitive ergonomics (Verillon & Rabardel, 1995) and its applications in mathematics education (Artigue, 2002; Guin & Trouche, 2002). One discussion point was the complexity of two key components: *instrumentation* and *instrumentalisation*. In particular: how (and whether) to interpret these from a user perspective or an instrument perspective; their meaning in digital and non-digital contexts; and whether to consider each separately or in a more dialectic relationship. However, as addressed by Paul Drijvers in his plenary, instrumental genesis or, in other words, the emergence of utilisation schemes, emerges from the intertwinement of mathematical concepts and the employed techniques for the proposed task. In this process the *tools* have a central role but such tools 'come with [their

own] affordances and constraints, with opportunities and obstacles'. Our discussion, and resulting consensus was that instrumental genesis is a *long* and *continuing* process (as exemplified by Paul Drijvers' piano recital in the Dom church), in which the user continually and spontaneously shapes his/her techniques and associated cognition. Consequently, the separation of instrumentation and instrumentalization as distinct processes is not an easy task and may not be observable. The paper by Bozkurt et al. prompted rich debate on the process of instrumentalization as, in their research, they had particularly 'focused on a stage of discovery' of a specific tool and how this related to the instrumentation of other tools.

Moreover, to describe the design of material in a technological context, Diamantidis et al. used the *documentational approach* (derived from the instrumental approach, Gueudet & Trouche, 2010). The interesting and new perspective introduced in this study is the involvement of students alongside with teachers in the phases of design.

An emergent phenomenon in the TWG15 contributions is the increasing number of studies that report the involvement of teachers in mathematical, technological contexts as active protagonists, not only as consumers of professional development made by researchers. The engagement of teachers in working, not only learning, is the novelty coming to the fore of the theme in the last years, over the world: teachers as designers, with researchers or with students, teachers involved in the research, teachers aware of the materials produced, of their role, of their choices.

And, for the future, it seems increasingly important to research situations where teachers are working more collaboratively with each other and more knowledgeable others for the purpose of developing knowledge of, and practice with, digital mathematical tools. For that reason, theoretical approaches that take care of praxeologies of the teacher both in the activity of teaching (i.e. didactical), as well as in the activity of working and learning (i.e. meta-didactical), can be used to describe possible evolution and improvement of teachers in their learning and working trajectories. The recently announced 25th ICMI Study: *Teachers of mathematics working and learning in collaborative groups* will be an opportunity to explore the role of technology in this respect.

### **Areas for further research**

Following the conference, the group created a ResearchGate<sup>1</sup> project page to enable the community to share, and comment upon research projects, articles and conference presentations that align with the TWG15 focus.

The group identified the following emergent research themes that might be included in future TWG calls for proposals:

- Teachers' decision-making for the selection and use of digital tools for teaching and learning mathematics.
- Quality criteria for digital tools that enable the teaching and learning of valuable and meaningful mathematics.

---

<sup>1</sup> <https://www.researchgate.net/project/CERME10-TWG15-Teaching-Mathematics-with-Technology-and-Resources>

- Developing collaborative groups to scale digital mathematical implementation – How to implement different technologies in schools? What are the challenges and barriers? What makes a successful implementation?
- The implications of the emergence of ‘big data’ in mathematics education and its impact on how mathematics is assessed.
- Teachers’ appropriations of emerging technologies, for example virtual and augmented reality, artificially intelligent digital tools etc.

# Teachers' strategic choices when implementing technology

Henrik P. Bang<sup>1</sup>, Niels Grønbaek<sup>2</sup> and Claus R. Larsen<sup>1</sup>

<sup>1</sup>Christianshavns Gymnasium, Denmark; [hb@cg-gym.dk](mailto:hb@cg-gym.dk)

<sup>2</sup>Dept. of Mathematical Sciences, University of Copenhagen, Denmark; [gronbaek@math.ku.dk](mailto:gronbaek@math.ku.dk)

*Keywords: Tools, technology, tasks, technics, teachers' choices.*

## Background

Teachers in Danish upper secondary schools are expected to independently plan and implement teaching, basing content and didactic approach on their own preferences - customized to student level, useful teaching materials, time spent etc. Use of technology - especially CAS – is extensive and reflected in tasks and techniques, in the sense of Artigue (2002), in both the classroom and within final examinations. The technological dimension changes the conditions for organizing teaching, which makes continued in-service teachers training an urgent need.

CMU has met these challenges by establishing a community of teachers and offering coaching to smaller groups or individuals, allowing for a dialogue that respects the teachers' wishes and needs while providing solid support in the process (Bang, Grønbaek, & Larsen, 2017a). Among the issues that we have identified during the coaching process are:

- The teachers' own mastery of the instruments – technically as well as educationally.
- Questioning how much the students themselves can do with the instrument in terms of time consumption, classes and student types, software for which the school has access, etc.
- The relationship between doing tasks with CAS and (also) doing without, expressing itself in many ways, e.g. which procedures you want to teach, what non-CAS assumptions you should have in terms of using CAS, and how work with CAS supports non-CAS work.
- Teachers' awareness of the relationship between procedural and conceptual development in a technological context, while respecting mathematical content in a longitudinal perspective.
- Standards for CAS responses opposed to non-CAS. The latter having a long tradition, while the first may depend on software, instrumentation, etc.
- Students' motivation - not least the motivation triggered by final exams.

## Fruitful aspects of the outsourcing metaphor.

The complexity of these interlaced issues involves many approaches, imposing a lot of theory on teachers not being one of them. We therefore need pragmatic ideas that can form a basis for dialogue with the participants and among the teachers themselves. Outsourcing (to technology/CAS) is to some extent used as a metaphor for how procedures that have been time-consuming maybe/may be advantageous with CAS. We have explored the concept, and its dual partner, insourcing, covering procedures and approaches done with or without technology, promoted in teaching (Bang, Grønbaek, & Larsen, 2017b). We are especially drawn to the control aspect, e.g. a company outsourcing procedures and thus losing control of them e.g. product quality, how the product fits in with the company's other production. Conversely, insourcing allows for control in the sense that you have clarity about qualities, resources, etc. Out-/insourcing can take place with or without technology.

## Interviewing teachers posting tasks for students on maps.

Based on the interviewee's generic teaching experiences e.g. 2nd degree polynomial, initial differential calculation, we asked her to post different tasks on a two-dimensional map (fig.1). The teachers quickly connected to the idea and although placing specific topics gave rise to discussion, e.g. possible placement in several places, there was rarely doubt about the general idea<sup>a</sup>.

Fig.1

Fig.2

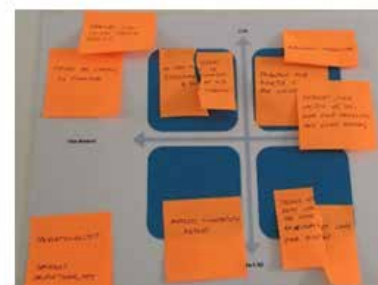

Fig. 3

### Identifying choices and research questions.

We have tentatively placed teachers' reasons for their choice in three interrelated categories (Fig.2):

1. Mathematics involved -derived from what promotes mathematics in a longitudinal perspective
2. Local pedagogical - approaches, that work in a specific class setting.
3. Systemic - approaches derived from e.g. requirements for examinations or grades.

Our RQs: How can analyses of teachers' choices promote better understanding of relations between (in-sourced) procedures and objects. What kind of activities with technology could stimulate interest in realistic mathematics? What kind of technology use at upper secondary mathematics is fruitful in a transitional perspective?

<sup>a</sup> One of the many tasks in question was the parallel shift of a parabola, e.g. to display formula for vertex. You can choose completely to outsource the procedure, but also choose to insource parallel shift of absolute value and do it by hand, or you can choose to look at Geogebra etc. to enhance students control of the procedure. A large part of the interview would be the teacher elaborating on their choice.

## Turning dilate from point tool into part of an instrument: an example of a preservice mathematics teacher working on a dynamic geometry system

Gulay Bozkurt<sup>1,2</sup>, Candas Uygan<sup>1</sup> and Melih Turgut<sup>1</sup>

1- Eskisehir Osmangazi University, Faculty of Education, Eskisehir, Turkey,

2- Charles University, Faculty of Education, Prague, Czech Republic;

E-mail: [gbozkurt@ogu.edu.tr](mailto:gbozkurt@ogu.edu.tr)

*The aim of this paper is to investigate a preservice mathematics teacher's instrumental genesis of 'dilate from point' tool in a dynamic geometry system. Data is collected through a series of task-based interviews including seven specific construction tasks regarding the use of dilate from point tool with a Turkish preservice mathematics teacher. Video-recorded interviews and screen recorder software productions were triangulated and analysed within the theoretical lens of instrumental genesis. According to the findings, the participant firstly explored the properties of the dilation transformation and its relation to other geometrical concepts and transformations. Secondly, the participant developed instrumented schemes related to the dilate from point tool for applying appropriate strategies in the construction tasks.*

*Keywords: Preservice mathematics teachers, Dynamic geometry system, Construction tasks, Instrumental genesis.*

### Introduction

Geometric similarity is regarded as a crucial concept in most school geometry curriculum. Likewise, in Turkish secondary school mathematics (MoNE, 2018a; MoNE, 2018b) this concept has its place focusing on making connections between measurement of angles and side lengths of two polygons through reasoning about the concepts of ratio and proportion. Considering the similarity related terms and concepts, the importance of dilation and scale factor has been emphasised in the related literature (e.g. Cox, 2013) since the deep understanding of these concepts do not only enable learners to solve similarity problems but also help them to involve in ratio-related problems. However, these concepts do not take place in the Turkish mathematics curriculums as a geometrical transformation. Instead, the focus is on investigating similar polygons in different sizes by focusing on the ratio between side lengths through paper folding tasks or drawing activities on a plotting paper (MoNE, 2018a). Also, tasks based on the basic proportionality theorem (MoNE, 2018b) are addressed without mentioning the concepts of scale factor or centre of dilation. Starting from this point, we focus on teachers learning of dilation as a geometrical transformation. This is particularly crucial in teacher education as it is essential for preservice mathematics teachers to have a wide and deep understanding of geometric similarity before their actual teaching in classrooms.

Focusing on these concepts, dynamic geometry systems (DGSs) in particular measurement and dragging facilities are considered as having a critical role to support learners' reasoning processes on the ratio and proportional relationships between two figures (Denton, 2017). In this regard, we focus on a preservice mathematics teacher learning dilation and scale factor concepts in a DGS as Simsek and Clark-Wilson (2018) in their review stated that there is a need to know about how dynamic technology tools shape teachers knowledge on geometric similarity related concepts. Considering the geometrical transformation tools in a DGS, it has become apparent that dilate from point tool is an unfamiliar tool for Turkish preservice mathematics teachers in its practical use as well as in its mathematical content. Along this direction, we focus on encouraging a preservice mathematics teacher to explore dilate from

point tool as a geometrical transformation tool in which she first had a difficulty in making the mathematical meaning of the tool.

## Theoretical Framework

Instrumental genesis offering a model to describe the process of learning to use technological tools is chosen as a theoretical perspective in this study (Artigue, 2002). This is derived from the instrumental approach issuing from cognitive ergonomics (Vérillon & Rabardel, 1995) pointing out the difference between the terms ‘artefact’ and ‘instrument’ and the fact that using a tool is a dialectic between the user and the instrument. In this approach, the process through which an artefact becomes part of an instrument is called instrumental genesis ‘involving the construction of personal schemes or, more generally, the appropriation of social pre-existing schemes’ (Artigue, 2002, p. 250). The instrument is used in a psychological sense, which is developed by the user through mental schemes in order to use it for specific tasks. Instrumental genesis consists of two interrelated processes *instrumentalisation* and *instrumentation*. The former is directed towards the artefact and concerns the way in which the artefact is shaped by the user. The latter is directed towards the user and concerns ‘the emergence and evolution of schemes of a subject for the execution of a given task’ (Guin & Trouche, 2002, p. 205).

For the aim of this study, both instrumentalisation and instrumentation processes are of crucial importance. For the instrumentalisation process, we will focus on a stage of discovery of dilate from point tool and a process of differentiation of this tool itself in which instrumentation of the other DGS tools can emerge (Guin & Trouche, 2002). For the instrumentation process, we will focus on instrumented schemes for working on dilation and scale factor related tasks in a DGS. Hence, the research question addressed in this study is: How does instrumental genesis process of a preservice mathematics teacher occur in utilisation of dilate from point tool while solving enlargement/reduction and scale factor related construction tasks in a DGS?

## Research Context and Methods

This paper is part of an ongoing research project that is designed as a case study focusing on instrumental genesis of preservice mathematics teachers while they commence GeoGebra. For the sake of page constraints, this particular study reports the case of one preservice mathematics teacher, Selin’s (pseudonym) appropriation of dilate from point tool in GeoGebra while working on construction tasks. She enrolled in a secondary mathematics teacher education program at a state university in Turkey. She took several courses (e.g. abstract and discrete mathematics, calculus, geometry and linear algebra) before the interviews were completed. She was selected mainly because she had no previous experience with GeoGebra in particular while solving construction tasks. Also, we considered her performance on geometry course since she achieved A from geometry for the grades F (fail) to A (excellent). In addition, her communication skills especially in terms of expressing her thinking clearly has been taken into account.

Data was collected from three task-based interviews, during which the participant talked/explained her solutions while working on a mathematical task. These interviews were recorded through a video-camera filming the participant’s working environment, which included a laptop with GeoGebra installed in front of her. Screen recorder software was also used to capture the techniques she employed during the tasks in detail. All the collected data were triangulated and analysed through thematic analysis techniques. Codes and themes were assigned by researchers according to the participant’s solutions for each task, and the tools

utilised by the participant and her reasoning behind it with reference to the used techniques during her solutions.

### The Tasks

For exploring the process of instrumental genesis of dilate from point tool, we prepared seven different construction tasks. Since the participant initially had no insight into how dilate from point tool worked, the first task consisted of the analysis of this tool. The interviewer showed Selin the icon of dilate from point tool in GeoGebra and the task was proposed as: explore this tool and explain its mathematical feature. Then she was asked three different construction tasks focusing on enlargement/reduction concepts without the use of this tool:

- Dilate a circle by scale factors of 2 and 3 (without using dilate from point tool),
- Dilate a triangle by scale factors of 2 and 3 (without using dilate from point and reflect object in point tools),
- Dilate the given QRS triangle from the centre point T by the scale factor of  $-1/3$  (without using dilate from point tool).

By this way the participant was encouraged to think about possible ways to obtain dilation transformation by using other GeoGebra tools. These three tasks were proposed in order for her to become familiar with the use of dilate from point tool and elaborate its mathematical meaning, hence the focus was on the instrumentalisation process. Finally in order to explore the participants' instrumented schemes for this specific tool, three more tasks were asked:

- Construct the centre of gravity point in a given triangle (without using line construction tools),
- Divide a line segment into two parts by a certain ratio (without using parallel line construction tool),
- Construct a trapezoid with a given triangle (without using parallel line construction tool)

During these tasks, the participant was asked to develop strategies without the use of some tools in order to encourage her to think indirect ways of constructing a figure which aimed to give deeper insight into the extent of the participant's knowledge.

## Findings

### Initial analysis of the 'dilate from point' tool

**Task 1:** Explore the dilate from point tool and explain its mathematical feature

Selin started her analysis by selecting the tool, respectively clicking on point A (as object) and point B (as centre of dilation), and entered the number 5 as a scale factor. As a result, she assumed that the distance between the two points (A and B) on the screen would be five (the image of the point A was not seen on the screen). After making use of distance or length tool, she found the distance AB 3.1 (Figure 1) and refuted her initial conjecture. She then said: "I would like to say that there is a certain proportion between points but I don't see a third point so I am confused".

Figure 1

Selin applied the dilate from point tool again for  $C$  as object and  $D$  as centre of dilation. Then she used the zoom out tool to look for a third point, to her, which was possible to emerge on the screen as the image of  $C$  (Figure 2). When she found the point  $C'$  (image of the original point) on the screen, she said: 'aha, now it is OK'.

Figure 2

She stated that the tool constructed a bigger triangle which was constructed by the ratio that was entered as 5.

She also worked on the two triangles and explained the similarity between them based on the basic proportionality theorem (Figure 3).

Figure 3

Selin then applied the dilate from point tool on various other figures (a triangle and a circle) and examined the relationships between the original figures and their images. She suggested that the scale factor affected each point of the original figures and made an assumption that the original shapes and their images were similar.

In order to support her assumption, she used the distance or length and area tools and justified it with proportional relational facts. Based on this, she explained the similarity of figures and ratios.

In the second step of the analysis process, she examined the simple fractions and negative numbers as scale factors. After examining the new shapes that appear as a result of her operations, she stated that for fractions the smaller versions of the original shape occurred as its images, whereas for negative numbers, the similar versions of the original shape occurred at the opposite side of the centre of dilation.

### Elaboration of the 'dilation' by the use of other types of transformations

**Task 2:** Dilate a circle by scale factors 2 and 3 respectively without the use of dilate from point tool.

During this task, she, by following the steps below:

- drew a circle with the centre  $P$  through point  $Q$  and chose a point called  $R$  as centre of dilation,
- reflected the point  $R$  in the point  $Q$  and also in the point  $P$  by using *reflect object in point* tool,
- obtained two new points  $R'$  and  $R_1'$ ,
- constructed the new circle with these points by using *circle with centre through point* tool, which was a dilation image of the original circle by scale factor 2 (Figure 4),
- reflected the point  $Q$  in the point  $R'$  and reflected the point  $P$  in the point  $R_1'$  for the dilation image by scale factor 3 (Figure 4).

Figure 4

The reasoning behind this instrumented action was notions of extending a segment by projecting it by its own length.

**Task 3:** Dilate a given triangle by scale factors 2 and 3 respectively without the use of dilate from point or reflect object in point tools.

At this step, Selin focused on the use of translate by vector tool. She, by following the steps below:

- drew a vector from the centre of dilation  $V$  to one of the vertices of the given triangle,
- translated the triangle by the vector (Figure 5).

After this operation, she noticed that while there was a ratio of 2 between  $V$  and one vertex of the constructed image, this ratio was not preserved for the other two vertices of the image and she concluded: “I now translated the whole triangle by the same vector”. Then, she, by changing her operations as follows:

- translated each vertices of the original triangle by vector (similar with the use of ‘reflect object in point’ in the previous instrumented action),
- drew three different vectors from the centre of dilation  $V$  to the three vertices of the given triangle and translated each vertex by the corresponding vector,
- obtained three vertices of the dilated image of the original triangle by scale factor 2 (Figure 6),
- did the same operation for scale factor 3.

The reasoning was again related to extending a segment by projecting it by its own length.

Figure 5

Figure 6

**Task 4:** Dilate the given QRS triangle with a centre of dilation  $T$  by a scale factor of  $-1/3$  without using the dilate from point tool.

Selin initially said: “the image should be on the right side of the dilation centre and needed to be smaller than the object. How can I do that? For instance, the image of point  $Q$  needs to be somewhere on the line  $QT$  (collinear) and its distance from the centre should be one third of the line  $QT$ . So then if I divide  $QT$  line segment into three parts and reflect the point in the dilation centre I think that I could obtain its image by  $-1/3$ ”.

In this sense, her initial aim was to divide line segment  $QT$  into three equal parts. At this point she, by following the steps below:

- drew two lines ( $QT$  and  $RQ$ ),
- constructed three equal line segments on the line  $RQ$  through constructing three new points called  $R'$ ,  $Q'$  and  $R''$  by using the reflect object in point tool (e.g. reflected  $R$  in  $Q$ , then reflected  $Q$  in  $R'$ , and reflected  $R'$  in  $Q'$ ),
- drew the line segment  $TR''$ ,
- constructed parallel lines passing other two points ( $R'$  and  $Q'$ ) to the line segment  $TR''$ ,
- constructed three equal line segments on the line segment  $QT$  based on the basic proportionality theorem (Figure 7),
- specified the point  $U$  on the line segment  $QT$ , which was the intersection point of the parallel line passing  $Q'$  and  $QT$  (Figure 8),

Figure 7

- applied the same division method on the other two lines ( $RT$  and  $ST$ ),
- constructed the vertices of a new triangle ( $UZW$ ) which was the image of  $QRS$  triangle by a scale factor of  $1/3$ ,
- reflected the points  $U$ ,  $Z$ , and  $W$  in the centre of dilation  $T$  and constructed  $U'Z'W'$  triangle, which was the reduction image of  $QRS$  triangle by a scale factor of  $-1/3$  (Figure 8).

Figure 8

### Construction of the centre of gravity point in a given triangle

**Task 5:** Construct the centre of gravity point in a triangle without the use of line tools.

In the solution process, she, by following the steps below:

- firstly constructed the midpoints ( $D_1$ ,  $E_1$ ,  $F_1$ ) of the sides of a triangle ( $A_1B_1C_1$ ) with the use of 'midpoint or centre' tool (Figure 9),
- and then reasoned on the ratio between the parts of median that separated by the gravity point.

Figure 9

In order to obtain the ratio between the parts as  $1/3$ , she decided to use dilate from point tool and thought about what value should be entered in the scale factor window by considering the procedural features of the tool. As a result, she chose  $B_1$  as object and  $E_1$  as the centre of dilation. She said: "since the image should be on the left side of centre of dilation, the scale factor should be positive and since the ratio is  $1/3$ , the scale factor should be  $1/3$ ". Therefore, she put the value  $1/3$  as a scale factor and completed the task.

### Division of a line segment into two parts by a certain ratio

**Task 6:** Selin was given two different line segments (called  $RS$  and  $UV$ ). The line segment  $RS$  was divided into two parts from the point  $T$  (Figure 10). The task was to divide the line segment  $UV$  into two parts with the same ratio of  $|RT|/|TS|$  without the use of parallel lines.

Figure 10

- constructed a line segment  $F_1G_1$  which was equal length to the ratio of  $|RS| / |TS|$  with the use of segment with given length tool (Figure 11),
- used dilate from point tool by choosing  $U$  as object,  $V$  as centre of dilation and the distance  $F_1G_1$  as a scale factor.

However, she noticed that the point, which she wanted to construct, appeared outside of the  $UV$  (Figure 11).

Figure 11

Then she said: "the image should be between object and the centre of dilation therefore I need to use a fraction as a scale factor". Finally she changed the scale factor as  $1/\text{distance}F_1G_1$  and repeated the operation again and finished her construction. She concluded that she could also use  $\text{distance}TS/\text{distance}RS$  as a scale factor which would have done the same operation.

### Construction of a trapezoid with a given triangle as part of the trapezoid

Selin was firstly asked to examine the properties of the given quadrilateral in Figure 12 ( $M_1N_1L_1K_1$ ) focusing on its variants and invariants through dragging. At this step, she stated that the given quadrilateral was a trapezoid for the reason that two opposed sides were always parallel within the quadrilateral. After her explanations, she was ensured to remember the diagonal based definition of trapezoid.

**Task 7:** A triangle ( $P_1Q_1R_1$ ) was given to her and she was asked to reason on how a trapezoid can be constructed if the given triangle was formed by the diagonals of the trapezoid (Figure 12) without the use of parallel line tool.

Figure 12

Selin focused on using dilate from point tool by considering the fact that the diagonals of a trapezoid divide each other into two parts by the same ratio. Then, she, by following the steps below:

- extended one of edges of the triangle by using the line tool and marked a random point on this line as third vertex of the trapezoid (point  $S_1$ ) (Figure 13),
- examined the ratio of the distances of the opposed vertices ( $S_1$  and  $R_1$ ) from the intersection point of the diagonals  $Q_1$  by using the length measurement tool (Figure 13),
- selected the dilate from point tool and chose  $Q_1$  as object,  $P_1$  as the centre of dilation, and distance  $S_1R_1$ /distance  $Q_1R_1$  as a scale factor,
- constructed  $U_1$  as the fourth vertex of the trapezoid (Figure 14) and completed the task by using the segment tool.

Figure 13

As a second solution to the same task, she dilated the given triangle ( $P_1Q_1R_1$ ) as a whole, by choosing the given triangle as object, the intersection point of the diagonals  $Q_1$  as a centre of dilation and  $-distanceS_1Q_1/distanceQ_1R_1$  as a scale factor.

Figure 14

### Discussion and Conclusion

This study focuses on instrumental genesis of a preservice mathematics teacher's use of dilate from point tool working on enlargement/reduction and scale factor related construction tasks in GeoGebra. For the initial analysis and elaboration of the tool, the participant discovered and understood the use of dilate from point tool particularly by engaging in thinking of the use of other tools to perform dilation. After that, she developed a number of instrumented schemes regarding the dilate from point tool while working on construction tasks related to proportional relationships.

During the initial analysis and elaboration of the tool, on the one hand, she differentiated the properties of the dilation from other geometric transformations (e.g enlarging the given triangle by the use of translate by vector). On the other hand, she made connections between the properties of dilation and other transformations, which enabled her to develop a deeper understanding of dilation concept. For instance, in the example of dilating the given triangle by a scale factor of  $-1/3$ , it was seen that she mainly engaged in geometric thinking and used other concepts/transformations (e.g. division of line segments for reduction, the use of reflect object in point for negative scale factors) to complete the task. By this way, she extended and supported her understanding of the dilate from point tool regarding its underlying mathematical meaning and its practical use.

Considering the instrumentation process of the dilate from point tool, it was observed that she developed different schemes for positive/negative scale factors as well as for integer/fractional scale factors. For the former, she referred to the direction of the image from the centre of dilation (i.e. when the value of scale factor is negative, the dilation takes place in the opposite direction from the center of dilation). For the latter, she considered the size of the image whether it would be bigger or smaller than the original object and also the proportional relationships between the distances of the points of object and its image. In addition, she developed schemes related to the concept of dilation as a geometrical transformation in which centre point and scale factor are considered as parameters. These schemes about dilation and scale factors in a DGS indicated also some connections between algebraic and geometric strategies of the participant (Cox, 2013).

To conclude, this study focused on the learning process of dilation transformation in a DGS in the context of the instrumental genesis of the dilate from point tool. The results of this research indicated that the instrumental genesis process for a DGS tool provided scaffolding in the construction and understanding of the dilation and scale factor related concepts. However, this study examined one specific preservice mathematics teacher's solution processes of different construction tasks, which needs to be borne in mind.

### Introduction

Although digital tools are available for everyday classroom practice, researchers as well as teachers are questioning how the use of digital tools can improve teaching and learning (Hillmayr, Reinhold, Ziernwald, & Reiss, 2017). Despite from the digital tool itself, two main factors are responsible for students' success: the teachers' integration of digital tools into classroom practice and a supplementary use of digital and traditional resources (Hillmayr et al., 2017). Teachers' integration requires change or innovation of current teaching practices. Research on innovation of teaching and learning shows that teachers are more likely to use digital tools if they address teachers' needs. Moreover, fruitful innovation in schools should rather be an incremental process building on current teaching practices than a revolutionary break (Bikner-Ahsbahr & Doff, 2019). These teaching practices are highly influenced by textbooks: on the one hand, textbooks specify the mathematical content; on the other hand, they shape the didactic style that teachers apply in their teaching (Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002). Thus, textbooks represent teaching practices as well as traditional resources. Taking this into consideration, to provide the potential for integrating a digital tool for learning in classroom practice, already the development of the tool should follow a user oriented design that supports students' learning and furthermore takes into account the textbook and teachers' practices and needs.

In the research and development project Multimodal Algebra Learning (MAL), the overall goal is to develop a digital algebra learning system (MAL-system) that supports the students' transition from arithmetic to algebra, however, this paper is restricted to linear equations. With the design of the MAL-system we want to overcome the disadvantages of using either digital or physical manipulatives by integrating physical manipulatives in a digital environment (Reinschlüssel et al., 2018). The subproject MAL textbook focuses on (A) integrating teachers' perspectives into the

design process of the MAL-system and (B) providing strategies for using the MAL-system facilitated by textbooks. This will be achieved by answering the following research questions:

- (1) What kind of teaching practices do teachers consider when confronted with the concept of the MAL-system?
- (2) What kind of needs for teaching do teachers address for the design of the MAL-system?
- (3) What kind of criteria for accepting or rejecting the MAL-system do teachers express?
- (4) Which principles for integrating the MAL-system into textbooks can be extracted from (1)-(3)?

This paper focuses on the methodical design of the MAL textbook study based on a Delphi study. It will show that this choice is fruitful to inform research and development of digital tools with teachers' practices. These practices are conceptualized in the subsequent theoretical framework.

## Theoretical Framework

In order to consider established teaching practices in the design of the MAL-system and, beyond that, to develop guidelines to include the MAL-system into established textbooks, the theoretical framework should address institutionalized forms of teaching and learning. This is possible by considering a theory that captures these teaching practices, the Anthropological Theory of the Didactic (ATD). The ATD (Bosch & Gascón, 2014) models human activities by the concept of *praxeology*. According to ATD, human activity splits up into a *practical* and a *theoretical component*. The former is broken down into a set of *types of tasks* and a *technique* that tells how these tasks are or might be carried out; the latter is broken down into *technology* and *theory*. The technology explains how and why a technique works. The theory comprises basic assumptions and views supporting and justifying the technology. In many cases, it is hard to reveal the theory because it is usually taken for granted. The practical component is often referred to as the know-how, whereas the theoretical component is the knowledge behind, in the sense of *raison d'être*. The set of all praxeologies of one person is called her *praxeological equipment*. In general a person's praxeological equipment emerges out of previous and current institutional settings including the people surrounding her.

## Algebra tiles and the MAL-system

The MAL-System is developed based on algebra tiles (Dietiker, Kysh, Sallee, & Hoey, 2010). Algebra tiles can be used for modeling linear and quadratic expressions and equations with integers. A small square represents the number one, a big square represents  $x^2$ , and a rectangle with the side lengths of the two squares represents the variable  $x$ . The three types of tiles usually have three different colors on one side and are all red on the other side. The red side indicates a "negative sign" (Figure 1 a). For modeling a linear equation a so-called equation mat with two distinct sides, left and right, is needed. By laying out the appropriate tiles, an equation is modeled (Figure 1 b). The equation can be solved by taking away or adding the same tiles on both sides and dividing both sides into the same number of equal sets. A subtraction zone – an area where all the tiles within are supposed to be subtracted – can be introduced; either to mark the difference of sign and arithmetic operator or to express subtraction without negative Tiles (Figure 1 c).

**Figure 1 a: algebra tiles; b: equation with negative tiles; c: equation with subtraction zone**

As the focus in this paper is on linear equations only,  $x^2$ -tiles are not addressed in this paper.

## Methodology and Method

In Germany, textbook authors are primarily in-service teachers. Therefore, they are familiar with established teaching practices in their schools and many of the teachers' needs for teaching. As these teachers author a certain textbook series in a team, they are also influenced by the teaching practices provided by this textbook series. Hence, their praxeological equipments are affected by their experience as teachers as well as textbook authors. This awareness of relevant praxeologies makes these teachers experts for the MAL textbook study to inform the design of the MAL-system through established teaching practices and relevant needs for teaching algebra. In order to gain main directions of consensus for adapting the MAL-system to these practices and needs, an expert study in the style of a Delphi study is conducted.

According to various definitions, any Delphi study comprises an expert group communication with several iterations and guided feedback to achieve consensus on a given question (Linstone & Turoff, 1975). The MAL textbook study conducts three iterations combining group discussions and questionnaires building on one another (Figure 2). Three groups of authors, working on books for three different performance levels are involved (*Math Alpha*: comprehensive school (covers and combines lower secondary education, secondary education and high school education); *Math Beta*: special school; *Math Gamma*: high school). These groups are selected because they cover a wide range of school types at different performance levels in Germany. The first iteration includes group discussions of the teams Math Alpha and Math Beta. Due to organisational reasons the team of Math Gamma did not participate. The topics are algebra learning, digital learning, gamified learning, and the MAL-system, introduced by a concept video. The second iteration includes all experts to answer an online questionnaire readdressing the topics from the first iteration by open and closed items. For example, the high relevance of the balance model to the experts came up in both discussions. As this was unexpected, the questionnaire asked for advantages and disadvantages of it within the whole expert group. In the third iteration, comprised statements based on the answers in the second iteration are evaluated by the experts. According to the example with the balance model, this iteration reveals tendencies on the central advantages and shows the willingness to make compromises concerning disadvantages.

The group discussions are audio taped, transcribed and analysed in a sequential way (Przyborski, 2004) based on ATD concepts to reconstruct the textbooks' and teachers' praxeologies, identify

teachers' needs and principles for textbook integration. The data set of the second iteration is analysed by theory-driven content analysis (Mayring, 2015) to capture individual praxeologies and needs based on the authors' experiences in school. The final data set is analysed by descriptive statistics to identify quantified relevancies of the praxeological elements from the iterations before.

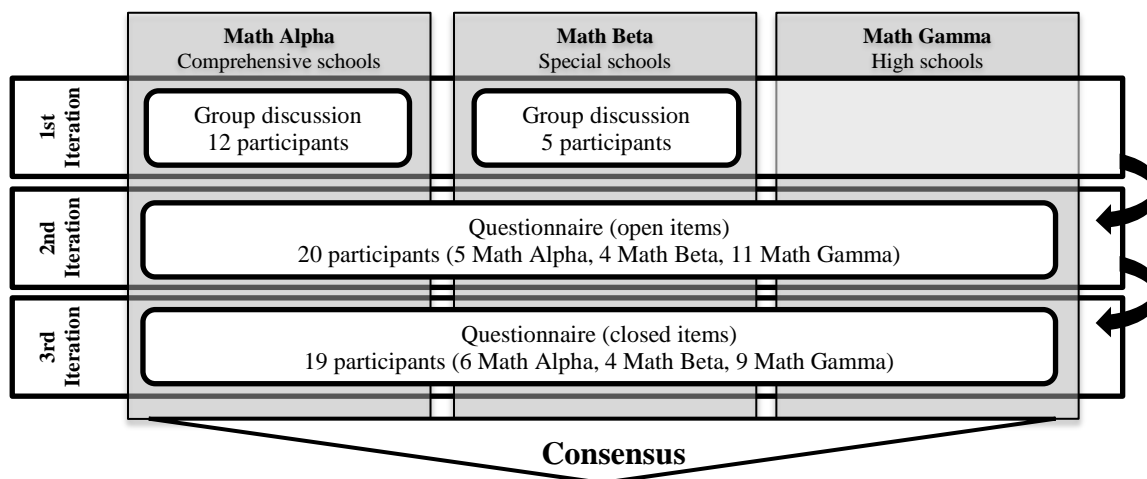

Figure 2: Procedure of the MAL textbook study

## Results

This section shows the three steps of data analysis applied to reconstruct the praxeological equipment of the expert authors. Presenting the results, we focus specifically on the balance model since the teachers have shown a strong commitment to it throughout the three iterations. Praxeological elements that came up while comparing algebra tiles and the balance model in the first iteration are presented. As the experts could hardly detach from the balance model while judging algebra tiles, the second iteration asked separately for advantages and disadvantages of the two models. The categorized range of experts' opinions extracted from data analysis is then presented. From the third iteration, the final evaluation of selected (dis-) advantages is presented.

### The first iteration

In the first iteration, the teams Math Alpha (12 participants) and Math Beta (5 participants) took part in a group discussion each. The researcher gave an introduction on algebra tiles and the experts were invited to work with them. Afterwards, the experts were asked if they can imagine using algebra tiles in class. Both groups immediately refused to do so, giving the same *technological*<sup>1</sup> arguments. Similar to expert A10<sup>2</sup>: “[the balance model] is just easier for the kids to understand” (#236-237)<sup>3</sup>, teacher expert B2 said: “the balance model is much easier” (#76-77) and narrowed to “more illustrative” (#78) by B3. Another *technological* argument that came up in both groups in the beginning is that algebra tiles are “too abstract” (A10, #238) or rather “very abstract” (B3, #82).

<sup>1</sup> The reconstructed praxeological elements are highlighted in italics.

<sup>2</sup> The experts from Math Alpha are named AXX and those from Math Beta BXX.

<sup>3</sup> (#236-237) refers to the lines in the original transcript that is not shown here due to the limited space.

In the discussion of the Math Alpha team, A1 then mentioned that “the problem of the balance model is clearly that I cannot express negative numbers with it” (#239). This was a turning point in the discussion towards algebra tiles, validated by three more experts. A1 continued to point at a *technique* based on algebra tiles: “one can slide the [...] *xs* that cancel out each other together” (#242-243). This was justified by the *technology* that “this [...] also always helps” (#243). At this point, the Math Alpha group stopped comparing algebra tiles and the balance model.

The process in the Math Beta group was slightly different. B6 presented a “counter *technology*” concerning two different *techniques*. One was working with the balance model on the iconic level; the other was working with algebra tiles on the enactive level. Based on the *technological* argument that the enactive helps in real life and the iconic does not, B6 saw an advantage of algebra tiles versus the balance model. Based on that, B5 suggested a didactic technique combining the two models. She started with the core *technology*: “the equal sign [...] means the balance” (#125-126) that was substantiated by the *technology* that the pupils should interpret the equal sign as a relational and not as an arithmetical sign. Based on that, her *didactic technique* related to the balance model began with using it, “this [equal sign] could maybe be introduced with the balance” (#126-127). But then B5 suggested to use algebra tiles “in the beginning really only using additive elements” (#128-129), before involving the subtraction zone or negative tiles. This was justified by the *didactic technologies* that the concrete action of laying out tiles is helpful and the subtraction zone “is a demanding conception” (#132).

This analysis shows that the experts’ praxeological equipments on teaching linear equations is highly bound to the use of the balance model. The experts could hardly think of *didactic techniques* involving algebra tiles that fit to their *theoretical arguments* and moreover they could hardly detach their *theoretical arguments* from the balance model. Even the positive statements on algebra tiles were mostly connected to weaknesses of the balance model. To reveal *theoretical arguments* detached from comparing the two models we asked for advantages and disadvantages of the two models separately in the second iteration.

## Second iteration

In the second iteration a questionnaire was sent to 37 experts. 20 of them answered (5 Math Alpha, 4 Math Beta, 11 Math Gamma) the questionnaire. The answers on the advantages and disadvantages of the balance model are summed up in categories in Table 1.

	Advantages	Disadvantages
Balance model	<ul style="list-style-type: none"> <li>• illustrative</li> <li>• intuitively accessible</li> <li>• enactive and iconic working</li> <li>• builds on students’ knowledge</li> <li>• prepares new knowledge</li> <li>• illustrates equivalence (transformations)</li> </ul>	<ul style="list-style-type: none"> <li>• no negative numbers or quadratic equations</li> <li>• hard to illustrate fractions</li> <li>• more enactive working needed</li> <li>• transition to symbolic level problematic</li> <li>• students do not know the balance</li> </ul>
Algebra tiles	<ul style="list-style-type: none"> <li>• illustrative</li> <li>• negative numbers and quadratic equations</li> </ul>	<ul style="list-style-type: none"> <li>• abstract</li> <li>• linking of area and term is difficult</li> </ul>

<ul style="list-style-type: none"> <li>• explain more than the balance model</li> <li>• link algebra and geometry</li> <li>• combinable with balance model</li> <li>• enactive and iconic working</li> </ul>	<ul style="list-style-type: none"> <li>• explanation takes much time</li> <li>• do not illustrate equivalence (transformations)</li> <li>• not intuitive for students</li> </ul>
--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Table 1: Categorized results of (dis-) advantages of balance model and algebra tiles**

We focus on the complementary findings in this iteration. As expected, the experts mentioned the core *technology* from the first iteration as an advantage: the balance model illustrates equivalence very well. In contrast, this is a disadvantage of algebra tiles, e. g. one expert from Math Alpha stated “[the] equivalence is taken for granted [...]”. This *technology* is connected to the *technological argument*: the balance model is intuitive for the students whereas algebra tiles are not.

The other way round, an advantage of algebra tiles is that negative numbers and quadratic equations can be illustrated. In particular, the lack of expressing negative numbers was mentioned as a disadvantage of the balance model several times. This also already occurred in the discussion of Math Alpha in the first iteration as a *technique* to favor algebra tiles.

The third iteration offers further clarity about the experts’ preferences by rating the findings above.

### Third iteration

In the third iteration, the 37 experts were again asked to answer a questionnaire. We received 19 answers (6 Math Alpha, 4 Math Beta, and 9 Math Gamma). Figure 3 shows the evaluation of the four complementary statements: (1) The balance model enriches my teaching because it illustrates the equivalence very well. (2) The algebra tiles are insufficient for my teaching because they do not illustrate the equivalence. (3) The use of algebra tiles would enrich my teaching because it can represent negative numbers. (4) The balance model is insufficient for my teaching because it cannot represent negative numbers.

**Figure 3: Ratings on complementary statements (BM: balance model; AT: algebra tiles)**

These results emphasize the importance of the core *technology* substantiating the use of the balance model. More than 80% of the experts agreed that the balance model enriches teaching because it illustrates the equivalence very well. In contrast to that, about 50% of the experts rated algebra tiles as insufficient for their teaching because the intuitive access to equivalence is missing. Only 20% did not take this as a barrier for classroom teaching.

The strongest advantage of the algebra tiles over the balance model is the possibility to represent negative numbers. More than 50% of the experts evaluated this feature as enriching for their

teaching, and only 10% disagreed on that. However, only one third of the experts evaluated the balance model as insufficient due the lack of negative numbers and as one half of them disagreed, the balance model was still rated positive on average.

All in all, the results show that the balance model is indispensable in current teaching practices, however, the lacking representation of negative numbers gives space for the algebra tiles to enter classroom practice.

## Discussion

The *didactic technique* - teaching linear equations with the balance model - reconstructed in the previous section reveals insight into current teaching practices. Independent of the type of school, the balance model turned out to be the most relevant model for teachers when teaching linear equations. However, the experts were aware of the problems and limitations of the model, e. g. no negative numbers, special kind of balance is unknown to kids, limited possibilities to explore equations concretely, aspects also discussed in the literature (e.g. Vlassis, 2002). Especially the missing representation of negative numbers points to a need in current teaching. The results from the third iteration suggest a complementary use of the two models allowing to address strengths of both models in a complementary way. We suggest introducing equations with the balance model by working enactively with the balance in class to make the students experience the equal sign as a relational sign of keeping two collections of weights in balance. The balance may then be readdressed in the MAL-system as a feedback symbol for equality when the students begin to work with algebra tiles. Starting only with positive tiles and additive equations, a balance in the middle, that is balanced or not (depending on the correctness of the actions carried out) instead of the equal or unequal sign is used.

As the authors *theoretical and technological arguments* on teaching linear equations are highly influenced using the balance model, it should not be replaced by the MAL-system. The balance model seems to be very fruitful for teaching in all the three types of schools in Germany since it provides intuitive access to the equal sign of equations and the equivalence relation. Addressing a current need like the representation of negative numbers which is missing in the balance model turns out to be a criterion for accepting the MAL-system. In addition, a careful integration of the MAL-system into textbooks could compensate the teachers' judgement of algebra tiles as being abstract. This could be done by creating a context that makes algebra tiles more accessible to students, for example by gamification or as an expanded digital environment for exploring problems. An important issue for increasing acceptance of the MAL-system is its correspondence to textbook praxeologies, as well.

Looking back to the methodology, the Delphi study with the three iterations has proven to be fruitful for investigating teachers' needs for teaching, their praxeologies and textbook praxeologies. The discussions have led to three important insights: the teachers' strong commitment to the balance model; contrasting the balance model with Algebra Tiles has made the teachers sensitive to disadvantages of a given technique that is normally not questioned; it has shown that a negotiation process is needed to disclose hidden needs for teaching underlying the praxeologies. The second iteration has provided the possibility to readdress aspects not considered before like the balance

model. The final questionnaire supplies a quantitative overview, showing possible differences according to the types of schools. In conclusion, the three steps of the Delphi study exactly fit the purpose of the MAL textbook study. As they are not tied to the topic of algebra, they unlock potential for further research on the role of textbooks in reform processes with a wider scope.

## Acknowledgment

## Project in preparation - Connected classroom technology (CCT) to enhance formative assessment in mathematics education

Mats Brunström and Maria Fahlgren

Karlstad University, Department of Mathematics and Computer Science, Sweden;

*Keywords: Connected classroom technology, formative assessment.*

### Background

It is well established that formative classroom practice in mathematics has a positive impact on students' learning and development. The widely used theoretical framework for formative assessment (FA) by Black and Wiliam (2009) identifies five key strategies and three agents (teacher, learner, peer). The strategies are:

1. clarifying and sharing learning intentions and criteria for success;
2. engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding;
3. providing feedback that moves learners forward;
4. activating students as instructional resources for one another; and
5. activating students as the owners of their own learning (p. 8)

The literature on formative assessment has emphasized the potential of technology to enhance FA strategies in mathematics education (Clark-Wilson, 2010). The European project *Formative Assessment in Science and Mathematics Education* (FaSMEd) investigated different aspects of the use of digital technology to promote formative assessment. Besides the five key strategies and the three agents introduced above, the FaSMEd framework identifies a third dimension consisting of three technological functionalities: (a) sending and displaying, (b) processing and analysing, and (c) providing an interactive environment. Interactive environment refers to a learning environment in which interactions, both between user and machine and between classroom participants, are based on mathematical exploration activities (Cusi, Morselli, & Sabena, 2017).

In the planned study, we will investigate educational use of the type of technology referred to as Connected Classroom Technology (CCT). Irving (2006) defines CCT as "... a networked system of personal computers or handheld devices specifically designed to be used in a classroom for interactive teaching and learning." (p. 16). To date, several studies, primarily conducted in the US, have demonstrated that CCT facilitates several FA strategies. This literature emphasizes how the 'sending and displaying' functionality of CCT can be used. For example, teachers could use CCT to access more comprehensive information about students' mathematical thinking which could be used to guide immediate adaptation of subsequent instructions (Shirley & Irving, 2015). Moreover, by facilitating the display of different student solutions, CCT can support the teacher in engaging students in whole-class discussions in which they receive feedback, both from the teacher and their peers (Cusi et al., 2017), providing a forum for reflection on their own responses in comparison to their peers. These activities relate to the third, fourth, and fifth FA strategy. Cusi et al. (2017) argue that this could also be a way to activate the first FA strategy by focusing on criteria for success when discussing different

solution strategies. Concerning the functionality, ‘processing and analysing’, CCT often includes a classroom response system (CRS) which processes student responses and presents statistics, e.g. in the form of charts (e.g. Clark-Wilson, 2010). In relation to the ‘providing an interactive environment’, Shirley and Irving (2015) describe how teachers have used CCT to collect and analyze student data received by laboratory-based investigations.

## Aim and study design

The aim of the proposed research and development activity is to develop design principles to guide formative teaching activities using CCT:

- principles for designing tasks that have good potential to make use of CCT facilities
- guiding principles for teachers in monitoring, selecting and displaying student solution(s) to use as a base for dialogues
- guiding principles for teachers in their choice of interaction type (e.g. group discussion, student presentation, whole-class discussion) in different situations
- guiding principles for teachers in the orchestration of various digital resources to enhance an interactive classroom in which all students are engaged

These principles will be refined through successive cycles of design-based experimentation, across a range of teaching contexts. In each cycle, the current version of the principles will be made operational in curriculum materials and teacher guides designed to support the use of formative teaching processes within a particular course unit. Through testing across a range of contexts in each cycle, and across a range of topic units over successive cycles, the principles – and classroom techniques through which they can be operationalised – will be refined.

The intervention to be developed and evaluated, then, consists of (a) the system of design principles to guide formative teaching activities using CCT, and (b) the operationalisations of these principles in the curriculum materials and teacher guidance for the (different) topic-specific course units designed in each cycle.

# Key Factors for Successfully Embedding a Programming Approach to the Primary Maths Curriculum at Scale

Alison Clark-Wilson, Richard Noss, Celia Hoyles, Piers Saunders and Laura Benton

UCL Institute of Education, University College London; [a.clark-wilson@ucl.ac.uk](mailto:a.clark-wilson@ucl.ac.uk)

*The ScratchMaths (SM) intervention was designed in response to changes in the primary curriculum in England to incorporate mandatory computer science - aiming to exploit this change in the interests of mathematics learning. In this paper we describe SM and its critical components for implementation with fidelity. We present preliminary case studies of two high-fidelity schools, which point to variation in fidelity of implementation. We conclude with a derivation of quantifiable measures for the identification of high, middle- and low-fidelity schools (O'Donnell, 2008).*

*Keywords: Primary mathematics, computer science, teacher professional development, coding, programme evaluation.*

## Introduction

In 2014 in England, the previous information and communications technology (ICT) primary curriculum was replaced by a new computing curriculum specifying mandatory content (but no pedagogical guidance) for the teaching of computer programming to all pupils (Department for Education, 2013). Some factors that contributed to Logo and other early programming initiatives not fulfilling their potential have been described in earlier work (Benton, Hoyles, Kalas, & Noss, 2016), a key factor being identified by Noss and Hoyles (1996) as the importance of fostering a sense of teacher understanding and ownership of any programming innovation.

There have been significant technological developments since this early teaching of computer programming, with a number of block-based languages such as Scratch now freely available and widely used. These environments have helped to address some of the difficulties of mastering programming syntax, but there remains the challenge of ensuring that teachers first appreciate why they are introducing programming as part of mathematics - and then have opportunities to develop appropriate skills to teach programming.

The ScratchMaths (SM) 2-year intervention<sup>1</sup> aimed to develop the mathematical knowledge of pupils (aged 9-11 years) through programming. The SM approach was to select and design activities around core computational ideas that would then be used as vehicles to explore specific mathematical concepts and promote mathematical reasoning. For example, the concept of variable is developed by enabling pupils to first explore the *Answer* block, initially on its own, but then in association with its companion block *Ask* in the context of a short script that draws polygons. Pupils encounter the limitations of the *Answer* block when confronted by a situation that needs the answer to contain two

---

<sup>1</sup> <https://www.ucl.ac.uk/ioe/research/projects/scratchmaths>

different values simultaneously, stimulating a need to introduce the new idea of **Variable**. This approach enables parts of computing to be taught within, or as a supplement, to mathematics lessons.

SM initially adopted a design research methodology to produce pupil and teacher materials along with professional development (PD) to support the teachers to exploit the powerful ideas of computational thinking as a way to engage pupils in mathematical thinking (see Benton, Hoyles, Kalas, & Noss, 2017 for a detailed account of the design of the study). SM is also being independently evaluated by another university through a randomized control trial (RCT, see Education Endowment Fund, 2016 for the detailed research design of the RCT). The first year's content (Y5 in England) focuses primarily on the computing curriculum and developing pupils' programming skills. In the second year (Y6), pupils utilise these programming skills to explore key mathematical ideas within the primary mathematics curriculum (place value, polygons and ratio and proportion). 111 English primary schools (6300 pupils) were recruited to the project by open invitation through networks such as the National Association for Advisers in Computing Education (NAACE) and regional information events. The schools were randomly assigned to the control and treatment groups at the school level. Schools did not pay to participate in the project and the teaching materials are freely available from the ScratchMaths website under creative commons licensing ([www.ucl.ac.uk/scratchmaths](http://www.ucl.ac.uk/scratchmaths)).

The primary research question for the RCT conducted by the external evaluators was "What has been the effect of the intervention on the development of pupils' mathematical skills as measured by a randomised control trial?" However, in parallel to this the authors of this paper sought to research how the curriculum materials were used by teachers to seek to understand its effects. The research reported here concerns the latter study.

### **Theoretical background of ScratchMaths and its pedagogical design**

The SM design was framed by constructionist theory whereby pupils would engage with the mathematical ideas by building programs to explore them. (See Noss & Hoyles, 2017). This constructionist approach was operationalized in a pedagogical approach structured by five key ideas, called the '5Es framework' derived from the theoretical underpinning of constructionism (Papert, 1980) and described in Noss & Hoyles (2017), see also Benton et al. (2016). These five unordered constructs are:

**Explore:** Pupils learn from computer feedback. Pupils should have opportunities to explore different ways of dealing with constraints and ambiguity as well as investigating their own and others' ideas and debugging different types of errors. Through this exploration pupils should be encouraged to take control of their own learning and understand the reasons behind different outcomes.

**Explain:** Pupils use different modes of communication to articulate learning and the reasoning behind choices of approach. Pupils should have opportunities to explain their own ideas as well as answer and discuss reflective questions from the teacher and peers. Pupils should be encouraged to use the programming language as a 'tool to think with' and to support explanations of key mathematical ideas.

**Envisage:** Pupils predict outcomes of their own and others' programs with specific goals prior to testing out on the computer. Pupils should be given opportunities to consider program goals and the

outcomes of different strategies before conducting their own exploration in Scratch. This should be balanced with activities which allow discovery through exploration.

**Exchange:** Pupils develop ideas through interacting and comparing with others. Pupils should have opportunities to share and build on others' ideas as well as being encouraged to both justify their own solutions and understand another's perspective on a problem.

**bridgE:** Pupils make links between contexts beyond the Scratch programming environment and the mathematics domain by explicit re-contextualization and reconstruction within the language of mathematics.

Our overall aim in developing this framework was to chart a course for pupils in which they could begin to express mathematical ideas in Scratch and to provide guidance for teachers on the pedagogical strategies (which the English National Curriculum does not stipulate) that could lead to successful implementation of the SM intervention.

### **Professional Development**

Prior to teaching each year of the SM intervention, teachers were offered two full days of professional development, spaced a few months apart. During these sessions, the teachers were introduced to Scratch and the SM curriculum content. The 5Es framework guided the design of these highly interactive sessions, with teachers given the opportunity to participate in activities that incorporated exemplars of these different pedagogical strategies. After experiencing for themselves the pedagogical approach, as modelled by the PD leaders, teachers were also explicitly introduced to the approach and the definitions of each of the constructs.

### **Curriculum Materials**

The learning objectives of all activities within the SM curriculum are focused towards one or more of the 5Es. The connection with the different constructs is made explicit within the teacher materials, with a range of activities such as Scratch-based tasks that require pupils to explore within the Scratch environment and then subsequently explain and exchange their programs with the rest of the class as well as 'unplugged' tasks (away from the computer) which require pupils to envisage outcomes of particular programs and bridgE to their existing mathematical knowledge to calculate the correct inputs.

## **Findings**

### **Measurable constructs for the fidelity of ScratchMaths**

Fidelity of implementation within an education context has been defined as "the determination of how well an intervention is implemented in comparison with the original program design during an efficacy and/or effectiveness study" (O'Donnell, 2008). Using the criteria of program differentiation, the SM team evolved some critical components for implementation with fidelity of the SM intervention, leading to the derivation of quantifiable measures for the identification of high-, middle- and low- fidelity implementation. There is a tension between a high-fidelity implementation of the original designed intervention and the potential for the intervention to be adaptable and flexible enough to fit within a range of contexts, which could lead to higher rates of adoption and sustainability

(O'Donnell, 2008). Therefore, finding an appropriate measure of fidelity that identifies the critical components of an intervention that must remain unchanged but allows for appropriation to local context was important.

The fidelity of implementation was defined in terms of five school-level measures as: days of professional development attended; availability of computer technology; curriculum coverage; the amount of time spent teaching SM and the sequence of progression followed through the materials. The criteria are given in Table 1.

<b>Fidelity criteria</b>	<b>High</b>	<b>Medium</b>	<b>Low</b>
Days of professional development	Y5 and Y6 teachers each attended at least two days of PD.	Y5 and Y6 teachers each attended at least one day of PD.	Y5 and/or Y6 teacher had limited PD from a more experienced person away from the organised sessions.
Technology	Computers running Scratch 2.0 online or offline.  Minimum 2:1 pupil to computer ratio.	<i>No classification</i>	Computers running Scratch 2.0 online or offline.  Minimum 3:1 pupil to computer ratio.
SM curriculum coverage	Pupils taught at least some of the core activities across 5 different modules.	Pupils taught at least some of the core activities across 4 different modules.	Pupils taught at least some of the core activities across 3 or fewer different modules.
Curriculum time	Time spent teaching SM is at least 20 hours in Year 5 and at least 12 hours in Year 6.	Time spent teaching SM is at least 12 hours in each year.	Time spent teaching SM is fewer than 12 hours per year.
Progression	The order of modules and order of activities are mostly followed in general.	The order of modules and order of investigations are mostly followed in general.	The order of modules is mostly followed in general.

**Table 1: The ScratchMaths fidelity criteria**

All schools participating in the trial received online surveys to complete at the end of the 2015-16 and 2016-17 school years to collect information about SM implementation. 28 of the 55 'treatment schools' provided data to both surveys and are included in our analysis presented below. Whilst a

more complete set of research data would have increased the validity and reliability of our findings, we could only work with the data that we received. Indeed, it is a finding that, despite their initial enthusiasm to participate in the project, with institutional participation agreed by the headteacher, approximately half of the schools did not respond to project communications. Hence the survey results of these 28 schools, alongside data triangulation by follow-up communications and school visits, were then used to classify the schools according to their fidelity.

### School level fidelity

The spread of fidelity scores for the 28 schools is shown in Figure 1.

**Figure 1: Spread of fidelity measures (n=28 schools)**

Probing the survey and interview data further revealed a number of findings.

**Professional development:** The school-level fidelity measure reveals high commitment to the PD. However, probing the data further revealed that 43% of schools were hampered by internal staff changes and teacher movement in and out of the schools (teacher ‘churn’). So, in fact the teachers who were trained did not necessarily match with the actual classes being taught SM.

**Technology access:** Only one school was unable to provide the pupil:computer ratio of at least 2:1, which resonates with recent OECD data on the high levels of computer access in UK schools (OECD, 2015).

**Coverage:** Three quarters of the schools reported that they had struggled to cover the SM curriculum. This was particularly evident in Y6 where the demands of the high-stakes National tests are great, with the result that a huge proportion of class time was spent ‘teaching to the test’ and associated revision activities.

**Curriculum time:** The allocation of curriculum time was challenging for about half of the schools, again more evident in Y6 due to pressures of the National test.

**Curriculum progression:** All of the schools were high fidelity in that they followed the order of the teaching modules and the activities within them. (In lower fidelity schools, teachers reported that they varied the sequencing or skipped activities).

This analysis identified 15 schools that were high fidelity for all five criteria. From this group, an opportunity sample of 2 schools was selected for follow-up visits and semi-structured interviews with teachers and headteachers during the 2017-18 school year, focusing on three general questions to elicit respondent's experiences and perceptions of the SM curriculum: How and why they got involved in the SM project? How they implemented SM, and what were their impressions of SM? Both schools were in the same geographical (rural) area about one mile apart. The resulting data was used firstly, to triangulate the fidelity judgement for each school and secondly, it was coded in relation to the 5 Es as a means to establish a deeper understanding of the quality of the implementation. Arriving at a school level judgement for a project that had spanned two years proved to be complex due to the differing experiences, perceptions and memories of the people involved.

The demographic information for the two schools is given in Table 2.

School	Number of pupils on roll	Scaled score in mathematics (100 = National expected score)	School progress in maths score <sup>2</sup>	% of pupils eligible for free school meals (Measure of socio-economic status)
School A	420	102	Average (-0.9)	28.9%
School B	424	101	Below average (-3.1)	3.6%

**Table 2: Overview of the schools<sup>3</sup>**

Although similar in overall size, the pupil demographic and attainment measures were notably different; one might have expected School A to achieve rather lower progress given the social background of the pupils. This difference is highlighted in School B's lower 'progress score', a comparative measure of pupil progress in similar schools. Both schools taught the SM curriculum in the teaching time allocated for the teaching of computing and none of the teachers in either school also taught mathematics to the same pupils. We now highlight aspects of the quality of delivery that were discernible from the research data, to provide deeper insight in relation to school-level implementations.

---

<sup>2</sup> A government-defined measure of school progress with respect to pupils' mathematical outcomes at age 11. [https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment\\_data/file/560969/Primary\\_school\\_accountability\\_summary.pdf](https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/560969/Primary_school_accountability_summary.pdf)

<sup>3</sup> 2017 data taken from <https://www.compare-school-performance.service.gov.uk>

School A was confirmed as a high-fidelity school as it became clear that the two teachers involved (Peter and Carol) had worked in a highly collaborative way and had both embraced the SM curriculum, dedicating their planning and preparation time to becoming familiar with all of the pupil activities in advance of the lessons, as highlighted by the following response:

Peter: You couldn't just pick it up and follow it, and then expect the children to understand. And, then we thought, 'Well, if we have got to spend this amount of time getting our heads around it, it is a big ask for the children to do it in the same time'.

Concerning the 5Es, Carol referred to the ways in which she encouraged children to *Explain*,

Carol: Once they got it, we kind of said, 'Well, try to show the person next to you, if they haven't,' and then sometimes, if they showed them one little bit, they were alright then...

Peter highlighted how the pupils *Exchanged* their ideas,

Peter: And, I make a point at the end of sessions now, I leave 15 minutes before the end so that anyone who has done what I have asked them to do, essentially gets to share their work. And, they absolutely love it, whether they have not quite got it, or they have done more... I put it up on the big screen for them.

In addition, School A had made the SM materials locally accessible and created files of exemplar student work, which had supported alignment between the two teachers' pedagogic approaches.

The overall fidelity criteria for school B was also confirmed to be high as the two teachers described how one of them (David) had taught the Y5 curriculum to both classes and the second teacher (Tim) had done the same in Y6. During interview, Tim described his pedagogic approach thus,

Tim: We sort of gave them the option to explore the bits and for them to ... trying to link it to the real world, to explain the steps behind it... why they have done what they have done, why they think it is may be more efficient or whatever. And as I say, I think we did the envisioning with a lot of the debugging ones [activities].

David commented on his use of the unplugged activities, highlighting how he encouraged pupils to *Envisage*, *Explain* and *Exchange* their ideas,

David: I would put up, for example, one of the algorithms and I say, "Well, what would this algorithm do if we clicked on it," and they would talk it through with a partner and then... I could pop one up on the board and say, "Right, what would this do?" And, "If we changed this bit, how would that change the outcomes?" and things like that.

## Final comments

It is hard to assess in such a large-scale study how far the implementation of SM was faithful to the designers' goals (Fullan, 2001). Many of these goals were generic, and we make no claim to originality on this score. For example, teacher 'churn' was both ubiquitous and destructive - quite

frequently SM teachers had not engaged fully with the PD. However, where we saw specific variation in fidelity, it tended to be related to the particularities of attempting a novel and demanding curriculum based on a somewhat daunting field of knowledge – programming – where teachers had little or no background. In such circumstances, the curtailment of teaching time due to the pressures of national testing was a strong impediment.

Clearly, some factors supported SM implementation: local access to the resources, exemplar student work and pre-written computer models. The excellent collaborative practice of School A that enabled them to overcome the challenges is noteworthy and echoed in other high-fidelity schools.

We noted little teacher adaptation at this first stage of implementation, but with more fluency and familiarity with the SM approach, this is likely to grow, leading, we conjecture to less emphasis on ‘curriculum coverage’ and more time to explore the mathematical ideas.

## Introduction

Proposing answers on how to create didactic objects that may provoke reflective mathematical discourse in the classroom, fostering students to make significant mathematical advances and transforming grounded conceptual understandings about certain mathematical concepts constitute a generic aim of instructional design research (Thompson, 2002). The design of didactic objects entails making assumptions on students' and teachers' way of participating in this discourse. However, there is a productive tension between teachers' intentions and actions when they design tasks and the students' activity when they are involved in them (Johnson, Coles & Clarke, 2017), that could be studied in more detail. Research into the design and use of mathematical tasks accommodating students' intentions, actions and interpretations to the same extent as those of teachers' is fragmented. Focusing on the use of digital media in mathematics education, the students' agency during the learning process and its confluence on instructional design could become more visible; students along with mathematics teachers may share the role of co-designers of digital resources that can be used as didactic objects. In this report we build on previous research about students' activity with a 'c-book' technology, a new digital environment where storytelling is blended with mathematical tasks (Papadopoulos, Diamantidis & Kynigos, 2016). But, now we make a step further, using c-book technology to put students in the role of the co-designer (the 'narrator') in the sense of building on the notion of design as a learning process and as a means to intervene in educational practice (Kynigos, 2015a). We focus on the question: How does the students' role as co-designer affect the mathematical meanings they make through the design process? In our research, we employed the Documentational Approach (DA) a framework hitherto used to understand and support teachers as they iteratively design and use resources in the classroom (Gueudet & Trouche, 2009), in order to understand classroom practice and student meaning making.

## Theoretical Framework

The focus of this research is on the design of a digital medium as a learning process; a group of teachers and students jointly design such a resource for learning mathematics through the pages of a

digital narrative. Assuming that the element of storytelling may provoke students' initiative, the design process could be a field of dense interaction between students and teachers. It could yield a series of digital artefacts (i.e. narrative meshed with constructionist digital 'widgets') as foregoing versions of the end product, along with discussion among the members of the group that refers mostly to argumentation about them, reconstruction and exchange of different versions of artifacts. From the constructionist point of view, this communication between teacher and students results to a learning collective where meaning making process occurs naturally (Papert & Harel, 1991). In this sense, the digital medium to be designed is more than a product for the designers' group; it may be an object-to-think-with (Brennan, 2015; Kynigos, 2015b). Especially for students, the design process of this kind of medium could foster the generation of new meanings around mathematics.

To investigate this aspect in detail we have chosen the approach of DA (Gueudet & Trouche 2009; Guin & Trouche, 1999) that describes the creation of new resources. Taking into account that DA has been used to study teacher's role as a designer of digital resources, we adopted it to study the students as they co-design resources with the teacher being part of the mathematics course. According to Documentational Genesis (DG) (Gueudet & Trouche 2009; Guin & Trouche, 1999), a 'document' is the set of the existing resources the designer uses together with the scheme of use for these resources in a certain class of situation; i.e. when a mathematics teacher constructs a certain task for teaching functions with a digital medium (this is the class of situation), he/she attaches a scheme of use for a set of resources (the curriculum, another related task, a discussion with other teachers etc), shaping a document. In parallel, this task can be a new resource for him/her or others. In this study, we have students collaborating with teachers in the design of new resources, shaping new documents about mathematics blended with the element of narrative, which might affect the set of the existing resources. Teachers, at the same time have their own teaching agenda. Thus, in terms of instructional design, the documents that teacher and students jointly create can be seen as didactic objects, as well. Thus, we found DA useful to help us enhance our understanding of a process through which new mathematical meanings for students may emerge.

In this paper, we present instances of students as they generate meanings around the concept of co-variation. Following Thompson and Carlson (2017) approach of co-variational thinking we build on the hypothesis that co-variation emerges when students conceptualize a situation envisioning two quantities varying simultaneously and dynamically. Quantity refers to students' conceptualization of an object's attribute that can be measured. A quantity is varying in the sense that students envision the object having momentary states, thus its attribute has momentary values (Thompson, 2002).

## **The Digital Medium**

### **The c-book technology**

C-book technology affords the design and use of modules named c-book units. Each c-book unit consists of a narrative blended with diverse "widgets"; hyperlinks, videos and mostly instances of digital tools like GeoGebra, DME (Digital Mathematics Environment) and MaLT2 (Kynigos, 2015b). DME provides also an authoring tool for the teacher to design new modules, while MaLT2 is a web-based Turtle Geometry environment which affords the design through Logo programming along with dynamic manipulation of 3D geometrical objects using sliders. GeoGebra and MaLT2 allow

customization and personal construction of tools (Healy & Kynigos, 2010) in the form of microworlds, fostering the meaning making process. The end users (mostly students) of a c-book unit can explore the narrative, experiment with the “widgets between the lines” and be involved in mathematical tasks. C-book environment also includes the “Workspace”, a tool that affords asynchronous discussions between the designers or the users of a c-book unit organized in ‘trees’ (Fig.1).

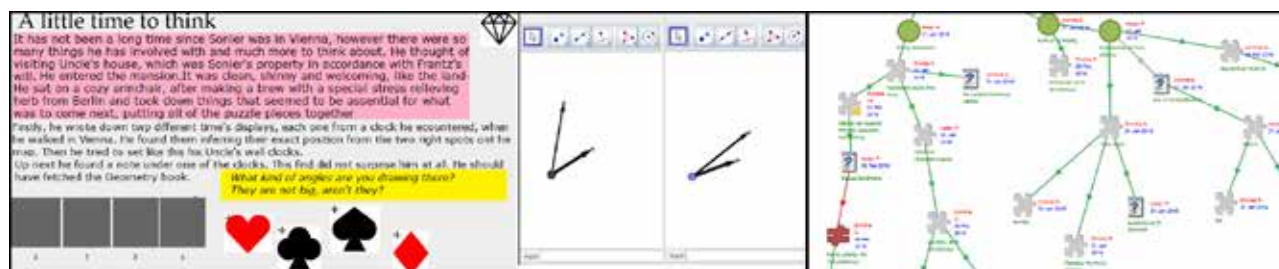

Figure 1: A c-book unit page on left hand side. The Workspace on right hand side.

## The Design of the Study

Jewelry c-book unit was jointly designed from scratch by a group of students and teachers, for the purposes of this study. The storyline in this c-book unit is about a dinky merchant named Sonier back in 1820 who got an inheritance after his uncle's death. However, the size of the uncle's assets was not clear, so Sonier got in a quest to detect the inherited goods. His adventure - full of math related riddles and playing cards - involved a trip from Berlin to his uncle's house in Vienna. His uncle's passion for gambling -in contrast to his love for mathematics- was well-known. Widgets were used by the designers' group to make up challenging tasks as parts of a riddle. A riddle was formed either by one task alone, or by a sequence of tasks, and the answer of each task was prerequisite for solving the next one and moving forward with the story. The plot was narrated through comic frames and text giving hints that might help the readers to solve the riddles (Fig. 1).

The group of designers consisted of three Grade-9 students in a public Experimental School in Athens (where teachers follow the same curriculum with other schools, adopting innovative teaching methods and/or conducting teaching experiments in collaboration with the University) and two teachers of mathematics. One of the teachers was the school teacher of the students and he additionally shared the role of the “participant observer”. The communication between students and teachers while making the c-book unit, took place exclusively in a shared digital Workspace. The whole process lasted almost two months. Students and teachers were exchanging ideas and widget drafts in the Workspace in order to discuss and decide their inclusion to the c-book unit. Whilst the students were akin to the use of digital media, they did not have the competence to make changes in an already designed widget, so when they wanted to suggest a modification of an existing widget, they used to “draw a picture” to inform their teachers. The 68 posts uploaded in the Workspace and the produced c-book unit constituted our data. The analysis of the collected data took place on the level of identifying and analyzing critical episodes defined as selected segments of (discourse) activity with a single theme as a focus in the discussion among the design group members in the Workspace (Kynigos & Kolovou, 2018). The focus in these episodes lies on instances that show how the storytelling affected the emergence of new mathematical meanings around co-variation.

## Results

The theme of “Jewelry” was used by the teachers as a sparker for the content of the c-book unit from the very first moment. As a result, one student posted in the Workspace a short story that triggered the whole group to make a decision about the main idea of the plot: The heir of a probably great but mysterious fortune. From the beginning of the discussion among students and teachers, the question “what kind of task should be constructed to be included in the c-book unit?” became the epicentre. Teachers (T1 & T2) proposed a couple of tasks, and posted them on the Workspace. The main issue for the reader was to fix a buggy-by-design diamond constructed in MaLT2 (Figure 2). The teachers’ aim was to underpin learning through tinkering. Students (S1 & S2) expressed a discontent, saying that this could be boring. Instead, they made a suggestion:

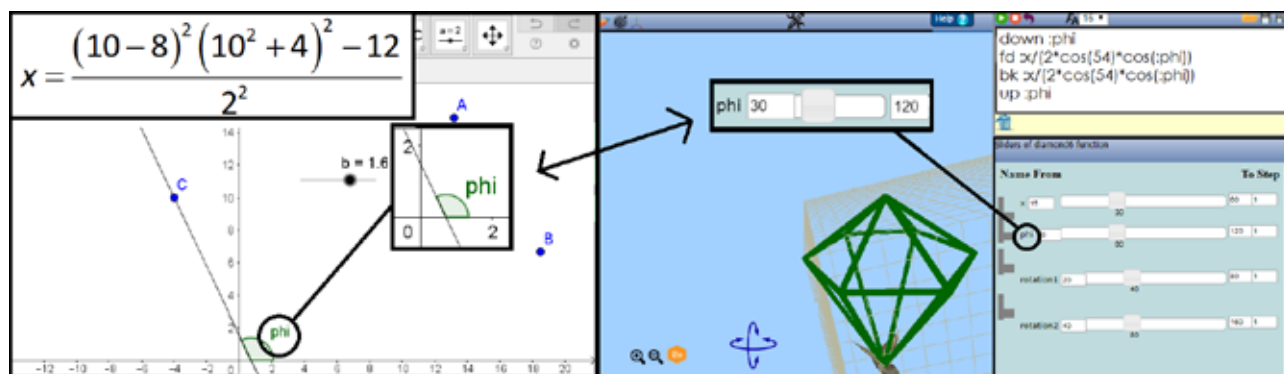

- 1     S1:            I think this could be a little boring. It seems better if we had riddles,
- 2                    not pure math problems; like an orientation game we recently played.
- 3     S2:            Yes! And the riddles could be connected to each other; you must solve one
- 4                    riddle before moving to the next, and go on with the story.

This was the designers’ first goal, to construct a ‘chain of riddles’ connected to each other in a way that the narrative would be garbled if one or more riddles remained unsolved. The teachers posted suggestions on possible twists of the narrative, including clues about riddles, as an effort to find out what a proper riddle might be for students, while students made their own suggestions. Soon, it was obvious that riddles’ selection would leave its mark on the narrative or vice versa:

- 5     S1:            The uncle could have hidden a different diamond in each room at his house.
- 6                    Sonier should replicate the correct diamond using MaLT2. The challenging
- 7                    thing is that Sonier should find the correct room number, by solving an
- 8                    equation, or by calculating a value of a variable  $x$  (Figure 2).
- 9     T2:            Why is it challenging?
- 10    S1:            It is more difficult to make these calculations, than having a number
- 11                    ready to be used.

In the previous extract, S1 uses the word “variable” referring to a numeric expression (Fig. 2), maybe just because the value of  $x$  is not obvious or easy to calculate. Students made a suggestion about a riddle, where the challenge was to unlock a room, by calculating  $x$ ’s value which was the door’s ‘key’. In the next couple of days students reflected on their design, inferred with frustration that if someone solves the door’ riddle once, then he/she had no interest in reading the c-book unit again, since he/she knows the answer:

- 12    S2:            The value of  $x$  must be different every time someone opens the c-book unit.
- 13    T1:            We could use a slider in GeoGebra.
- 14    S1:            T1, in which way? S2’s idea reminds me of a book I read. The story
- 15                    had many different endings. We could also do the same; the flow of
- 16                    the narrative can vary in relation to the value of the variable  $x$ .

**Figure 2: The GeoGebra widget-riddle on left hand side. The ‘diamond’-riddle in MaLT2 on right hand side. Designers used these artifacts in the c-book unit to form a narrative with alternate endings.**  
**On top left hand side: the ‘x’ of line 8.**

This might be considered the ultimate aim of the designers; A c-book unit that would be interesting to be read repeatedly. Soon, they realized that it was not feasible to have a different answer for the riddle every time someone opens the c-book unit. Hence, there was a shift in the group’s effort. They turned to the connection between the readers’ choices and the alternate versions of the narrative. Teachers made up a microworld that afforded the variation of a line’s position on the Cartesian plane, by the use of two sliders in GeoGebra, as a sparker for students to make a riddle. Therefore, the use of the slider came up again, as an option (Workspace):

- 17 T1: See the graph in GeoGebra. What changes when you move the sliders?  
 18 S1: The position of the line.  
 19 S2: We can relate the diamond’s shape that Sonier asks for, with the line.  
 20 T1: To what characteristic of the line?  
 21 S2: The sliders change the angle between the line and x-axis. We could imply  
 22 through the narrative that this angle should be equal to diamond’s angle.

It seems that the designers came up with the idea of using the notion of angle as an element that would give a potential relation between two riddles. Thus, students made up a story in GeoGebra as the first riddle. There was a map of Vienna on a Cartesian plane with a line on it. The position of the line was determined by two sliders. The reader should put the line in a position of his/her choice, in order to make a path. Then, using the size of the angle between the line and  $x$  axis in degrees, as a hint, the reader should fix the buggy diamond in MaLT2 (Fig. 2) that had been proposed by the teachers at the beginning; this was the second riddle. The twist of the narrative was depended on the diamond that was constructed, since its shape was crucial for the storyline. It seems that the designers used the answer of the first riddle as an output magnitude necessary for solving the second one. When the content (microworlds and narrative) was ready to be used, students suggested making a trial on how it works focusing on the use of constructions:

- 23 S1: We should play a couple of times, maybe more, to see how it works.  
 24 S2: Yes, we should draw a line that changes smoothly and normally in order to  
 25 coordinate its angle with the angle of the diamond.

So, the students tested the two microworlds many times, to observe if the variation of the line's position in GeoGebra had an elegant effect on the diamond's shape in MaLT2, through the common angle measure. Finally, they decided to use the same name 'phi' as the name of the variable for both the diamond's angle in MaLT2 and the angle in GeoGebra, too (the angles mentioned in line 25).

## Discussion

For the analysis of the Jewelry's design, under the lens of DA we have distinguished four phases. In the first phase, although they shared the same class of situation, i.e. to design a c-book-unit, students and teachers seemed to have their own separate agendas. Teachers suggested an instance with a buggy-by-design figure of diamond in MaLT2 which mostly promoted the added value of learning mathematics through tinkering, while students overrated the amusement of the reader. Furthermore, students at first almost rejected the microworld as 'pure mathematics' (line 2), suggesting to use riddles 'like in a game they recently played' instead of mathematical problems. This reaction may be in line with the hypothesis that students' set of resources was mostly related to storytelling, than to the design of mathematical tasks. This became more evident in the second phase, where the designers tried to make up riddles linked to each other, which probably is a good description of the new class of situation for the group. Despite the consensus on that, there was no common understanding of what kind of riddles should be used. Students made up an intriguing story about hidden diamonds in locked rooms, trying in the same time to involve a variable  $x$  as the 'key number' to unlock the door. We assume that they made an effort to use resources with mathematical content, such as a narrative based on the use of a variable, representing it with  $x$  (line 8). However, this effort was fruitless, since they did not manage to operate the variation of  $x$ . In the sense of co-variational thinking, the dysfunctional use of  $x$  seems to be congruent to Thompson's view (2002); although a person operates successfully on algebraic representations, it is hard to talk about the represented relationship. In the third phase, the aim of the design was more apparent. The riddles should be constructed in a way to provoke the reader to read the c-book-unit many times, which as a class of situation was more specific. To construct this kind of riddles, teachers proposed an instance in GeoGebra where a line changed position through the use of sliders (line 13). The core idea was to relate each time the 'key number' of the locked door to a different position of the line; Unfortunately, this did not work. It seems that the relation between sliders' manipulation and the line's changing position was not a usable case of co-variation for the students, since the varying attributes of the line might not be clear in the momentary states of its variation (Thompson, 2002). Using this kind of instance as a design unit might not be feasible for the students according to their scheme of use for their set of resources. However, students made a contribution which determined the final product, the c-book-unit as a 'document'. They proposed that the c-book-unit should have alternate endings, in order to be provoking. This idea, came up from a resource related with storytelling, (i.e. a book read by S1, line 14), and was soon adapted by the rest of the designers as the main goal of their efforts, during the fourth phase. Therefore, the role of instances-riddles was to give to the narrative the characteristic of different twists of the plot. To achieve this goal students and teachers used the instance in GeoGebra, along with buggy diamond in MaLT2, trying to 'link' them. Thus, it seems that they conceptualized this linking as a situation of two objects (the diamond and the line) varying simultaneously and dynamically. This became clearer, when students tried to coordinate the manipulation of the line in GeoGebra with the

diamond in MaLT2 (lines 23-25), so that a move of the sliders in GeoGebra should correspond to an ‘elegant’ and ‘normal’ change of shape of the diamond. This action seems to be in line with Thompson’s (2002) view of co-variation that points out the importance of coordinating actions among two attributes with an ‘operative image’ of their co-variation so that one can act out how the two are related. In phase four, students’ goal was to conceptualize and define a ‘co-variational relationship’ between two attributes; the position of the line in GeoGebra and the diamond’s shape in MaLT2. It seems that students, by making use of the two sliders that represented angles’ measures (one related to the line and another related to the diamond), they envisioned these two attributes’ momentary states varying simultaneously (lines 17-22). Thus, they decided to use a common variable ‘phi’ related with both angles as an operative image of the co-variation between line’s position and diamond’s shape, linking the two riddles. According to Johnson, McClintock, Hornbein, Gardner and Grieser (2017) students are facing fewer difficulties to discern co-variation among quantities (in the sense of Thompson) that can be measured with linear units. Building on this position, we assume that, in our case, students employed such a quantity ‘phi’ (that represented an angle’s measure) to define and use a ‘co-variational relationship’ among two objects/attributes (the position of the line and the shape of the diamond) that could not directly be measured.

## Conclusions

In this study, the focus was on the role of students as co-designers of a digital medium, a c-book-unit, i.e. a digital narrative blended with tasks and constructions with mathematical content. We used the DA theory to understand in detail the way new meaning around co-variation during the design process emerged. During the four phases of the design process the students’ set of resources and their scheme of use seemed to be in flux. In the beginning, the use of resources had mostly to do with storytelling. This changed progressively, and in the last phase a combination of narrative with mathematical resources was used. It was in this phase when, according to our analysis, students made meanings around the concept of co-variation, while ‘building’ a relationship for the needs of the storyline. It is remarkable that, after building this relationship, students tried to attune the mathematical content to the narrative, referring to the line in GeoGebra, as a path on a map. It seemed that initially, the differentiation between students’ and teachers’ resources and their schemes of use, worked as a barrier to the design process. However, from the analysis of the ‘document’ is evident that when resources were related to both narration and available mathematical tools, this led to the emergence of new meanings. From this point of view, it seems that when students act as designers using this kind of media, they take the role of both the storyteller and learner. Given the lack of research in this field, we believe that such enquiries should come up, assuming that these two roles -of storyteller and learner- should not be seen as separated, since the interaction between different kinds of resources was crucial for the design as a learning process.

# Addressing the problem of digital tools with digital methods

Jonas Dreyøe

Aalborg University, Department of learning and Philosophy, [jmd@learning.aau.dk](mailto:jmd@learning.aau.dk)

*Keywords: Digital tools, wicked problem, capacity building, data handling, digital methods.*

## Introduction

This poster presents a research design on how mathematics teachers can be involved in creating a shared understanding of their declared intentions and practices with digital tools in their mathematics teaching. The context of this poster is an ongoing PhD project with two strands. On one hand it aims to investigate and map the reasoning for mathematics teachers' use or non-use of digital tools (CAS, Spreadsheets, Dynamic geometry) in their practice. On the other hand, it aims to explore a method of high practitioner participation with data and digital methods. The project's research question is: How can the utilization of the workshop format inspired by participatory data design involve mathematics teachers in creating a shared understanding of their declared intentions and practices with digital tools in their mathematics teaching?

## Digital tools in mathematics teaching as a wicked problem

Digital tools heavily influence mathematics teaching on many levels. The presence of tools amounts to a more complex teaching situation, because the tools themselves affect the teaching (Tabach, 2013). On one hand the process of learning mathematics is different when the tools are used because they transform mathematical actions and goals. These transformations can certainly amount to new ways of learning mathematics, they also cause a series of problems and difficulties as the key mathematical operations can be accomplished without the students understanding the underlying mathematical processes (Jankvist & Misfeldt, 2015).

In this way, digital tools can amount to barriers in learning mathematics as a metacognitive shift towards the tool can occur instead of focusing on the mathematical concepts in question. On the other hand, it is also known that digital tools can increase children's mathematical horizon and competence. The mathematics teacher is thus situated in a dilemma; if digital tools are included without critique/blindly it can lead to learning difficulties. If they are not included the students' mathematical competence can be subverted. The usage of digital tools, that is the object of inquiry, in the Danish primary and lower secondary school can by this be viewed as a *wicked problem* – a problem, which does not have a single solution, but only more or less appropriate solutions. To handle a wicked problem, it is needed to create a shared understanding of the problem and consider concrete dilemmas (Rittel, 1972). Pedagogical research highlights collaboration as a valuable impetus for professional development of teachers. The aim of this project is to support capacity building of teachers by teacher collaboration and dialogue concerning their didactical practices and intentions with digital tools.

## Addressing and understanding the wicked problem by using digital methods

Collaboration and discussions among teachers can be improved and qualified if data about teaching and learning is included. It is especially recommended by the learning analytics field, which has shown that data can be utilized in facilitating well-informed decision-making processes. This project

thus aims at developing an approach where the collection and visualization of data is utilized to qualify teacher collaboration. Currently, there are different approaches to use data in supporting teacher work such as databased best-practice, as Hattie's visible learning project is an example of and using data to inform local development in improving professional judgment which Qvortrup's project about professional judgment is an example of. I aim to involve teachers even more in the handling of data. In facilitating such a process, I take my point of departure in Participatory Data Design, which involves stakeholders in the development and structuring of data that are used to describe, valuate, guide and develop the stakeholders' own work (Jensen et al., 2017).

	Provisioning	Selecting data	Visualizing data	Interpreting	Implementation
Participatory Data Design (Jensen et al., 2017)	E	P	P	P	P
Datainformed local change (Qvortrup et al., 2017)	E	E	E	P	P
Databased best-practice (Hattie, 2009)	E	E	E	E	P

**Practitioner participation in data handling; E = only Experts, P = Practitioners involved**

Handling of data in research projects can be described to work in five iterative phases. 1) A provisioning of data which entails in, figuring out what data is possible to obtain and cleaning the data for the intended use 2) Selecting the appropriate data for the concrete research purpose. 3) Visualization of the data to be able to see patterns. 4) Interpreting the data and visualizations at hand. 5) Implementing the decisions from the interpretations into practice. I propose a model to depict practitioner participation in data handling, where I have placed the three different approaches.

The ongoing PhD project will thus involve practitioners in as many phases as possible in data handling. And thus, provides a frame for investigating their declared intentions and practices in a way that both support data from their own classrooms as well as more generic data. This data will be interpreted and visualized in workshops with teachers, researchers and data-visualization experts collaborating. In this collaboration they will investigate the problem of digital tools in small groups and propose answers to why teachers would choose to use or not-use digital technology. These answers will inform the mapping of declared intentions and practices of teachers using technology.

## The forgotten technology. Teachers use of mini white-boards to engage students

*Keywords: Classroom techniques, discussion, learner engagement, peer teaching, problem-based learning.*

This day and age, the focus in education is for the most part on how we can use technology to make it easier for children to learn. While there is a lot of amazing technology that aims at this, we want to make the case that we should not throw away all the tools that are not part of the new wave. This poster focuses on the use of mini white-boards to engage students in their learning of mathematics. There might be things to learn from this forgotten technology when designing and implementing new technology into mathematics. This project arose from observations of an exceptionally talented teacher. The observation focused primarily on discourse, structure, and tools used. We were intrigued by the way this relatively young teacher utilized an old tool in the lessons to a seemingly great effect.

### The structured use of mini white-boards

#### Gathering the students

The teacher gathered the students around the Smartboard at the beginning of the class. Here, the students sit tightly together on benches without desks, where they spend most of a typical lesson. The teacher uses a PowerPoint presentation on the Smartboard, where definitions, assignments, videos, and students answer to homework assignments are presented for discussion. A main tool in these gatherings was the mini white-board, where they solved tasks and shared methods and thoughts. Hiebert & Grouws (2007) writes that the way a teacher chooses to organize their students, and in what way time is prioritized, plays a role in the students' opportunity to learn. By gathering the students around the Smartboard, the teacher signals that conversation is a priority. According to Lee (2006), such organizing will make the students more included in the conversation and increases the probability of conversation. By using a substantial part of the lesson for a gathering, the teacher prioritizes conversation and sharing of methods.

#### The mini white-boards

This mini white-board was a simple A4 sized white-board, which the students were handed at the beginning of the lesson. The students were given one to three minutes to solve the different tasks the teacher presented on the Smartboard. For example, the students could be asked to find the volume of different figures shown on the Smartboard, where the solution method was the teacher's primary goal. The teacher made it clear to the students that they had to write down their answers and how they came by them. They could also be asked to write their own definition of mathematical terms or more open tasks such as drawing three-dimensional shapes. Whichever task the students were given, the white-

boards gave them the opportunity to work by themselves for a short time, which in turn gave them the time to consider the given task. This method is henceforth called *individual work time*. The typical tasks were to do calculations, write definitions and draw explanations.

In one instance, the teacher told the students to write the answer right after the task was given, for then to show their answer to the rest of the group immediately. This direct approach makes the students give an answer fast, without time to think and without checking it against other students' answers. Making this approach is what Wiliam (2007) calls an *all-student response system*, as opposed to a *single student response system*, which gives the teacher an overview over which of the students got it right and which did not. This method is henceforth called *direct use* and might be used to fast check fluency and understanding of concepts.

After *individual time* and *direct use*, the white-boards were used in three different ways, which all started with the students showing their solutions or explanations. One way was to ask a student to explain their own method. A second way was to ask a student to explain another student's method. A third way was that the teacher selected a solution and explained the method. All this means that the teacher orchestrated the conversation by selecting student work and then constantly probing and pressing for information. The result is a practice with a strong focus on sharing and understanding student thinking.

Individual use		Plenary use		
Work time	Direct use	Students explain their own method	Students explain another's method	The teacher explains a student's method

**Table 1: The use of mini white-boards**

## The way forward

This work is part of a project (SUM) which purpose is to look at how inquiry-based learning can contribute to coherence in the students' motivation for and learning of mathematics at the transitions in the system of mathematics education. By utilizing these mini white-boards together with tasks where there is more time for inquiry, maybe we can involve the students more fully in the tasks given in the lessons in SUM. The findings in this poster will be used together with teachers to take a closer look at how this forgotten technology can help improve learning and understanding in mathematics. In addition, we have a long-term goal of using the insights from this forgotten technology to make our mathematics teaching with ICT more productive.

## Introduction

The DIM-project (Digital Interactive Mathematics Teaching) is a developmental research project exploring the use of digital tools in three lower secondary mathematics classrooms in Norway. One such innovation is the use of student-produced videos (later termed SPVs) as a medium for presenting strategies related to inquiry-based tasks. This idea emerged from the teachers as they wanted to explore different uses of videos in teaching, both teacher- and student-produced. The three-part lesson sequence used in the analysed lesson was developed by both teachers and researchers in a workshop. The aim for both teachers and researchers was to develop an approach for eliciting student talk in full-class mathematics discussions.

The transcripts originated from a follow-up discussion related to similar triangles and the use of this idea to measure the heights of objects, the task and lesson sequence is presented in detail in the methodology section. While planning the discussion, the teacher viewed SPVs to identify aspects of interest in the students' work. The teacher also used videos while enacting the discussion. As such, the paper addresses the topic of using student thinking in mathematics teaching. The paper aims to characterise how the teacher used the SPVs in teaching to promote students' active engagement in a full-class discussion. Our analysis is based solely on video recordings of the teaching, as the authors sought to investigate how looking through the lens of teacher moves can inform how the teacher is positioning the students in the discussion.

## Key concepts

Research has demonstrated that effective instructional practices demand students' mathematical talk (Walshaw & Anthony, 2008). To achieve this, teachers need approaches to elicit students' thinking and promote mathematical discussion. An area of interest for the teachers and researchers in the DIM-project is to foster what Goos defines as a community of inquiry; a classroom "...where students learn to talk and work mathematically by participating in mathematical discussions and solving new or unfamiliar problems" (Goos, 2004, p. 259). This moves beyond being mathematically correct as the students are "...expected to propose and defend mathematical ideas and conjectures and to respond thoughtfully to the mathematical arguments of their peers" (Goos, 2004, p. 259). An approach to studying such discussions is analysing the moves used by the teacher

to facilitate students' active engagement. Krussel, Edwards and Springer define a teacher move as "a deliberate action taken by a teacher to participate in or influence the discourse in the mathematics classroom" (Krussel, Edwards, & Springer, 2004, p. 309). In the following paragraphs, we introduce frameworks of teacher moves and actions used as guidance for the research presented in this paper.

Scherrer (2013) classifies twelve types of moves to investigate teaching practices in relation to theoretical notions of effective teaching. Scoring guidelines are used to code and evaluate the effectiveness of teachers' discussions, where each move is scored according to the surrounding moves. In this framework, the teacher moves that are prompted by student thinking generally receive positive scores. Scherrer refers to five such teacher moves, categorised as rejoinders, used to elicit and use student thinking rather than evaluate it. The moves categorised as rejoinders are uptake, collect, connect, lot and repeat. Uptake is an open-ended question that invites student thinking while using a student response to extend, clarify, or elaborate the discussion. Collect is a move aiming to provide different student responses to the same question. Connect is a question related to different responses and how they may be connected. Lot are occurrences where the teacher acknowledges a student's response and indicates that the topic will be revisited in the future. Repeat is a move related to echoing a student's response.

Mueller, Yankelewitz, and Maher (2014) perceive teacher interventions as crucial to introduce the students to the mathematical discourse. The authors state that "[t]houghtful interventions, implemented according to students' developing ideas, allow students to take ownership of their learning and solutions" (Mueller et al., 2014, p. 2). In order to investigate teacher moves, they present three categories which encompass student thinking; making ideas public, eliciting student ideas, and encouraging justification and explanations. In this paper, we use these categories as an initial coding scheme for the interactions. We expand the categories to incorporate the elements needed to investigate the use of SPVs to promote a community of mathematical inquiry.

We view the investigated episodes to involve a *didactical performance* in accordance with how the term is outlined in the framework of instrumental orchestration (Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010). This performance is the ad-hoc decisions made by the teacher within the orchestration. Teacher moves can be planned, but they also involve some aspect of improvisation from the teacher, as the teacher must manage the feedback provided by the students. The teacher's moves are related to specific didactical intentions. Such intentions are typically implicit rather than explicit. As such, the didactical intentions referenced in this paper are deduced by the authors based on observed patterns in the data. The teacher moves are integral in this process as they are used by the teacher to benefit the didactical intentions. In the transcripts analysed for this paper, the teacher is asking the students to explain why a solution "makes sense". Thus, the perceived didactical intention is "a discussion using a SPV to validate a strategy for solving similar triangles problems".

## Methodology

The lesson analysed for this paper was number two of in all four lessons the teacher enacted using SPVs in plenary discussions over a six-month period. Four lessons were video recorded from three

different teachers' classrooms totalling twelve lessons of about 45 minutes. All these lessons utilised a fixed three-part sequence. Part one is a group investigation of an inquiry-based task in school (see an example of such a task below). Part two is to present the work of the group in a video, this serves as homework, and every student produces one video and sends it to the teacher. Part three is a full class discussion related to the topic investigated in part one and two. The discussion is based on the presentations in the SPVs, and the teacher watches all the videos while planning the full class discussion. The transcripts used in this paper is from one such discussion. One of the aims of this paper is to pilot an analytical approach to investigate the discourse in these discussions. As such, one lesson was selected at random and analysed for this paper. The process of selecting a lesson was done by double-clicking a random folder.

23 tenth grade students and one teacher attended the 43-minute lesson analysed for this paper. The mathematical topic was similar triangles, and the lesson was a follow-up discussion at the end of this topic. One of the teachers in the DIM-project designed the task below after a brainstorming session at a workshop where both teachers and researchers attended.

The task investigated and solved in the SPVs was (the authors' translation from Norwegian):

*Look at the drawing (Figure 1). There is a mark on the wall (green dot). Nils has placed a mirror in front of him and placed himself so that he sees the mark in the mirror.*

*He can measure the following lengths; from the ground to his eyes, from himself to the mirror, and from the mirror to the wall. Can he, by using these measurements, find the final measure (from the ground to the green dot)?*

Figure 1: Drawing provided to the students (“Kan måles” translates to “Can be measured”)

*Record a video where you show your measurements and explain how you can find the height of the building. Also, show generally how you can find the sides of similar figures if you know measurements of some of the sides. Maximum 5 minutes.*

Data was collected using a video camera. The SPVs and the google presentation used in the lesson were shared with the first author before the lesson. The data was transcribed and translated by the first author.

The data was analysed using the approach presented in Powell, Francisco, and Maher (2003, p. 413). The authors perceive the process of analysis in seven non-linear phases (comments related to

our process in brackets); Viewing attentively the video data, describing the video data (data reduction), identifying critical events (identifying instructional episodes where student thinking is central), transcribing (selected episodes of interest for the topic of this paper), coding (using the codes presented in this paper and constructing new codes if needed), constructing storyline (looking at the context of the code), and composing a narrative.

The transcripts presented in this paper are from one specific episode within the lesson. The notion of an episode is to be understood as a sequence within a lesson related to a specific goal, with a specific didactical intent. There were six episodes in the lesson. The time-span of the episodes were from three to ten minutes. The episodes with titles indicating the content were:

1. Discussion related to misconceptions and issues identified in the SPVs
2. Introduction to figures often used in similar triangle problems
3. Discussion related to validating a strategy for solving similar triangles problems
4. Discussion related to validating a similar strategy for solving similar triangles problems
5. Discussion related to a different strategy for solving similar triangles
6. Discussion related to solving similar triangle problems using GeoGebra

The third episode was selected to be analysed for this paper based on; a SPV being shown in the episode, the narrative being constructed by both teacher and students, and being an episode of length fitting for the page constraints of this paper. The episode is mainly a conversation between the teacher and one student (Harald). The transcript also presents the narrative from the video (SPV) as it is central to the dialogue which emerges. Additional information is in square brackets. (..) is used to indicate a short pause in the narrative.

## Results and analysis

At the start of the lesson, the teacher elaborated on two issues emerging from the videos. The first issue was the definition of similar triangles, as some students stressed that all the angles *and* the shape had to be the same, not recognising that they are the same criteria. The second issue was a lack of explanation of why the two triangles used to solve the task were similar. This issue can be identified in the transcript below, from Svein's video.

SPV (Svein): Okay, if we have (..) for example (..) two triangles and all the angles are the same, and they have the same shape. They do not necessarily need to have the same size, but. (..) We can see that all the angles are the same in both figures. Therefore, these are similar. Okay, we measured from the feet to the eyes.

Teacher: And the measurements are here [pointing to the measurements on the screen].

SPV (Svein): It was 165 cm, and from the feet to the mirror, which is from here to here [points with the mouse on the video], it was 178 cm. And (..) we want to find the ratio between these, so we divide (..) 165 by 178 and get 0,926966 and so on. And then we measure from the mirror, which was here (..) to the church [points with the mouse on the video], because we wanted to find the height of the church. Eh (..) and we got 1448 cm. Eh (..) then we calculated 1448 times 0,9269 and so on. And

we got 1342,247 cm. And that is 13,42 m. So, from the church (..) up to here [points to the top of the church in their figure] it is about 13,42 m.

Teacher: And we will stop Svein there. Eh (..) we will look further later with. That is good. If you look at the drawing here, (..) the height of Svein or Harald, I do not know who is measuring, it is 165 from the ground to the eyes. And from the ground to the mirror it is 178 cm, and 1448 from the mirror to the church. And then he calculates that the church wall is 1342 cm or 13,42 m. My question to you; does this make sense?

The transcript above illustrates how the teacher guides the students towards his didactical intent. It appears as if the purpose for showing the video was an introduction to the task and one approach to solve it. The teacher interacts with the video to highlight the measurements used in the calculation, adding emphasis to the presentation in the video. We consider this a parallel to a pushback rejoinder move, to add emphasis to important aspects of the presentation through intervention. Pushback is usually done through a question, as in “could you point to the measurement?”. However, as the presentation is through a pre-produced video, the teacher elects to point to the measurements himself. It appears as if the objective is to make students reflect on how to validate that the strategy works; if this calculation makes sense. This is to be explored through a discussion, hence the didactical intent appears to be a discussion using a SPV to validate a strategy for solving similar triangles problems.

The teacher sets the scene to further the student’s presentation, all the while emphasising that this is the student’s work. Furthermore, it is not clear from the context of the question what kind of validation the teacher wants, as such; the request is an open-ended Uptake. As the question is also directly related to student thinking (presented in the video), the teacher is requesting the students to make their ideas public. In the following transcript, the teacher further establishes what such a validation entail.

Student: Yes.

Teacher: Why does it make sense?

Student: Because the church is about 13 meters.

Teacher: You know that, but I did not know that. But why does it make sense? It could be about 14 m. Why does it make sense? [awaits response]. If they had done it like this, divided 178 by 165, and found another solution. They chose to do 165 divided by 178, but if they had changed these numbers they would have gotten 1,079. And if they had taken the length to the church [14,48] and multiplied by 1,079 the answer would be (..) eh (..) they would have [looks in his notes]. I have not calculated it, but they would have about 1500. That is another answer. Why is one of them correct? You need to know the height [of the church] to say that it is 13 m. Harald, why does what you did make sense?

In this section, the teacher's idea of a validation becomes clearer. It would appear as if, in his view, the validation should result from the information at hand, not from prior knowledge. This might explain the decision to repeat the measurements from the students' work in the prior section, and not to go into detail about the calculations they used. Such negotiation of what the argumentation should entail is important in understanding what mathematical discourse is (Cazden, 2001). The teacher's statements exemplify the complex relationship between the planned teacher moves and the didactical performance of the teacher, used to bring the discussion towards a validation. At first, there is a rebuttal; the student knows that the church is about 13 meters, but this is not the kind of validation the teacher expects. This move must be ad-hoc as the teacher did not know the student's validation strategy before the question was asked. As the reinitiation of the original uptake is left unanswered, the teacher provides a starting point towards a validation, by changing the ratio and finding an alternative solution. The level of planning in this "thinking aloud" move is unclear, but one would assume that this is a pre-planned move being enacted. In this process, the teacher is limiting the cognitive demands from the initial "find a strategy to validate this calculation" to "find a strategy to determine which calculation is correct". The initial request to make ideas public is limited to following through with the specific strategy initiated by the teacher, by encouraging an explanation from one of the students with ownership of the work. The following extract shows the reply from Harald and the teacher's response.

- Harald: Because, if you divide 165 by 178 you get 0,9 and so on, (...) and if you multiply that by 178 you get the height of the person. But if you had divided the opposite way, and multiplied 178 by 1,078, you would have 180 and so on. That is not the height we measured. So, we have the ratio between the bottom and the height. Then we can multiply with the other height to find the height [of the church].
- Teacher: I will repeat what I perceive he said. He divided this by this [points to the ratio calculation] and got 0,9. And then he is saying that if you use that number, the bottom [178], and multiply by 0,9 you get 1,65. And then I understand you said that if you then take the other bottom and multiply by 0,9 you get this [points to the church height]. Did I understand you correctly?
- Harald: Yes.

In this exchange, the teacher obtains what appears to be a satisfactory validation in his view and confirms this through his comments. The teacher's moves are interesting, as the aim of the initial and follow-up moves was to get the validation. However, the rephrasing from the teacher does not stress the validation presented by the student. The student explained that the ratio calculated by the teacher would provide the wrong height for the person. As such, the ratio used by the group must be the right calculation in this situation, as it provides the correct height of the person. The teacher's rephrasing is mostly related to the overall strategy used and does not highlight the validation, *why* it provides the correct solution. This may be regarded as a missed opportunity to zoom out of the computational perspective and connect the task to the general proportional relationship, which underpins similar

triangles problems. While the teacher does acknowledge the backwards calculation to get the height of the person, it is not clear from the extract that this is the student's validation of the strategy.

Teacher: So, we must think about which numbers to multiply. Not just choose freely. But, there is also something logically correct with these numbers. Can you look at the numbers, why is it logically correct? You can keep going Harald.

Harald: Because the height is less than the bottom.

Teacher: Yes, do you see that the height is a bit smaller than the bottom here? [points to the smaller triangle]. Then it makes sense that this [points to the church's height] is a bit smaller than here (..) to the church [from the mirror to the church]. So it makes sense. Okey, now there is some red text [in the teacher's notes]. You get two minutes to write. What was Svein and Harald's strategy?

The student's affirmation regarding the teachers rephrasing is followed by two statements, or "words of warning", to conclude Harald's validation. The statement "...think about which numbers to multiply" is the key to the deduced goal of the episode, to validate why the initial strategy worked. The student's idea of backwards calculation showed this, but as the teacher did not highlight this during his rephrasing, it might get lost on the students. Rather than generalising or expanding the idea, the teacher moves on to another strategy, by relating the question directly towards the measurements and visual information. It appears as if this is what the teacher was working towards the entire episode. Evidence of this is the emphasis on measurements at the start of the episode, and the need to introduce two approaches to validate the strategy provided in the SPV.

### Concluding remarks

To encourage students' active engagement in mathematical discourse is instrumental in establishing a community of mathematical inquiry. In the transcripts provided, the process of negotiating what a validation entail is directly related to student work. By addressing the students and narrowing the initial uptake to steer the discussion towards the goal, the teacher appears to get a satisfactory validation. Still, the analysis illustrates the need to dig deeper than codes, exemplified by the teacher's rephrasing of Harald's idea of backwards calculation. The teacher validates the student's response. However, he de-emphasises what we perceive to be an important contribution to the discussion. Furthermore, the teacher keeps a computational perspective throughout the episode, not zooming out to connect the discussion (and initial task) to the concept of similar triangles in general. To account for such instances, we emphasise the need to analyse transcripts qualitatively as oppose to quantitatively to understand the potential of the moves throughout the discussion fully.

The three-part sequence presented in this paper might unlock possibilities for more active engagement from the students. More work is needed to understand the potential of this model. In future work, we aim to incorporate the teacher's perspective and to investigate the design process of the individual teachers in the main study. We made a conscious decision to only use the video recordings as data for the analysis in this paper as one of the aims was to investigate the potential of using the lens of teacher moves to analyse mathematical discussions. The analysis showed that the teacher utilised teacher moves to steer the discussion towards the didactical intent, and the goal of

the episode. In the future, we hope to contribute to the understanding of both the intention and impact of teacher moves in a classroom discussion.

In the context of the Norwegian school system, digital tools are on the rise. Such tools are integral in the framework presented in this paper. Throughout the discussion, the teacher utilised the interactive blackboard in varying ways. To play videos, pause at desirable moments and show actual student work are integral elements in the design of the lesson. These elements enable the teacher to use students' own voices extensively throughout. However, the implementation of such ideas does require a lot from the teacher. In the analysis presented, we realise the importance of both being alert and open towards student ideas and being conscious about the goals of the episodes. The episode investigated is illustrative of this dialectic relationship. Although it would appear as if the teacher had a specific validation strategy in mind when the episode starts, he does not avert from Harald's strategy of backwards calculation. Not only does he confirm that the student's idea is usable to validate the strategy, he also repeats the idea while acknowledging that this is the student's work and not his own.

*Keywords: Silent video task, formative assessment, task design.*

### Introduction

This poster presents the development process of assigning silent video tasks and the criteria a video must fulfill to be eligible to be used as a silent video task. Some preliminary results regarding the use of silent video tasks in four different Icelandic upper secondary school mathematics classrooms were presented at PME42 in Umeå, Sweden and at the 5th ERME topic conference MEDA in Copenhagen, Denmark in 2018. These presentations were focused on teachers' role in assigning tasks and using technology in mathematics classrooms; teachers' expectations and experiences with using the silent video task in their classes (Kristinsdóttir et al., 2018). During the discussion at these conferences, it became clear that a more precise definition of the silent videos and the silent video tasks was needed. This poster presents results of further work towards such definitions.

### Using silent video tasks in the classroom

The process of assigning a silent video task involves selecting a silent video; showing this video to the whole class; giving students the link to the video to watch as often as they want; dividing them into groups of two; and asking each group to prepare and record their voice-over for the video. The teacher acts as a facilitator, encouraging students e.g. by asking them to bear in mind that their solution might help their peers to gain access to the mathematics shown in the video. In order not to restrict this open task in any way, no list of concepts for students to address should be handed out. In case students find it hard to start recording, a suggestion for them to draft a script might be helpful.

By only assigning the task something might be gained, but to reach the full potential of the task, discussing the solutions in a follow-up lesson is key. By listening to the students' solutions, the teacher prepares a whole-group discussion for the follow-up lesson. Usually the range of solutions shows how differently students think about what is presented in the video. Either the teacher selects some solutions to show in the follow-up lesson (e.g. if there is a sequence of solutions ranging from everyday language to a more formal mathematical language) or asks students to volunteer for presenting some example solutions. The preparation involves listening for topics to address in the follow-up lesson discussions, e.g. different levels of conceptual understanding and precision in language use. After the whole group discussion, students can be asked to write about their experiences.

The goal is, on the one hand, to encourage students to engage in discussion about the mathematics shown in the video. On the other hand, the goal is to make misunderstandings and imprecise word use accessible to the teacher so that they can be discussed. In this process, students might get aware of that explaining mathematics to others can bring them to understanding it better themselves.

### Potentials of the silent video tasks as a tool for formative assessment.

Improving students' learning should be at the forefront of assessment practices (Suurtamm et al., 2016). In silent video tasks, students get the opportunity to explain to others and to receive explanations from their classmates. Students' discourse is encouraged both in the process of preparing students' solutions and in a whole class discussion in the follow-up lesson (Kristinsdóttir et al., 2018).

Even in mathematics classrooms where discussion was seldom or never practiced, silent video tasks showed to be easily implemented, and students put their thoughts into words as they explained the mathematics shown in the video. In the process, they may become aware of aspects of the mathematics that they have not yet fully understood. Also, misunderstandings and imprecise word use can be addressed explicitly by the teacher with reference to the student solutions in the follow-up lesson.

After the follow up lesson, decisions about the next steps in instruction are likely to be better founded and the process could fulfil Wiliam's definition (2011, p. 43) of formative assessment. Wright et al. (2018) list six potentials that technology-based formative assessment strategies have to support learning: providing immediate feedback, encouraging discussion, providing a meaningful way to represent problems and misunderstandings, giving opportunities to use preferred strategies in new ways, help raising issues that were previously not transparent for teachers, and providing different outcomes feedback (Wright et al., 2018, p. 219) and the silent video supports all but the first one.

### **Requirements for videos used in silent video tasks**

To be used in a silent video task, a video should be short (less than 2-3 minutes in total), with no text or sound, and show mathematics dynamically. The theme should be as clear and focused as possible (not try to squeeze in too many things) and the video should offer different descriptions, aiming at exposing the students' different levels of conceptual understanding. Some proofs without words (e.g. <https://ggbm.at/jFFERBdd>) might serve as an example but the video themes are not only restricted to proof. They can also include definitions such as the general definition of the sine and cosine functions using a unit circle (e.g. <https://ggbm.at/BfRqGSKq>) or rules like how the area of a triangle can be calculated (e.g. <https://youtu.be/xnPworcoGcM>). These ideas will be presented in the poster with additional details.

### **Introduction**

Understanding three-dimensional representations on a two-dimensional representation system can be challenging. It mainly means to be able to understand around a virtual dimension additionally to the representation of two dimensions. With the advent of production technologies that can quickly generate three-dimensional objects, being able to construct in three dimensions is becoming a key skill. Especially, since 3D printers have become widely available due to declining costs. Being affordable by schools, a 3D printer can help teachers to explore mathematical concepts with their students by printing their own materials. Knill and Slavkovsky (2013) claim that while models in the real world do not help much to prove mathematics, they do very much help in understanding the results of mathematics. In this poster, we intend to share with the Mathematics Education community how teachers can use 3D printing examples to trigger students' internal needs to develop mathematical proofs. In other words, through the manipulation of models students could feel the necessity to prove their observations or conjectures from their interaction with 3D printing. We feel that often students are "forced" to prove theorems that they don't have internal connections, but in this case, if students ask themselves whether or not it is sufficient to use a particular case to generalize cases they could be motivated for proving.

These daily life demands can also trigger fruitful discussions to mathematical ideas, particularly in 3D environment. Due to that, we consider the importance of sharing new approaches among teachers and exchange perspectives in how these initiatives with upcoming technologies can contribute for mathematics teaching.

### **3D printer at schools**

The use of manipulatives in the classroom has been advocated for a long time. In his work, Post (1981) brings perspectives from Lesh, Piaget, and Dienes, who emphasize the importance in applying concrete materials with students, especially the young ones. The increasing application of 3D printing in different areas led us to discuss possibilities for using it in education settings, as creating, adapting and printing such manipulatives. Lieban et al. (2018) discuss ideas, and describe activities that make use of 3D printing in the school context. Some of the objects explored were logical games. They were developed in GeoGebra and Tinkercad, and then printed in a 3D printer.

These two resources were chosen due to their intuitive interface for educational purposes, and friendly connections with 3D printers.

Besides enhancing modeling competencies, these approaches with 3D printing can be a good opportunity to promote a student-centered learning environment. Students increase their motivation when working on activities that they create themselves (Nussbaum, 2013). In addition, moving from playing to making games, teachers and students develop skills that go beyond mathematics, like communication, creativity, collaboration and critical-thinking, the 4C's for 21<sup>st</sup> century demands.

**Figure 1: Game that already exists were adapted and explored by students and teachers**

### Perspectives in using 3D printing

The feedback from both experiences we had using 3D printing, which includes a school in Canada and a teacher-training program in Israel, opened our minds and booster our desire to explore further this powerful tool. We are now focusing in manipulatives that foster mathematical explorations, either to facilitate spatial reasoning or to open questions and discussions from them. Our first step in that direction is to evaluate a range of materials that are already available online in collaborative platforms (e.g. Thingiverse, GeoGebra, Tinkercad, ...), and from which users can easily download a printable file. We are collecting, adapting, and testing many of these materials and evaluating their perspectives for using them in different levels of education.

### Proposal

The digital poster will present some perspectives in using 3D printing for mathematics teaching in different educational levels as well as how can these physical manipulatives be integrated with other digital tools. Some examples will be shown and explained, even as printouts in 3D.

*In this paper, we investigate mathematics teachers' conception of the relationship between mathematics and programming. The context of the investigation is a recent curriculum reform in Sweden that makes programming a compulsory element of the national mathematics standards. Following up on an in-service training initiative, we conducted a pilot survey (N = 133) exploring – among other things – the teachers' conception of the relationship between mathematics and programming. The results suggest that the teachers, on average, feel that there is a strong, but not very strong, relationship between the two subjects. Furthermore, the results suggest that mathematics teachers are interested in working with programming but that they do not feel well prepared for taking on that task. These results are used to discuss the mathematical potential of the different ways in which compulsory programming can be introduced in schools.*

*Keywords: Programming, mathematics, computational thinking, curricular changes.*

## Introduction: Programming as a new element in compulsory school

Programming, computing, computational thinking (Wing, 2006), technology as a subject, and similar topic formulations are currently being included in the curriculum of compulsory schools in many countries. The purpose of these changes is ostensibly to support students in becoming technologically literate and able to participate in the society of the future, as well as to promote STEM careers. Different countries are taking different routes to implement this change. In Great Britain, the main idea has been to develop a computer science curriculum as a new topic, whereas other countries such as France, programming is included in the mathematics curriculum. European approaches to computing in schools differs (Vahrenhold et al., 2017) but most countries have technological skills and literacy as increasingly important objectives of K–12 teaching students, and they share the challenge of building the necessary teacher capacity (Wilson et al., 2010).

The specific relationship between mathematics and programming have been explored by scholars such as Papert (1980) and Dubinsky and Harel (1992) and we know that the potential for learning mathematics through programming depends on a number of other contextual factors (Misfeldt & Ejsing-Dunn, 2015). Investigations of the relation between programming and mathematics, have typically taken aim at the potential of using programming as a vehicle for developing mathematical competence. The current situation is almost the converse; programming is included in the national curricula and standards and mathematics, is in some cases used as a vehicle to meet that goal.

In Sweden programming became a compulsory part of mathematics (and science) in autumn 2018. Therefore, several in-service activities have been developed and were already started in spring 2018 and all three authors of this paper have been involved in the development. As part of this work, we

decided to conduct a survey of how Swedish mathematics teachers have experienced the introduction of programming as a topic in their teaching. This paper is our first report on the data from this survey<sup>1</sup>, and we will continue by describing the Swedish situation and then go on to the theoretical understanding that underpins our work, as well as our method. In the last part of the paper, we present descriptive statistics on the teacher's conception of the relationship between mathematics and programming in his/her class. We end the paper by discussing how to implement programming in relation to mathematics in light of the presented results.

## **An in-service professional development program in Sweden**

The structure of the Swedish national curricula of both primary and secondary mathematics (grades 1–9) as well as upper secondary school builds on certain special “central content,” such as algebra, numbers, statistics, and geometry as well as five to seven competencies (e.g. problem solving, reasoning and communication). The grading criteria mostly relate to these competencies. Programming has been included in school mathematics through the revision of the curricula, in which it is referred to in connection with the specified central content.

The Swedish National Agency of Education is responsible for the implementation of programming in grades 1–12, while Swedish schools are governed by municipalities, companies, or nonprofit organizations. The National Agency has arranged courses in programming for teachers. These courses are not related to mathematics teaching but are simply oriented towards developing the teachers' own programming competency. To attend to the didactical question of how to include programming in mathematics teaching, the National Agency also decided that specific professional development (PD) modules should be designed<sup>2</sup>.

The context for the creation of these modules is that Sweden has recently carried out a large-scale PD program involving all teachers of mathematics in grades 1–9 and in upper secondary school. Boesen, Helenius and Johansson (2015), describes the program and effect and Lindvall, Helenius and Wiberg (2018) describes the program theory that was used in the initial design. Briefly, the program consists of several different PD modules that teachers may choose among. These modules were designed by researchers and teacher educators. Each part of the module follows a cycle in which teachers first study the PD material individually (60 minutes per part), then meet in groups and discuss the PD material and plan lessons together (90 minutes), after which they carry out those lessons with their regular classes (one lesson), and then again discuss the material and the lessons (60 minutes). Schools are monetarily compensated for teachers to attend two such modules, but the modules are free to use for teachers or schools that want to do more PD. As support for the implementation of programming in school mathematics, the National Agency decided that a special programming module should be designed. The first and third author of this paper were part of the

---

<sup>1</sup>Since the data collection is ongoing, this paper can be regarded as a pilot study. More results and insights will be explored further in the continuing work.

<sup>2</sup>The digital material supporting the professional development program can be found here: <https://larportalen.skolverket.se/#/moduler/0-digitalisering/alla/alla>

design team. We describe the conceptual framework underlying this module below, but one interesting difficulty was that the level of programming competency among teachers was unknown. From reviewing teacher education, based simply on our background knowledge of Swedish teachers, we knew that their programming knowledge and experience were probably rather basic and probably lower the earlier in the school system that the teachers taught. However, at the time, the time frame available for the design of the module did not allow more research into this question. The future effects of such a large-scale programming reform will be interesting to follow up, and as an aid to better understand such effects, we carried out a survey among 133 teachers. The intent of this survey was to establish a knowledge base for understanding the situation among teachers now and to form a basis for further longitudinal investigations. The present paper describes the design of this survey by relating it to some of the ideas we developed when constructing the PD module and presents some preliminary survey results.

### **Conceptual framework and ideas about the relationship between programming and mathematics**

When designing the PD module, a view of mathematics that we found helpful was the Piagetian-based work by Vergnaud, in particular his work on representations (1998). Briefly, mathematical ideas (concepts, theorems, etc.) are, on one hand, related to situations where some particular mathematics makes sense and, on the other hand, related to representations, such as language or other semiotic systems used to signify mathematical matters. Vergnaud's reasoning can be extended to programming, but here, situational phenomena are instead represented in terms of programming code. A real-world situation hence can be modelled either by programming code or by mathematical concepts. Moreover, for understanding, analyzing, or improving the code, it may often make sense to use mathematics, and conversely, if a mathematical model of a situation already exists, that can often be translated into code. This creates an interesting and quite complex dynamic among real-world situations, the world of code and the world of mathematics.

This prompted us to consider two different programming situations in relation to mathematics. Type 1 is where the programming concerns some concrete phenomenon – to take a classic example, a model of a turtle moving in some particular pattern. For type 1, mathematics is not necessarily a part of the modelling of, for example, the turtle's movements. This modelling can be done purely in programming code. Therefore, for mathematics lessons based on type 1 programming, the teacher must assume the responsibility of extracting or inserting mathematics into the lesson. Using the work of Misfeldt and Ejlsing-Dunn (2015) on programming and mathematics, we described three intersecting points or potentials: (1) viewing students as producers of code; (2) supporting abstract thinking; and (3) developing algorithmic thinking. Awareness of such potentials could, we hypothesized, assist teachers when helping students to mathematize their work in type 1 situations.

The type 2 situation, is when the programming part concerns something that is already mathematical, as in using programming to build a mathematical tool, solve a mathematical problem, or to explore mathematical phenomena. In type 2 situations, the mathematics is already relatively fixed, but an important responsibility of the teacher, particularly when working with pupils who are programming novices, is to make sure that the pupils are properly introduced to elements of

programming that can be useful in approaching the mathematical problem at hand (Guin & Trouche, 2002).

In order to investigate the teachers' ideas about the relation between mathematics and programming empirically, we have chosen to focus on how the teachers conceptualize this relation. We use the notion of *conceptions* to signify what the teachers think are important aspects of the relation between the two areas of knowledge. Our construct of conception is built upon the same constructivist post Piagetian approaches as our mathematics education approaches (Papert, 1980; Vergnaud, 1998), and as a consequence, active articulation and representation of the relation between the mathematics and programming plays a critical role in shaping individual conceptions. We explore the conceptions through questions focusing on importance of the relation, preparedness of the teachers to teach programming and the qualities of the relations between the two topics, based in the three intersection points from Misfeldt and Ejsing-Dunn (2015).

## **Methods and instruments**

To understand how the change in curriculum and the work in the PD modules are experienced by Swedish mathematics teachers, we designed a survey addressing various aspects of these issues.

### **Participants**

The participants were teachers from school years 1–12 in municipal schools in Stockholm. Some months before the study, the participants attended seminars organized by the Education Administration that aimed to facilitate the introduction of programming into school mathematics. Prior to these seminars, the participants – as well as the vast majority of Swedish mathematics teachers – had no formal education in and very little experience in programming. When attending the seminars, teachers submitted their email addresses, and these addresses were subsequently used to contact them about the survey. Answering the survey was optional, and the teachers were guaranteed anonymity. After the responses were gathered, the teachers who responded received the opportunity to participate in the present study. They were informed that their answers and personal data would be stored according to the current GDPR regulations. Currently, 133 teachers have chosen to participate in the study, 77% (102 teachers) from primary school and 23% (31 teachers) from upper secondary school – however, not all teachers answered every question of the survey.

### **The survey**

The survey was developed by the authors of this paper; the included statements are based on the revision of the Swedish curricula with regard to programming in mathematics, on feedback from teachers at seminars about introducing programming, and on authors' experience of designing PD programs for mathematics teachers. The statements deal with 17 topics, representing the categories: a) teachers' prior experiences of teaching mathematics and programming; b) teachers' conceptions of how programming should be implemented in mathematics; c) teachers' conceptions of how programming could develop pupils' understanding of mathematical concepts and procedures, and pupils' problem-solving competency. In order to achieve an appropriate level of reliability and validity of the responses (expected to be above 100) – in concordance with studies about survey scales in social sciences, that point out that the "optimum number of alternatives is between four

and seven” (Lozano, Garcia-Cueto, & Muniz, 2008) – we decided to use a four-alternative Likert scale. By using an even scale, i.e., a scale without a neutral middle category – and by taking into consideration that the participants had little or no previous experience of programming – we aimed to discern participants’ responses in more distinct ways. Thus, participants were asked to answer to every statement on a scale of 1 (meaning “not at all”) to 4 (meaning “to a great extent”).

The survey underwent a substantial a priori testing with a group of teachers with similar levels of experience in programming in mathematics as the participants, thereby confirming that included statements were compatible with the aims of this study. In this paper, we are focusing teachers’ answers to 12 statements – displayed at the next section – related to mathematical thinking and mathematics as a topic and a set of learning objectives on one side, and programming activities and objectives on the other. The first eight statements focus on teachers and pupils’ mathematical knowledge and potential related to programming, and on their understanding of mathematical concepts, procedures and algorithms in the context of programming. The last four statements deal with teachers’ enthusiasm and preparations related to programming, their views on programming and mathematics as different subjects and on learning programming by tinkering.

## Results

We performed a simple descriptive analysis in this paper, thus, the paper does not present or confirm any hypotheses. Rather, we generated an overview of the replies and present our questions and their relationship to the framework.

In the survey, we gathered data about a number of things as described above. We asked the eight questions shown in Table 1, and the distributions of the answers were more or less the same.

Question	Not at all	2	3	To a great extent
I benefit from my mathematical knowledge when I am programming.	8	32	59	32
My pupils benefit from their mathematical knowledge when they are programming.	7	36	57	28
I can do more things related to mathematics when using programming.	12	34	60	22
My pupils can do more things related to mathematics when using programming.	11	39	62	15
I can obtain a better understanding of mathematical concepts by using programming.	20	43	48	14
My pupils can obtain a better understanding of mathematical concepts by using programming.	19	33	57	16
I can obtain a better understanding of mathematical procedures and algorithms by using programming.	15	33	54	27
My pupils can obtain a better understanding of mathematical procedures and algorithms by using programming.	9	26	64	29

**Table 1: The distribution of the number of answers to respective questions about the relationship between programming and mathematics.**

As seen in Table 1, the most typical answer was category 3. The answers to every question have more or less the same distribution; almost half of the teachers answered 3 and less than one fifth of them answered 4 (“to a great extent”). The rest of the teachers, less than one third of them, were divided between 1 (“not at all”) and 2 (that might be interpreted as “to a small extent”).

Do you feel enthusiastic about teaching programming in mathematics?	23	29	55	23
Do you feel well prepared to teach programming in mathematics?	40	42	43	6
Programming and mathematics are two different disciplines that should not be taught within the same subject.	52	38	24	18
It is important that students learn to modify and adapt given programs according to certain criteria (tinkering).	12	29	64	20

**Table 2: The distribution of the number of answers associated to respective statements about teachers’ motivation for and self-esteem regarding teaching programming in their mathematics classes.**

According to Table 2, the answers associated to the teachers’ levels of preparation to teach programming in mathematics respectively to their opinion about the relationship between programming and mathematics as disciplines, are distributed towards less affirmative categories. All together, we take the results shown in Table 1 and Table 2 as signs of two issues that both need further statistical inquiry in order to be considered stable results: (1) Swedish mathematics teachers do see a clear relationship between mathematics and programming – however, this does not mean, that the teachers view these topics as coinciding; (2) despite admitting the benefits of programming, Swedish mathematics teachers are not well prepared for teaching programming in mathematics. Rather, the teachers express that they and their students can use their mathematical competencies while programming and feel that it is a good idea to do this. Yet, simultaneously, they do not currently feel well prepared to take on the task of teaching programming. In the following section, we will discuss these results.

## **Discussion: approaches to including programming in compulsory schools**

Many countries, municipalities, and schools are currently struggling with how to introduce programming as a body of knowledge in the school system. Mathematics tends to play an important role in a number of these attempts. There are many ways in which this can be done in terms of curriculum structure. Programming can be included in mathematics and science curricula, as in the case we have explored here. Of course, this can also be done in different ways, and different teachers will have different competencies in this regard. Another approach is to develop programming as a topic in its own right. However, such a topic can have different “flavors” and foci and different relationships to the more traditional school topics. The Swedish case is an example of a country addressing this problem by imbedding programming into mathematics (and science), and the data from our case suggest that there are a number of synergies and potentials with such an approach. In general, the teachers who answered our survey do see a relationship between programming and mathematics, and they do want to build on that relationship in their teaching. This tells us that the route of integrating programming into mathematics seems feasible in Sweden. However, we should be aware of the fact that both the sample size and current sampling strategy challenge the generalizability of the results. Accordingly, these results say nothing about whether

combining mathematics and programming is the best way to address the integration of programming in Swedish schools or even if this integration is a good idea in the first place. Yet, the relationship between the topics and the motivation for taking on the task seems to be there, even though the capacity for teaching programming is not yet in place. We are not free from the problem of training teachers to take on this specific task.

The introduction of programming in the mathematics curriculum poses an interesting implementation problem. What are the critical choices and concerns that we need to consider in this respect? In this paper, we have addressed mathematics teachers' conception of the relationship between mathematics and programming, but this is not the only relevant concern. Stakeholders such as end users (pupils and teachers), implementation plans, the potential for diffusion, etc., are important concerns. We also believe that the discussion of whether to teach programming in relation to other topics or as a topic in its own right could benefit from a broader "implementation framework," such as the one discussed by Century and Cassata (2016). To mention just one concern, it is critical to have sound implementation of programming in relation to mathematics education, and that could benefit from being viewed through the lens of implementation research; we can look at teacher's resistance to programming as part of mathematics. This resistance is rare but might exist, as seen in Table 2. If programming is included as a part of mathematics at all levels, no mathematics teachers can avoid teaching it. Accordingly, programming – that is, not a priori natural tool for mathematics education – might also be viewed in the light of instrumental distance and double professional geneses from the part of the teachers (Haskepián, 2014). In that sense, this structure is more fragile for the minority with negative views, whereas the development of an entirely new topic might make it easier for teachers to choose whether they want to engage in the teaching of programming.

## Conclusion

In this paper, we have presented an initial descriptive analysis of Swedish mathematics teachers' experience regarding the relationship between mathematics and programming. The data collection is still ongoing, and the sample size is expected to increase. Furthermore, we are not yet in a situation where we can conduct a strong statistical analysis of the data, so the stability and generalizability of the results are currently limited. However, the results that we do have point in the direction of a meaningful relationship between mathematics and programming that can be used to support the teaching of programming within the subject. Yet, they also suggest that this will not be easy and that Swedish teachers – despite a positive attitude towards working with programming in mathematics – do not feel that they are prepared to take on this task. This result indicates that it might be a good idea to build the capacity for teaching programming from within the topic of mathematics. However, the capacity problem seems to persist in the sense that it is indicated that teachers need to be prepared and trained to teach programming. Furthermore, it might be the case that some teachers do not at all see the relationship between mathematics and programming, nor the relevance of teaching programming in their mathematics classes, and such teachers might also experience the task as very challenging. However, we assume that further data collection and statistical analysis will allow us to better understand the detailed clustering of teachers' attitudes on the subject of programming.

# Designing an problem for learning mathematics with programming

Morten Munthe

Norwegian University of Life Sciences, Faculty of Science and Technology, Norway;

[morten.munthe@nmbu.no](mailto:morten.munthe@nmbu.no)

*Keywords: Programming, design-based research, problem solving*

Programming has a long history within mathematics education. From the introduction of programming languages such as LOGOS, Basic and Pascal in the 1970s, to the more recent use of computer algebra systems (CAS). More recently, programming has received an increased focus from both the academic community and society. The combination of mathematical knowledge and the knowledge of programming is considered a valuable skill set in the future work marked (Gravemeijer, Stephan, Julie, Lin, & Ohtani, 2017). In response to this, programming is to be included in the mathematics classroom in Norway from autumn 2020.

This poster presents a part of a larger project involving students electing science mathematics in upper secondary school (16-18 y.o.). In this project, the students receive extra lessons at the beginning of the school year, where they learn a set of basic programming commands (such as print, input, mathematical operations, *if*-statements, *for*-loops, and *while*-loops). They are then given mathematical problems, which facilitates for deep learning through discussions, problem solving and programming. This project follows the students for two consecutive years, and periodically presents them with problems from different areas of mathematics. The project investigates how the use of programming can facilitate for the learning of mathematics in the classroom and this poster illustrates the creation of problems that facilitates for learning mathematics with programming.

The project is design-based. Design-based research (DBR) has many focal areas, and this poster presents parts of DBR where the focus is the creation and development of mathematical problems through iterations. The problems are vital as they create ways to learn and discuss mathematics not easily achieved or not possible without programming.

The design process combines Rabardels instrumental approach (Rabardel, 1995) with Vygotsky's activity theory (Vygotsky, 1980). The instrumental approach is used to create problems that facilitate for the development of utilization schemes, and activity theory is used to create problems that facilitate for students discussions. Discussions are vital for learning mathematics. In activity theory, the mediating artefact that helps the students learn mathematics is here the programming language. The learning is mediated through social interactions between groups of students and between students and their teacher. In instrumental approach the instrument is defined as a two-part entity consisting of both the artefact and the utilization schemes (Rabardel & Samurçay, 2001). The utilization schemes will start as basic usage schemes, where the students will learn a set of commands and their affordances. As their abilities and network of commands increases, they will develop instrumented action schemes. The action schemes will enable the students to create programs to solve mathematical problems (Drijvers & Trouche, 2008).

To illustrate the iteration process, the poster will show the overarching structure of the project, give an example of a mathematical problem, and present responses from students through logs and

interviews. The structure will show how problems develop over time, and the responses will show how student input affects the development of problems. To embody a problem, an example from the mathematical area of quadratic equations is used. Articles targeting quadratic equations suggest that students struggle with them (Zakaria, 2010). This includes solving quadratic equations instrumentally, validating solutions, and understanding the relationship between different forms of visualisation such as function, graph, and zero-points.

### **The mathematical problem of quadratic equations**

The students were asked to create a program that would solve any quadratic equation. The problem was set up as a building block scheme, where they started solving quadratic equations with one or two solutions. Afterwards they were asked to solve a quadratic equation with no solution, and then problem solve how they could circumvent the error they received. As the problem progressed, they were given further questions and/or hints of what to discover. This included intersection with the axes, an expression for the derivative, factorising the equation, and so on. The students were given freedom to program what information the user would receive when they input a quadratic equation.

A couple of weeks after the quadratic equation problem, ten of the students were interviewed. Amongst their responses, they compared programming to the ready-to-use CAS in programs such as GeoGebra and reported that with CAS they merely typed in equations and pressed solve, but in programming they had to understand the process deeper to create the code that solved the equation.

The mathematical problems given to the students' have changed considerably from the initial iteration to the present iteration. The initial design of the problem focused on using programming to solve a general quadratic equation. As the work progressed, the design changed to increasingly include problems and formulations that forced the students to discuss and critically review their program to progress. The problems have now a design that helps the students should they feel frustrated about the programming. The problems have also focused on using programming as a tool to facilitate mathematical discussions and the creation of mathematical ideas. The next iteration will run in autumn 2018, and the poster will include the examples and results from this study as well.

# Developing MAP for integrating mathematical applets in teaching sequence

Gal Nakash-Stern<sup>1</sup> and Anat Cohen<sup>2</sup>

<sup>1</sup>Tel-Aviv University, Faculty of Education, Tel-Aviv, Israel; galnakash@mail.tau.ac.il

<sup>2</sup>Tel-Aviv University, Faculty of Education, Tel-Aviv, Israel; Anatco@tauex.tau.ac.il

*In this paper, we present the way in which the math teacher proceeds to select an applet, and especially its main considerations when preparing for the lesson or preparing the study unit. In addition, this study examines what the teacher's meta-data should be in order to make a knowledgeable select of applets and integrate them into the teaching sequence. This study aims to help the teachers cope with the heavy load of the Open Educational Resources (OER) and help them in their day-to-day management of the study units. Therefore, qualitative research was carried out to examine the teachers' choices and considerations regarding their goals and sequence of teaching. The present study offers a way to deal with this difficulty by means of a Map that will link the teacher's pedagogical-content considerations. This map may be used by the teacher as a tool for intelligent choice of applets.*

*Keywords: Mathematical applets, Map, Meta-data, teaching sequence.*

## Introduction

A well-informed integration of technology in teaching and learning at school positively affects students regarding cognitive features and effective ones (emotional and motivational), as well as features connected with the teachers' choices in the classroom and outside of it. Using technological tools for the purpose of teaching is very common nowadays (Stehr, He, & Nguyen, 2018). These tools are often used for the sake of innovation, and for introducing a fresh aspect to increase students' motivation (Horzum, 2015; Smith, Shin, & Kim, 2017). This occasionally leads to the development of new technological tools that are not always best fitted to the students, and do not attach importance to mathematical content. Thus, if mathematical content is not taken into account, the choice of using certain technology for the purposes of teaching and studying does not grant any educational benefits, and may indeed miss the actual goal (Dębowska et al., 2013).

The recent development of various educational resources containing digital learning materials for the use of teachers is especially relevant to this study (Cohen, Kalimi, & Nachmias, 2013). These educational resources - most of which are free for use (such as the Israeli Ministry of Education's "Educational Catalogue") - offer various activities and material and in varying formats, from short texts, videos, and applets up to full lesson plans. Hence, teachers are given a chance to make use of existing learning materials in order to optimize and improve their work. Among these educational resources there is specifically a major supply of game-based applets, interactive web utilities (Pejuan, Bohigas, & Jaén, 2016), aimed at various subjects in Mathematics and for a broad age-range. It is a well-known fact that using these applets has a positive impact on students (Hershkowitz, Tabach, & Dreyfus, 2017), and that using the applets through a guided model can provide better outcomes in the acquisition of language and of mathematical terminology (Dijanić & Trupčević, 2017).

Despite the potential for teaching and learning encompassed within existing learning materials, and their many benefits, studies suggest that their usage, as well as their combinations to match the specific user's needs, are relatively low (Hilton, Lutz, & Wiley, 2012; Pirkkalainen, Jokinen, Pawlowski, & Richter, 2014; Bernstein, 2015). One argument is that many educators are not aware of these growing educational resources, or that they are not entirely convinced of their effectiveness (Cannell, Macintyre, & Hewitt, 2015). Furthermore, there is a concern that the abundance of displayed information might lead to confusion, discrepancies and wasting time when searching for information - due to the lack of a single unified system which would license and catalogue learning material (Nash, 2005). It could also lead to difficulties in evaluating the quality and reliability of information and its management (Clements, Pawlowski, & Manouselis, 2015; Gurung, 2017).

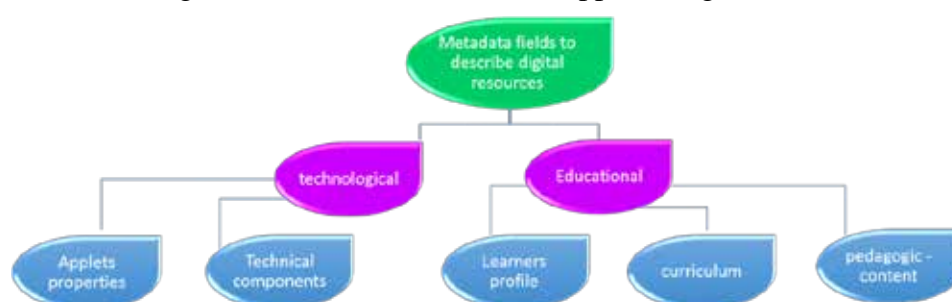

There are two significant challenges facing those teachers who are interested in using mathematical applets and making informed usage of them. The first is related to the stage of searching and selecting the materials that will best suit the goals of their specific teaching subject; and the second is regards to the optimum usage of those materials within the teaching process in class during a lesson, or during a few consecutive lessons.

## Main research goals and questions

Three main goals for this research (1) Understanding what data is needed for teachers to integrate applets within their teaching sequence; (2) Identifying specific features within applets that will enable an informed integration within the teaching sequence; (3) Creating a Map based on meta-data fields that teachers can choose an appropriate applet and integrate it within the classroom's teaching sequence. In order to achieve these goals two questions were asked: (1) What are the main considerations that teachers operate in order to integrate applets into teaching sequence? (2) What is the meta-data that can help teachers to make decisions about using those applets? Meta-data in educational aspects (pedagogic - content) and, Meta-data in technological aspects.

## Methodology

The research was conducted in three main stages. The first stage included a review of various meta-data models connected to the world of studies and education. A theoretical framework was built based on these models (e.g Dublin Core and LOM) including the meta-data of existing mathematical applets. The meta-data was divided into educational dimensions and technical-technological dimensions. The educational dimension contains the teachers' pedagogical requirements and contents, and the technological dimension describes the applets (Figure 1).

**Figure 1: The theoretical framework**

The meta-data fields which describe the Mathematical applet in each dimension are grouped into different categories of metadata. The branching of these metadata categories shows a comprehensive view of all the characteristics that can be considered when examining applets.

The second stage included semi-structured interviews with 12 mathematics teachers who use applets in elementary schools. The interviews aimed to establish the theoretical framework, and to examine the teachers' perception of integrating applets within their teaching sequence in accordance with their teaching goals. The interviews were divided into four stages in accordance with the stages the teacher faced when implementing the applets: applet searching, locating, using, and feedback. The interviews were conducted as one-off sessions with each teacher. This qualitative stage draws its data from the natural system, in which the researcher and the interviewees are on the same communication level, and the research output is created from opportunities in their interaction.

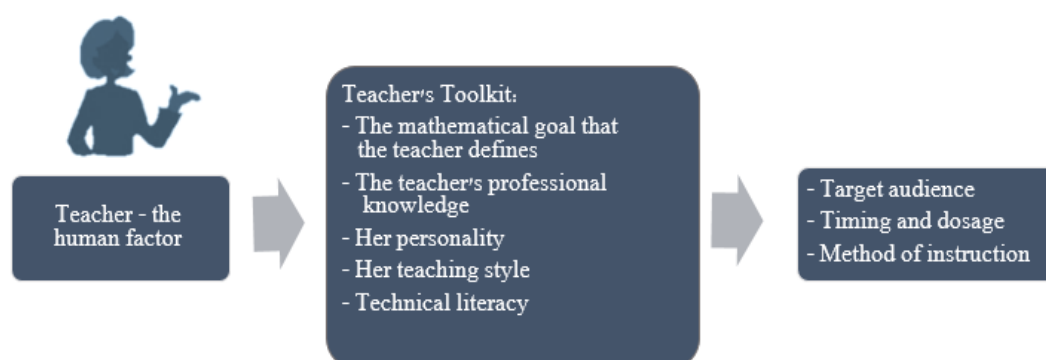

The third stage dealt with analyzing the findings, and developing a tool in the form of a Map for applets integration. This stage of analysis and tool-building placed emphasis on the teachers' answers concerning their ways of choosing applets and integrating them into their math class teaching sequence. This research was based on Grounded Theory, in which data collection was carried out before the study is fully understood (Shkedi, 2003).

## Preliminary findings

The findings' analysis was divided into two levels: addressing the teachers' considerations regarding the integration of applets within their teaching sequence, and addressing the meta-data they would find useful for their decision making process. Based on these, a comprehensive Map was constructed.

### Teachers' considerations

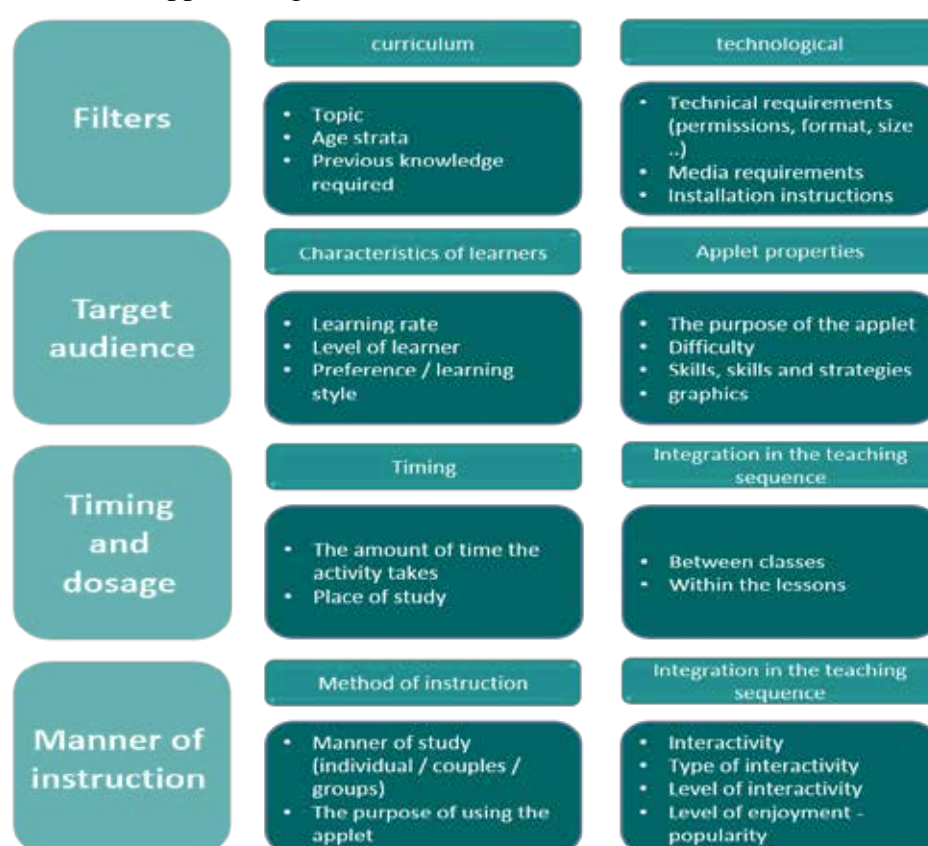

A number of considerations arose regarding the teachers' select of an applet and planning of their teaching sequence - mainly pedagogical and technological considerations. From the teachers' point of view, the main considerations were pedagogical considerations which included mainly the teaching goals, the pedagogy, the mathematical content, the location and time frame. Moreover, it was found to be important to consider their teaching experience and professional knowledge, their teaching style and even their personality. The technological considerations include mainly authorizations, certification (Figure 2).

**Figure 2: The teacher's considerations for integrating applets**

## Meta-data

Beyond the considerations that the teachers must use when choosing an applet, there is also the matter of the specific data that is required from the applet or database they are examining. The teachers defined the meta-data from pedagogical aspects as well as technological ones. Pedagogical aspects included mainly the teaching sequence in relation to the objective of use, the way of studying, acquired skills, students' profiles in relation to difficulty levels, timeline, mediation levels, the student experience evoked by motivational factors and configuration. In accordance with the findings' analysis, a set of Metadata fields was created for the purpose of assisting the teachers in an optimal search for the applet most suitable for their teaching sequence. Figure 3. presents the main meta-data fields that can assist the teachers in their decision-making process while constructing their teaching sequence with the use of applets (Figure 3).

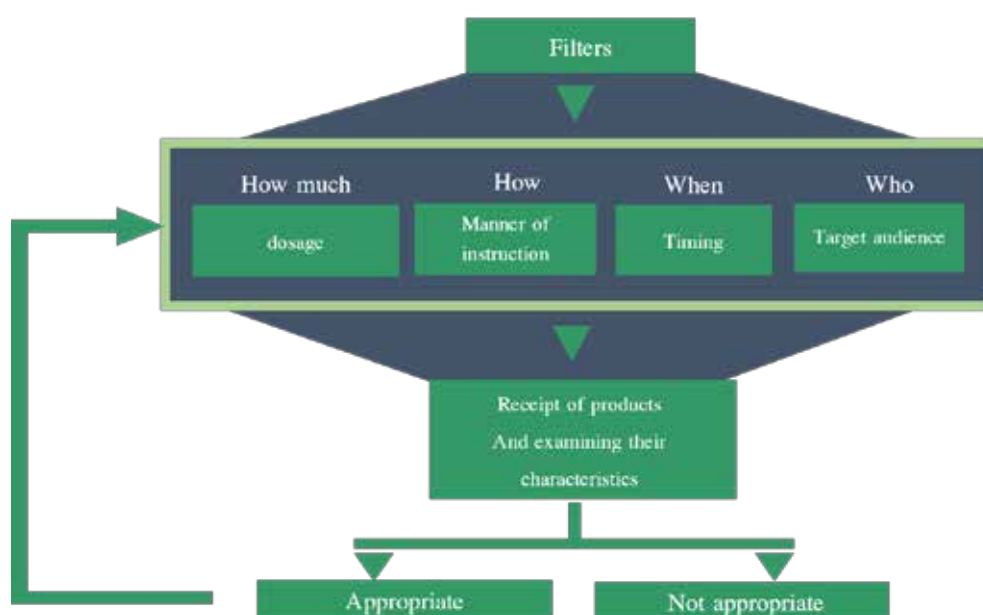

**Figure 3: Pedagogical and technological metadata fields**

## A map for applets integration in teaching sequence

The pedagogical and technological considerations as well as the set of metadata are presented by process map. This map shows the teacher's way of thinking in making the choice in four stages: the search stage, the detection stage, the use stage, and the feedback stage. At each stage the teachers referred to a number of different categories. In the search phase, the teachers referred mainly to the availability of information, pedagogical considerations and a structural model. At the point of identification, the teachers referred mainly to the data they had in the applet and to the superlative information that still did not exist, when they referred mainly to the information they knew and their

experience. At the point of use, the teachers referred to their meta-goals, motivational factors, and time and place of use of the applet. In the fourth and final stage, the teachers referred to the effectiveness of feedback, the type of feedback required, feedback interactivity, and feedback as a learning tool.

According to the map (Figure 4), the teacher can filter out the considerations that lead her to decide whether to select an applet. The integration applet Map is presented in four main steps: filters, properties, receipt of products and choice of characteristics and in the end decision-making, from the search stage to reaching the desired applet. The filter stage includes all the pre-requisite knowledge the teacher needs when choosing an applet that includes her professional knowledge, her personality, her mathematical goal, and more. At this stage, the teacher also defines her target audience, the method of instruction and the timing of her teaching sequence. The properties stage includes the different characteristics of the applet and its target audience. The third stage, which is defined as the receipt of the products and the examination of characteristics, is from a stage in which all the knowledge that the teacher has is integrated into this stage and it examines the continuation of the process in order to select the applet. In the fourth and final stage, the teachers arrive at a crossroads where they have to make a choice: Should they choose the current applet, or should they go back to the second and third stages, and re-examine other applets.

**Figure 4: A map for applets integration in teaching sequence**

In conclusion, this research looked at the considerations and the metadata which would influence teachers when choosing applets and integrating them into the teaching sequence. The interviews indicated great significance attached to the teacher's personality, needs and authority. Another issue that emerged through the interviews was the students' needs - the teacher's understanding of what the student needs to get; how the students will connect to the applet; and how we get the students to understand mathematics by using the right applet. Another issue which is just as important as the teacher and student's needs, is the teachers' learning process during their search for the desired applet. During the interviews, the teachers explained how they approached searching and choosing the applet,

as well as how they integrated it within their teaching sequence, and these led to conclusions regarding their method of learning.

## **Discussion and conclusions**

In this research, the pedagogical consideration was the main one for choosing applets. According to the pedagogical consideration, teachers choose the applet most suited to their teaching sequence. Since the mathematical content is highly significant in building up the students' mathematical knowledge (Kimeswenger, 2017), the teachers will first search for an applet appropriate for that content. Most of the teachers interviewed stated that without that element of information they would not be able to begin the search, hence - this is a primary filter when choosing a database or applet. Similarly, Namukasa, Gadanidis, Sarina, Scucuglia, and Aryee in their research (2016) found that among the most important considerations were the pedagogy and content that the teachers wanted to teach in their mathematics lessons. They also stated that mathematical terms or "mathematical thinking" would be the most critical when choosing a digital object. This issue was addressed as well by Kotsopoulos et al. (2017), who explained the importance of the students' computational mathematical thinking, which should take precedence.

The study found that technical components such as installation instructions and necessary hardware and software programs were not essential elements when choosing an applet. Most teachers, when asked about the technical aspect of choosing an applet, answered that they do not attribute much importance to those aspects when choosing to use an applet. The teachers stated that the only factor impacting on their choice would be the hardware or program's digital license - as defined by Green (2017) during his OER license research, where he examined how they influence studying. The teachers stated they are already used to the "wonders of technology" and that they know how to handle anything that comes their way. Much to our surprise, the technical aspect that we had emphasized at the beginning of the research did not end up being a hindrance or even a consideration when choosing an applet. This surprised us a great deal, since some populations find study-suitability very difficult during times of technological advancements (Göthe, Oberauer, & Kliegl, 2007).

During this research, we mapped out the considerations and information the teachers would need when choosing an applet or mathematical resources. Then, similar to Kimeswenger (2017) we recognized the need for developing a tool, which will help teachers to navigate in the heavy load of resources and to assess learning materials. Thus, we built a Map for integrating applets in teaching sequence. The Map consists of the knowledge the teachers will need for choosing the applet and for integrating it into the teaching sequence. We believe that the Map we have created may assist in developing a technological tool with which teachers may integrate all the elements necessary for their teaching. Beyond the teacher's familiarization with the educational resources and applets, it is necessary to develop a tool in the form of Google, consisting of mathematical educational resources and applets, with the added option of feeding it criteria that would make it possible to obtain the desired product, and which could assist the teachers' choice of an applet, and shorten search duration.

Since this research did not deal with the construction of lesson units by teachers, it is vital for future research to deal with that subject in greater depth and regarding the following influencing factors: How long it takes the teachers to learn the usage of applets; how long it takes to build a lesson plan -

whilst relating to pedagogical components as well as to the teacher's teaching goals; the chronology of lesson building; and how the applets assist the teachers.

In an age of rapid and frequent changes, we must pay attention to the fact that teachers are required to implement new technologies on a daily basis as part of their lesson structure. Hence, the main importance of this research is in assisting teachers integrate mathematical applets within their teaching sequence in the classroom. Teachers nowadays are laden with a huge amount of applets and resources (Peralta, Alarcon, Pichara, Cano & Bozo, 2017) which is why we developed the presented Map. Teachers are expected to have an extremely high level of literacy due to current usage of many technological tools. Therefore, it is important for future research to address the way in which the teachers learn how to use technological tools, and to actually implement them in the classroom.

## Acknowledgment

This study is founded by the Education Ministry's chief scientist.

# The impact of technology on the teachers' use of different representations

Helena Rocha

UIED, DM, FCT, Universidade NOVA de Lisboa, Portugal; [hcr@fct.unl.pt](mailto:hcr@fct.unl.pt)

*The potential of using different representations is widely recognized, but not much is known about how teachers use them nor about the impact of the technology on such use. The goal of this study is to characterize the teachers' representational fluency when teaching functions at high school level, discussing, at the same time, the impact in the use of representations resulting from the use of technology. Adopting a qualitative approach, I analyze one teacher's practice. The results suggest that algebraic and graphical representations are seen as more important, that tabular representation is assumed as irrelevant and that the access to technology impacts the representations used and how they are used.*

*Keywords: Technology, different representations, functions.*

## Introduction

Work with different representations is recognized by several authors as an important experience to promote the development of links and strengthen the understanding of mathematical concepts (Dreher, Kuntze, & Lerman, 2016). And the technology is pointed as having the potential to easily allow the students to alternate among representations (Cavanagh & Mitchelmore, 2003). Although the potential of using different representations is widely recognized, only a few authors paid attention to how they are used (Dreher et al., 2016; Molenje & Doerr, 2006). And even those who do it, do not focus on the impact of the technology on the teachers' choices in what concerns the use of the different representations. This is the new aspect addressed in this article. The goal is to characterize the teachers' representational fluency when teaching functions at high school level in a context where technology is available, discussing, at the same time, the impact in the use of representations resulting from the availability of technology. With this focus, I specifically intend to answer the following research questions: How does the teacher balance the use of the different representations of functions? How does the teacher articulate the multiple ways of representing a function within and among representations? What is the impact of technology on the teachers' balance and articulation of the different representations?

## Representational fluency

Zbiek, Heid, Blume and Dick (2007) characterize the representational fluency as the ability to move from one representation to another, transferring the knowledge from one representation to another and combining it with the new knowledge available on the new representation. And this includes the transition between representations of different kinds but also transitions between different representations of the same type of representation, as emphasized by Moore et al. (2013) and Even (1998). This means that it is important to consider a transition, for instance, from an algebraic representation of a function to a graphical representation, but that it is also important to consider a transition from a graphical representation of a function to another graphical representation of that

same function (for example, when we are using technology and we need to look for a suitable viewing window for the graph).

Kendal and Stacey (2001) use the expression *privileging* (used originally by Wertsch in 1990) to refer to the teachers' specific way of teaching. And the authors think of it as a reflection of the teachers' beliefs and professional knowledge that characterizes their practice. Privileging includes the teachers' options about what they teach and how they teach it. In what is relevant to this study, privileging includes the teachers' decisions about what representations are (intentionally or unintentionally) used and about how they are used. And how the teachers privilege a specific approach and devalue others can tell us much about their professional knowledge (Dreher et al., 2016; Rocha, 2016). When studying the teacher's representational fluency it is important to know if some representations are preferred over others. I use the word *balance* to refer to how the teachers privilege specifically the use of some representations over others.

Although several authors recognized the relevance of using different representations based on the contribution it can bring to the development of mathematical understanding (Duval, 2006; Zbiek et al., 2007), the way how the teachers balance the representations has not received much attention. Molenje and Doerr (2006) conducted one of the few studies with this focus. Their conclusions suggest that the teachers express some concern about how they balance the different representations. Nevertheless, the use of algebraic and graphical representations is dominant in relation to the numerical representation. And this study also achieved another interesting conclusion: when the teachers actually use the different representations, it is possible to identify a pattern in the way how they do it. According to the authors, some teachers tend to start by an algebraic representation, move to a graphical representation and then to a numeric representation. Other teachers tend to move from the algebraic representation to a numerical representation and only then to a graphical representation. In a previous study conducted by myself on the teachers' use of different representations (Rocha, 2016), I found more diversity on the articulation of representations than the one found by Molenje and Doerr (2006), but I also found some preference for the use of some specific sequences of representations. These options will promote a limited use of representations by the students (because they tend to reproduce their teachers), with consequences for the students' learning and for their flexibility with different representations and with functions in general (Rocha, 2016). As Dreher et al. (2016) emphasize, the use of different representations is not enough to promote learning, it is essential to pay attention to how they are being used. And these findings suggest that besides studying how the teachers balance the different representations, it is also important to understand how the teachers articulate them. I use the word *articulate* to refer to how the teachers privilege a specific pattern when going from one representation to another. The way how the teacher balances and articulates the different representations is assumed as central on the characterization of the teacher's representational fluency. As so, these are the concepts used to analyze the teacher's representational fluency.

## Methodology and study context

Given the nature of the problem under study and in line with the ideas advocated by Yin (2003), the study adopts a qualitative and interpretative methodological approach, undertaking one teacher case

study (in the part of the study presented here). Data were collected by semi-structured interviews, class observation, and documental data gathering. The teacher's lessons with one of her classes were followed while she taught functions. It was performed an interview after each lesson, with the purpose of knowing the analysis that the teacher did of the events. A test, with questions about changing between representations, was applied to the students by the researcher at the end of the study. The results of this test and some selected answers given by the students were used on a final interview to the teacher as a starting point to discuss her use of representations in her lessons. It was only at this point that the teacher became aware of the specific focus of the study on the use of representations. During the study, 12 lessons of 90 minutes at 10<sup>th</sup> grade (age 16) were observed. All interviews and observed lessons were audio-recorded and later transcribed. Data analysis was mainly descriptive and interpretative in nature, and guided by the goals of the study. The tasks proposed by the teacher were assumed as the unit of analysis. For each task the representations adopted by the teacher and the articulation between them were identified. Each type of articulation identified was then analyzed with the intention of characterizing it and understand the balance ascribed by the teacher to each representation. The representations taken into account were the ones usually available on the technologies and used on the study of functions: algebraic, graphical, numerical and tabular. Due to the goals of the study, when analyzing a task what was taken into account was the teacher's point of view, ie, the representations she chooses to use or suggests to the students.

The teacher participating in the study has a professional experience of about 20 years and a positive attitude towards the use of technology to teach mathematics. She likes to use computers on her practice, but when teaching functions she prefers to use graphing calculators and avoid the trouble of moving to a different classroom. As so, the graphing calculator was the only technology she used during this study, and this is why this is the only technology mentioned in this article. All the 25 students in this class had their own graphing calculator, which they could use at all times.

## Results and discussion

An analysis of the tasks proposed by the teacher allowed the identification of nine different types of articulation between representations. Table 1 presents the sequences of representations used, a brief description of the strategy used to solve the task and an example of a possible task (please take into account that the examples presented were simplified due to space constraints). The sequence algebraic ® graphical ® numerical was used often on tasks with a real context and asking something about it (for instance, corresponding to the zeros or maximum of the function, or to the values for which the function is increasing or assumes positive values). It was also used on strictly mathematical questions, namely to solve inequalities. The sequence algebraic ® graphical was used when the goal was the graph of the function. And when the standard window did not offer a good viewing of the graph, the sequence became algebraic ® graphical ® graphical, including a change among graphical representations, ie, using different representations of the same type of representation. The sequence algebraic « graphical was used on exploratory tasks where the teacher intended the students to relate these two representations, expanding their mathematical knowledge, or to use previous knowledge to guide their successive attempts to solve the task. All these four sequences required the use of technology. And in all the other five sequences the

technology was not used. However, some of these sequences were not as used as others. That is the case of the sequence graphical ® algebraic that was only used once, and of the sequence graphical ® numerical that was only used on an introductory lesson to the theme. Besides that, it is possible to notice that certain sequences were never used and that the tabular representation was never used as well.

Representation	Teacher's approach	Example of task
algebraic ® graphical	Insert the function on the calculator and press graph	Draw the graph of $f(x) = -x^2 + 3x + 5$
algebraic ® graphical ® graphical	Insert the function on the calculator and press graph Use zoom / change the window	Draw the graph of $f(x) = -x^2 + 100$
algebraic ® graphical ® numerical	Insert the function on the calculator and press graph. Use menu <i>calc</i> In some cases (see 2 <sup>nd</sup> example) it is possible an approach without using the calculator	Knowing that the height of a remote controlled airplane is given by $f(x) = -x^2 + 4x$ find the maximum height reached by the airplane. Solve the inequality: $x^2 + 4x + 3 > 0$
graphical ® algebraic	Use paper and pencil and visually get information from the graph (calculator used at most to check)	Look at the graph of the function and find its algebraic expression
algebraic « graphical	Insert one (or more) function on the calculator, see the graph, change the function and move back and forward between the representations trying to come to a conclusion	Study the family of functions $y = ax^2, a \in \mathbb{R} \setminus \{0\}$ Slalom: Find a polynomial function to represent the course of a skier when he goes through both doors without touching the flags at (1, 4), (2, 4), (5, 4), (6, 4)
algebraic ® numerical	Use paper and pencil	Find the zeros of $f(x) = 2x^2 - 8x + 6$ Solve the inequality: $2x^2 + 12x + 10 < 0$
algebraic ® algebraic	Use paper and pencil	Write the polynomial function $f(x) = x^3 - x$ as a product of factors
numerical ® algebraic	Use paper and pencil	Write the expression of the 2 <sup>nd</sup> degree polynomial function with a zero for $x=1$ and $x=-2$ and going through the point (0, 4)
graphical ® numerical	Direct reading of the graph (use paper and pencil)	What is the maximum value reached by the function on the graph?

**Table 1: Sequence of representations used by the teacher**

The teacher recognizes the importance of using different representations to promote a deeper understanding of the concepts and emphasizes in particular the contributions of graphic representation to the understanding of algebraic representation:

T: I think that using graphs and algebraic expressions is very important. Some students have some difficulty in working analytically. They get lost and at a certain point they no longer understand what they are doing. For instance, they don't know why they equal the expression to zero when they are looking for the zeros of the function... and why they can't just replace the  $x$  by 0. Having the graph helps to understand... we want the value of  $x$  when  $y$  is 0. (...) I think the graphical representation is easier for them and if you work with it and with the algebraic representation you are helping them.

And she assumes that the technology allows the students to quickly access a wide variety of graphs and that it turns the work around functions much easier. It becomes possible to link different aspects about functions in a way that was not possible before:

T: Technology changes everything! The technology allows us to move instantly from the algebraic expression to the graph. And that turns possible to develop deeper relations among these representations. We can see on the graph the impact of changing a parameter on the function. This is not possible without technology.

The results achieved by the students on the test on representations suggest that they are effectively familiar with the relationship between algebraic and graphical representations. Nevertheless, the results also show that the students have difficulties in getting information from a table. 48% of the students failed to identify, based on a table including the relevant information of a function  $f$ , an interval for  $x$  where the values of  $f$  were increasing; but 80% managed to answer the same question based on a graph. 88% of the students were unable to find the expression of a function using the information on a table of values; but all recognized the quadratic function when the information was provided by a graph and 92% were able to find the algebraic expression. When confronted with these results, the teacher recognizes she does not use the tabular representation, assuming that the students' lack of familiarity with the representation might be the source for the difficulties of some students. But somehow she seems surprised and expresses her belief about the similarity between the numerical and tabular representation. A similarity that is actually recognized by several authors, such as Goos and Benninson (2008). In the teacher's own words:

T: I have to admit that nowadays I don't use tables so much. When I was a student we didn't have technology and we use a table to register some values of the function and then mark them on a graph or whatever... With technology we don't need that and... I know the calculator provides a table but we can get everything from the graph using the menu *calc*, so there is no need... for the table. It's the same. But maybe not for them. I think they get confused and didn't know in what column they should read the values. Maybe I should use the table. I don't know... I thought it was the same.

About privileging paper and pencil or technology when moving from one representation to another, the teacher says that she tries to balance the two options:

T: I try to do everything with and without technology because our syllabus requires that. (...) There are some exercises that they don't know how to do without the technology. For instance, find the maximum of a function. And there are also others that they cannot do on the calculator. For instance, factor a polynomial function... But we solve inequalities with and without technology. I think we achieve a deeper understanding when we can do something in two different ways.

Nevertheless, some sequences are always done using (or not) technology (see Figure 1). In some cases there is no surprise on that. For instance, the change from one graphical representation to another is usually due to an unsuitable choice of the viewing window. So it is to expect that it happens always when the technology is being used. But there is no reason to never use the technology when moving from a graphical representation to an algebraic one (and this is the option of this teacher). This suggests that the teacher is not fully aware of her options in what concerns the use of the different representations.

**Figure 1: Representations used by the teacher and their sequence of use**  
(pp - paper and pencil, t - technology)

## Conclusion

Algebraic and graphical representations seem to be assumed as more important than other representations. A conclusion in line with the results achieved by Molenje and Doerr (2006), who also concluded that these representations are used more often than others, meaning that representations are not equally balanced by the teacher. This can be related to the characteristics of the representations. As stated by Friedlander and Tabach (2001), algebraic representation is concise, comprehensive and effective, being also the most valued representation in Mathematics. But students tend to find it difficult (Quesada & Dunlap, 2008). The graphical representation provides a visual representation and an intuitive approach to the concepts, turning learning more intuitive (Friedlander & Tabach, 2001). It is thus understandable that these two representations are the most used. After all, the graphical representation helps the students understand the most valued representation: the algebraic one. And this is the central point. The representations beyond the algebraic one are mainly used to promote understanding over the most important representation and not so much to promote a global understanding of functions, as advocated by Dreher et al. (2016) and several other authors. The numerical representation, whose relevance is assumed to be minor due to its focus in particular cases (Friedlander & Tabach, 2001), is also used, although not so often. However, that is not the case of the tabular representation that is never used. The reason for the lack

of use of this representation has to do with the fact that numerical and tabular representations provide similar information and, as a consequence, tend to be assumed as identical, a result also identified by Rocha (2016).

Although the teacher enrolled in this study articulates the different representations in a flexible way, it is possible to identify a preference for certain sequences and to the use (or not) of technology in each one. It is also possible to notice that the algebraic and the graphical representation are the ones who are articulated in a more diversified way, a circumstance that is certainly related to the fact that these two representations are the ones used more often. These are also the two representations that seem to suffer a deeper impact from the use of technology. The ease of access increases the moments where the graphical representation is used and consequently impacts the balance and the articulation the teacher does of the representations. Simultaneously, the ease of access to numeric values straight from the graphic (when technology is being used), relegates the tabular representation for a situation where its value is no longer recognized. The technology changes the teacher's use of the tabular representation. At the same time, it prevents the teacher from realizing, that from a mathematical point of view, there is a difference between this representation and the numerical one. A difference that somehow is emphasized (or even created) by the technology where is often possible to get a numerical representation based on some automatic process (eg., using technology someone asking for a zero can get an answer even if he has no idea about what that is).

The presence of technology impacts the way how the teacher articulates and balances representations, turning the work around some representations more usual than around others and allowing some different sequences on the use of representations, this implies that technology modifies the teacher's representational fluency. And this fluency is known to be closely related to the teachers' professional knowledge (Dreher et al., 2016; Rocha, 2013). As so, an analysis of the teachers' representational fluency could give important information about their knowledge. And it would be interesting to analyze if different types of representational fluency are related to different levels of teachers' knowledge and, of course, practices.

# An overview of gamification and gamified educational platforms for mathematics teaching

Cecilia Russo<sup>1</sup> and Zsolt Lavicza<sup>2</sup>

<sup>1</sup>Johannes Kepler University, Linz, Austria; [ceciliarusso@msn.com](mailto:ceciliarusso@msn.com)

<sup>2</sup>Johannes Kepler University, Linz, Austria; [lavicza@gmail.com](mailto:lavicza@gmail.com)

*Keywords: Gamification, education, motivation, platform.*

## Introduction

Gamification is widely present in our daily lives and it is becoming increasingly important in 21st century education to enhance students' motivation for learning. Students live in highly technological environment and recently efforts are made to adapt for this in education. Therefore, in this research we consider technology to assist in gamifying learning and to create a gamification editor or platform that offers teachers opportunities to develop or customize their own gamified environment based on their needs. We believe it is important, because currently gamification appears in various educational technology platforms, but designed by their developers and these environments do not always cater for the specific needs of teachers, students or courses. Such gamified environments will be also valuable for mathematics teachers as they can integrate gamification elements with other mathematics related technologies and resources.

## What is gamification?

Gamification is defined as “the use of game design elements in non-game contexts” (Deterding, Dixon, Khaled, & Nacke, 2011, p.10). It is present in our daily lives, for instance, we receive points for different activities or rewards in order to increase our motivation. These gamification tools proved to be successful in business, marketing, personal development and there are already some attends to use gamification in education.

## Gamification elements

Werbach and Hunter (2012) classify the elements in three categories: dynamics, mechanics and components. Dynamics are no visible game elements, but they impact in the player such as emotions and progression. Mechanics are processes that drive the player through the game, these can be challenges, feedback, or rewards. Finally, dynamics and mechanics happen in the game through components and they are the most visible elements in the game, for instance, achievements, badges, levels, points and leaderboards. Game elements can be integrated since one or more work in order to achieve the others.

Although gamified environments had been created as an integrated system, the selection of each elements is very important in order to motivate and engage all player types. In general, players can be interested in different elements of a game. According to Bartel (1996) it is possible to identify four general kinds of players according to their preferences of the game, achiever, explorer, socializer and killer.

## Gamification and motivation

According to some motivational approaches such as the self-determination theory (SDT) (Ryan & Deci, 2000) or Flow theory (Csikszentmihalyi, 2014) a person will experience motivation if the environment satisfies three external needs: competence, relatedness, and autonomy and if the person finds challenges, clear goals, immediate feedback, and balance between skills and challenges in the task. To design a gamified environment to raise the students' motivation, we need to add games elements and to choose activities that drive students through the autonomy, competence and relatedness feelings at the same they experience flow.

Currently, there are some educative platforms with gamification features, which can be used by both teachers and students. Some of them let teachers to create materials or environments with some gamification features, or others offer their materials for a gamified environment. However, these platforms are quite limited and a more general editor to create gamification environment would be desired.

## Proposal

The digital poster will introduce a description of the most used gamification elements as well as the connection between them in order to achieve students' motivation. As a part of this research, several educational platforms with gamification features have been reviewed, which will be presented in the poster through a brief description and a summary of their features. In addition, some recommendations will be offered to help developing a new kind of gamification editor platform; especially focusing on how mathematics teachers can utilize such platforms and how they can combine mathematical software and mathematics resources with gamification elements.

# Professional development through a web-based portal: The progress of mathematics teachers teaching algebra based on hypothetical learning trajectories

Dilek Tanışlı<sup>1</sup>, Nilüfer Köse<sup>1</sup> and Melih Turgut<sup>2</sup>

<sup>1</sup>Anadolu University, Eskisehir, Turkey

<sup>2</sup>Eskisehir Osmangazi University, Eskisehir, Turkey; [mturgut@ogu.edu.tr](mailto:mturgut@ogu.edu.tr)

*The aim of this paper is to present preliminary findings of a large-scale project for designing a web-based portal to contribute to the professional development of mathematics teachers for teaching algebra in lower secondary education. Eleven teachers volunteered to participate in this research that aimed to design hypothetical learning trajectories (HLTs) for sixth-grade algebra context over a three-week period. The teachers designed their own HLTs through a web portal by receiving feedback from mathematics teacher educators online. Their processes of designing and applying lesson plans during the first and third week were analysed according to the components of HLT and the theoretical perspective of the quartet of subject matter knowledge. Data analysis revealed that the teachers managed to define more coherent learning goals and hypothesis for their students' learning as well as making connections between the concepts.*

*Keywords: Mathematics teacher, Professional development, Hypothetical learning trajectories.*

## Introduction

In Turkey, as in many countries, studies on the mathematics teacher knowledge received particular attention from researchers (Gökkurt & Soylu, 2016; Türnüklü, Akkaş & Gündoğdu Alaylı, 2015). Research on in-service teachers commonly indicates that a number of issues exist regarding teachers' subject matter knowledge of mathematics. Researchers have addressed major problems in the Turkish context: (i) a lack of certain professional development programs and their sustainability; and (ii) a gap between research and practice, which, in particular, means a lack of communication between mathematics teacher educators and in-service mathematics teachers (Yıldırım, 2013). The latter is of crucial importance since professional development activities are generally organised independently by each public school whereby teachers prepare termly plans without any collaboration with mathematics teacher educators. This research study elaborates the design and use of a web-based portal to contribute to the professional development of mathematics teachers, in which they design their own teaching-learning algebra activities within a perspective of hypothetical learning trajectories (HLT) (Simon, 1995) through close interaction with mathematics teacher educators.

We focus on the algebra context of Turkish (lower) secondary school curriculum and design a large-scale research project adopting a number of theoretical and conceptual elements, such as *mathematics teaching cycle* and HLT (Simon, 1995) and the *mathematics subject matter knowledge quartet*, as described by Rowland, Huckstep and Thwaites (2005).

## Theoretical Framework and Description of the Project

The notion of a *learning trajectory* corresponds to possible (anticipated) learning paths that students could follow in a proposed content designed under certain objectives. Since learning, in itself, is a complex process and depends on phenomenological experiences, Simon (1995) adds the word *hypothetical* to learning trajectory to emphasise a teacher's prediction about students learning and elaborates the notion of HLT under three components; 'the learning goal that defines the direction, the learning activities, and the hypothetical learning process' (p. 136). In fact, Simon (1995) considers the HLTs as a part of mathematics teaching cycle, which includes certain key components such as a teacher's knowledge and an assessment of student knowledge (Figure 1).

**Figure 1: Mathematics Teaching Cycle (adapted from Simon, 1995, p. 136)**

In Figure 1, particular emphasis is given to the teacher's knowledge as a starting point. Therefore, in this research, we consider and refer to a quartet of subject matter knowledge of mathematics (Rowland et al., 2005) that has four dimensions; *foundation*, *transformation*, *connection*, and *contingency*. The first component, foundation refers to a repertoire of the teacher's academic knowledge for teaching-learning mathematics including his/her beliefs regarding why mathematics is important and why it should be taught. Here, transformation refers to the transformation of theoretical knowledge into practice by designing and planning pedagogical tasks in terms of choosing appropriate examples and activities for the construction of mathematical meanings. The notion of connection refers to the coherence of designed parts of a lesson or series of lessons through deliberately chosen activities and domain-specific tasks. Such pedagogical task sequences enable students to make a connection between different concepts as well as to the interplay between different representations. The final component contingency refers to 'classroom events that are almost impossible to plan for' (Rowland et al., 2005, p. 263).

Related literature confirms that Simon's (1995) mathematics teaching cycle within HLTs could be a heuristic tool for teachers' professional development (e.g. Wilson, Mojika, & Confrey, 2013). Consequently, we exploit mathematics teaching cycles as twofold: as a perspective for designing interfaces of the web portal (which will be explained in the next subsection); and as an analysis tool to explore teachers' progress as a part of their professional development. In order to elaborate development of teachers' knowledge in depth, we also refer to the subject matter knowledge quartet as an additional analysis tool while looking deep into the teachers' lesson plans.

## The Project and Research Question

Since the Internet is now widely used in different platforms as well as in educational contexts, we designed a sustainable and specific web portal to ensure mathematics teachers' professional

development regarding algebra content of the (lower) secondary school mathematics curriculum. We specifically focused on algebra content as the researchers in the project team have background knowledge in epistemological issues and misconceptions regarding learning algebra. In order to create such a portal, at first, a domain <http://megedep.anadolu.edu.tr> was taken, where ‘megedep’ referred to a shortcut of the project’s title in Turkish. Figure 2 displays the (homepage) interface of the website.

Figure 2: Megedep's (Web portal) interface

The interface includes some practical information in addition to theoretical foundations that are necessary for participating teachers in the project. More precisely, the interface includes a video describing the aim of the project, a manual for using the website, an introductory description for constructivism and the notion of HLT, as well as exemplary lesson designs under the notion of HLT. After registering to the website, the teachers could connect to a user interface including the components of the mathematics teaching cycle, which is sketched in Figure 3a.

(a)

(b)

Figure 3: a. The user interface (translated), b. The user interface to enter components of HLT

When a teacher selects ‘Process’, Figure 3b is shown, where the teacher enters the class level, the topic and the related learning objectives determined by the Turkish Ministry of National Education (MoNE, 2018) of Turkey. In the portal, we followed Khan (2005) for designing an e-learning platform where there exists an effective *feedback* system. When teachers enter the learning goal, possible activities and their hypotheses for students learning, the mathematics (teacher) educators

(MTEs) (in this paper, the authors) of the project receive alerts by email. Through entering their own interface, MTEs review the teachers' input and give feedback to the teachers to improve the anticipated teaching and learning processes. Thereafter, the teachers make revisions, and if they complete necessary improvements, then they could proceed to design a more fine-grain teaching plan. After that, the MTEs again review their plans and provide feedback. The progress continues in a cycle like this. However, it ends when the teachers record their own teaching episode and upload videos to the web portal after having written their responses to some reflective questions (described in the methods section) regarding the process. Thereafter, the MTEs watch the teaching episodes and review the teachers' responses to reflective questions by taking notes and then communicate their ideas to the teachers through the portal for the teachers to prepare and develop the next episodes.

In this paper we provide a brief analysis of the teachers' initial lesson designs and the final (third) lesson designs created within the web portal to explore their professional development progress. We address the research question: How does mathematics teachers' professional development progress when they use megedep portal to design HLTs and lesson plans for teaching algebra?

## Methods

Theoretical insights of the mathematics teaching cycle (Simon, 1995) and quartet of subject matter knowledge (Rowland et al., 2005) refer to a qualitative paradigm. In this paper, in order to explore progress of teachers' professional development in depth, we consider the same perspective and adopt a case study design (Bogdan & Biklen, 1998). Eleven (all six grade teachers) secondary school mathematics teachers (T1–T11) with different teaching experiences (ranging 1–15 years) volunteered to participate in the project. All of the participants work in the same city located in central Turkey and have experience of the objectives (algebra) of the national curriculum, having all graduated from faculties of education from different universities. In addition, while T1, T5, T6, T8 and T10 have only a bachelor degree, T7 is studying for a master's degree and also T2, T3, T4 and T11 are studying for doctorates. One participant, T9, already holds a master's degree. All of the participants learnt of the notion of HLT for the first time as they become involved in the project. During the first project meeting (lasting around three hours), all of the participants were introduced to the philosophy behind constructivism, the use of the megedep web portal, and the notion HLT with a number of exemplary cases.

## The Data and Analysis

The data comes from two sources: the first is based on the MTEs' evaluations of the teachers' designs of HLTs. In other words, the teachers designed their initial HLTs and MTEs wrote feedback to improve each part. After the teachers' improvements on the HLTs, the designs were reviewed once more. The first part of the data comes from the MTE final reviews of the HLTs. The second part of the data comes from the teachers' responses to reflective questions that were proposed after they completed teaching episodes. Three reflective questions were asked before the teachers applied their HLTs whereas four questions being proposed after they applied their lesson plans.

Table 1 shows the reflective questions that were proposed to the teachers through the megedep interface.

Before application of the lesson plans	After application of the lesson plans
<i>-What were the key elements in your lesson plan?</i> <i>-How and why did you determine the activities in your plan?</i> <i>-How did you determine your hypotheses for students learning?</i>	<i>-Which learning goals were obtained and which were not? Explain in detail.</i> <i>-Which parts of your plan worked well, or which did not? Explain in detail.</i> <i>-Which hypotheses of student learning appeared in the classroom? Did all? Were there any contingency cases? If so, what did you do?</i> <i>-In the teaching process, which concepts were conceptualised and which were not? Explain in detail.</i>

**Table 1: Reflective questions proposed to the teachers through the megedep interface**

The teachers prepared three teaching episodes corresponding to three weeks. In other words, they prepared an HLT for each week considering the objectives of the curriculum. MTEs evaluated the first and third week's HLTs, in order to explore the teachers' progression. Similarly, the MTEs also collected all of the responses given to the reflective questions. A thematic analysis (Miles & Huberman, 1994) was employed to elaborate emerging main themes within a perspective of components of HLT and the quartet of subject matter knowledge.

## Findings

Since our focus is on designing HLTs and lesson plans as components of professional development, we will present our findings in two subsections; an analysis of the teachers' designs of HLTs and an analysis of the teachers' designs and applications of lesson plans.

### Analysis of the Teachers' Design of HLTs

The analysis of the teachers' first HLT designs revealed: four themes appeared for determining learning goals; three themes for determining activities; and four themes for determining the hypotheses for students learning. Table 2 describes these themes and their respective frequencies.

Determining Learning Goals	Determining Activities	Determining Hypotheses
<i>-Defining learning goals coherent with curriculum objectives (T1)</i> <i>-Not sequencing learning goals (T2, T3, T4, T5, T6, T7, T8)</i> <i>-Referring to objectives as learning goals (T9, T10, T11)</i> <i>-Defining learning goals, not in relation to objectives (T8, T7, T6, T2)</i>	<i>-Determination of coherent activities (T7, T8, T6, T11, T9, T3, T2)</i> <i>-Activities not based on the curriculum objectives (T8, T6, T7, T10)</i> <i>-Writing only the title of activities (not based on any objective) (T5, T1, T4)</i>	<i>-Writing hypotheses based on activities (T2, T3, T11)</i> <i>-Formulating a partial hypothesis not focusing on entire student learning (T4, T9, T1, T5, T10, T8)</i> <i>-Hypotheses not based on the activities (T7)</i> <i>-Not a clear formulation (T6)</i>

**Table 2: Themes regarding the teachers' design of the first HLT**

Table 1 reveals that only one teacher defined learning goals according to the objectives of the curriculum, whereas seven teachers could not define sequencing learning goals, i.e. they were not able to express learning goals in order. Three teachers directly referred to the curriculum objectives

as learning goals, while four of them defined the learning goals independent of the curriculum objectives. With respect to a determination of the activities, seven teachers managed to define coherent activities, i.e. activities that are coherent with curriculum objectives and also with the learning goals that they defined. Four teachers expressed activities not based on the objectives and three teachers only wrote the title of activities without giving any details. Three teachers expressed their hypotheses that are coherent with the learning objectives and activities that had been written before. However, it should be noted that these three teachers thought that students would follow the same learning trajectory. Six teachers formulated their hypotheses partially, without focusing on the students' entire learning of the proposed concepts, while one teacher proposed a hypothesis independent of the activities and learning goals. Moreover, one teacher expressed his possible teaching steps, including no trace of the hypotheses of students learning.

After all the teachers had used the megedep portal for three weeks, we analysed their resulting HLTs. Table 3 shows that there were two emerging themes for determination of the learning goals; one theme for the determination of the activities and two themes for the determination of the hypotheses.

Determination of Learning Goals	Determining Activities	Determining Hypotheses
<i>-Defining learning goals based on the curriculum objectives (T6, T1, T3, T4, T7, T11, T5, T2)</i> <i>-Defining learning goals part by part, not based on all curriculum objectives (T10, T8, T9)</i>	<i>- Determination of coherent activities (T6, T1, T3, T10, T4, T7, T11, T5, T2, T8, T9)</i>	<i>- Writing hypotheses based on activities (T3, T11, T5, T2)</i> <i>- Formulating a partial hypothesis not focusing on entire student learning (T6, T1, T10, T4, T7, T8, T9)</i>

**Table 3: Themes regarding the teachers' design of the third HLT**

Eight teachers managed to define learning goals based on the curriculum objectives. However, there were still three teachers who defined learning goals part-by-part, not based on the curriculum objectives. All of the teachers were able to define activities coherent with the learning goals and curriculum objectives and also explained them in detail. With respect to a determination of the hypothesis, four teachers expressed the hypotheses of students' learning that were coherent with the learning goals and activities, while seven teachers formulated hypotheses part-by-part, not focusing on the conceptual learning.

### **Analysis of the Teachers' Designs and Applications of the Lesson Plans**

The teachers' responses to the reflective questions posed after the first and the third weeks' lesson plans were analysed according to the quartet of subject matter knowledge. When the authors compared the personal analyses on the reflective questions, it was agreed to consider the same themes for the first and the third week's results. As a result, four themes emerged for the foundation component, three themes emerged for transformation component, five themes emerged for connection component, and three themes emerged for the contingency component. Table 4 summarises the emerging themes with the arrows indicating some themes that have specific meanings. For instance,  $a \rightarrow b$  means that  $a$  is the number of teachers in the first week, while  $b$  is the number of teachers in the third week.

Foundation	Transformation	Connection	Contingency
<i>-Recognition of students' misconceptions (7→11)</i> <i>-Proposing affective questions (3→5)</i> <i>-Focusing on computational applications (7→2)</i> <i>-Referring to multiple ways assessing student knowledge (3→8)</i>	<i>-Using multiple representations (11→11)</i> <i>-Selecting and/or preparing carefully-designed problems (2→9)</i> <i>-Explaining mathematical concepts in several ways (3→11)</i>	<i>-The interplay between mathematical concepts and notions (3→11)</i> <i>-The interplay between mathematical problem-solving techniques (4→11)</i>	<i>-Thinking all the goals were achieved by students: no contingency action (2→0)</i> <i>-Explaining which parts of the plans worked and why (6→11)</i> <i>-Explaining how and why certain activities did not work (2→11)</i>

**Table 4: Overview of the teachers' design and application of the lesson plans**

Table 4 indicates that there is an increase in the number of the teachers, who recognised students' misconceptions, proposed effective questions and referred to multiple ways of assessing student knowledge by the end of the third week's application. In parallel with this finding, the teachers' focus on computational applications decreased. No change occurred in the use of multiple representations while selecting and/or preparing carefully-designed tasks, and the teachers' emphasis on explaining mathematical concepts increased. Similarly, at the end of the third week, the teachers' interplay between mathematical concepts and interplay between mathematical problem-solving techniques increased. With regard to the contingency component, after the first week's application, two of the teachers believed that all of the goals had been achieved by the students. However, at the end of the third week, there is an indication that most of the teachers' beliefs were changed. Moreover, at the end of the third week, the teachers managed to explain how and why certain parts of the plans and proposed activities did not work.

## Conclusions and Further Steps

In this paper, we present preliminary findings of an on-going large-scale project aiming to contribute to the professional development of mathematics teachers through a web-based portal. The findings of the study suggested that at the end of three weeks' usage of the megedep portal, the participant teachers managed to define more coherent learning goals, classroom activities and hypotheses for students learning regarding (lower) secondary school algebra. Most progress is observed in the teachers' interplay between the mathematical concepts by referring to different mathematical problem-solving techniques. These conclusions were possible for the teachers' own readings of the existing literature on learning algebra and the MTEs feedback that was given at each step for designing HLTs through the megedep portal. However, expressing hypotheses for students learning as well as determining learning goals based on curriculum objectives are not trivial tasks for the teachers. We aim to acknowledge this fact by showing or preparing more examples from the literature (e.g. Simon, 1995; Simon & Tzur, 2004) in order to provide teachers with a detailed understanding to write hypotheses for their own classroom context. In summary, the main contribution of this paper is to show how a web-based portal could mediate the professional development of mathematics teachers, where the key component in such progress is peers' review

and feedback in lower algebra context provided by the megedep portal. The use of acknowledged digital technologies here constructs a link between a *collaborative design* for teaching-learning algebra and *classroom practice*, which can be considered as novel progress for their professional development. The main ease here is the collaboration, which is independent of time and place.

The next steps of the project can be summarised by conducting the same process with seventh grade teachers, but over seven weeks and this time focusing on the students learning and the use of pre-test and post-test tasks. The results of these steps will be the focus of future research papers.

### Acknowledgement

*Despite the potential of digital technology to enhance the learning of mathematics the use of graphing tools with or without computer algebra systems (CAS) remains low. For this reason, there is a need to identify and understand factors that lead to greater technology uptake. In this quantitative study with 198 upper secondary in-service teachers from Germany the relation between self-efficacy beliefs and frequency of technology use in the mathematics classroom is examined. Results show that higher self-efficacy beliefs are strongly associated with a more frequent use of technology. Based on the results, recommendations for teacher education are given.*

*Keywords: Self-efficacy, technology, teacher-education, graphing calculators, professional development.*

## Introduction

Research in the last decades has shown that digital technology like function plotters or computer algebra systems can facilitate the learning of mathematics in many different ways (Drijvers et al., 2016). For this reason, there is an ubiquitous call for the integration of these technologies into mathematics teaching. However current use of technology in the mathematics classroom still remains low:

“Nowadays there exist countless ideas, classroom suggestions, lesson plans and research reports for the use of new technologies in mathematics classrooms. But the situation concerning the real use of DT [digital technology] in mathematics classrooms has not succeeded in the way many had expected in the last decades.” (Weigand, 2014, p. 5; see also Heid, Thomas, & Zbiek, 2013, p. 599)

This indicates that the implementation of technology into the mathematics classroom is not a straightforward task and draws attention to the need to understand the factors influencing technology uptake. This is particularly important for the design of professional development (PD) programs which aim at supporting teachers' when integrating digital technology. Research shows that beliefs and knowledge as well as external factors like school culture and resources play an important role (Heid, Thomas, & Zbiek, 2013, p. 630). However, less attention has been given to self-efficacy beliefs which capture a persons' perceived ability to organize and execute courses of action (Bandura, 1997, p. 3). Therefore, this paper explores to what extend self-efficacy beliefs in the domain of teaching mathematics with technology influence the uptake of technology.

## Theoretical background

Digital technology in the mathematics classroom comprises a plethora of different technologies. These range from general technology that can be used across different subjects (e.g. word

processing software like MS-Word) to subject-specific technology like digital learning environments, function plotters, geometry packages and computer algebra systems (CAS) that are specifically used in mathematics education. In this paper, unless stated otherwise, the term “technology” is used to refer to these specific tools, that are also known under the term “Mathematics Analysis Software” (MAS; Pierce & Ball, 2009). In the last 30 years, a great number of research projects has shown that MAS can support student learning in many different ways. For example, these tools can facilitate constructivist teaching approaches like discovery learning by giving pupils the opportunity to explore mathematical links on their own. In addition, digital tools can enhance conceptual understanding of mathematics by providing easy access to multiple and linked representations (Drijvers et al., 2016). For this reason, the use of technology in the mathematics classrooms is advocated for by researchers as well as teachers.

Despite this call for a deep integration of technology into mathematics teaching there is a “widely perceived quantitative gap and qualitative gap between the reality of teachers’ use of ICT and the potential for ICT suggested by research and policy” (Bretscher, 2014, p. 43). Reasons for this are multifaceted and many different factors have been proposed in the last decade which can affect the uptake of technology. These factors include external factors like time constraints and resources (Thomas & Palmer, 2014, p. 72; Heid, Thomas, & Zbiek, 2013, p. 630). However, research indicates that the most important factor is the teacher who is ultimately responsible for how and when technology is used: “Clearly, schools can go only so far to encourage ICT use; actual take-up depends largely on teachers’ personal feelings, skills and attitudes to IT in general” (Mumtaz, 2000, p. 337). Therefore, internal factors like teacher knowledge and teacher beliefs have become the focus of attention. For example, the concept of TPACK (Mishra & Koehler, 2006) acknowledges, that a special type of knowledge is needed by teachers to teach mathematics with technology. Also, pedagogical beliefs, for example about constructivist or traditional philosophies of teaching mathematics, and beliefs referring to the teaching and learning mathematics with technology have been studied, showing that these beliefs can play an important role.

However, it seems that research has given little attention to teacher self-efficacy-beliefs when teaching mathematics with technology. Self-efficacy beliefs are defined as “a judgement of one’s ability to organize and execute the courses of action required to produce given attainments” (Bandura, 1997, p. 3). This means, self-efficacy beliefs don’t capture the actual ability of a person but rather describe how someone perceives it. Research about the integration of general technology like word processing or presentation software across different subjects has found that self-efficacy beliefs play a crucial role for the uptake of these technologies (Ertmer & Ottenbreit-Leftwich, 2010; Wang, Ertmer, & Newby, 2004). As Ertmer & Ottenbreit-Leftwich note: “Although knowledge of technology is necessary, it is not enough if teachers do not also feel confident<sup>1</sup> using that knowledge to facilitate student learning” (Ertmer & Ottenbreit-Leftwich, 2010, p. 261). Therefore, it is

---

<sup>1</sup> The term “confidence” is often used interchangeably with the terms “self-efficacy” or “self-efficacy beliefs”. However Bandura notes that „Confidence is a catchword in sports rather than a construct embedded in a theoretical system“ (Bandura, 1997, p. 382). Therefore, we will use the term “self-efficacy beliefs” throughout this paper.

particular surprising that self-efficacy beliefs have not been studied in much detail in the context of teaching with MAS. Apart from the works of Cavanagh & Mitchelmore (2003, p. 16), Doerr & Zangor (2000, p.159) and Hong & Thomas (2006) where the role of self-efficacy beliefs becomes apparent subliminally at some points, we could only identify the work of Thomas & Palmer (2014) explicitly taking self-efficacy beliefs into account. They show that 42% of the surveyed teachers do mention lack of self-efficacy as an obstacle preventing teachers to use calculators more in their teaching. In addition, teachers with higher self-efficacy beliefs showed a more positive attitude to technology and to the use of technology in the learning of mathematics. Hence, they include confidence as a key factor in their model for technology integration. In summary, there seems to be some indication that teacher self-efficacy beliefs play an important role for the integration of technology into the mathematics classroom, but empirical evidence that teachers' self-efficacy beliefs about teaching with MAS is indeed linked to the classroom usage of technology is lacking.

### **Research question & methodology**

The study aims to explore the link between self-efficacy and use of MAS. To achieve this goal, it is necessary to measure teachers' self-efficacy beliefs as well as teachers' technology use. Since the frequency of technology use can be more validly be self-reported by teachers compared to the quality of their teaching (Mayer, 1999) we focus on self-reported frequency of technology use and addresses the following questions: Do teachers with higher self-efficacy beliefs use MAS more often than teachers with lower self-efficacy beliefs? Which areas of technology use show particular strong links to self-efficacy beliefs?

To capture the frequency of technology use we used a likert-scale questionnaire (Thurm, 2018) assessing the use of technology in the following areas: (f1) use of technology for discovery learning, (f2) use of technology for linking multiple representations, (f3) use of technology when practicing, (f4) use of technology to support individual learning. In addition, a category capturing how often the use of technology was subject to critical reflection was included. Items in this category asked for example how often limitations of technology were discussed or how often there was a critical reflection about when to use pen & paper skills and when to use technology to solve a given task.

To measure teachers' self-efficacy beliefs, we developed a questionnaire that assessed self-efficacy in two domains (see below). For each of these domains a set of items was generated and refined until validity of the items was agreed on by teachers and experts. Response category was chosen according to Banduras "Guide for constructing self-efficacy scales" (Bandura, 1997) which recommends that teachers rate the strength of their belief in their ability on a scale from 0-100. In the following we give a brief description of each domain:

(s1) Self-efficacy related to task design & task selection when teaching with technology (4 Items)

The design of tasks is one of the most important factors when teaching with technology: „The inclusion of technology requires an understanding of the kinds of tasks that may utilize the resources provided by the technology to support students' high-level thinking“ (Sherman, 2014, p. 225; see also Drijvers, 2015). If teachers don't feel able to select and design appropriate tasks they are most likely to use their old tasks that are usually not tuned to the use of technology. Two sample

items of the scale were: I can design task for the use with MAS. I can distinguish between good and bad tasks for the use with MAS.

(s2) Self- efficacy related to lesson design & lesson implementation (4 Items)

These tasks however will not unfold their potential on their own. They need to be embedded in carefully designed lessons. Hence teachers must feel able to design and carry out appropriate lessons:

“[...] the teacher has to orchestrate learning, for example by synthesizing the results of technology-rich activities, highlighting fruitful tool techniques, and relating the experiences within the technological environment to paper-and-pencil skills or to other mathematic activities.” (Drijvers, 2015, p.148)

Two sample items of the scale were: I can design and implement lessons that support discovery learning using MAS. I am able to design lessons that make versatile use of MAS.

Both scales were administered in 2014 to 198 upper secondary school teachers within a larger research study (Thurm, Klinger, & Barzel, 2015) in North Rhine-Westphalia, Germany. In this state the use of MAS is compulsory in the final examination in upper secondary since the schoolyear 2014/2015. The average age of the teachers was 43 years, which is comparable to the average age of 45 years for all teachers in North Rhine-Westphalia. Teaching experience with mathematics was distributed as follows: 0-5 years (27%), 6-11 years (19%), 12-17 (16 %), 18-23 (11%), more than 23 years (25%). Due to the fact that MAS had been made compulsory only shortly before the study took place, there was a large number of teachers without any previous experience in teaching with MAS. In total, 52% had no previous experience teaching mathematics with technology and only 12% had more than 5 years' experience in teaching mathematics with technology.

## Results

In a first step we used a confirmatory factor analysis to scrutinize the quality of the questionnaires on an empirical base. The goodness of fit was judged using the chi-square-fit index, the root mean square error of approximation (RMSEA), the standardized root mean square residual (SRMR) and the comparative fit index (CFI). The result for the self-efficacy questionnaire showed a good model fit with RMSEA = 0.041 SRMR = 0.022, CFI = 0.994, and  $\chi^2/df = 1.327$ . The scales (s1) and (s2) also showed a good reliability with Cronbach' s alpha equal to 0.92 and 0.9 respectively. The goodness of fit and the reliability of the questionnaire assessing frequency of technology use were also high (see Thurm, 2018).

In first step we checked to what extend experience in teaching mathematics and teaching with MAS correlated with self-efficacy and frequency of technology use. As can be seen (Table 1) there is a small correlation between self-efficacy and the number of years teachers previously used technology in their classroom. Subsequently, we calculated the correlation between all scales on a latent level (Table 1). It is obvious that there are significant correlations between all subscales indicating that higher self-efficacy beliefs correspond to more frequent use of technology. Self-efficacy in the area of task design (s1) is most strongly linked to discovery learning (f1) and practice (f3), self-efficacy in the area of lesson design and implementation (s2) is most strongly

linked to discovery learning (f1) and individual learning (f4). In addition, it is remarkably that the scale (s2) consistently shows higher association with frequency of technology use than the scale (s1). Lowest correlation between self-efficacy and frequency of technology use is observed for the areas of multiple representation (f2) and reflection (f5).

		Self-efficacy			
		(s1) Designing tasks	(s2) Designing & implementing lessons	TE mathematics (years)	TE technology (years)
Frequency of use	(f1) Discovery learning	0.427***	0.564***	-0.03	0.14
	(f2) Multiple representations	0.230*	0.317**	0.06	0.07
	(f3) Practice	0.435***	0.445***	0.13	0.13
	(f4) Individual learning	0.391***	0.516***	-0.06	0.11
	(f5) Reflection	0.289**	0.293**	-0.15	0.03
	TE mathematics (years)	-0.08	-0.12	1	0.13
	TE technology (years)	0.27**	0.33**	0.13	1

**Table 1: Result of the correlation analysis (\*  $p < 0.1$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , TE=Teaching experience)**

## Discussion

The study aimed to provide empirical evidence for the link between self-efficacy and using MAS. The results clearly indicate a strong relationship showing that higher self-efficacy beliefs are associated with more frequent use of technology. In addition, self-efficacy correlates only to a limited extent with teaching experience with technology, which indicates that teachers need additional support for developing their self-efficacy beliefs. In total, the results support the model of Thomas & Palmer (2014) who include self-efficacy as a key variable in their model of technology integration. Furthermore, the importance of self-efficacy becomes even more pronounced when noticing that the size of the correlation between self-efficacy and frequency of technology use is higher compared to the correlation of technology-related beliefs and frequency of technology use found in Thurm (2018). This indicates that self-efficacy beliefs might be even more influential for technology uptake than beliefs about the value of technology in the learning of mathematics.

But why do self-efficacy beliefs seem to play such an important role? One explanation might be, that teaching with technology poses a plethora of new challenges because it requires many changes in the teaching routines and attitudes. For example, traditional task that requires routine pen & paper skills easily become obsolete in the presence of a CAS. In addition, teaching with MAS can lead to more individualized learning, with greater uncertainty for the teacher who cannot longer simply follow a strict teaching plan. For example, Dunham & Dick (1994, p. 443) stress, that teachers teaching with technology need to be much more used to deal with unplanned situations,

show more flexibility and may experience a perceived loss of control. Especially for teachers that are used to a traditional style of teaching this can pose a major challenge:

“[...] the use of technology often means more individualized, student-centered classrooms in which teachers are no longer the sole source and authority of knowledge. This could be very disturbing to many teachers who are used to lecturing and other teacher-centered approaches because it require them to abandon their routines and learn new ways of teaching.” (Zhao & Cziko, 2001, S.18)

From the results several recommendations for teacher education and professional development can be inferred. Firstly, programs must place a stronger focus on developing teacher's self-efficacy beliefs. Currently, knowledge, pedagogical beliefs and beliefs regarding the teaching of learning with technology seem to be the focus of most technology related professional development programs (e.g. Chamblee et al. 2008). Even though these factors might also increase self-efficacy, the most effective way of increasing self-efficacy is to enable successful mastery experiences for teachers. For example, Tschannen-Moran & McMaster (2009) compared different approaches for fostering self-efficacy beliefs in PD-programs and concluded that authentic mastery experience embedded in the teachers regular teaching context was the most powerful way to foster self-efficacy beliefs. In particular, they stress the role of individual support for teachers: “Without coaching to assist teachers in the implementation of the new skill, a significant proportion of teachers were left feeling more inadequate than they had before“ (Tschannen-Moran & McMaster, 2009, p. 241). However, programs that individually assist teachers to put theory into practice in this way appear to be quite rare in the context of teaching with technology (Gugeon et al., 2009, p.343). This might be due to the fact that individual coaching is quite resource intensive and hard to scale up.

For this reason, it might be fruitful to develop strategies for increasing self-efficacy even when individual coaching is not possible due to a lack of resources. For example, teachers might prepare a class for their fellow PD-participants and carry out part of the class during the PD-meetings. With this respect, approaches like micro-teaching or approximations-of practice (Grossmann, Hammermess & McDonald, 2009) could be a fruitful approach. Another way to increase self-efficacy could be the use of vicarious experiences which refers to hearing about or observing other teacher's successful technology integration (Wang, Ertmer & Newby, 2004).

Finally, the results from this study also give some indication about content selection for PD-programs. The result that self-efficacy beliefs are stronger correlated with frequency of technology use for supporting discovery learning than with frequency of technology use to support multiple representation might reflect that discovery learning requires much stronger self-efficacy beliefs due to its complexity. In contrast, the use of multiple representations is perceived as less complex and less challenging. PD-programs could therefore choose the support of multiple representations as starting point for novice teachers and advance to discovery learning in later stages.

In summary, this study shows that teachers' self-efficacy beliefs are an important factor when teaching mathematics with technology. PD-programs must provide means to strengthen teacher's self-efficacy beliefs if we want to take teachers needs seriously and change the degree of technology integration. Otherwise the outcome of PD-programs might be limited to knowledgeable

teachers that are convinced about the benefits of technology, but lack the self-efficacy to put their knowledge and beliefs into practice. We should not miss the final step that might be self-efficacy beliefs.

# How to distinguish simulations? Development of a classification scheme for digital simulations for teaching and learning mathematics

Jan Franz Wörler<sup>1</sup>

<sup>1</sup>Julius-Maximilians-University, Wuerzburg, Germany; woerler@mathematik.uni-wuerzburg.de

*Computer simulations are used to teach and learn mathematics, and didactic research also uses the term. However, there are sometimes very different meanings of the term ‘simulation’. As a possible result didactic research on the use of simulations can only be compared to a limited extent. The present article therefore clarifies the concept of simulation. Based on this, a scheme for the classification of digital simulations, independent of the concrete content, is designed, which allows to distinguish simulations a priori and objectively according to theoretically derived didactic criteria and thus to order the wide field of “simulations”. Finally, it is briefly outlined how the scheme can help teachers to select suitable simulation implementations for teaching and learning purposes.*

*Keywords: Simulation, mathematical models, educational experiments, representations*

## Introduction

There is a multitude of computer programs, apps and files for learning and teaching mathematics, which are called “simulations” by their authors. These are, for example, Excel data sheets for the replication of cube throwing (Böer, 2012) or algorithms in computer algebra systems for calculating hiking trails within the framework of mathematical modelling (Bracke, Götze, & Siller, 2015). In the online portal GeoGebra Materials ([www.geogebra.org/materials](http://www.geogebra.org/materials)), on which authors can publish GeoGebra files, over 1000 hits are listed under the search term *simulation* for the year 2017. It can be assumed that at least some of these documents were designed for teaching-learning contexts and are actually used for learning mathematics. MathEduc ([www.zentralblatt-math.org/matheduc/](http://www.zentralblatt-math.org/matheduc/)), a database for publications with a mathematics didactic background, currently lists over 2000 publications that contain the term *simulation*.

These are just a few examples of “simulations”. However, their consideration already suggests the interpretation that research, theory and practice for learning and teaching mathematics are currently concerned with simulations: simulations are used to teach mathematical content or procedures at present. The above examples also show how differently the term simulation is used: the examples refer to a broad variety of mathematical contents, use different representations, are based on different types of mathematical models, allow partly very extensive manipulations and partly none, are used to pursue different objectives or to fulfill different functions. This leads us to the thesis that the term *simulation* is used in connection with the teaching of mathematics, but that its meaning remains in general individual and vague.

If, however, didactic research aims to collect empirical research data on the use of computer simulations for teaching and learning mathematics and if these data and results are to be comparable, then a common conceptual basis for simulations is indispensable.

This article presents ideas for the design of such a basis by theoretically deriving a multidimensional classification scheme for digital simulations. For this purpose, essential characteristics of simulations

are first deduced, which then depending on their traits are combined into a system to distinguish between simulations. The article therefore investigates the following research questions:

(Q1) Which central characteristics and features do digital simulations for learning mathematics have? Which traits of these characteristics can be derived?

(Q2) How can these characteristics and traits be used to assign computer simulations a priori and objectively into classes and to distinguish them from each other?

## Methodological approach

In order to clarify research question Q1, a hermeneutical approach is pursued: it derives essential characteristics of simulations from existing theories (e.g. systems theory) and application sciences by means of a literature research and thus searches for the theoretical meaning of the term *simulation*. The focus will be on those aspects that are important from a didactic point of view. The approach is alternately confronted with a comparison with such properties of programs, apps and files which exist in reality (on the Internet, in textbooks, as learning apps or the like) and which are called "simulations" by their authors. They show concrete characteristics of the properties. In this way, the question is examined in the alternation of deduction from theory and induction from teaching-learning practice and thus does not lose its relation to the practice of teaching mathematics.

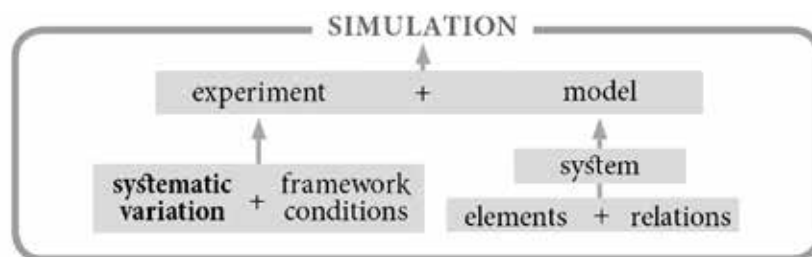

## Theoretical foundations

When it comes to simulations, a distinction was usually made between physical simulation with concrete models and simulation with abstract or mathematical models (Krüger, 1974). In the latter case, simulation is a calculation carried out on a computer, which Krüger (1974, p. 27) calls "calculation experiment" and which Hockney and Eastwood (1988, p. xix) call "computer experiment". On the one hand, this distinction is very rough. On the other hand, the two categories become blurred as soon as physical experiments are virtually mapped on the computer, as explained in detail in Wörler (2018). Therefore, they are not useful for classification.

For this reason, we assume a more general approach: we interpret simulation—in close agreement with Krüger (1974), Kobayashi (1981) and Greefrath and Weigand (2012)—as the conduct of experiments with models of systems. It is therefore necessary to clarify the terms *experiment* and *model* in order to understand the concept of simulation.

## Models

According to Henn (2011, p. 419), "models are simplifying presentations, which consider only certain, somehow objectifiable parts of reality". This characterization corresponds well with the examples of simulations mentioned above, because they refer to a real situation or a real object, which is reproduced virtually on the computer. In addition, simulations are also conceivable that take up intra-mathematical phenomena: experimental work with geometric figures or with integral and derivative can serve as examples for simulations that have no explicit reference to reality.

**Figure 1: Components of a simulation**

Therefore, the term *model* has to be understood more broadly with regard to simulations. For example, Velten (2009, p. 3) states: models are “simplified descriptions of a system”. A system in turn “is an object or a collection of objects whose properties we want to study” (Velten, 2009, p. 8). It consists, according to Bossel (1992), of individual elements connected by relations. A model therefore contains a mapping of the relevant elements and relations of the system. This is illustrated in Figure 1.

### Experiments and variations

Experiments are particularly widespread in the social and natural sciences, where they are a central method of gaining scientific knowledge. They can be used to create or to test hypotheses and usually they use the observation of the effects of targeted manipulations of a system. For physics education, for example, Kircher, Girwidz and Häußler (2009, p. 244) describe how to proceed in experiments: “Under fixed and controllable framework conditions, observations and measurements are carried out on physical processes and objects; variables are systematically changed and data are collected”. Accordingly, the systematic variation of independent variables within defined framework conditions is the central component of conducting experiments—and thus also of simulations.

The important role of systematic variation in the learning and teaching of mathematics has already been emphasized: Schoenfeld (1985) sees variation as a heuristic principle in problem solving. Schupp (2002) adds that variation as a student activity can help to convey an authentic picture of mathematics and enable a deeper understanding.

Philipp (2013) interprets intra-mathematical experimentation—in the sense of hypothesis formation and hypothesis testing—as explorative problem solving. She considers this type of problem solving to be a process characteristic of mathematics, but also sees it as a fundamental competence with four partial competences: generating examples, structuring, formulating hypotheses, checking hypotheses.

These activities are addressed in the same way when experimenting with models of objects or systems in simulations. To vary allows the creation of different *system states* (called “data” by Kircher et. al., 2009, p. 244, and called “examples” by Philipp, 2013, p. 156) that can be analysed to learn something about the given system or to understand it. This applies to students as well as to scientists, which is why experimentation is also a central activity inquiry-based approaches (e.g. Artigue & Blomhøj, 2013). Therefore, in the following we will distinguish simulations according to what types of variation they allow.

### Types of variation

According to the above considerations, models can be traced back to their elements and relations. Furthermore, experiments are characterized by variation within controlled framework conditions.

Under these assumptions, six different types of variations in simulations can be derived theoretically (Wörler, 2018). Only the following three should be mentioned here, because the other three have mainly theoretical-epistemological value: these types are the possibility of variation of ...

- 1) the number of model elements,
- 2) the properties of the model elements,
- 3) the relations between model elements,

They are hereinafter referred to as *Possibilities of Interaction* between the experimenter (e.g. the learner) and the underlying (mathematical) simulation model. Their existence can be checked objectively and a priori for each concrete implementation of a simulation. In this way, simulations can be distinguished according to the type and the number of implemented Possibilities of Interaction. We use this approach to clarify the research question Q2 below.

### **Specifics of digital simulations**

With regard to the research question Q1 we conclude: Experiments involve the activity of varying. They also require the observation of the effects of the manipulation on the modelled system and its behavior. If experiments are transferred to the computer as digital experiments, these two aspects have to be translated, too.

This means that at least some of the Possibilities of Interaction (see above) have to be technically implemented and offered to the experimenter. Some control elements like checkboxes, sliders, input fields or selection menus must be available in every digital simulation to set and change parameters; Moreno and Mayer (2007) call this type of interaction “manipulating” (p. 311). They distinguish manipulating from “controlling” (p. 311), which includes control elements for the speed or sequence of content (such as pause/play key) but does not influence properties of the modelled system. It occurs especially with moving images or animations. It is, however, consequent also to consider controlling in the classification scheme for simulations: On the one hand, both types of interaction occur in simulations side by side, although only manipulating allows experiments. On the other hand, the connection to preliminary work on the potential of moving images for learning mathematics (Kautschitsch, 1985; Samson, & Schäfer, 2012) succeeds.

Digital experimentation also requires the possibility to observe and evaluate the modelled system and its states. Therefore, a computer output device is indispensable. This can be a conventional PC or smartphone screen. Alternatives could also be virtual reality glasses or simply a PC printer. On such output devices the result of a digital simulation (as final state after a manipulation) or the respective simulation model itself (with intermediate states during manipulation) has to be represented, for example as table, graph or diagram, but also as dynamic visualization of processes or experimental environments. Each digital simulation is therefore necessarily connected with an external representation of these model states.

Based on Bruner's modes of representation (enactive, iconic, symbolic) from 1964, Ladel (2009) proposes a scheme for the analysis of mathematical learning software on the basis of the forms of external representation used. She derives eight computer-based forms of external representation and

specifically distinguishes between static and dynamic representations. Ladel (2009) also shows that how computer programs can be classified with regard to these forms.

### Result: classification scheme

In order to answer the research question Q2, the above explanations were combined into a two-dimensional classification scheme: The first dimension is formed by the *Level of Manipulation* (LoM). This number indicates how many Possibilities of Interaction are implemented in a concrete digital simulation, i.e. whether and to what extent a concrete digital simulation allows variations by the experimenter.

For clarification, imagine a dice throwing simulation with two sliders: One controls the number of the dice, one the number of the throws. There are then two ways to interact with the underlying simulation model, which gives the simulation a LoM of 2 (labeled as: LoM 2).

In the broadest sense, the LoM indicates the degrees of freedom that the implementation gives the experimenter for interaction with the underlying simulation model (in the sense of *manipulating*, according to Moreno & Mayer, 2007). In this way, different implementations of a simulation can be analyzed with regard to their LoM and arranged on an ordinal scale.

If we accept LoM 0 (zero) on this scale, animations (generally: moving images) can also be located in the range between LoM 0 (no *controlling* or *manipulation* implemented) and LoM 1 (*manipulation* implemented). We thus take into account the type of interaction in the model that Moreno and Mayer (2007) call “controlling” (p. 311). The distinction between animation and simulation, which is not clear to outsiders in many cases, is transferred into the concrete specification of LoMs: If any controlling option is implemented, the LoM is increased by 0.5.

The second dimension of the classification scheme presented here can be defined according to the scheme of Ladel (2009): The eight types of external representations she proposes can be aggregated into the disjoint categories *isolated static representation* (ISR), *isolated dynamic rep.* (IDR), *multiple static rep.* (MSR) and *multiple dynamic rep.* (MDR). Every concrete implementation of a simulation can be analyzed in terms of how the changes in the model states triggered by the variation are represented on the output device.

		Level of Manipulation							
		0	1	2	3	4	5	LoM	
external representation	isolated	ISR							
		IDR							
	multiple	MSR							
		MDR							

**Figure 2: Two-dimensional classification scheme for digital simulations**

The result is a  $5 \times n$ -classification scheme with the dimensions *external representation* (with the four traits ISR, IDR, MSR, MDR) and *plurality of variations* (indicated in LoM), see Figure 2.

Each digital simulation can be assigned to the scheme: Let's assume that the dice throwing simulation from above represents only the final results of the experiment as bar chart. That would be an isolated static representation (ISR). The simulation would therefore be classified in the cell  $\text{ISR} \times \text{LoM } 2$  of

the schema. If, in contrast, the dice throws are represented sequentially so that the result of the experiment is assembled step by step and the bars in the chart “grow”, the representation is dynamic (IDR), so that the classification  $IDR \times LOM$  2 results. And if, in addition, a further controller is integrated which allows the speed of the process to be regulated, the LoM would be increased by 0.5 (classification:  $IDR \times LoM$  2.5); in this case, the position between two cells indicates that a dynamic sequence can be controlled that does not affect the final result.

## Discussion and outlook

The classification scheme currently presented indicates the possibilities of experimentation in the form of LoM. With this construct, simulations can be ordered locally, i.e. two implementations of the same phenomenon or mathematical model can be compared with regard to their cognitive requirements: The higher the LoM is, the higher the cognitive requirements are.

### Limitations of the scheme

Global ordering is currently not possible with the scheme, however, as the following example shows: A simulation is given in which one unbound variable  $b$  can be manipulated (LoM 1) and which displays the function graph (IDR). While the effect of the manipulation is easy to interpret for the graph of the function  $f(x) = x + b$ , it is much more difficult for  $f(x) = x^2 + b \cdot x$  or even  $f(x) = x^b + 2$ .

Thus, the scheme currently lacks an analysis of the complexity or difficulty of the content, which is reflected in the complexity of the underlying mathematical model. It should take into account the prior knowledge of the experimenter (or learner). Therefore, it is planned to extend the scheme by a didactic analysis of the concrete simulation that examines the mathematical requirements for each possibility of interaction. In this way, the model could also enable global ordering of simulations.

### Learning and teaching mathematics

Since extra-mathematical references are often taken up in simulations in order to learn mathematics, content references to related sciences are indispensable in mathematical simulations. Therefore, the scheme is not limited to learning and teaching mathematics. It can be useful whenever mathematical representations are used to experiment with models as a learner activity. That is the case, for example, in teaching and learning of modelling or problem solving in mathematics, but also in biology, physics or technology. This makes the classification scheme useful for Science, Technology, Engineering and Mathematics (STEM) education, too. Here, mathematical competences (e.g. Process Standard “Representation”, National Council of Teachers of Mathematics, 2000, pp. 67–71) are also addressed via subject-specific content (physics, biology and so on).

### Implications

A first explorative application of the category system to randomly selected “simulations” from GeoGebra Materials provides that in most cases the user can vary one to four aspects of the application (LoM 1–4; hardly  $LoM > 5$ ). Often dynamic representations occur and also different forms of representation are combined to multiple dynamic representations (MDR).

One of the aims of the research work on the scheme is also to use the scheme to assess whether a concrete simulation is good or less suitable for a (concrete) learner. According to this, there should

be good and less suitable classes in the scheme, depending on the individual prerequisites and goals. First cautious pointers to such classes are: for a pure visualization of dynamic processes, an implementation with  $0 < \text{LoM} < 1$  is sufficient; this includes video clips as well as animations. If simulations are to be used for explorative work in the context of teaching and learning, they have to allow some variations. Thus, only implementations with  $\text{LoM} \geq 1$  are suitable. With them, the modeled system can be understood by linking variation and effect, which can serve in problem solving, mathematical modelling or generating and testing hypotheses. It can be assumed that simulations with a high LoM generate a high cognitive load (according to Chandler & Sweller, 1991) for the experimenters (i.e. learners). The performance of the users would thus determine how high the LoM should be at most when selecting a simulation. The respective external representations offered in a simulation, although they bring benefits for the learning process, can also create further obstacles in the learning process (e.g. Ainsworth, Bibby, & Wood, 1998; Ainsworth, 2006; Duval, 2006). Building on this, at least one implication is conceivable: in order to keep the simulations understandable, rather small LoMs should be used for MDR, whereas higher LoMs would be suitable for ISR and IDR (as indicated in Figure 2). By means of such considerations, the presented scheme can help teachers to find suitable simulations for a certain group of learners.

A detailed analysis of the classification scheme as well as the empirical and theoretical validation of the conclusions is still pending.

*While it is obvious that teachers need to have mathematical knowledge under different domains, few studies put forward teaching practices associating them with teacher moves in the background of the mathematical knowledge used in teaching in a technology enhanced classroom environment. Moreover, characterizing those practices can show a practical understanding of the knowledge for its usefulness in teaching in which tools and dynamic technologies are deemed necessary. In this study, we examined the characteristics of teachers' mathematical practices in a classroom teaching where the students engaged in a sequence of GeoGebra-integrated tasks designed to support students' conceptualizations of slope of an object. The results suggest teacher moves for the GeoGebra-integrated tasks for conceptualization and suggestions for teaching practices from pedagogical perspectives.*

*Keywords: Middle school mathematics teachers, GeoGebra, mathematical practices, slope.*

### Introduction

We all accepted that there are prominent frameworks on mathematics teaching. However, while these frameworks provide tremendous contributions, how teachers' knowledge is used and developed in classroom teaching practice for specific learning areas need to progress when it comes to combining theory and practice (Doerr, 2004; Wasserman, 2015). Specifically, investigating teachers' mathematical practices in slope teaching in school algebra requires having a distinctive spectacle. Although slope is one of the big ideas in curricula, we do not know teachers' mathematical practices in slope teaching during the implementation of an instructional sequence (Cheng, Star, & Chapin, 2013). In this regard, research on knowledge of algebra teaching (McCorry, Floden, Ferrini-Mundy, Reckase, & Senk, 2012) can enlighten this process which includes mathematical practices in connection with the content knowledge. Therefore, the mathematical practices dimension can be used and developed for investigating particular mathematical practices of teachers as their didactical performance.

Dynamic mathematics software (e.g. GeoGebra) is seen as the indispensable part of mathematics teaching technology in 21st century. However, although there are research studies that integrate curricula including new approaches and technology into algebra teaching in the classroom (Bozkurt & Ruthven, 2017; Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010), studying the practice of slope teaching within the technological environments need further elaborations to reveal mathematical practices of teachers. Thus, interpreting mathematical practices of teachers in slope teaching from the perspective of algebra teaching can provide in depth insight about the mathematical practices in the work of mathematics teaching in technology enhanced classroom environment.

## Framework of the Study

The mathematical practices are moves or actions which are seen as the ways for using content knowledge in teaching (McCrory et al., 2012; Wasserman, 2015). That is, they involve teacher's actions with specific goals and perspectives on particular mathematical ideas that are centralized through the interactions with students in classroom teaching. In terms of algebra strand, McCrory et al. (2012) characterize Knowledge of Algebra Teaching (KAT) framework that is developed for assessing teachers' mathematical knowledge on algebra teaching. In the framework, considering three domains of knowledge (i.e. knowledge of school algebra, knowledge of advanced mathematics, and mathematics-for-teaching knowledge), teachers' mathematical work as mathematical practices is emphasized under three categories: bridging, trimming, and decompressing. By means of bridging, McCrory et al. (2012) emphasize ways of making connections across topics, concepts, representations, and domains. In the framework, trimming practices are described as ways of removing complexity of mathematical ideas while holding mathematical integrity (McCrory et al., 2012). Introducing slope in linear functions graphs in consideration with the future mathematics (instantaneous rate of change in calculus and analysis) can be given as an example for trimming practice (McCrory et al., 2012). However, making an unfortunate explanation of "multiplying makes bigger" in teaching multiplication of whole number is an example of 'over' trimming when considered the multiplication of fractions and rational numbers (McCrory et al., 2012; Wasserman, 2015). At last, decompressing is described as making explicit complexity of mathematical ideas in ways that make them comprehensible for students (McCrory et al., 2012). McCrory et al. (2012) gave examples of unpacking the algorithm for solving equations and meaning of identities.

In this current study, the KAT framework was used for the analysis of teachers' mathematical practices in classroom teaching. In this regard, bridging refers to teachers' mathematical practices of connecting topics, concepts, representations, domains, and activities in teaching slope of an object (i.e. the slope concept in physical situations) in a technology enhanced classroom environment in which GeoGebra materials and concrete objects were used. Beyond, we characterized the mathematical work of bridging with an agglutination of using tools and technology by putting terms of concrete object and GeoGebra material. In detail, this category involves mathematical situations (e.g. position of a ladder as a physical situation), mathematical concepts (e.g. horizontal length, line segment, ratio, etc.), concrete objects as mathematical objects, and GeoGebra material for representing a mathematical idea. Since teachers can use various kinds of tools and technologies in classroom teaching, we cannot ignore the use of concrete objects and dynamic technology in such kind of mathematical work. Similar characterization of the mathematical work is also considered both for the practices of trimming and decompressing. Trimming refers to teachers' mathematical practices of removing the complexity of slope of an object while holding the mathematical integrity (e.g. by omitting/adding details, modifying level of rigor) in both eighth-grade mathematics curriculum and advanced mathematics in the technology enhanced classroom environment. In other words, we looked for the ways of mathematical work that teachers considered the complexity of slope in the context of physical situation, while maintaining the integrity of slope concept anticipating further slope conceptualizations. Therefore,

this kind of practice corresponds to trimming up or down of the mathematical idea for the essential content anticipating further mathematical ideas related with slope. Moreover, decompressing refers to unpacking the complexity of slope of an object in ways that make them comprehensible to eight-grade students in the technology enhanced classroom environment (e.g. looking for the ways of mathematical work that teachers unpack the computational algorithm of slope as the rate of change of vertical distance relative to horizontal distance of that object/feature).

This paper introduces teachers' actions in their mathematical work in specific to using GeoGebra materials and concrete objects while enacting an instructional sequence in the technology enhanced classroom environment that was designed for eight graders based on the national curriculum. In this regard, characterizing such actions in teaching with the teacher's rationales for them and interrelations among them is the focus of this study. Therefore, the aim of this paper was to answer the following research questions: What are the characteristics of the teachers' mathematical practices while teaching the slope concept in technology enhanced classroom environment? How do those practices emerge and interrelated with each other in the moment of teaching?

## Method

This study was a part of a long term study and used design research method to understand teachers' knowledge base and expertise within the complexity of classroom teaching (Zawojewski, Chamberlin, Hjalmarson, & Lewis, 2008). In the light of Lesh and Kelly's (2000) multi-tier design experiment method, this study involved four tiers. While the tier of students developed mathematical ideas and computational algorithm on slope, the tier of teachers developed and implemented activity sheets involving GeoGebra-integrated tasks through an instructional sequence while examining students' mathematical understanding with the support of the first author. In addition, the tier of facilitator (the first author) developed sessions for teachers and the tier of researchers (two authors and a doctoral student) produced interpretations of teachers' and students' experiences. The whole process of this study involved a prototype study with a teacher and a main study with another teacher after the preliminary research was done and tentative design principles for sessions with teachers and products for data collection were determined. In this paper, we presented findings of the tier of the teacher from the main study which involved the topics of teaching slope, linear equations and their graphs.

## Context and Participants

The sequence of activities involving GeoGebra integrated tasks formed the basis for a two-week course for students in two eighth grade classes. The teacher had eight years of experience of teaching middle school students. There were 20 students in 8A class (12 girls, 8 boys) and 23 students in 8B class (12 girls, 11 boys). Throughout their work on the tasks, the teacher set the class seating plan considering group work (heterogeneous, 6-7 students) in collaboration. The teacher allowed the students to study and discuss within the group and between the groups. The groups completed the tasks using laptop computers for the groups, and the teacher's computer with a Bluetooth mouse in addition to the related activity materials. The teacher engaged in whole-class discussions that involved the students discussing their slope computation algorithm and how that slope changes when the attributes of the objects changed.

In this regard, the students were asked (1) to notice and describe slope as a measurement of steepness of a physical object, (2) to describe slope of an object being independent of the length of an object, (3) Relate vertical and horizontal distances to the slope of an object, (4) to structure the computation of slope of a given physical object, and (5) evaluate the effects of horizontal and vertical distances on the computation of the slope of a physical object as a ratio given in GeoGebra materials integrated activities. The teacher also wanted to have students use concrete objects for experiencing the slope of an object practically. In the beginning of the course, the students were given concrete objects (i.e. fixed length battens), tape measures, and Positions of Battens (PoB) activity sheet. In the activity, the students were expected to measure the horizontal/vertical lengths of the objects, to describe the slope as a measurement of steepness and being independent of the length of the object, and to collect data for relating the horizontal and vertical lengths to the slope of the object. The GeoGebra material of the activity was used to have students relate the horizontal/vertical lengths to the slope of the object in the dynamic environment. Then, the students were given Fire Truck (FT) activity sheet and the GeoGebra material. In this activity, the students were expected to compute the slope of a fire truck ladder in different positions with a constant horizontal length and to evaluate the change of the slope as the vertical length changed using GeoGebra. At last, the students were given Tent (Tt) activity sheet and the GeoGebra material. The students were expected to compute the slope of a tent rope in different positions with a constant vertical length and to evaluate the change of the slope as the horizontal length changed using GeoGebra (See materials on <https://ggbm.at/sbffsxt>). The lesson was structured as PoB for the first hour and FT and Tt for the second hour.

### **Data Sources and Analysis**

The data sources of this study included videotapes of all classroom sessions, written field notes and memos, students' activity sheets, students' computers screen records. Following the classroom teaching, there was an analyzing instruction session involving audio recorded semi-structured interview. In this process, the teacher reflected, commented, and made decisions on her practices and students' learning in the lesson and reflected on the further changes for the lessons in the instructional sequence, while watching the episodes of video recording of the classes. In this paper, the data constituted 180 minutes lessons for two classes (90+90) and 90 minutes analyzing instruction session. The data was collaboratively analyzed considering the iterative approach of design research and the comparative analysis method of grounded theory (Glaser & Strauss, 2006). In the analysis, primarily, the researchers met to develop and evaluate the instructional sequence, the progress of the students in classes, and the observations/comments about students' thinking about slope of an object and their use of GeoGebra materials and other representations. The researchers wrote the analytic memos documenting their emergent understandings of the teacher's mathematical practices and observations about students' learning. Secondly, the researchers started with the microanalysis of the transcripts of the videotapes through line-by-line analysis. While doing systematic coding in the analysis, the teachers' acts, events and activities were conceptualized and classified when the actions of the teacher occurred in a pattern during the classroom teaching. Moreover, theoretical comparisons were made to identify the derived properties and dimensions of the concepts from the incidents in the literature. Additional evidences were used

from the interviews with the teacher to confirm and disconfirm the actions and the teacher's reasoning about those actions. In this paper, we present two results of the analysis of the teacher's mathematical practices that involves interrelations among each other: trimming slope computation and its relation to a bridging practice and decompressing components of slope and its relation to trimming slope computation.

## Findings

### Trimming slope computation and its relation to a bridging practice

In the PoB activity, as a trimming practice, the teacher trimmed the computation of slope of the batten using the GeoGebra material by showing/checking change in the slope. In detail, this practice involved actions of showing and checking the correctness of the computations of slopes of the battens through the use of slope checkbox (that opens dynamic slope computation text) with slider (that changes horizontal length of the batten), and horizontal and vertical lengths checkboxes (that shows their images and values). As evidence, for example, after the groups of students made measurements on their battens and the teacher showed/checked the horizontal and vertical lengths of their battens using GeoGebra material, in the conversation with students the teacher said:

Yes. You take the vertical length of the batten as 57 cm (*The teacher checks the value of the vertical length on the computation after moved slider to make students' vertical length of the batten*). Let's look. Is the value of your slope like this? (*The teacher shows the value of the slope on the slope computation text in the GeoGebra graphics view*).

That is, the teacher moved the slider to create the students' battens and then showed and checked those values on the GeoGebra material. Thus, she both constrained the slope computation as ratio of vertical length to horizontal length and provided various slope computations with different values.

In addition, that trimming practice took place in the background of bridging practice of connecting mathematical situation/concept and GeoGebra material. That is, as a bridging practice, the teacher used the slider tool in connection with the line segment (i.e. the batten) in the GeoGebra graphics view while posing the questions about the position of batten. Therefore, when relating such trimming and bridging practices, the teacher put forward her intention of using the line segment to create a model of a batten at the beginning of the students' learning process and then a model for reasoning about the slope as steepness at the end of their learning experience.

### Decompressing components of slope and its relation to trimming slope computation

In all activities, as a decompressing practice, the teacher interpreted the components of the slope of an object using GeoGebra materials in the following of the practice of trimming computation of slope using GeoGebra materials. In detail, in the PoB activity, the teacher interpreted the factors of slope (i.e. attributes that affect/do not affect the slope of the line segment representing the object of batten) using the GeoGebra material (i.e. using the slider tool and the graphics view) and interpreted logic in computation of slope using GeoGebra material after she trimmed the slope computation. That is, after the teacher showed/checked horizontal and vertical lengths of the batten (i.e. line segment object in the GeoGebra graphics view) using the slider of the horizontal length and checkboxes of the lengths and showed/checked the slope of the batten using the slope checkbox

(that opens dynamic slope computation text) with the slider and the checkboxes of the lengths, the teacher and students discussed on how the slope changes in accordance with the changes of the horizontal and vertical lengths while representing slopes of various positions of the batten with their horizontal and vertical lengths values. In the continuum of the discussion, she also used ‘trace’ tool on the line segment (i.e. batten) that shows the trace of the line segment as the slider of horizontal length moves from 1 to 60 with the dynamic slope computation. As evidence, the following conversation occurred:

- Teacher: Ok then, I want you to see how the slope value changes when I change the [position of] batten. Even I clicked trace on command in GeoGebra. Look at both the batten [line segment] and the slope. The value of the computation of the slope! What happens to the slope? *(The teacher moves the slider to the lower part, which increases the horizontal length of the batten, and eventually that moves the batten)*
- Student: Decrease!
- Teacher: It decreases, doesn't it? Look it is 1.17 and then 1.12. What happens gradually?
- Students: Lessens. Becomes smaller.
- Teacher: The slope decreases more and more. What happens when it moves to the other part? *(The teacher moves the slider.)*
- Students: Increases!
- ... *(The students discuss it in their groups)*
- Student: Our batten has the longest vertical length and the least horizontal length with the biggest slope.

As seen from the conversation, the teacher paid attention to the complexity of change of the slope that depends on the change in the horizontal length and the vertical length. Therefore, as evidence of decompressing, she unpacked the idea of slope in the physical situations context that involves proportional approaches.

As another example of interpreting logic in computation of slope using GeoGebra material, in the FT activity, the teacher had students interpreted the change in computation of the slopes of fire truck ladder (that stops away 5-unit constant distance from a burning building) using vertical length slider tool after clicked the slope checkbox (that shows dynamic slope computation text) in GeoGebra graphics view and interpreted the change of slopes of the ladder when the horizontal length of the ladder was constant using the slider tool. For instance, while students using the GeoGebra material of the activity in a similar conversation given in below, she said “*We have two variables. One is the vertical and the other is the horizontal length (The teacher shows them on the GeoGebra graphics view). In this question, which one is constant?*” After the students explicitly mentioned the horizontal length was constant in that situation. The teacher added, “*... Thus, we can see how the vertical [length] affects the slope. Could we see clearly the effect of one variable on the slope when the other one is constant?*”. Therefore, the teacher again paid attention to the complexity of change of slope that depends on the vertical length when the horizontal length is constant. In this regard, she unpacked the idea of the slope that involves direct relationship with the vertical length when the horizontal length does not change in a physical situation. Similar

decompressing practice emerged in the Tt activity that the teacher unpacked the idea of slope involving indirect relationship with the horizontal length when the vertical length is constant.

## Discussion and Conclusions

This study began with the development of an instructional sequence involving GeoGebra integrated tasks and activity sheets to develop students' conceptualizations of the slope and interpret the slope computation in physical situations. The design of that sequence provided opportunities for students to experience slope with concrete objects and GeoGebra materials, to decide the factors that have an effect and do not effect on the slope of an object, to give meanings to various representations from concrete objects to dynamic visuals and mathematical notations, and to reason about the slope concept.

In accordance with the findings about teachers' mathematical practices, when teachers are engaged in such GeoGebra integrated activities after students experience the slope with the concrete objects, they need to have understanding of what is the meaning of the mathematical idea of the slope as a concept of steepness and as a process of measurement and computation in physical situations, and how this meaning of slope is in connection with measurement, ratio, rate, and division. Therefore, during the decompressing practices in those activities, teachers are likely to enhance students' proportional reasoning underlying the slope computation for an object (i.e. the slope and the vertical length directly proportional when the horizontal length is constant, slope and horizontal length indirectly proportional when the vertical length is constant). Current studies also emphasized this understanding of slope as steepness through its relationship with proportional reasoning (Cheng et al., 2013; Lobato & Thanheiser, 2002). In this regard, such kind of mathematical practices require teachers to have the understanding of the relationship between the concrete and visual (i.e. as having knowledge of the goals and subgoals of steps in using intertwined multiple representations for the computation and the environment in which the computation is used) and the way of giving the aforementioned relationship considering the students' experiences and reasoning. In addition, teachers need to have a mathematical understanding of how to give visual representations in a connected way not also for translating the selected concrete examples but also for generating all possible situations with the concrete object using the dynamic properties of the software (i.e. the constitution of relationship between deep knowledge of computational skill and knowledge of the dynamic representations of mathematical ideas) since this understanding is likely to enhance the background of removing the complexity of slope computation (i.e. trimming). In this regard, while using dynamic software to represent such situations, teachers' knowledge of content and technology come to the forefront. Therefore, while the KAT framework (McCrary et al., 2012) and other studies (Wasserman, 2015) did not mentioned a knowledge dimension related with the technology, it is considered that teachers knowledge of teaching mathematics with technology should be considered as a source for fostering the bridging and trimming practices in classroom teaching. In sum, interrelations among those practices are likely to vary depending on the mathematical idea, teachers' understanding of this mathematical content and their knowledge of students' understanding in this content. As Clark-Wilson (2013) suggested, this paper elaborated the situated nature of use of mathematical knowledge in technology-enhanced classrooms. In this regard, that elaboration illustrate content-specific mathematical practices in teaching with technology that could

be involved in various kinds of activity formats as Bozkurt and Ruthven (2017) exemplified and explored through Drijvers et al.'s (2010) orchestrations. In further research, such kind of mathematical practices could be investigated in teachers' various ways of orchestrations for elaborating their mathematical work as didactical performance.

### Scope and focus of the Working Group

The scope of this working group is to address opportunities and possibilities, as well as challenges and limitations, of information and communication technology (ICT) and other resources for student learning (see Trgalová, Clark-Wilson & Weigand 2017). ICTs include software programs, various kinds of hand-held devices, online and classroom activities, and sensors. In addition, ICTs are considered in relation to more traditional non-digital resources such as textbooks, worksheets and various types of tools and physical manipulatives. We want to establish an overview of the current state of the art research in technology use in mathematics education, including practice-oriented experiences, research-based evidence, and theoretically enriched perspectives, as seen from an international perspective and with a focus on student learning. We also aim to suggest important trends for technology-rich mathematics education in the future, including a research agenda. Even though TWG 15 is closely related to this theme, it focuses more specifically on the role and practices of the teacher.

In TWG 16, we had 28 presented papers and 14 posters. To promote more indepth discussions, we split up for some sessions into TWG16a and TWG16b.

### Relevant topics

In TWG 16, we might roughly classify the presented topics as follows:

- **Content-related topics:** rational numbers, variables, stochastics, multiplicative reasoning, equation transformation, functions;
- **Assessment:** assessment with Dynamic Software Systems (DGS), digital tests (possibilities and limitations), self-assessment, feedback, especially also with ITS;
- **Modelling:** understanding the process of modelling, giving special examples like the “Math City Trail – a mathematical journey through a city”, long-term effects of modelling;
- **Specific tools:** APPs, dynamic geometry, graphic calculators, virtual and augmented reality;
- **Activity structures:** gamification, online courses, flipped classroom, collaborative work.
- **Theoretical perspectives:** activity theory, embodied cognition (esp. gestures).

## Some Comments on the result of the TWG 16

### Assessment

Assessment is an important part of the teaching and learning of mathematics. On the one side, it is associated with the evaluation of student knowledge and learning at the end of a course or teaching unit (summative assessment). On the other side, assessment should provide constant feedback to students during the learning process (formative assessment). Digital technology can be used in or can enhance both summative and formative assessment in many different ways. Three examples from this TWG: *Irene van Stiphout & Madelon Groenheiden* reflect on the construction of a digital diagnostic test for middle school in the Netherlands. They focused on the constant struggle between testing higher order skills, concrete description of curriculum goals on the one hand, and the limited possibilities of the digital test environment on the other hand. *Yael Luz* describes a pilot experiment in adaptive assessment. A system that automatically analyzes answers and generates immediate feedback is developed. Finally, *Sietske Tacoma, Bastiaan Heeren, Johan Jeuring and Paul Drijvers* investigate how providing automated feedback in an Intelligent Tutoring System can help students in an introductory university statistics course. Over all, assessment will remain a very relevant topic in the years to come.

### The big variety of digital tools

It is very difficult to give an overview of present forms of digital technologies. On the one hand, there are still the classical software programmes used like computer algebra systems, dynamic geometry software, and spreadsheets. *Markku Hannula & Mika Toivanen* use Geogebra for problem solving activities and give a critical view to the use of computers, *Edith Lindenbauer* shows how Geogebra can be used to develop functional thinking. *Myrto Karavakou & Chronis Kynigos* create connections among different aspects of trigonometric functions in a programming environment. Some new features have been added to this traditional software, especially 3-D-geometry. On the other hand, mobile technology like tablets and smartphones with a big variety of apps are becoming more and more embedded in students' lives, which leads us to consider their wider use as an educational resource. For example, *Chorney, Gunes & Sinclair* presented the multi-touch App *TouchTimes*, which is designed to support multiplicative thinking. At TWG 16, there was also a first glance of the use of virtual and augmented reality for the learning and teaching process. This will be a very relevant topic for the future, too.

### Elementary School

Learning how to use digital technologies starts in Kindergarten and Elementary School. Therefore, it is very important to discuss and evaluate chances and possibilities, but also restrictions and difficulties of the use of software in Elementary School as done within the TWG 16. For example, *Ana Donevska-Todorova & Katja Eilerts* develop criteria for reviewing the quality, potentials and limitations of tablet apps for elementary geometry. *Eitan Ben-Haim, Anat Cohen & Michal Tabach* discuss the suitability of the character of the graphic design on the students' achievements while engaging with mathematical applets. *Melanie Platz* creates a learning environment applying digital learning tools to support argumentation skills in primary school. *Axel Schulz & Daniel Walter* create the tablet-app 'Stellenwerte üben' (Practicing place value)<sup>1</sup>

---

<sup>1</sup> The German version of the tablet-app is provided on Google Play. An English version is in progress.

for practicing the place value concept. They show that previous experience with concrete physical material overlaps and influences the intended use of the implemented virtual features. Finally, an exploratory study by *Sean Chorney, Canan Gunes & Nathalie Sinclair* with *TouchTimes* focuses on how students interact with a new model of multiplication inspired by Davydov's unitising approach, and, in particular, how they develop particular two-handed gesturing practices that involve coordinating two quantities—multiplier and multiplicand—in an embodied way. They argue that this approach provides an alternative to the model of repeated addition, which is frequently over-used in students' initial encounters with multiplication.

### **Online courses**

Nowadays, there is a variety of online courses. They are used mainly at the university level as a substitute for face-to-face lectures. There are “blended learning” approaches in which the online course is used as an additional resource to face-to-face courses, or as an optional resource for special topics, which are not in the mainstream of traditionally taught topics, or as remedial courses (especially for first-year students) that cover basic school mathematics topics. Online courses pose many didactically interesting questions, e.g. how to present the topics, the effect of online in comparison to face-to-face courses, and the behaviour of the students while working online. *Eirini Geraniou & Cosette Crisan* created an asynchronous course on the use of digital technologies in mathematics education where students are not interacting with the lecturer or their peers in real time. They evaluated how the tutors' design considerations and their online pedagogic strategies have influenced students' learning experiences and their engagement with its resources, such as content, peers and tutors. The results show on the one hand students liked the flexible mode of study, but on the other hand, they show the effect of the missing conversations among the students and the necessity of an orchestration of the timing of online contributions.

### **Games and gamification**

Gamification is a topic of much discussion in relation to learning, teaching and motivation. Gamification means the transfer of game principles, game design and game strategies to external fields, like the learning and teaching of mathematics. *Carlotta Soldano & Cristina Sabena* developed game-based activities within a dynamic geometry environment—e.g. one player drags a vertex of a dynamic geometric configuration and the other player must respond in a way that maintains or breaks a constraint—for primary school to foster the development of students' mathematical understanding and their argumentation competencies. *Georgios Thoma* examines problem-solving techniques in the context video games and illustrates the game's potentiality as a problem-solving environment.

### **The growing variety of theories**

The vast and diverse amount of theories related to technology implementation in mathematics education, as already reported in previous CERME research (e.g. Donevska-Todorova & Trgalová, 2017) brings the challenge of their applicability and relatedness with appropriate research methods. There are some well-known theories from other scientific disciplines as the theory of instrumental genesis, the theory of semiotic mediation and activity theory. There is also a growing interest in theories of embodied cognition, particularly in relation to the use of technologies

that offer new ways for students and teachers to express themselves mathematics, through gestures and other body movements, as in the work by Chorney, Gunes and Sinclair. Given the plenary lecture by Paul Drijvers, who also promoted the incorporation of theories of embodiment into existing theories (such as instrumental genesis), and the growing number of non-dualistic theories of learning (of body and mind), we anticipate that this will become an area of fertile growth and change in the upcoming years.

### Some thoughts about upcoming topics

A guideline of TWG 16 is to envisage upcoming trends and topics in relation to digital technologies. Online-courses, assessment and gamification are present topics which should be of great interest to mathematics educators and educational researchers in the coming years. There are other topics, which are also represented in the papers of TWG 15. One is space geometry. *Xavier Nicolas & Jana Trgalova* created a virtual environment dedicated to spatial geometry to support the development of vision in space. Another topic is the use of digital technologies in out-door mathematics. *Joerg Zender & Matthias Ludwig* created the mobile app MathCityMap, which poses questions and provides help for questions posed while students do a math trail in the city. *Osama Swidan & Eleonora Faggiano* see modelling under a semiotic lens. While modelling activities are introduced by dynamic digital artefacts, they want to understand the ways students' transit between the simulation of real phenomenon and the mathematical representation. Interesting and challenging is for sure the relation of school mathematics and social media, or digital culture and school culture. *Giulia Bini & Ornella Robutti* use "Internet Memes" combined with augmented reality (AR) technology, to "cultivate classroom discourse and maximize linguistic and cognitive meta-awareness in high school students" (Abstract of the paper). *Florian Schacht & Osama Swidan* address pre-calculus concepts using augmented reality-technology. They use technology design-principles to create an AR-environment, to address technological constraints experienced in experimental situations and discuss alternative ways. And finally, flipped classroom situations (see the paper of *Stefanie Schallert & Robert Weinhandl*) have to be investigated in more detail concerning the learning outcome.

Finally, as technology moves from being an epiphenomenal part of our lives, and of classroom practice, we anticipate that in future CERMEs, many of the content-specific contributions will migrate to other TWGs, as might contributions focused on themes such as assessment. This may be a healthy shift in mathematics education research.

## Desirable difficulties while learning mathematics: Interleaved practice based on e-learning

Maria Afrooz and Rita Borromeo Ferri

University of Kassel, Faculty of mathematics education, Germany;

[mafrooz@mathematik.uni-kassel.de](mailto:mafrooz@mathematik.uni-kassel.de)

*Keywords: Desirable difficulties, interleaved learning, blocked learning, e-learning, geometry.*

### Focus and rationale of the poster

The focus of the poster is the presentation of the project about interleaved practice based on e-learning with the focus on geometry. The poster is intended to provide an overview of the theoretical constructs, the indication of the content, the study design and possible implications.

### Indication of the theoretical framework of the study reported

The theoretical framework of the study refers to the theory of desirable difficulties, which is a new approach from empirical research of learning according to the idea: “To make things hard, but in a good way” (Bjork & Bjork, 2011, p. 55). The learning is made difficult in the short term, but in the long term the learning development improves. Research shows (Rohrer, Dedrick & Stershic, 2014; Bjork, 1994) that desirable difficulties lead to a more sustainable learning success.

The poster focusses on the “interleaved learning“, which represents a desirable difficulty. Interleaved practice is defined as an alternating and arrangement of several different learning contents, e.g., A, B, C (Lipowsky et al., 2015, see Figure 1).

**Figure 1: Interleaved Practice with the learning contents A, B, C**

The positive effect of interleaved practice is explained by the cognitive theories of learning psychology, because the sustainable learning results from a higher cognitive demand and a better memory performance (Bjork & Bjork, 2011; Sweller, Ayres & Kalyuga, 2011).

In contrast to the interleaving is the “blocked learning“, which represents one kind of the traditional learning in mathematics lessons. Blocked learning, in turn, facilitates learning by teaching one learning content at a time before moving on to another, e.g., A, B, C (see Figure 2).

**Figure 2: Blocked Practice with the learning contents A, B, C**

The possible consequence of blocked practice is that the learners can not remember the first topics after the learning the last learning contents (Bjork & Bjork, 2011).

## Indication of and justification for the content

The described project aims at investigating, whether the learning achievements of interleaved learning students differ from blocked learning students by the use of e-learning. Digital media are an important part of today's society and also used in school education for information, communication and networking processes. In the change of society, traditionally structured teaching must also be adapted (Bönsch, 2015). Using e-learning enables an innovative and current method for school education and promotes self-regulated learning (Blaschitz, Brandhofer, Nosko & Schwed, 2012).

## Implications for existing research in the area

Possible practical implications for the existing research in e-learning seems to be the development of an e-tutorial for educational settings at school.

One goal of the empirical research in didactics of mathematics should be the promotion of sustainable learning in mathematics school lessons. If interleaved learning proves to be a successful new teaching concept in geometry, the few studies on interleaved practice based on e-learning (e.g., Ziegler & Stern, 2014) have to be expanded in various learning contents of mathematics to explore the effects of interleaved practice further.

# Types of graphic interface design and their role in learning via mathematical applets at the elementary school

Eitan Ben-Haim, Anat Cohen and Michal Tabach

Tel Aviv University, Israel; [bh.eitan@gmail.com](mailto:bh.eitan@gmail.com), [anatco@post.tau.ac.il](mailto:anatco@post.tau.ac.il), [tabachm@post.tau.ac.il](mailto:tabachm@post.tau.ac.il)

*The research goal was to test the suitability of the character of the graphic design on the student's achievements while engaging with mathematical applets for elementary grades. This quantitative research compares two pairs of mathematical applets, which differ only by the type of graphic design; in the extent of detail and the amount of distraction, while the mathematical problems are identical. The first applet has animated graphics based on designs by Matific, a repository of mathematical applets. The second applet was designed specifically for this research in a schematic and visually simple version of the same activities. Students in the schematic graphics group made fewer mistakes and needed less time to complete the activity than students in the animated graphics group. In addition, students with lower mathematics ability succeeded better in the schematic group. No differences between the two groups were observed regarding the level of students' enjoyment.*

*Keywords: Educational design, graphic design, schematic graphics, cognitive load, mathematical applets.*

## Introduction

Gamification is an effective learning strategy in mathematics education at the elementary level. Moreover, a clever integration of educational computer games during the learning process contributes to the student's learning, and provides positive experiences (Wouters & Van Oostendorp, 2013). During integration of mathematical computer games both cognitive processes and motivational implications on the learning are taken into account.

The cognitive load theory and the dual-coding theory (Kalyuga, Chandler, & Sweller, 2000) depicts the learning process as two independent learning channels, a visual and a textual channel. The decoding of each channel is processed separately in our minds, and only then can be processed together to create a unified meaning alongside prior knowledge. The decoding and processing procedures strain the working memory, which has a limited load capability (Cook, 2006). The split between the two channels can ease the learning process if the two channels are supplementary. However, an ineffective split may cause additional load on the working memory and therefore decrease learning efficiency. Learners who face difficulty with the learning material, and those who have less prior knowledge, are more likely to be "sensitive" to the dual channel split. Prior studies have shown that such learners are less capable of utilizing visual content that accompanies textual content (Tsai et al., 2016; Mason, Tornatora, & Pluchino, 2013).

Aside from the cognitive aspect, another perspective on the effectiveness of learning by computer games, is through the motivational influence it may have on the learner. Enjoying the learning activity may lead the learner to identify with the learning goals and values (de Lope et al., 2017; Chang, Evans, Kim, Norton, & Samur, 2015; Sedighian & Sedighian, 1996). Graphic design which is

consistent with the learner's interests can help the learner relate to the game. Relatedness, as used by Ryan & Deci (2000), is crucial for achieving intrinsic motivation.

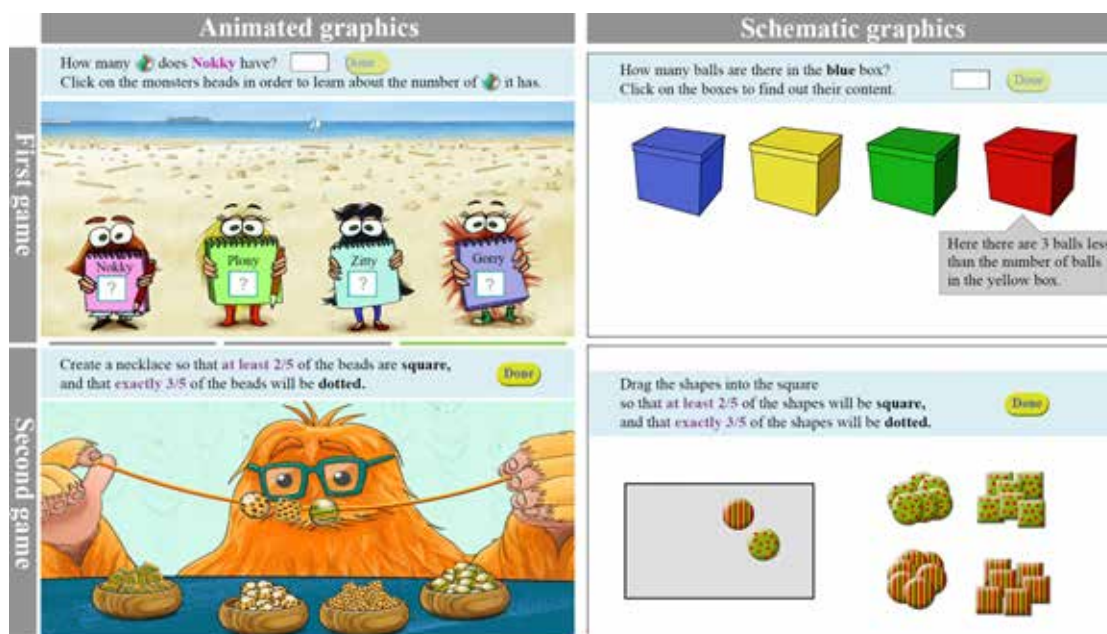

Many studies compare computer games to traditional teaching and identify three advantages of digital technologies: increase entertainment, enhancing motivation of the students, and augmenting their ability to feel involved and active in a learning environment that is individually fitted to their needs (Wouters & Van Oostendorp, 2013; Giannakos, 2013; Chang et al., 2015; de Lope et al., 2017). However, there is a lack of research comparing learning from different computer games. A gap exists between developers, who are not familiar with the design domain, and designers who are not proficient in the educational and pedagogic area of expertise. This gap causes the challenge of creating digital educational materials consistent with theoretical knowledge in the field (de Lope et al., 2017). Learning applets can be compared with many different parameters. This research focuses on one issue: how to design the interface. Specifically, should one use schematic or animated graphics. This research provides a partial and specific response to the lack of empirical work in this area.

## **The study**

The present research stems from a broader study which examines possibilities of better utilizing web-based games in the mathematics classroom, given the practical need for a framework for teachers' choice of mathematical applets, and their integration within the sequence of lessons. Informed by the cognitive load theory and the dual-coding theory, the goal of the presented research is to test the suitability of the character of the graphic design on the student's achievements, in mathematical applets for elementary grades. Three research questions have been studied: (a) How does the learning process differ in learning from animated graphics versus schematic graphics? (b) In what ways are these differences affected by students' proficiency in mathematics? (c) What are the differences in students' enjoyment between graphic designs? Due to space limitation, in this paper we present only the findings relating to the working time and the level of accuracy of the answers (for more details See Ben-Haim, 2018).

## **Methodology**

This research defined two types of graphics: "animated graphics" and "schematic graphics", which differ in the extent of detail and the amount of distraction (Figure 1). This quantitative research compares two mathematical applets. The two applets differ only by the type of graphic design, while the mathematical problems are identical. The first applet has animated graphics based on designs by Matific, a collection of educational math applets which is in use by many schools in Israel. The second applet was designed specifically for this research in a schematic and visually simple version of the same activities.

**Figure 1: Screenshots of two applets from the two types of graphics**  
(translated into English - originally in Hebrew)

287 fifth and sixth grade students (50.9% males, 49.1% females) from three elementary state schools in the center of Israel participated in the activity to collect data for this research. All the children were randomly divided into two equal groups: animated graphics group vs. schematic graphics group. The schematic group employed simple and abstract graphics, based on geometric shapes and solid colors (with no shading or hues). In contrast, the animated group employed more complex and colorful graphics, including simple animation. In the animated graphics there is the appearance of depth and space. The elements are figurative and include expressive characters creating an accompanying narrative.

This research monitored students' activity during their play, which enabled the identification of different levels of success between the two groups, differences in working times, and comparison of the students' reports of their degree of enjoyment from the activity. We examined the differences in the learning processes in the two groups. In addition, the students from both groups were divided into two levels based on their proficiency in mathematics. The differences between the groups in performance throughout the activity were compared using statistical tests (t-tests, ANOVA and chi-square) to identify statistically significant differences. Privacy of the children was protected in this research. The schools' names were replaced by numbers, and students' names were not mentioned.

## Findings

### Differences in the learning process between the two groups

The research results show evidence that students in the schematic graphics group made fewer mistakes than students in the animated graphics group. Figure 2 shows the percentage of students who answered correctly on the first, second or third attempt (light blue and light orange refer to the percentage of students that answered correctly on the first attempt). As can be seen, for all three questions included in the applet, the schematic group (blue) answered with fewer attempts (meaning

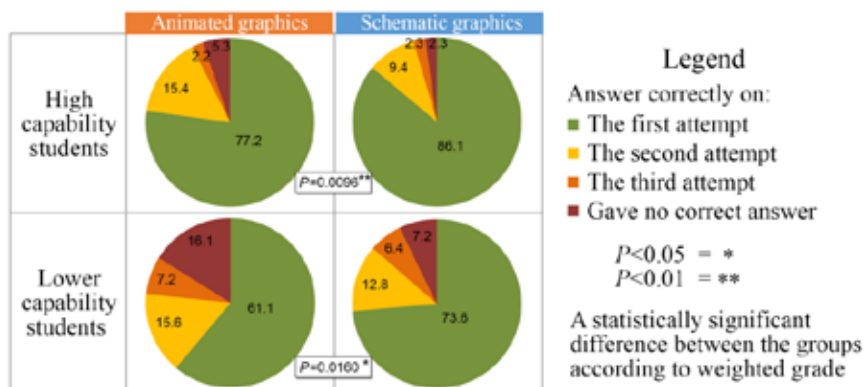

fewer mistakes) than the animated group (orange). The differences between the groups are greater in the first and third questions, which were more difficult than the second. Further results show that the schematic group needed less time to complete the activity. Notably, these differences between the groups were observed on the first game of the applet, but not the second.

**Figure 2: Percentage of students according to success in answering during the applet**

### Differences between the two groups and the students' proficiency in mathematics

The difference between the two graphic groups is even greater among the students with weaker math achievements (Figure 3). Students with lower mathematic ability succeeded better in the schematic than in the animated graphic group.

**Figure 3: Percentage of attempts to answer during the first applet, comparison of groups and of students' proficiency**

Further results arise from two measures by which the students are classified as having low- or high-scores in mathematics: according to the student's school's performance, or according to the student's answer to a final question which was identical in the two groups. Some differences were found, though not always consistently, in distinguishing between low- and high-performing students. In some cases, the animated group was more challenging to low-performing students than to high-performing students. Also, low-performing students in the animated group, required significantly more time than other students.

### Differences in students' enjoyment between graphic designs

Contrary to expectations, no differences were observed regarding the level of enjoyment that students reported at the end of the activity with the applet. Students from both graphic groups, and from both

performance levels reported similarly on how much they liked the applets. These findings show no advantage for the animated graphics design with regards to satisfaction.

## Discussion

The findings of this research show differences between the two graphic groups. Students in the schematic graphics group made fewer mistakes and needed less time to complete the activity than students in the animated graphic group. In addition, students with lower mathematic ability succeeded better in the schematic group. These findings consistent with the literature on cognitive load theory and on the dual-coding theory (Kalyuga, Chandler & Sweller, 2000). In some cases, the animated group was more challenging to low-performing students than to high-performing students. Also, low-performing students in the animated group, required significantly more time than other students. These results are consistent with professional literature claiming that low-performing students and students with lower prior knowledge, encounter difficulties integrating visual and verbal inputs (Cook, 2006; Mason, Tornatora, & Pluchino, 2013). This means that graphic design of mathematical applets must be adapted to the mathematical knowledge of the learners. Students may find the activity harder when the graphic design is complex, if the activity generates significant cognitive load on the working memory. These findings lead to the conclusion that complex graphics may cause inhibitive cognitive load depending on the learning situation and on the student's performance. Notably, no differences between the two groups were observed regarding the level of students' enjoyment.

The advantage of gamification in the learning process is in its ability to hide the real necessity to learn mathematics (that is remote to the child), and present a goal that the learner can understand and relate to, which also leads the learner to achieve the real goal of learning mathematics (Sedighian & Sedighian, 1996). Gamification may lead to learning via inner motivation, out of interest and curiosity with a clear goal in mind. The design of learning materials should speak in a familiar tone and be relevant to the learner's world (Hui, 2009).

The common misconception regarding digital learning is to think of technology as if it were "chocolate covered broccoli" (Bruckman, 1999, p.75). The advantage of digital gamification is not simply as a means of up grading conventional learning through external motivation (Habgood & Ainsworth, 2011). In order to truly leverage digital integration, the applet must be embedded in the learning process, and must stimulate an active intellectual activity (Sedig, 2008). The visual graphics of mathematical applets must act as the starting point for understanding the problem in a given exercise, leading the learner to insight and solutions (Van Garderen & Montague, 2003). To do this, the graphics must integrate between the game-play of the applet, its plot and the learning content (Wouters & Van Oostendorp, 2013).

The philosopher Marshall McLuhan saw the medium as the source of change in society and coined the phrase "the medium is the message" (McLuhan & Fiore, 1967). In his view, it is not the content transmitted through the medium, rather than the medium itself that comprises the meaning, it is the medium itself that significantly influences the society. In our opinion, this insight echoes in the context of integrating applet-games into the classroom. Applets excite the learner simply by the use of the screen, rather than by the displayed content. It is our belief that as educators, we must not "take

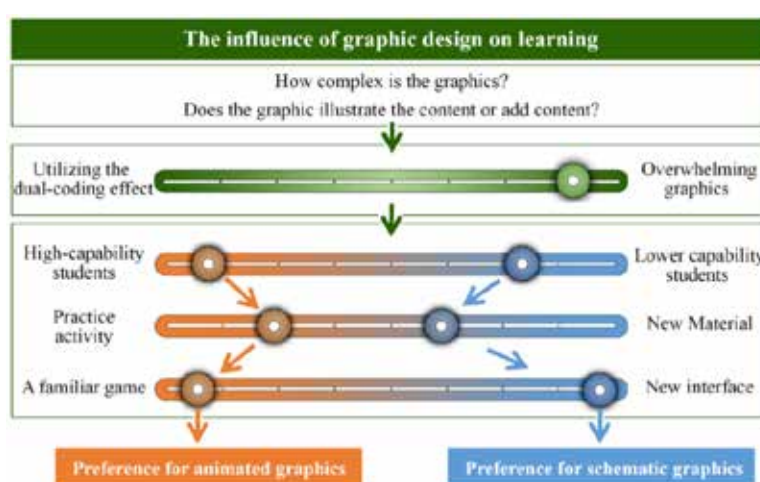

a step back" when the computer enters the classroom. Rather, we must insist on taking an active role directing and navigating the digitally enhanced learning process.

This research was performed with the attempt to maintain objectivity as much as possible, in the collection and analysis of the data. However, there are some limitations in this research. From practical considerations, the studied population was limited, and comparison between the groups was based on only two applets among a large pool of applets. Hence the studied population is not representative of Israeli students, and the activities are not representative of general mathematical learning games, nor of Matific applets in particular. It should be noted that, from among the three schools, only students from school 1 were not familiar with Matific before data was collected. While this research advances the understanding of development and design of digital learning interfaces in math education, further research is needed to extend these preliminary insights, to enhance the benefits of digital learning, and to sharpen teachers' guidelines for implementation.

## Conclusion

The results of this research assist us in formulating indicators for teachers, that will enable them to address both personal/experiential aspects of the learner, as well as cognitive aspects. In light of this research, three guidelines have been deduced which could assist developers, designers and teachers to reach a more effective integration of mathematical applets in the elementary school environment: (1) Different graphic designs are suitable for different audiences and for different learning situations. Complex and animated design can cause difficulties if the learning situation is challenging; (2) A schematic graphic design, with few unnecessary details, is more appropriate for applets that tend to have a high cognitive load on the learner; (3) The design must consist of a narrative that connects between the interests of the learner and the content of the learning material. Figure 4 presents the conceptual chart flow that enables practical application of the research findings.

**Figure 4: A conceptual chart for selecting graphics according to the characteristics of the students**

As shown in figure 4, the teacher must first identify the characteristics of the existing graphics in the applet in question. Two parameters need to be taken into account: (1) complexity of the graphics, and (2) to what extent the graphics serve a pedagogical role. Graphic complexity is rich in detail, contains animations, describes facial expressions and may contain a third dimension, similar to the animated

group in this study. In contrast, schematic graphics portray minimal detail often represented abstractly. The role of graphics covers a spectrum from pedagogical to motivational. Pedagogical graphics are integrated with the learning content and complete that content by visualizing it. Motivational graphics merely motivate and do not clarify the learning material.

In the second step, the teacher may examine the applets suitability to the target audience. Figure 4 depicts the questions that can be asked in the process and portrays two possible scenarios, each leading to a different outcome with respect to a different type of graphic design. Applets identified as having "overwhelming" graphics should lead to closer attention to the following indicator in overall decision making. The three scroll bars at the bottom of figure 4 express different aspects for the given audience. The right-hand side (blue) indicates difficulties that the learners encounter. The left-hand side (orange) indicates less challenging learning situations. The two scenarios depict clear-cut cases, where the three markers clearly lead to one side or the other. To conclude, schematic graphics is preferable when encountering challenging learning situations.

The research conclusions can assist developers and designers of instructional materials in decision making regarding graphics in relation to learning content. Applets built on a linear continuous sequence of activity can design a gradual increase of the graphic load, so that the learner in the early stages of the applet will gradually adapt to the new interface. As the learner progresses throughout the activities, the graphics may unfold into a more complex environment, without having a negative effect on the learner due to the familiarity with the interface. Another rule of thumb regards applets addressing the learning stages of instruction in which the graphics may maintain simplicity and a schematic abstract approach, as opposed to the stages of practice, assessment, evaluation, or recall in which the graphics may consist of a more complex design. This implies that the design team and the pedagogic team must work together in planning educational applets.

While the animated group presents a more attractive design than the schematic group, the former does not incorporate the learning content within the visual design. This is a common major disadvantage among applets. Developers and designers must manage the split between the applet plot and the learning material in order to truly utilize the advantages of digital gamification. This study provides rules of thumb on considerations regarding future development and design of mathematical applets.

## Acknowledgment

This study was funded by the chief scientist of the Israel Education Ministry.

## INTRODUCTION

Internet memes have become a viral form of Web 2.0 communication, with an ever-increasing number of occurrences on social platforms as Instagram (from 37 million in March 2018 to 76 million in March 2019). Nevertheless, Knobel & Lankshear claim that “understanding successful online memes can contribute much to identifying the limitations of narrow conceptions of literacies and new technologies in classrooms” (2007, p.221) still remains almost unanswered. In fact, up to today, the possible didactic relevance of Internet memes is nearly unexplored by academic research and their meaning and use in mathematics education is an unmapped territory. Even if popular culture is playing an increasingly important role in the lives and learning opportunities of young people, Peter Applebaum’s regret that “little work, if any, has been done by math educators to probe the efficacy of mass culture criticism for education in math” (1995, p. 24) strikes for its up-to-dateness.

Levering on the influence and use of social media in students' perception of learning mathematics, this project has a twofold purpose: the research aim is to contribute in breaking away from the idea that digital culture can be considered as opposed to school culture, investigating the epistemic and didactical affordances of mathematical Internet memes, combined with Augmented Reality technology. The coupled educational aim is to cultivate classroom discourse and maximize linguistic and cognitive meta-awareness in high school students. The project is a work in progress of which this paper presents the theoretical background used to frame the study and the results of a first exploratory teaching experiment - conducted with a group of 24 students attending the 12<sup>th</sup> grade of Liceo Scientifico in Milan - together with the methodology and the next steps of the study.

## FROM MEMES TO INTERNET MEMES

In 1976, well before the digital era, evolutionary biologist Richard Dawkins coined the term *meme* as “a unit of cultural transmission”, examples of which are “tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches” that “propagate themselves in the meme pool by leaping

from brain to brain via a process which, in the broad sense, can be called imitation.” (Dawkins, 1976, p.249). Web culture ([https://en.wikipedia.org/wiki/Internet\\_meme](https://en.wikipedia.org/wiki/Internet_meme)) gives credit to Mike Godwin for revamping the concept of memes in 1993, identifying Internet memes as a subset of memes and describing them as an activity, concept, or piece of media that spreads through social channels, evolving in the hands of the digital users and reaching a large audience.

Internet memes can be in the form of viral images, videos or files: in this work, we will focus on those made of “verbal and pictorial parts, which unfold their meaning through collective semiosis” (Osterroth, 2018, p.6); as they integrate different modes of communication, we think they can fall into the category of multimodal artefacts. They usually have a humorous or satirical intent and are widely shared by young people through social platforms (Facebook or Instagram), since they connect the participatory potential of the Internet with the quest for user-generated content that - through shares and likes - provides a form of social validation.

They are deeply rooted in visual media culture and catch users’ attention with their puzzling vibe that calls for the active contribution of the viewer to unlock the meaning and thus adds a gratifying flavour. Internet memes are created by users according to collectively established and shared rules that govern the so-called *memesphere*: these rules dictate the conventional meaning of the pictorial parts and the position, font, syntax and narrative structure of the text, they “cannot be enforced by a specific person, but the community sanctions wrong uses by downvoting, not liking or simply not spreading the misused meme” (Osterroth, 2018, p.7). These same rules shape meme generators websites as <https://imgflip.com/memetemplates> or <https://makeameme.org/>: there are several accepted structures, two of the most common being those in Figure 1.

**Figure 1: Two prototypical meme structures**

Pictorial parts, usually identified with names, might have local or global recognisability: in Figure 2, a blank template of the *Success Kid* meme - globally used to boast of something good - is shown, followed by a general example of the meme propagation by imitation and an example of its psycho-pedagogical adaptation, to end with its mathematical variation.

**Figure 2: Template and propagation of the *Success Kid* meme (source Google search, Sept 18)**

The last example is representative of a rare situation in which mathematics *spontaneously* leaves the school context and is used to identify the belonging to a group and to set the author's position in the group. This kind of memes, in fact, are usually shared within specialized Internet groups, where products are scrutinized by skilled peers and acceptance grants the author the cited social validation.

## MATHEMATICAL INTERNET MEMES AS KNOWLEDGE CARRIERS

To focus more on the concept of mathematical Internet memes and illustrate their epistemic potentiality, we shall analyse two examples of the *Drowning kid in the pool* meme (Figure 3), used to describe a situation where something is typically forgotten. On the left a correct version posted in May 2018 within a [Reddit thread](#), where was identified as “the quintessential math joke”, on the right its wrong variation, posted in another [Reddit thread](#) in June 2018.

Figure 3: *Drowning kid in the pool* correct (left) and wrong (right) memes

Taking a look at the exchange triggered by the wrong one (some excerpts are listed below), we see how memes can act as knowledge carriers and starters of meaningful mathematical discussions:

- |          |                                                                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bike0121 | This is not really correct. The function $\text{sqrt}(x)$ is always greater or equal to zero. The inverse of $x^2$ is indeed $\pm\text{sqrt}(x)$ , but $\text{sqrt}(4)$ is always $+2$ , not $-2$ .                                          |
| Dat_J3w  | Yea it's positive by convention; the square root of four is still plus/minus two                                                                                                                                                             |
| functor7 | Absolutely not. $\text{Sqrt}(4)$ is 100% only the value 2. The solutions to the equation $x^2=4$ are $\pm 2$ . $\text{Sqrt}(x)$ is a function, which means it only has one value. $\text{Sqrt}(x)$ is a number, not a collection of numbers. |

Dozens of Reddit and Facebook mathematically-themed groups (some with evocative names like “Complex Analysis Memes For Holomorphic Teens” and “The Name Of This Group Is Left As An Exercise For Its Members”) with thousands of users showing off their mathematical knowledge, discussing, posting and sharing mathematical Internet memes on a daily basis, suggest that the meaning of a meme can be looked for in a “sphere of practice (SP), [...] defined as the ‘community’ adhering to a common set of rules, within which mathematical meanings are constructed” and could be a suitable setting to address the issue of “communicating, transforming and negotiating the social meaning of school mathematics” (Kilpatrick et al., 2005, p.10).

## PARTIAL AND FULL MEANINGS OF A MEME

As a first step of the study on mathematical memes, we tried to figure out how memes act as carriers of meanings and we identified a *triple-s construct* of the three partial meanings that contribute in building up the full meaning of a mathematical Internet meme.

- The first meaning of a meme lies in its being a meme, namely to have a specific and shared structure and graphics (font, colour and text position). It can be considered at a *structural* level (Figure 1).
- The second meaning of a meme is conveyed by the shared conventions connected to viral images, compositional setups and accepted syntaxes. It is at a *social* level (Figure 2, first image).
- The third meaning of a meme is borne by images, symbols or text referring to a specific topic (mathematical, but also political, physical or other). This is at a *specialised* level (Figure 2, last image, textual part).

The first two meanings ground in the popular culture rules that govern the *memesphere*, acting as Kilpatrick's sphere of practice, while the third calls some mathematical skills into action. The interplay of all three *partial meanings* unlocks what we call the *full meaning* of the meme, that triggers the surprise/membership effect. There are people who can only access the first meaning, merely recognising the artefact as a meme (and not a cartoon, for example). Others will stop at the second level, identifying the viral elements only. On the other hand, those who understand the specialized mathematical signs in the meme, but are not aware of the other meanings, will equally miss the full meaning. But those who succeed in appreciating all three meanings will crack the full meaning of the meme: they will laugh and feel part of a community. In fact, "meaning mobilizes feeling, and emotions only translate if we process images and captions in the same way" (Benoit, 2018, p.41).

To sum up, we think that it would be fruitful to investigate whether mathematical Internet memes can contribute to the construction of mathematical meanings and explore the possible epistemic affordances implied by their multiple referents (one of many being their visual component that can cater to different intelligences and learning styles). To pursue this research path we imagined that, having mathematics spontaneously already crossed the boundary between formal and informal learning, it could be worth exploring how to facilitate the crossing in the opposite direction and test mathematical Internet memes in a standard school context.

## THEORETICAL FRAMEWORK

It is beyond the scope of this study to evaluate why Internet memes in general, and mathematical Internet memes in particular, have this success in the social arena, although that "aha" moment we all experience when we finally grasp the joke resonates with what Mason (2014, p.1) describes as a "disturbance, experienced as surprise, as puzzlement or perplexity" that somehow "provoke[s] learners into taking initiative" and "call[s] upon learners to make use of their undoubted powers of making sense." Zooming in, we will focus our attention on the learning dynamics connected to the use of mathematical memes within the classroom: in this optics we will try to read our data through the lenses of the Boundary Objects framework as introduced by Star & Griesemer (1989) and further developed by Akkerman & Bakker (2011) and of Anna Sfard's (2001, 2008) theory about discourse and communicational approach to cognition in a Vygotskian sociocultural perspective.

According to Star & Griesemer, (1989, p.393) "boundary objects are objects which are both plastic enough to adapt to local needs and the constraints of the several parties employing them, yet robust enough to maintain a common identity across sites. [...] They have different meanings in different social worlds, but their structure is common enough to more than one world to make them

recognizable, a means of translation.” Our point is that mathematical Internet memes can be looked at as boundary objects between social media and mathematics, two separate worlds with separate rules and languages, whose “intersections of cultural practices open up third spaces that allow negotiation of meaning and hybridity—that is, the production of new cultural forms of dialogue” (Akkerman & Bakker, 2011, p.135), and therefore they can be fruitfully trialled in boundary-crossing activities. In a complementary way we argue that memes, together with the inner discourse brought into being to make sense of them and the collective discussion they trigger in the class group, are aligned with Sfard’s statement that “the term discourse will be used to denote any specific instance of communicating, whether diachronic or synchronic, whether with others or with oneself, whether predominantly verbal or with the help of any other symbolic system [...] learning mathematics may now be defined as an initiation to mathematical discourse, that is, initiation to a special form of communication known as mathematical.” (Sfard, 2001, p.28).

The research questions we are searching answers to are the ones below, they are big and complex ones and we are aware that this study just put a small dent into them, but we think they deserve to be stated because they outline the bigger picture we strongly believe is worth looking for:

RQ1: What are the epistemic affordances, if any, of mathematical Internet memes?

RQ2: Does creating and/or interacting with these memes implies/determines learning?

RQ3: Which characterizations identify a boundary object in this context? Which interactions among the communities of students, teachers and researchers are triggered by these boundary objects?

RQ4: Can memes, students’ explanations vehiculated through the narrative virtual content and classroom discussion be identified as parts of a mathematical discourse?

## METHODOLOGY: THE BUILDING OF THE TEACHING EXPERIMENT

The beginning of this project dates back to a few years ago when one high school student (of the first author) provokingly said that he had finally grasped a math concept only when coming across a mathematical Internet meme on the same subject in a social platform. Moving forward from this first naïve appearance of memes in the school environment and trying to figure out how to build a significant task to test our assumptions in an almost unexplored territory is, of course, a challenge that can be tackled only by small steps. We started observing students’ reaction to mathematical Internet memes found in the web (examples in Figure 4) and used by the teacher to catch and hold attention, to stress specific aspects of already taught topics and to trigger classroom discussion.

Figure 4: Examples of web-found mathematical Internet memes

The quality of the mathematical discourse enthused by these mathematical Internet memes convinced us that interacting with them calls mathematical competencies into play but, to dig deeper into the

epistemic of memes, we realised that students had to create the memes themselves and shoot videos to keep track of the explanations of the mathematical meanings.

This is when Augmented Reality (AR) comes into action: vision-based AR technology refers to the triggering of a superimposed computer-generated layer (usually a video) when pointing a smartphone or other GPS-enabled device to a precise spot; it allows the connection of the meme to the corresponding explanatory video, that can be then viewed scanning the meme into the phone. Hopefully, the bonded couple meme+video will thus give origin to a multimodal and multimedia learning object, providing opportunities for the single student to maximize his linguistic and cognitive meta-awareness and systematize knowledge, for the class group to connect and revise knowledge and for the teacher to assess students' comprehension of previously studied concepts, to single out possible misunderstandings and misconceptions and give a formative assessment. Last but not least, it could cross the threshold of the school environment, be shared on the web and become part of the global network heritage as a viral meme.

Having students create memes and videos themselves matches different goals: it allows taking advantage of the aforesaid participatory thrust of the digital world, it leverages on the notion of identity as “a perfect candidate for the role of “the missing link” in the researchers’ story of the complex dialectic between learning and its sociocultural context” (Sfard and Prusak, 2005, p.I-43) and finally it will hopefully facilitate the emergence of the students’ linguistic and cognitive meta-awareness, which are the declared educational aims. This last expectation grounds in the concepts of “active response” and “meaningfulness” advocated by Burbules in his description of the virtual, that “should not be understood as a simulated reality exposed to us, which we passively observe, but a context where our own active response and involvement are part of what gives the experience its veracity and meaningfulness” (2006, p.38).

## A FIRST TEACHING EXPERIMENT

At the end of May 2018, a first exploratory teaching experiment was conducted with a group of 12th-grade students, aiming at testing the potential educational effectiveness of memes. The assigned task, to be done individually at home, was to create a meme on one of the year's math course topics (optionally using one of the said meme generator websites) and shoot a video with the smartphone explaining the mathematical concept recalled by the meme. Students then were asked to bond meme and video through [HP reveal](#) (a free augmented reality web app) and post the meme in the collective space, using the free web app [Padlet](#), set up for the occasion to mimic the social media environment, allowing the sought-after tribal reward reactions.

Connecting students' memes to our *triple-s* analysis, we can see that all productions comply with the structural meaning and that they all call for the viewer's engagement mobilizing an emotional reaction due to a misalignment between different parts of text or between text and image. Looking at the social meaning, that seems the element that crosses the boundary “maintaining the common identity” (Star & Griesemer, 1989, p.393), we have identified three main categories (examples in Figure 5).

Finally, examining the memes' specialized meaning, further clarified in the coupled videos, we completed the possible analysis in Table 1 (videos – in Italian - can be seen downloading the HP

Reveal app to a smartphone, following *lifeonmath* and then scanning the images in Figure 5 – due to monitor light reflections, it works better with printed images).

Figure 5: Example 1 (left), Example 2 (centre), Example 3 (right)

CATEGORIES	SOCIAL LEVEL	SPECIALIZED LEVEL
Figure 5 Example 1	memecaption starting with a “when you/they” statement	mathematical terms in the memecaption.
Figure 5 Example 2	memecaption describing the effect of an action or operation	image connected to the mathematical action, mathematical symbols used to label elements in the image
Figure 5 Example 3	memecaption creating a pun based on a bivalency of meanings	memecaption with terms that have a mathematical and a common use meaning

Table 1: Analysis of the produced memes and videos

Considering these data, a first observation is that technology seems to intervene with different roles: it acts both as an instrument for students to create the learning objects and as an environment with rules that informs designers and users. From the educational point of view, their creations seem to confirm that students knowingly selected a topic in which they felt comfortable (cognitive meta-awareness) and made an effort to explain it clearly using appropriate lexis (linguistic awareness). Looking this preliminary analysis through the lenses of our framework theories, we ventured that the boundary object could be looked for in the social level that “maintain[s] a common identity across sites” (Star & Griesemer, cited), while the couple meme+video appears effective in triggering a special form of mathematical communication in which meta-cognition and language accuracy play a relevant role. This is, of course, a first rough attempt that has to be refined, breaking it down and trying to identify the steps of the boundary crossing (identification, coordination, reflection and transformation) and the commognitive constructs (word use, visual mediators, narratives, and routines), once the observation of the cognitive processes will be implemented.

## NEXT MOVES

Although the results of this first exploratory teaching experiment seem encouraging, there are still many shadows hanging over this project, one among others being its replicability. In order to dispel at least this first doubt, in the upcoming months, we are planning to set up a focus group observing 2/3 students, coming from a different school environment, during the process of creating memes and videos on a fixed topic. In the light of the data collected, we will hopefully structure a larger study in

a class group, giving space also to class discussions, teacher's feedbacks and possible students' revisions of the products, together with the assessment of the learning after a few months.

As we recalled in the opening paragraph, this work is still in progress, with no assessed conclusions and many unanswered questions, but we strongly believe it is worth to keep venturing in this almost unmapped territory because this is something more than a traditional technological learning experience, as memes produced by students can leave the school environment and spread virally in the web. It is a unique situation in which the virtual world comes into contact with the school world, expectantly enabling us to learn something new about the impact of the digital revolution and new communication technologies on epistemological pathways and learning practices.

*This paper focuses on the process of university mathematics students engaging in a sequence of programming-based mathematical project tasks as part of a course. Data of this naturalistic research was collected mainly through four student projects and semi-structured individual interviews. The analysis led to narratives of students' development process (instrumental genesis) in which enacted strategies (instrumented actions) are highlighted. In this paper we discuss a participant's development process. Results suggest that the student, after 1 course, has appropriated programming as instrument for creating a tool for pragmatic purposes; however, not yet as instrument for mathematics investigations and applications, i.e., as an object-to-think-with (Papert, 1980).*

**Keywords:** Programming, Instrumental Genesis, Strategies, University Mathematics Education.

## Introduction

There is a resurgence of interest in integrating computer programming—more broadly, computational thinking (CT)—in education (e.g. in UK; Benton et al., 2017). This interest reflects how scientific fields, including mathematics, have developed computational counterparts (Weintrop et al., 2016), as well as the rise and need for proficiency in computational practices as 21st century skills. We see a crucial need to understand how students can be empowered to participate in such computational thinking, now an integral part of the mathematics and broader community.

In our work, we want to better understand how students come to appropriate programming as an instrument for mathematics investigations and applications “as mathematicians do”. This appropriation involves students developing fluency (e.g. enacting strategies to progress forward) as they are (in the process of) engaging in this kind of mathematical work. This includes, not only becoming skilled at programming, but also designing and interpreting the mathematical work facilitated, or made possible, by programming. In this proposal, we discuss the case of a student's fluency development, analysed from the first-year data that was collected as part of a five-year study that examines how postsecondary mathematics students learn to use programming as a CT instrument for mathematics. It is a naturalistic (i.e., not design-based) research that takes place in a sequence of three project-based mathematics courses (called ‘MICA’) implemented in the mathematics department at Brock University (Canada) since 2001, where undergraduate mathematics majors and future mathematics teachers learn to design, program (e.g. in VB.net), and use interactive computer environments to investigate mathematics conjectures, concepts, theorems, or real-world applications (Buteau, Muller, & Ralph, 2015; Muller, Buteau, Ralph, & Mgombelo, 2009).

## Conceptual Framework

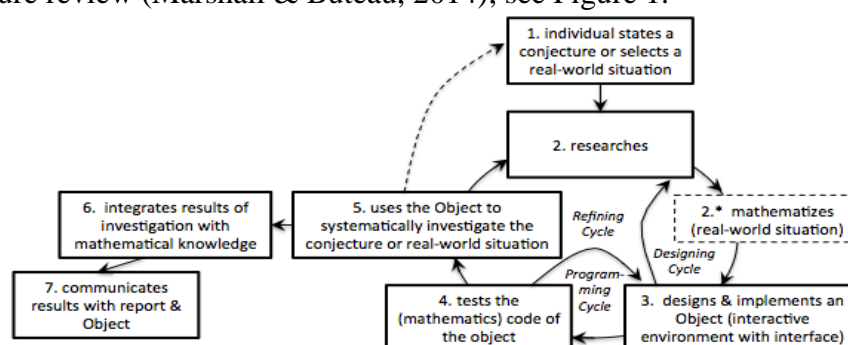

Our work is framed by various interrelated concepts reflected in the literature on CT, CT in mathematics, and in mathematics education (Buteau, Muller, Mgombelo, & Sacristán, 2018). Wing (2014) defines CT as “the thought processes involved in formulating a problem and expressing its

solution(s) in such a way that a computer—human or machine—can effectively carry out” (p. 5), while Hoyles and Noss (2015) consider CT as abstraction, algorithmic thinking, decomposition, and pattern recognition. CT is an underlying process to computer programming described e.g. by Weintrop et al. (2016) as understanding, modifying, and writing codes (e.g., in *Python* or *C++*). Brennan and Resnick (2012) identify key dimensions for developing CT, namely *computational concepts* (e.g. iteration), *computational practices* (e.g. debugging projects or remixing others’ work), and *computational perspectives* (e.g. a designer’s evolving views about what could be programmed).

CT has changed the nature of contemporary research in mathematics; for example, we now see computer-based proofs and new domains of research related to mathematics and computation such as bioinformatics. The European Mathematical Society (2011) recognizes this emerging way of engaging in mathematical research: “Together with theory and experimentation, a third pillar of scientific inquiry of complex systems has emerged in the form of a combination of modelling, simulation, optimization and visualization” (p. 2).

Based on their literature review and interviews with experts who use CT, Weintrop et al. (2016) outline what they believe to be the integral CT practices for mathematics and science, in particular encompassing this third pillar (Broley, Buteau, & Muller, 2017), across four main categories throughout which programming is an underlying practice: *data practices*, *modelling and simulation practices*, *systems thinking practices*, and *computational problem-solving practices*. E.g., the latter practice involves interpreting and preparing problems for mathematical modeling, assessing different approaches, developing modular solutions, and creating computational abstractions.

In the field of mathematics education, CT is not new; indeed, it has a 45-year legacy that started with the LOGO programming language (Papert, 1980) and extended into the theory of constructionism. Studies of constructionism in undergraduate-level mathematics education show how programming supports students’ understanding of mathematical concepts and contributes to the development of critical thinking skills (e.g., Wilensky, 1995). As for students’ processes when engaging in using programming for mathematical investigations and applications, we proposed a model based on insightful reflections on MICA student experiences (Buteau & Muller, 2010) which was later refined through a literature review (Marshall & Buteau, 2014); see Figure 1.

**Figure 1. Development process model of a student engaging in programming for a mathematical investigation or application (Marshall & Buteau, 2014)**

We use Lave and Wenger’s (1991) concept of “legitimate peripheral participation,” which describes how learners enter into a community of practice and gradually take up its practices, to understand how undergraduate students learn mathematics through CT activities. Based on this idea, mathematics is not knowledge to be acquired but rather is a process of participation through which the student

gradually gains membership to a community (of mathematicians). We thus focus on how students create and use computer tools to engage in opportunities to participate peripherally in practices considered to be integral to the mathematical community as outlined by Weintrop et al. (2016), i.e., in the four CT practice categories. Thus, our work is focussed on how students (newcomers) engage in computational thinking for mathematics as mathematicians (elders) do. In fact, the proposed development process of a student engaging in programming for mathematical work as summarized in Figure 1 (removed of its numbering) seems to align with the process by which pure mathematicians use programming in their research work (Broley, Caron & St-Aubin, 2018).

In this proposal, we focus on this process and the strategies that students enact when engaging in CT-based mathematics work. In the instrumental approach framework (Rabardel, 1995/2002), the process is related to a student's *instrumental genesis* (Artigue, 2002): the process by which the student transforms an artifact into an instrument through schemes of usage and action. The instrumental genesis is a twofold process: instrumentalization –directed towards the artefact–, and instrumentation –directed towards the user–concerning “the development and appropriation of schemes of instrumented action which progressively take shape as techniques that permit an effective response to given tasks” (Artigue, 2002, p. 250). These schemes of instrumented action consist of technical and conceptual components. According to Drijvers, Godino, Font, and Trouche (2013), techniques may be considered “as the observable part of the students’ work on solving a given type of tasks (i.e., a set of organized gestures)” (p.27), e.g., strategies used by a student at a certain step/cycle (see Figure 1) when engaging in a given programming-based mathematical task; and the schemes “as the cognitive foundations of these techniques that are not directly observable, but can be inferred from the regularities and patterns in students’ activities”(p. 27). As Bozkurt et al. (2018) summarize:

An artefact is initially not meaningful to the user until he or she develops associated schemes of instrumented action to use the artefact for achieving a task, and effectively turning the artefact into a useful mathematical instrument. (p.44)

E.g., turning (VB.net) programming into an instrument for mathematics investigation or application as mathematicians do, which we call ‘a CT-instrument for mathematics’. In this proposal we discuss first results commencing to address our research question: *How do post-secondary students come to appropriate programming as a CT-instrument for mathematics?*

## Methodology

Our research uses iterative design methods whereby some parts (participant recruitment and data collection) were designed in a way that would be least intrusive to (or constrained by) the natural learning environment. The study follows students’ development over the course of (and beyond) their MICA I-II-III courses as they engage in 14 *exploratory object* (EO) mathematics project tasks, each resulting in an interactive environment and a report of mathematical findings (Muller et al., 2009). This paper focusses on a first analysis of data collected from the first year of our research. It thus draws from MICA I students where six (among 46) participants were recruited (voluntarily). In the MICA I course, there are 4 EO project tasks (which count for 71 % of students’ final grades): 3 assigned individual ones, and a fourth one where students select the topic and can work in pairs or individually. Two-hour weekly labs progressively integrate through guided exercises the learning of computational concepts (variables, loops, etc.) in a mathematical context, whereas two-weekly hour

lectures introduce the math background needed for engaging in the EO tasks (Buteau et al., 2015).

Data from the participants included each participant's 4 project assignments (EO and report) and individual semi-structured interviews after completion of each of these EO tasks. The design of the interview guiding questions was informed largely by the students' development process model (Figure 1). In addition, data collected included weekly post-laboratory session online reflections (answering guiding questions) and an initial baseline online questionnaire before the beginning of MICA I course. Lab session and EO assignment guidelines were also collected and were complemented by an informal understanding of the MICA I course from the research team members' experiences in different capacity (researcher, instructor, course approver, former student).

All of the collected student data were analysed through thematic analysis techniques. Codes were developed based on categories informed by the conceptual framework (and associated literature). Each participant's interview and lab reflection data was coded individually by two coders, followed by a thematic analysis done jointly by the two coders. Themes were consolidated among the six participants' analyses, and led to sixteen themes regrouped in five main meta-themes, one of which concerned strategies. Narratives were composed, following the model steps from Figure 1, of each participant's process of engaging in their four EO projects, highlighting their enacted strategies, and overall summary. We now present preliminary findings by illustrating one of the six participants' development process with a focus on her use and development of instrumented techniques, i.e., *enacted strategies* (in italic, below), as a way to gain insights into her instrumental genesis towards appropriating VB.net programming into a CT instrument for mathematics.

### **Findings: the case of Hannah**

Hannah (pseudonym) is a mathematics and computer science co-major, and thus had programming experience (in Java) prior to her MICA I course. In her first assigned EO project –exploring a conjecture of their choice about prime numbers or hailstone sequences–, Hannah struggled with the initial step of conjecturing (steps 1-2 in Figure 1); once she was passed this, she incrementally designed and programmed (steps 2-3) with ease her interactive environment (EO). When the time came to interpret the mathematics output of her program (steps 5-7), Hannah struggled and provided only data examples without mathematical explanation. In the EO 2 project on a RSA encryption application, Hannah reported feeling more satisfied and confident, finding it overall easier, in particular since she could start right away with designing and programming (i.e., step 1 was provided by the assignment guidelines). However again, her focus on the mathematics (step 5-7) seems to have been limited. We elaborate next on Hannah's engagement in her third EO task.

### **Hannah's development process and enacted strategies in her third assigned EO project task**

Students are then asked to design, program, and use an interactive environment to explore, graphically and numerically, the behavior of a dynamical system based on a two-parameter cubic (Buteau et al., 2015). It follows an introduction of discrete dynamical systems in lectures, guided computer lab activities to program an EO to explore the logistic function system (quadratic, 1 parameter), including an instructor guided exploration of the system as the parameter is changed. At this time, students have been introduced to all basic computational concepts for mathematical work: variables, interface design, loops, conditionals, events, sequencing, and graphing. This assignment has a significant component on mathematical investigation. For Hannah, it is a critical learning opportunity since she

struggled with the mathematical components of the previous two EO projects.

Similarly to EO 2, the assignment guidelines provided the focus of the EO project (step 1 in Figure 1). Hannah voices that she did not research the related mathematics (step 2) when beginning the assignment because the lectures and labs were sufficient; however, in reflection, she believes she would have needed more time spent on the math concept to grasp it. In fact, Hannah missed some lectures due to illness and felt unable to catch up with the mathematical concepts. As in the past assignments, Hannah understands the programming concepts and is able to start designing and programming her project (step 3) in lab time by *remixing from the two previous labs* on the logistic function dynamical system. She used the *computational practice of incremental steps* with testing to complete the programming (programming cycle) – see Figure 2 for a screenshot of her EO:

Hannah: the first step was setting up everything. ... we have to setup the graph... regardless of ... 'a' and 'b'... we're converting it to pixels instead of x and y's... So, we had to make sure that was working first before you could plug in anything.

**Figure 2. Screenshot of Hannah's third EO project about the 2-parameter cubic dynamical system**

Hannah *tested the mathematics* output of her program *against other students' work and known examples from class* (step 4); e.g., Hannah says:

Hannah: I used the, um, same values that, um, [the instructor] put in the labs. And, um, I checked, I compared the sequence and saw the math was working and then the graph and how it looks.

However, she had difficulty in investigating the given math topic or understand its meaning (steps 5 & 6), although she did *investigate* the cubic function *by systematically varying its parameters*:

Hannah: I left 'b' fixed at zero and I increased 'a' a little bit and little bit and I see how it affected the curve....So, yeah, I played around with [a and b] until, um, until I got the fixed points.

but struggled with understanding the cobweb:

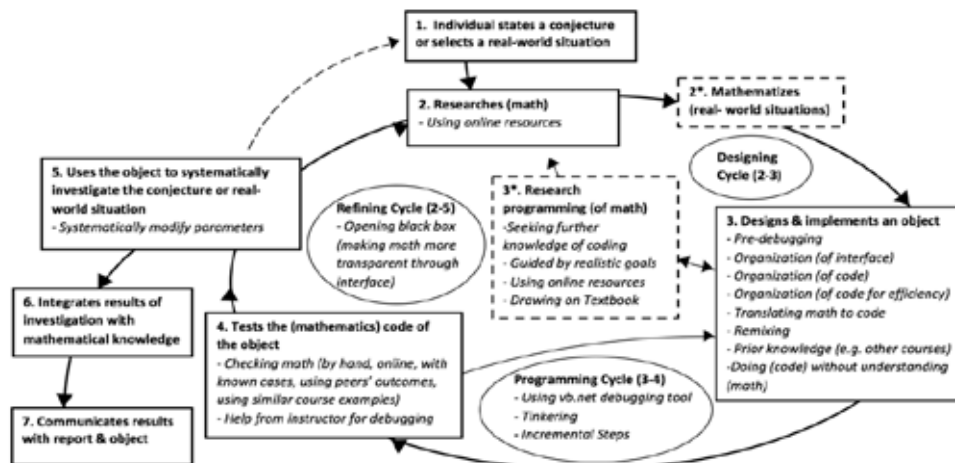

Hannah: one of the challenges was, um, the, um, trying to figure out if it actually does converge. Because, um, the way we visualize it is, um, for each of the points. So, if you have 10 points, uh, 10 sequence numbers that you have, you draw lines between them. But, because we don't have like, sort of like, the starting point of the line and the ending point, you don't know if it is going that direction, which direction are going.

In the final part of the assignment, the report, Hannah's lack of understanding becomes clearer. Although her program works, her report does not reflect understanding; in particular, she *uses the*

program to generate an example, rather than elaborating calculations and drawing it by hand as asked (similar to how she completed her EO 2). Her report is lacking in explanations or conclusions to communicate her mathematical knowledge (step 7) and the discussion portion of the report is missing. This EO project could have been a great positive learning experience for Hannah to use programming for mathematics (learning) as this assignment was heavier on the mathematics investigation than previous ones. However, Hannah missed the opportunity partly due to external factors (illness).

### Hannah's overall trend over the 4 EOs

Throughout the course, Hannah's focus seems to remain on programming rather than moving on to programming for mathematics, as revealed through her general approach to the 4 EO assignments. Hannah finds difficulty in identifying on her own, a mathematics topic relevant to a programming-based approach (step 1). She prefers to be given a conjecture (as in EO 2) and avoids creating her own when possible (as in EO 4). Once the mathematics problem or conjecture is sorted out, Hannah becomes much more comfortable. Most of the time, she researches thoroughly and uses resources to be well prepared for a solution before starting to program. She wants to understand the mathematics *a priori* and then program it, rather than using programming to understand (her general approach to 'interpreting and preparing problems for mathematical modeling' practice). This method causes difficulty in EO3 as programming for investigation is an intended way for students to understand.

**Figure 3. Hannah's summarized enacted strategies during the development of her 4 EO projects**

Hannah uses her previous programming experience to help her complete the design and programming (step 3) with ease and little help from others: she *works incrementally* and *uses functions and modules to structure her program* (her approach to 'developing modular solutions' practice). Hannah developed multiple methods of *checking her mathematical work* including *using online resources*, *calculating by hand*, and *comparing known examples*. Because of her heavy preparation (in step 2) and strong programming skills (in step 3) there are not often many bugs to solve (step 4). When attempting to use the program to investigate the math problem (step 5) beyond the creation of the project, Hannah seems to lack confidence. She often isn't sure how or what to conclude from the program output. She doesn't seem to know how to use the program for investigation and wants to understand first, then "explore" later to confirm what she knows rather than to discover new ideas. Her limited investigations make it hard to integrate the results with her math knowledge (step 6). She finds some results noteworthy, but not necessarily what is intended as part of the investigation and

her insights, rather than mathematical, are more often related to programming. Lastly, when communicating her results in her written report (step 7), her descriptions are often short and not thorough in explanations. She provides examples that are either too simple to demonstrate knowledge or uses her program to generate an answer without further explanation of the process. Figure 3 summarizes Hannah's enacted strategies over the course of her 4 EO tasks.

Overall, Hannah seems to treat the course as a programming class for designing mathematics calculators rather than a mathematics class using programming as a tool for understanding and investigation, i.e. as an "object-to-think-with" (Papert, 1980). This perspective seems to limit her ability to dive in and explore new mathematical concepts deeply. In the final interview, Hannah said she intends and is looking forward to take the MICA II course. It will be interesting to see how (and if) she adapts her approach, enacting new strategies, in this more mathematically demanding course.

## Conclusion

We have described Hannah's development process (including her strategies) as she engages with designing, programming, and using mathematics EOs. We observed that Hannah seems to appropriate programming as instrument for creating a tool for pragmatic purposes –i.e. as a calculator– however, not yet as instrument for mathematics investigations and applications –i.e., as an object-to-think-with (Papert, 1980). The findings provide insights on Hannah's development of fluency and instrumental genesis –i.e. how far she has come, through MICA I course, to appropriate (VB.net) programming as a CT instrument for mathematics investigations and applications. The transition from an instructionist to a constructionist approach to learning mathematics seems to have remained a challenge for Hannah, even with her previous programming background. In the near future and with the current trend, it is expected that students will arrive in mathematics department with programming skills. The case of Hannah can thus be considered as of a typical 'student' of the near future, and as such, provides insights of how these typical students' instrumental genesis may develop.

The first year student data analysis led to refine further the development process model (see step 2 and step 3\* in Figure 3) to better capture the different strategies enacted by students. By highlighting how Hannah's strategies are enacted in the development process model, our study provides a beginning of how we can explore the role of strategies, as techniques, in students' instrumental genesis, leading next to study the related instrumented action schemes. The next steps, in our 5-year research, are also to bring together all of the thematic analysis findings and the development narratives for a deeper insight into students', including Hannah's, instrumental genesis, and to continue follow our participants into their upper-year MICA courses. It will also include the examination of instructors' adoption of learning environment (i.e., instrumental orchestration).

*Keywords: Mathematics, outdoor learning, math trail, student motivation, big events*

The intention of this poster is to present several big events held in Portugal, in the cities of Porto and Matosinhos, and in France, in the city of Lyon. We consider mathematics learning outside of the school building and we use day-to-day materials (monuments, buildings, traffic, gardens, etc.) as support materials. It is important to bring learning to life and learning outside the classroom (DfES, 2006). One way of experiencing outdoor mathematics is to walk a math trail. We used the Shoaf, Pollak, & Schneider (2004, pp. 4) statement to guide our work and to advise our implementation of math trails. The math trails can be created using the traditional way – paper sheets with tasks on them. But, nowadays, they can be created using smartphones, combining the concept of math trails with advanced technology in a modern learning environment. The MathCityMap-application (MCM-app - [www.mathcitymap.eu](http://www.mathcitymap.eu)) provides a new approach to an already well-known idea - experience mathematics in outdoor activities and using smartphones (Jesberg & Ludwig, 2012; Cahyono, Ludwig & Marée, 2015; Cahyono & Ludwig, 2016; Zender & Ludwig, 2016). Through the MCM\_app, students went on an outdoor walk along a route and solved mathematic problems that were contextualized with the surrounding environment. The students passed through special places in these cities, where mathematic can be experienced in everyday situations. For example: buildings for logic problems, statues for numbers and counting, lakes and fountains for geometry, a swing to calculate angles measures, lake bridge to calculate areas, garden benches to apply combinatorial calculus, functions to model the proportions of colors along a corridor, or using the GPS tasks to pinpoint the foci of a very large ellipse. A task which was really appreciated was an introduction to the Dewey classification system with decimal numbers, because a new theme can always emerge, since there are always a decimal between two different decimals, there is always room for improvement in this system. And the task was to find the decimal number associated with a given book from the library. Finding the number of pages of mangas in there was as well a hit but the GPS tasks where one had to finish a square or place oneself at the middle between two inaccessible points were unexpected by the students. We have streamlined math trails held around Porto, Matosinhos (Portugal) and Lyon (France), based on the MCM\_app: “Matemática vai à Baixa” – Mathematics goes to downtown (competition), June 8, 2016, Porto. Participants - exactly 297 students (age range 9 to 18 years) and 40 teachers; “Matemática vai ao Jardim” – Mathematics goes to the Garden (competition), March 23, 2018, Matosinhos. Participants - exactly 170 students (age range 9 to 18

years) and 23 teachers; Math.en.Jeans Congress, March 22nd-24<sup>th</sup>, 2018, Lyon, France. Participants - around 700 (students - age range 9 to 25 years, teachers and researchers); the national gathering of the Collège commission, June 21st-23<sup>rd</sup>, 2018, Lyon, France. Participants – exactly 130 (lower secondary teachers in France). It is very gratifying to note that in all events, teachers and students participated in mass. Stands out the great enthusiasm from the students and mathematic teachers, they participate in general with energy and are willing to repeat the experience. All students and teachers can take advantage of a new context to transmit knowledge, contributing to greater motivation for learning mathematics. Students were amazed to participate in the math trails, but to cross a math trail using mobile devices and GPS functions to find the tasks location were fantastic. These activities generally increased the students' engagement to learn mathematics. The teachers were interested not only to play but as well to understand the different types of questions that could be addressed. These actions were fairly disseminated by the media. Usually mathematics appears in the news surrounded by a negative scenario, but with our events, mathematics came to the house of families in a positive, constructive and dynamic way. In the poster, we would present examples of tasks of the routes from the math trails, highlighted the details to consider them like starting points to promote the modelling process in the learning. To evaluate the degree of satisfaction of teachers and students were conducted surveys in different events, which show the high degree of satisfaction and evaluate the impact on learning (see, for example, Caldeira, Faria, Figueiredo & Viamonte, 2016).

# Multiplicative reasoning through two-handed gestures

Sean Chorney, Canan Gunes and Nathalie Sinclair

Simon Fraser University, Canada; [sean\\_chorney@sfu.ca](mailto:sean_chorney@sfu.ca); [cgunes@sfu.ca](mailto:cgunes@sfu.ca); [nathsinc@sfu.ca](mailto:nathsinc@sfu.ca)

*This exploratory study focuses on two-handed gestures when using an innovative iPad application called TouchTimes. We suggest that the use of the two hands is relevant to multiplicative reasoning as it provides a way of expressing multiplication as a coordination of two quantities, rather than simply as repeated addition. We report on the use of TouchTimes by two third-grade girls; we first exemplify the designed two-handed gestures the girls used and then identify some emergent gestures that we see as being relevant to multiplicative thinking, particularly in terms of the relation between the multiplicand and the multiplier in a multiplication expression.*

*Keywords: Two-handed gestures, multiplicative thinking, touchscreen technology.*

## Introduction

In this paper we report on an exploratory study involving a pair of grade three students working on an iPad application called *TouchTimes* (TT, Jackiw & Sinclair, 2018) that was designed to offer an accessible model of multiplication that does not rely on repeated addition. TT uses the multi-touch affordance of the iPad to express the relationship between multiplicand, multiplier and product through the use of specifically designed two-handed gestures. It is an extension of *TouchCounts*, also designed by Jackiw and Sinclair (2014), which enables gesture-based actions for counting, adding and subtracting and has been shown to improve subitizing, the ability to differentiate between cardinality and ordinality (Sinclair & Pimm, 2015) as well as basic number sense (Sedaghatjou & Campbell, 2017; Sinclair, Chorney & Gillings, 2016). TT builds on this *TouchCounts* research by extending the gesture-based arithmetic. In this research study, we are interested in the way two handed gestures can support young students' multiplicative thinking.

## Research on learning multiplication

Multiplication is difficult for many students, yet very important for subsequent higher-grade topics such as proportion and algebra (Siegler et al., 2012). One of the difficulties with multiplication results from students' excessive exposure to multiplication as repeated addition (Askew, 2018). It is important to develop students' understanding of multiplication in terms of relations, particularly the relationship between the multiplicand and the multiplier. Designed to develop the bi-directional functionality of multiplicand and multiplier, TT allows for both the multiplicand and the multiplier to be changed either during and after a multiplication computation. We hypothesise that this offers not only an empirical environment for experimentation, but also the possibility of noticing the relationship the multiplicand and the multiplier have on the product.

In the work of Clark and Kamii (1996), multiplication has two levels of abstraction. The shift from the many-to-one and an inclusion relation between multiplicand and multiplier. Multiplication is relational and functional in that both multiplier and multiplicands are abstractions that affect each other. For example, in the case of  $3 \times 4$ , if 3 is the multiplicand and 4 the multiplier, 3 to 1 is the abstraction of three becoming one (the unit) and the 'inclusion relation involves a transfer of units in

that the multiplicand “3” counts the number of items while the multiplier “4” counts the number of triples of these’ (Boulet, 1998, p. 14). In *TT* the physical use of two hands is meant to enact this dual abstraction. We are thus interested in studying the extent to which students’ gestural interactions with *TT* supports their multiplicative thinking.

### Brief description of *TouchTimes*

The initial screen of *TT* starts blank, except for a vertical line (Figure 1a). A user can create two kinds of mathematical objects: pips and pods. The first finger(s) down on the screen produces pips, which are coloured discs that appear under each finger. For example, if the user places three fingers on the left side (LS) of the screen, three differently coloured pips appear (Figure 1b). If the user then places four fingers on the right side (RS) while holding the three pips, four ‘pods’ of three pips appear (Figure 1c). Each pod is a bounded object containing a smaller version of the number, colour and configuration of the LS pips. If a finger is lifted on the LS, then there will be two pips there and each of the four pods will contain two pips. More pips can also be created by placing more fingers on the LS; this will affect the RS pods accordingly). If all the pip-making fingers are lifted, the pods disappear too (multiplication by 0), and the screen goes blank. Additional pods can be created on the RS; once created they remain on the screen even when fingers are lifted (this enables multiplication of numbers bigger than  $n \times m$ , where  $n + m = 11$ , which is the maximum number of simultaneous touches allowed). The situation can be completely reversed: if the first touch is on the RS, then pips are produced there and touches on the LS produce pods.

**Figure 1: (a) Initial screen of *TT*; (b) Creating 3 pips; (c) Creating 4 pods**

As soon as there are both pips and pods on the screen, a multiplication expression appears on the top of the screen. For the above situation, the mathematical expression is  $3 \times 4 = 12$  (Figure 1c). Once created, pods can be dragged anywhere on the screen and can also be trashed. Pips can also be moved, as long as the fingers are not lifted. In the reversed situation, the multiplication expression is  $12 = 4 \times 3$ . The two hands have different functions, and in this way, multiplication is experienced relationally, rather than in terms of repeated addition.

### Theoretical framing

Research into iPads is still relatively new and there have been various frameworks proposed to study how the iPad interrelates with mathematical thinking. Embodied theories have been common since the iPad offers unique kinaesthetic experiences with number, particularly in terms of the gestures required to create and manipulate mathematical objects. Bairral and Arzarello (2015) use the idea of embodiment to suggest that the action of the body in any type of activity acts as a grounding for cognition. However, we align with researchers based in a nondualist paradigm (challenging the

separation of mind and body), and see embodied action not as a reflection of thought, nor as a grounding of thought, but rather as an aspect of mathematical thinking (de Freitas & Sinclair, 2014).

We employ an embodied framework that sees both the tool (the iPad and application) and the children as a cohesive unit, as an assemblage (de Freitas & Sinclair, 2014). By seeing *TT* not as a separate entity from the students but as ‘entwined’ (Nemirovsky et al. 2013; Arzarello et al., 2002) we can theorize a formation of bodily-based mathematical activity. This form of embodiment shifts from the tool-student duality, suggesting instead that the mathematical thinking *is* action-with-tools.

Given the design of *TT*, we are particularly interested in how gestures are indicative of students’ mathematical thinking. We follow Sinclair and Pimm (2014) in seeing gesture on the iPad as epistemic *and* communicative. Bairral and Arzarello (2015) claim that there are “six basic finger actions for input on a touchscreen: tap, double tap, long tap (hold), drag, flick, and multi-touch (rotate)” (p. 2). For *TT*, we suggest that the last type of gesture, multi-touch, can be expanded and elaborated, particularly in relation to the use of two-handed gestures, on which little research has been conducted in mathematics education. An exception is Duijzer et al. (2017), who study the coordination of action and perception in terms of proportional reasoning in an environment where children move their two hands in the same direction, but at different rates. Bairral and Arzarello (2015) address two kinds of two-handed gestures: (1) when one hand is holding and the other is dragging; (2) when both hands are doing the same gesture (as in when two fingers are dragging away or towards each other to expand or reduce an image). In *TT* each hand performs different movements and different functionalities. One hand acts as the multiplier; the other as the multiplicand. Our research questions therefore are: What are the different types of two-handed gestures used by novice, young learners? How do the two coordinating hands express multiplicative thinking?

## Methods

In this study, we examined two students’ first contact with *TT*. We worked with two grade three students in an elementary school in a downtown part of British Columbia. We will call them Jessica and Ava in this paper. This pair of students was chosen by the classroom teacher who thought that they would work well together and to provide Jessica, who often ignores instructions, with a different kind of mathematical experience. We video recorded their interaction with the application. The session lasted for 27 minutes. For the initial seven minutes, the students interacted with the tablet without being given a specific task by the interviewer (third author). After the seventh minute, the interviewer occasionally proposed a mathematical task. We transcribed the video, paying attention to when the girls made two-handed gestures, as well as to their awareness of multiplication. For example, if the girls moved their fingers in such a way that the multiplicand reduced by one, we identified their awareness of changes based on what they said. We distinguished situations in which each girl used a hand, which we call a two-person bi-handed gesture, from situations in which one girl used two hands, which we call a solo bi-handed gesture. We see the former as being highly relevant to exploring the social aspect of joint coordination (see Sebanz & Knoblich, 2009).

## Analysis

We present our analysis in two parts. First, we use an *a priori* analysis of the “designed” gestures, that is, the gestures that *TT* was designed to allow, and describe which ones were observed in the

video. We then present two of the “emergent” gestures found, that is, gestures that were not explicitly designed, but that were identified as being relative to the girls’ thinking about multiplication.

### A priori analysis of designed gestures

Each gesture identified in Table 1 is done with a single hand. The two-handed gesture comes into existence when any two of these gestures (including identical gestures) are done on different sides of the screen and with different hands (though it is technically possible to use one hand to touch both sides of the screen). The number of two-handed gestures then grows to include all the combinations of any two of the gestures in Table 1.

Single tap (T): Tapping the screen with one or many fingers.
Hold (H): Pressing a screen object continuously without lifting the finger/s.
Drag (D): Moving an object with finger/s on the screen continuously without lifting
Hold and tap (H&T): While some fingers are holding, other finger/s are tapping
Hold and drag (H&D): While some fingers are holding, other finger/s are dragging
Hold and lift (H&L): While some fingers are holding, other finger/s are lifting

**Table 1: Designed gestures in *TT***

In Figure 2, we depict three of the more frequent gestures: T, T; T, H; H&T, H. Below, we provide a brief description of each as it occurred in the video.

**Figure 2: (a) T, T; (b) H, T; (c) H&L, H**

From the students’ perspective, in Figure 2a the middle finger of the first hand taps the RS of the screen and the index finger of the second hand taps the LS of the screen. This two-handed gesture was mostly observed at the beginning of the video as the girls were first exploring *TT*. They stopped using this gesture after a while, either because they realized that this did not create more than one object at a time, or that a holding gesture was necessary to create a pod. In Figure 2b, the first hand holds five fingers on the LS all-at-once, the second hand taps the index finger on the RS. This gesture produces one pod, which is a unit of five pips. In Figure 2c, there are three fingers of one hand on the LS, while lifting the pinky and thumb, while the index finger of the second hand was held on the RS. This gesture was very common and changed the number of pips within each of the pods.

### A posteriori analysis of the emergent gestures

We will present two episodes, each of which involved the use of an emergent gesture, which we will refer to as a *three-handed gesture* and a *dancing gesture*, respectively.

At the beginning of the first episode chosen, Jessica holds five fingers of her right hand on the RS and Ava holds two pods on the LS (H, H). There were 15 pods on the screen showing  $75 = 15 \times 5$ . Jessica then used her left hand to make another pip, thereby making six pips in total (Figure 3a), changing the equation to  $15 \times 6 = 90$ , and changing all the pods to include six pips.

Jessica: What the  
 Ava Wooow (*drags index finger, producing 7 pips, as in Figure 3b*)  
 Jessica di di di di didi di di di di oh wait I can change the shape

When she put her sixth finger down, Jessica brought her second hand into play so that the girls were making a *three-handed gesture* of hold pips, drag pip and hold pods (Figure 3a). When she said “What the” she seemed to be surprised at the effect of the sixth pip, which changed the configuration of each of the 15 pods, as well as the multiplication statement. Ava then let go of the pods she was holding with her left hand and used her index finger on the RS to create another pip, which she dragged on the screen, saying “woooow”. There were now seven pips in each pod and a new equation  $105 = 15 \times 7$ . This new three-handed gesture now included a hold, a drag and a drag (Figure 3b). As Jessica dragged her sixth finger, the shape of each pod changed to mimic the configuration of her six fingers, which she seemed to realise when she says “I can change the shape”.

**Figure 3: (a) Adding a 6th pip; (b) Adding a 7<sup>th</sup> pip**

In this episode the girls make two different three-handed gestures. In the first instance, Ava had been busy making pods and it was only when Jessica brought her third hand into play that she seemed to notice that the additional pip created an important change on the screen, prompting her to say “What the”. Then when Ava sees what Jessica is doing, she changes from a holding pods gesture to a dragging pips gesture. In the first three-handed gesture, Ava does not need to be holding the pods, so the gesture might feel extraneous to the activity. However, it is perhaps because of the fact that she is holding pods that she noticed the interesting effect produced by Jessica’s added pip (the pods would have changed size and configuration right under her fingertips, so to speak). In the second case, Ava and Jessica are both doing drag-pip gestures, and so replicating the same gesture that could have been done by just one hand. However, it is in wanting to mimic Jessica that Ava starts dragging a pip, and so we see how the third hand enables both girls to do the same thing at the same time, together producing a change in the shape of the pods that is more than what each of them could have produced on their own.

In the second episode, Ava was holding five fingers on the left screen (which she held for the complete episode; see Figures 4a, 4b) and Jessica had just finished creating pods and dragging them around the screen. There were 31 pods on the screen and the multiplication sentence at this point was  $5 \times 31 =$

155. Jessica touched one finger on the LS under Ava's hand (H, T) and then lifted it up again (H, L). Once more she tapped in the same spot, down and up. The multiplication sentence changed from  $5 \times 31 = 105$  to  $6 \times 31 = 186$ , back and forth. She repeated this a third time and said, "They're dancing again" and both girls giggled. She continued to tap this way for a total of eight repetitions. Jessica, still maintaining one finger on the screen, then adds a second finger, causing each pod to increase to seven pips (Figure 4b). She then began to touch up and down repeatedly with two fingers; the multiplication sentence changing from  $5 \times 31 = 105$  to  $7 \times 31 = 217$ , back and forth (Figure 4a, 4b). This time, however, Jessica added a secondary rhythm. She sang 'di di didi di di' while tapping; on each 'di' she tapped once' on the 'didi' she tapped quickly, and in between phrases, she did not tap. She continued to tap with two fingers like this through four phases of 'di di didi di di'.

**Figure 4: (a) Jessica about to tap; (b) Jessica tapping two**

We see this 'dancing gesture' as an emergent one that actually combines a repetitive set of (H, T) gestures. It becomes a single gesture for the girls that enables them to make the pods "dance". Aside from the evident visual appeal of this dancing gesture, it also embodies the girls' functional awareness of the relation between the pips and the pods, showing as it does how the number of pips affects the shape and colour of each of the pods. With it, the girls can change the multiplicand very quickly, seeing the effect on both the visual dynamics of the screen, as well as on the multiplication sentence.

## Discussion

Our first research question asked, what were the different types of two-handed gestures used by novice, young learners? In our *a priori* table we identified the designed, that is, the basic gestures supported in *TT*, which were the gestures that we expected the children to make. The most frequently-used gesture was the (H, T) in which one girl would hold pips (usually Ava), and the other would create pods one finger at a time. The girls rather quickly began to use hold gestures when they realised that lifting their fingers off the pips would clear the screen. They can often be seen holding both pips and pods, especially at the beginning. Dragging was used both to move pips on the screen, as discussed in the first episode above, and also to drag pods to the trash. The use of the gestures in Table 1 provided a starting point for their developing fluency with the tool.

We also identified emergent gestures that seemed to play more important roles in the girls' understanding of how the pips and pods related to each other. In the first episode, we describe two different three-handed gestures made by the girls that helped both to draw their attention to the relation between the number and position of pips on the screen, and to the shape of the pods. The second three-handed gesture seemed to also have an important social component in allowing both girls to do the same gesture at the same time. As with these *three-handed gestures*, the emergent *dancing gesture* combined two or more of the gestures from Table 1. The dancing gesture can thus

be seen as a bundling of several, sequentially produced (H&T, H) and (H&L, H) gestures. Over the course of the experiment, this gesture occurred multiple times with different numbers of pips and pods. The girls' continued return to this gesture, as well as the identification of its presence by such utterances as, 'they're dancing again', highlight their awareness of the multiplicative relation between multiplicand and multiplier.

Our second research question asked: How do the two coordinating hands express multiplicative thinking? It was in the use of the two emergent gestures that the girls seemed to express and notice the relation between pips and pods. In making the number of pips change, the girls noticed that the number of pips determined the shape and size of the pod, thus observing the effect of the size of the unit on the pods. The fact that the relation between the pips and the pods took some time to notice and control suggests that this is not a simple relation to understand, both in terms of physically coordinating two hands (or more) across two people, and in terms of tracking the bi-directional relation between multiplicand and multiplier. This embodied approach to multiplication seemed to initiate gestures through which the girls could explore/express this multiplicative relation.

## Conclusion

In this exploratory study, which looks at how gestures were used in the *TT* app, we identified 6x6 different “designed” gestures and exemplified three of the most commonly-used ones. We then described two additional emergent gestures that were used several times by the girls and seemed important to their growing fluency with the app and their awareness of the multiplicative relation between the pips and pods (multiplicand and multiplier). We propose that the gesture-based multiplicative actions of the girls offered them novel ways to explore and express multiplicative relationships. In the repeated addition approach, the relation privileges a focus on the multiplier ( $3+3+3+3+\dots$ ). In *TT*, however, both operands can be manipulated with immediate feedback, both in terms of the visual presentation of the pods, and symbolically through the equation. If repeated addition tends to be algorithmic, linear, sequential and unidirectional, *TT* seems to offer a more interactive, bi-directional and simultaneous instantiation of multiplication.

This research provides insight into the link between action and mathematical reasoning, and has implications for supporting students' multiplicative thinking. In future work, a closer examination of how learners coordinate the gestural expression with symbolic expressions (the equations shown on the screen) should be examined more closely. Also, the collaborative interactions of learners working together, as expressed through the three-handed gestures described here, deserves further attention.

# Physical and virtual classroom in the learning of mathematics: analysis of two episodes

Agnese Del Zozzo<sup>1,2</sup> and George Santi<sup>1,2</sup>

<sup>1</sup> Free University of Bolzano, Italy; [adelzozzo@unibz.it](mailto:adelzozzo@unibz.it), [gesanti@unibz.it](mailto:gesanti@unibz.it)

*Keywords: Virtual classrooms, didactical contract, Chevallard's triangle.*

## Purpose of the study.

The aim of this study is to investigate how a virtual classroom can foster the physical classroom activities in order to create a new learning environment that enhances peer education. The introduction of a virtual space, in addition to the physical one, offers new forms of social interaction that could allow students to overcome their difficulties. This space is available beyond the school time shared in the physical classroom and gives students the opportunity to design it according to their needs, cognitive styles and social practices. Analyzing two episodes, we propose a tentative framework to design an effective implementation of a virtual classroom in the physical classroom.

## Introduction.

In a secondary school of Bologna (Italy) where several teachers of different subjects used the G Suite for Education, some mathematics teachers started using [Google Classroom](#) (GC). The following two episodes involved two classes with different mathematics teachers. All the students were acquainted with the basic functions of GC. The first episode happened in a 10th grade class where the teacher proposed GC as a daily tool used by the students to share their questions and doubts with the teacher and the rest of the class. This episode regards the spontaneous behavior of a student who supports her classmates in the solution of an exercise. She shared on the [GC Stream](#) a photo of her notebook (with the solution in pen and some additional comments in pencil) supported by the comment “*I was able to get the right answer. If you want, you can have a look. I added in pencil the passages that I skipped so that you can better understand them*”. This spontaneous behavior of the student inspired a further study for a deeper analysis of the potentiality of virtual classrooms in addition to the physical one.

The second episode regards an experiment carried out with a mathematics teacher available to introduce, for our research, GC in a 12th grade class for a limited period. The teacher proposed GC as a social environment where the students could share their ideas and support each other to overcome their difficulties. An item of a multiple-choice test carried out in the physical classroom highlighted students' difficulties in dealing with the domain of logarithmic functions. The teacher decided to trigger the students' social interaction in the GC to find the correct answer. Therefore, the teacher assigned the same multiple-choice exercise asking the students to answer and compare the results on the Stream. Students posted in the GC Stream only the letter (A, B, C or D) of their answer without discussing the inconsistencies of their results. The students, in the next lesson, admitted that they actually had a debate but on their WhatsApp group avoiding the use of the GC. After this episode, the teacher decided to use GC only to assign homework and to communicate with the students.

## Theoretical framework, research questions and methodology.

This study suggests that the introduction of a virtual classroom requires a didactical design that takes into account the relation between the vertices of Chevallard's Triangle (Chevallard & Joshua, 1982): teacher, pupil, and knowledge. From the two episodes, it emerges that the characteristics of the side pupil-teacher determines the students' interaction with the virtual classroom. In the first episode, the students did not perceive any imposition on the part of the teacher. They felt free to use the virtual space spontaneously. Instead, in the second episode the teacher explicitly invited the students to work on a specific task. We believe that an appropriate theoretical framework for an effective introduction of a virtual classroom is Brousseau's (1997) Theory of Didactical Situations. In fact, the first episode can be interpreted as a non-didactical situation where there is not a specific teaching design. Although the students used the GC as a peer education environment, there was no evolution after the episode we described. The second episode can be interpreted as a didactical situation that constrained the students in the clauses and effects of the didactical contract (D'Amore, Fandiño Pinilla, Marazzani, & Sarrazy, 2018). The teacher had an explicit objective that she declared to her students and the potential of the virtual classroom seemed to be absorbed by the dynamics of Brousseau's Didactical Contract. The students, in the GC Stream, strictly attended the teacher's requests. The inconsistencies of the students' answers emerged on the GC Stream and triggered the expected social interaction but the discussion among students took place on the WhatsApp students' group. This kind of virtual group cannot be considered a true virtual classroom because it discards the teacher from Chevallard's triangle. The introduction of a virtual environment requires the presence of all the actors of Chevallard's triangle. The teaching design should realize an a-didactical situation that fosters personal implication on the part of the students and the breach of the didactical contract. Within this framework, the research questions that inform further studies are: how can we design an a-didactical situation in an enlarged learning environment that includes a virtual classroom entangled with the physical one? How do we manage this new variable, the virtual classroom, when designing an a-didactical situation? Within an effective interaction between the physical classroom and the virtual classroom, what artifacts and Semiotic Means of Objectification could emerge (Radford, 2008)?

*Keywords: mathematics education, geometry, quality, technology, design.*

## Current state of research and theoretical framework

In contrary to the high speed of technological expansion, the research on didactical quality of technology-supported materials for school mathematics seems to have been less rapid in the last two decades. The current approaches for its evaluation are various but not extensive enough which grounds an intensive ongoing debate in the TWG 16 of the upcoming ERME congress. On the one hand, a conventional approach is the usage of criteria catalogues or checklist. On the other hand, researchers argue against their usage due to different reasons, e.g., their inconsideration of socio-constructivist view of learning (Squires & Preece, 1999) or their tangible usage which is exposed to many factors that cannot be controlled (Krawehl, 2010), e.g., the dynamic feature of the online market changing on a daily basis. Moreover, the usefulness and effectiveness of technological tools may depend on the settings, context and instructional goals, what make it difficult to follow a straight-on checking list for their quality estimation. An undertaken analysis of geometry apps regarding pedagogical, mathematical and cognitive fidelity has shown that the majority of them had limited potential to support students in developing geometrical conceptual understanding (Larkin, 2016). It has emphasized the importance of further reviews and this is relevant not only in Australian context but in other contexts such as the German one. Another study has shown that the majority of existing apps are created for pre- and elementary schoolchildren but are not aligned to the content standards of the targeted audience (Powell, 2014). Therefore, this study focuses on a comprehensive approach for identifying essential potentials and limitations of apps along with analogue media that considers multimedia learning (Mayer, Borges, & Simske, 2018) in addition to educational standards and curricula for mathematics (e.g. in Berlin-Brandenburg schools) referring to content-related- and process-oriented competences as coherent, rather than distant proficiencies.

## Research question and methodology

How can the quality of technology-enhanced resources for supporting the development of students' competences regarding "Space and shape" be analysed through a comprehensive approach, is the question to be tackled in the study.

The poster shows a multi-dimensional evaluation instrument (EI) that is a specific part of a comprehensive multidisciplinary and dynamic evaluation model, developed through a research-based design involving qualitative approaches. The EI includes mathematics, didactics and media facets in an appropriate incorporation. A systematical peers- and experts review about its objectiveness, validation, and importance of its criteria items has taken place. Collected feedback was used for adaptation and re-design of the EI, and pilot trials as different phases of the design cycle.

## Results and their implications in practice and research

The review criteria in the created EI are grounded on a national framework about excellence of learning environments. Hence, the development of the EI resulted with review criteria structured in six dimensions: (1) mathematical and didactical significance, (2) articulation, communication and social organization, (3) differentiation, (4) logistic and technical support, (5) assessment and (6) networking of resources similarly as the key characteristics of learning environments (Wollring, 2009) and recommendations about implementation of digital media by Krauthausen (2012).

The outcomes of the design-research process would be implemented in a teachers' professional development program about elementary geometry. The aim of the designed instrument is to offer teachers a possibility to systemize the overwhelming amount of apps and actively engage themselves in reviewing processes and sharing best-practice instances, which would enable them to think about the benefits and limitations of a meaningful usage of technology in their classrooms.

Other beneficiaries may also be designers who could consider potentials of technology in future re-designs and novel designs. Finally, the study may contribute in further research in mathematics- and media education towards development of a sustainable evaluation model that may have a potential for both national and international scaling up.

### Formal presentation of the research work on the poster

Besides information about the theoretical framing, the poster (A0 size) illustrates the research design in a form of a diagram. Exemplary excerpts of the created on-line EI are presented as tables. Previews of selected apps for elementary geometry available in the German language also appear on the poster.

# Student engagement in mobile learning activities: breakdowns and breakthroughs

Khristin Fabian

Perth College, University of Highlands and Islands, Perth, United Kingdom;  
Khristin.fabian.perth@uhi.ac.uk

**Abstract** *The ubiquity of mobile devices together with the potential to bridge classroom learning to real-world has added a new angle to contextualising mathematics learning. The goal of this research was to evaluate student engagement in a series of mobile learning activities. The study uses critical incident analysis to evaluate the breakdowns and breakthroughs of mobile learning. Twenty-four Primary 7 students participated in the study. The mobile learning activities were found to have facilitated visualisation, encouraged reflection and promoted active learning. However, some issues regarding mobile use affected student engagement with the activity. The challenges identified highlighted the role teachers play in designing and carrying out novel technology use.*

**Keywords:** *Mobile learning, Mathematics education, Technology enhanced learning, Student engagement, Issues of mobile learning*

## Introduction

The challenge to connect mathematics learning to real-world is not new, but the mobility and connectivity afforded by mobile technologies has renewed interest on this challenge. Potential benefits of using mobile technologies include facilitating learning across context and personalised learning (Cochrane, 2010). Previous mobile learning studies have shown various approaches to bridge the gap between school mathematics and the real-world. For example, Spikol and Eliasson (2010) utilised the built-in sensors of mobile devices to facilitate distance measurement while Crompton (2015) used the mobile camera and an interactive geometry application to facilitate investigation of angle properties. These examples illustrate how mobile technologies seem to be a good fit for contextualising school mathematics.

Sawaya and Putnam (2015) proposed an integrated framework to help teachers design mobile learning activities for maths. The framework consisted of three issues to consider when designing learning tasks: (a) learning goals, (b) activity types and lastly (c) affordances of the technology in reference to what mobile devices offer to support mathematics learning. These technology affordances are not unique to mobile devices but it is the combination of these affordances in a single device that highlights the potential of mobile technologies in supporting various learning activities. A representation of the framework is shown in Figure 1.

Systematic reviews of mobile learning in mathematics have shown an increasing interest in the use of tablet devices in schools (Crompton & Burke, 2016; Fabian, Topping, & Barron, 2016). These studies reported that the majority of mobile learning studies found positive results, typically in the form of evaluation surveys or through an experimental pre-test post-test evaluation of student achievement. A meta-analysis of studies that looked into student achievement have found that using mobile devices for mathematics had a medium effect (Fabian et al., 2016). However, while these results evidence the learning that occurred, these numbers do not communicate the sort of engagement that happens in the classroom.

**Figure 1: Framework for the design of mlearning activities for mathematics (Sawaya & Putnam, 2015)**

Other positive outcomes reported in systematic reviews refer to positive student attitudes towards the use of mobile devices in maths, typically measured using a Likert-type survey (*ie* Did you find the activity fun?). Studies that focus on how the mobile technologies have engaged students are few and mostly short-term evaluations (Baya'a & Daher, 2010; Shih, Kuo & Liu, 2012). In response to this gap, the current study focuses on the evaluation of student engagement in mobile learning activities, drawing a focus on the breakdowns and breakthroughs of using mobile devices for learning mathematics.

The field of mobile learning is relatively new and its potentials and issues related to school use are still being mapped out. Sharples (2009) argued that “there is a need to understand what distinguishes mobile learning from classroom learning or learning with desktop computers (p.18).” Some examples of the distinctive aspects of mobile learning include mobility, portability and its capacity to support both formal and informal learning environments. Adopting new technologies in the classroom provides an array of possibilities but the practice of introducing new technology in the classroom is not without challenge. It was the goal of this study to identify issues in using mobile technologies for maths learning as well as identify advantages afforded by mobile technology use.

## Methodology

Twenty-four Primary 7 students participated in mobile-supported constructivist learning activities that covered topics on geometry and information handling. Participation was voluntary. The teacher participant for this study is a female teacher with five years of teaching experience. The student participants (12 boys, 12girls), aged between 10-11 years old were the Primary 7 students assigned to the teacher participant of this study.

The programme consisted of eight mobile learning sessions conducted over a period of 3 months. The activities included topics on geometry and information handling and were all conducted in paired or group settings. Table 1 provides an indication of the mobile learning activities carried out. The activities were recorded and later analysed using critical incident analysis to identify the breakdowns and breakthroughs of the learning activities. Breakthroughs refer to the “observable critical incidents which appear to be initiating productive new forms of learning or important conceptual change” and breakdowns are “observable critical incidents where a learner is struggling with the technology, is

asking for help, or appears to be labouring under a clear misunderstanding (Vavoula & Sharples, 2009, p. 56).”

**Table 1: Activities carried out**

Session	Mobile Learning Activity	Activity Type
Session 1 - Symmetry (Phase 1)	Students took pictures of symmetrical objects and annotated it with its line of symmetry. Using an application, they also created symmetrical pictures of non-symmetrical objects in their environment.	Practicing math skills; Investigating; Creating content
Session 2 - Area and Perimeter (Phase 1)	Students investigated area and perimeter of surrounding environment using an application. They also investigated properties of area and perimeter of objects using a manipulative.	Practicing math skills; Investigating; Applying mathematical problems
Session 3 - Information Handling (Phase 1)	Students administered surveys on the mobile device. After which they interpreted the data collected and shared these findings with the class.	Investigating; Applying mathematical problems; Creating content
Session 4 - Angles (Phase 1)	Tasks were encoded in QR codes. Students took pictures of objects that corresponds to certain types of angles. They annotated the pictures to show the angle and its' estimated angle measurement.	Practicing math skills; Investigating; Applying mathematical problems; Creating content
Session 5 - Angles (Phase 2)	Using a scavenger hunt theme, students took picture of objects which were man-made and natural angles.	Practicing math skills; Investigating; Applying mathematical problems; Creating content
Session 6 - Symmetry (Phase 2)	Following a scavenger hunt theme, students looked for specific symmetrical objects from their environment.	Practicing math skills; Investigating; Creating content
Session 7 - Area and Perimeter (Phase 2)	Students took pictures of objects and annotated them with their area and perimeter. They then tagged the actual object with this information to create augmented realities.	Practicing math skills; Investigating; Applying mathematical problems
Session 8 - Information Handling (Phase 2)	Students used the phone sensors to gather data from their environment. Data were encoded and analysed collectively.	Investigating; Applying mathematical problems Creating content

## Results

Using critical incident analysis, a total of eight breakthroughs (23 occurrences) and 21 different breakdowns (53 occurrences) were identified. Admittedly, there were fewer breakthroughs identified because the focus of the incident analysis was to identify issues within this pilot study. In addition, the wearable camera was worn by the researcher who was also providing the technical support and as such, capturing more of the technical issues that happened as opposed to capturing how the rest of the class was engaging with the activities.

## Breakdowns of mobile learning

The breakdowns were categorised into three headings: technical, social and activity design issues. Technical issues refer to problems with the use of the tablet like application stability, responsiveness and network connectivity. Activity design issues refer to problems caused by the learning activity (for example, students not being clear about what to do next or students not having a good grasp of the topic covered). Social issues relate to problems that are related to the social layer of the activity (like collaboration and participation in the activity). There were 10 distinct technical issues, nine activity design issues and two social issues identified. For a list of the breakdowns identified, refer to Table 2.

**Table 2: List of breakdowns**

Breakdowns	No. of Occurrences	Category
Tablets were not charged	3	Technical
It was not possible to check on students' work remotely	1	Technical
Stability of the applications being used	5	Technical
Access to applications	3	Technical
Difficulty in handling the tablets with the cases	1	Technical
Network connectivity issues	3	Technical
Visibility of the screen in outdoor conditions	2	Technical
The measurement given by the tablet was not accurate	2	Technical
There was no way to verify the app measurement	1	Technical
In a collaborative worksheet, it was not possible to track student input	1	Technical
Too many handouts confuse the students	1	Activity design
Students were not clear about what to do	7	Activity design
Students were not clear about the meaning of some words used and the symbols used in the application	2	Activity design
Some students did not have a good grasp of the topic.	5	Activity design
Students were not sure how to use the application	3	Activity design
Students used the tablets for non-activity related tasks	1	Activity design
Weather conditions were not suitable for the activity	3	Activity design
Students did not finish on time	2	Activity design
Students get tired of repetitively switching between applications	1	Activity design
Students did not participate in the activity.	3	Social
Students did not collaborate.	3	Social

There were far more technical issues identified in the first activity than in the succeeding activities which shows that although students were already familiar with the use of the tablets, the transition to using these devices for learning activities still required some training. It is also possible that fewer issues were identified in the succeeding sessions because students have learned to troubleshoot the issues themselves, as was seen in some footages where more tech-savvy students helped other students encountering technical problems. This observation was also noted by the teacher in the interview---that students were initially worried about all the technical glitches but have adapted over time.

The most common technical issue is the stability of applications being used and this problem has impacted students work. When the tablets or the application malfunctions, students work were not always recovered and would require students to re-do the work. As one student phrased it:

“If it doesn't work then all that you've done is gone unlike when you're working with paper. If you've got sheets there will always be spares but with tablets, you don't... so you do it again, then you get bored of it.”

This issue is problematic particularly for activities that require data gathering as the instability of the tablet could make students lose a significant amount of work. For activities that are chunked into several steps, while this is still an issue, its effect is not as much as that only require going back a few steps.

The most common activity design issue is that students were not clear what to do next (n=7). There were several instances where the students started working on the tablet but end up not being clear about the task and this required an intervention from the teacher to get the class's attention and pause for a while so that the teacher could walk them through the task that they needed to do. This problem typically occurred when students used several applications in one session. For example, in session 1, there were two activities and two different applications used. Students were given an orientation on what they needed to do at the start of the session. They went on to do the first task with one application but got confused with what they had to do next because it required a different application.

Another common issue refers to students' grasp of the topic (n=5). In some instances, students appeared to lack the foundation to be able to work on the activity. For example, in the symmetry activity, although the concepts were covered before the activity, some students were not clear what symmetry was. Although this is a breakdown, because the teacher could observe what the students were doing, this breakdown was resolved by a brief explanation from the teacher, clarifying what is symmetrical and what isn't.

In the outdoor setup, the weather was a contributing factor in the implementation of the activity (n=3). For example, during the area and perimeter session outdoors (Session 7), the weather condition started satisfactory but towards the middle of the lesson, it started to drizzle and thus affected the screen sensitivity of the tablet. This illustrated the need for contingency plans should the weather not be permitting.

There were two issues in the social layer: students not participating in the activity and students not collaborating. Both categories related to student disengagement. In the first issue, students were not participating because of difficulties they encountered in the activity. For example, one student did not complete the activity because the technical difficulty she encountered required that she had to do the activity again. In the second issue, there were cases where students were observed not to be collaborating probably because they were not the ones operating the tablet. Both categories can be argued to be a result of failings of the technology and a shortcoming in the design of the activity.

### **Breakthroughs of mobile learning**

Several breakthroughs were also observed throughout the mobile learning activities. One of the observed advantages of using mobile technologies is that they facilitate contextual learning. For example, in Session 3, the students designed a survey using an application which they later administered in class. Afterwards, they analysed the results using the generated bar graphs from the survey. The process of data collection can be said to add depth to the usual textbook exercise of analysing presented bar graphs. In this exercise, they were not just presented with the data but as they administered the survey, they were also seeing how the survey was being populated.

Another advantage is that it facilitates visualisation of abstract math concepts, thus facilitating the link between abstract math concepts and its concrete representation in the environment. For example, in the angles learning activity, students adjusted the object in their environment to fit the properties that they needed.

The activities were set up as paired or group activities and this allowed students the chance to work collaboratively using the tablets. Collaboration is not limited to the learning activity but also evident in students working together to overcome a technical difficulty. Some students have acted as technical helpers and helped other groups without being asked to do so.

Another advantage of these activities is their capacities to promote active learning environments. The activities provided in the session are all hands-on activities which have been mostly received positively, technical breakdowns aside. The breakthroughs discussed in this section match the potential benefits of mobile learning. The mobile learning activities facilitated active networked learning, but also facilitated visualisation of math concepts as students matched the abstract math concepts with their concrete representations.

## Discussion

A critical incident analysis identified technical, social and activity design issues in the mobile learning activities. The technical difficulties of the mobile learning sessions included issues with the battery, stability of the application, accuracy of the measures given by application, and network connectivity. The activity design issues included problems with the content and student background knowledge. The social issues included problems with collaboration and students' adaptability. These problems are not new and has been covered by previous math and mobile learning literature (Kalloo & Mohan, 2011; Wijers, Jonker, & Drijvers, 2010).

The effects of the technical problems in the activity varied. When only a portion of the activity was lost due to the unresponsiveness of the application, students quickly recovered from the problem. When it happened towards the end, with the majority of work being lost, this left some students frustrated. Students tolerated the technical issues up to a point. Students who had encountered several technical issues had mixed views about the use of mobile technologies and these views consequently affected their behavioural engagement. Some students persisted while there were those who became disengaged from the activity. This links back to the technology acceptance model that suggests that there should be a balance of usability and utility (Davis, 1989).

The non-technical issues related to the activity were more difficult to troubleshoot because these were mostly issues related to students' skills and the design of the activities. For example, when students did not have a good grasp of the topic, this meant that the teacher had to quickly go over the maths lesson with the whole class. In this case, it occupied some of the time for the activity. The other option was for the teacher to support the struggling student, and in that case, the teacher became temporarily unavailable to support the rest of the class. Both situations called for a re-think of the design of the learning activity.

The problem was partly caused by bringing in the technology without fully considering the learners and partly by not having fully considered the different scenarios that could go wrong in the classroom. The lesson plans were linear, restrictive and time-bound and did not allow much flexibility in terms of carrying out the lesson. Other mobile learning studies, particularly those carried out outside the

classroom environment identified the need for careful planning of scenarios and flow of activities (Spikol & Eliasson, 2010). This then leads to the concept of classroom orchestration, “the methods and strategies empowered by a technology equipped classroom that an educator may adopt carefully to engage students in activities conducive to learning” (Chan, 2013, p. 515). This highlights the important role of the teacher, their flexibility and adaptability to carry out novel use of technology.

One of the advantages of using mobile devices is the range of activities they are able to support in a single device. While the activities could have been delivered in the same way without a mobile device, the mobile device in these instances allowed students to create artefacts which they shared with the rest of the class at the end of the activity. The artefacts also served as records of how abstract maths was situated in the environment. In addition, the mobile devices facilitated the activities as students moved in and out of the different learning spaces, from gathering artefacts “in the wild” and creating new content as they annotated the artefacts they had gathered, to sharing these new artefacts with other members of the class.

These observed breakthroughs tally with the students’ perceived advantages of mobile learning for math: facilitate visualisation of abstract math concepts as well as engagement in fun and active learning activities that use technology. There was also the benefit of allowing personalisation, ownership of learning and improved student engagement, as the teacher suggested. These tangible benefits map well into Cochrane’s (2010) potential benefits of mobile learning: facilitating learning across contexts, facilitating contextual learning, and providing personalisation in both personal and collaborative environments.

The mobility offered by the technology facilitated learning as students moved in and out of different learning spaces, investigating math properties within their environment. The process of finding concrete representations of abstract math within the environment facilitated a personal learning environment as the students worked on their own devices.

## Conclusion

This study evaluated the breakdowns and breakthroughs of using mobile devices for learning mathematics in learning activities that transitioned between the indoor and outdoor environment. It has identified technical, activity design and social issues involved in implementing tablet use in a primary school setting. Some of the issues identified could have been avoided through a more careful orchestration of the learning activity. This points back to the important role that teachers play in designing and carrying out novel technology use. In the activities carried out, there was a shift in the teacher’s role and responsibility, from the person guiding and stimulating discussion to that of a “curator—a collector, organiser and guarantor of educational opportunities (Crompton & Traxler, 2015, p. 230)”. As such, it would be worthwhile addressing how teachers are being trained to target issues surrounding orchestration in addition to training on the use of new technologies..

# **A picture is worth a thousand words: visualizing collaboration through gaze synchrony graphs**

Enrique Garcia Moreno-Esteva, Jessica F. A. Salminen-Saari, Miika Toivanen & Markku S. Hannula

University of Helsinki, Faculty of Educational Sciences, Finland;

[enrique.garciamoreno-esteva@helsinki.fi](mailto:enrique.garciamoreno-esteva@helsinki.fi)

*Keywords: Math problem-solving in class, collaboration, mobile gaze-tracking, gaze synchrony, analytic methods*

## **Introduction and research questions**

In our case study, in which we attempt to understand the reasons why collaborative behavior arises, we turned to eye tracking during a live lesson involving a mathematics problem solving session in a classroom, and measured shared attention via gaze synchrony. Gaze synchrony is a measure of how much the locus of gaze of the different participants in the study overlaps. Together with a qualitative analysis of the episode, we tried to determine what produces gaze synchrony and why. Our data collection took place in a classroom and not in a lab, making our results ecologically valid. Our resulting picture, an annotated graph, is worth a thousand words when supplemented with specific knowledge about the key events it identifies. With the graph we are able to locate moments when (gaze) focused communication and interaction takes place, and identify what brings about that communication and interaction.

## **Background**

Collaboration is a process whereby two or more people work together towards achieving a particular goal. Intellectual work has become increasingly collaborative. There is remarkable consensus among educational policy makers, that the future labor market needs primarily non-routine analytic and non-routine interpersonal skills, including problem solving, interpersonal communication, and self-management (OECD, 2013). Although the nature and learning of such 21st century skills (see Binkley et al. 2010) has been studied both in psychological and educational research there are some areas that have received little attention, if any. In our study we address the question of what brings about collaborative behavior during non-routine mathematics problem solving in class.

## **Methodology**

In order to study patterns of collaboration during mathematics problem solving sessions in the classroom, student teachers at the University of Helsinki were asked to solve a non-routine problem during a lesson while wearing mobile eye-tracking devices. The problem consists of finding the optimal way to connect four cities located at the vertices of a square with cable, using the shortest amount of it (the optimal solution is given in Figure 1b). Several kinds of data were collected in addition to the eye-tracking data, such as notebook scribble, screen content when laptops or tablets were used, video, voice, and a stimulated recall interview with the subject wearing the eye-tracking devices during which they could see the eye-tracking recording as a form of stimulus. The students work first alone, then in pairs, and then in groups of four. The role of the teacher is to encourage

students to find the best solution possible without providing information about it. Four students were wearing the gaze tracking glasses. The gaze tracking data was processed to measure gaze synchrony and produce the graph in Figure 1a. The red line represents a statistically generated mean of the measure of gaze synchrony. The blue line represents the amount of overlap as given by the gaze tracking data relative to this statistically derived mean, in standard deviation units. The green lines are three standard deviations away from the red mean curve.

**Figure 1: (a) 3-way gaze synchrony graph (b) the optimal solution to the problem**

## Results and discussion

The graph above and the careful analysis of other audio and video data allow us to construct a storyline that describes the problem-solving episode and which highlights collaborative behavior. Gaze synchrony occurs at the peaks. Leading to these moments is the need of one or more of the students to verify their belief that they have identified a plausible solution (something we call goal proximity). When this belief wanes, students return to work on their own in hope of finding a better solution and gaze synchrony is lost, as indicated by the troughs in the figure. For example, in the picture, towards the right, there is a long trough followed by a high plateau. During the trough, the students are working alone, but then, one of the students thinks he has found the best solution and asks everyone to look at the board to verify this, and the verification process ensues. The graph helped us identify this pattern of collaboration in which discovery and verification alternate, with discovery taking place while students work on their own, and verification signaled by increased gaze synchrony, occurring while the group works together and the visual attention of the group members is more focused on the same targets. We believe that with this tool we might be able to identify, with more data, other collaboration patterns occurring in problem solving sessions in the mathematics classroom and provide teachers with valuable insight informing her interventions.

*Promoting students' active and meaningful engagement in online learning environments, and especially in asynchronous courses where students are not interacting with the lecturer or their peers in real time, can be challenging. This paper presents the initial results from an exploratory study on how the tutors' design considerations of a ten-week online asynchronous master's course, together with their online pedagogic strategies have impacted on students' learning experiences and their engagement with its resources, such as content, peers and tutors. The data we focus on consists of students' online contributions and one-to-one interviews. Our research aims to gain an insight into students' views on how their engagement impacted on their online learning for this course, leading thus to identifying opportunities and barriers to take into account when designing for active learning in an online course.*

*Keywords: Online learning, asynchronous communication, student engagement, digital technologies, mathematical learning.*

## Introduction

Active learning has a reputation of being effective in supporting students' retention of knowledge, addressing potential misconceptions, promoting engagement and encouraging positive attitudes towards learning (Michael, 2006). Considering these arguments, educators should be encouraging active learning in every mode of study, such as face-to-face traditional teaching, online synchronous, asynchronous or blended learning. Even though active learning strategies, such as Think-Pair-Share, Role Playing, Group Discussion, etc., are widely used and have been shown to be successful in face-to-face, as well as virtual yet synchronous teaching situations, achieving active learning in an online asynchronous learning environment presents a number of 'new' (as is not widely researched and addressed) challenges (Riggs & Linder, 2016). For example, some authors (e.g. Picciano, 2002) claim that online discussions and learning could distance students from convergent thinking, instructor directed inquiry and scientific thinking compared to face-to-face discussion. Others (e.g. Jiang & Ting, 2000; Dixon, 2010) found that students' online learning very much depends on the quantity and quality of their peers' postings in online discussions, which is certainly an unpredictable factor. Haythornthwaite (2002) and Rovai (2002) found that the greater variability in the online social interactions between students in terms of regular presence, participation, etc. and their sense of belonging in a community and trusting their peers in their mutual learning journey can take longer than face-to-face learning in a classroom environment. And just as importantly, practical issues such as easy access to the online platform and the course resources and student support when technical difficulties arise, need to be offered (e.g. Hewitt, 2003).

There are great benefits of learning in an asynchronous environment. Students have more time to reflect on the resources, the tasks, their tutors' and peers' contributions, but they also have more time to invest in offering more thoughtful and insightful contributions (Collison et al., 2000), than perhaps in a face-to-face interaction. Riggs and Linder (2016) found that more students choose online asynchronous courses due to the flexible mode of study, i.e. managing their time to work on the given tasks as and when their own schedules permit, but also spending as much time as they want per task. For more introvert students and those who are not given the opportunity to share their thoughts in face-to-face learning environments due to time constraints in sessions, the authors concluded that online asynchronous courses can give them more time to compose their thoughts and contribute.

To address the above-mentioned challenges, educators have striven to design asynchronous online courses that promote active learning and meaningful engagement from students and offer support by adapting their own pedagogical strategies accordingly (Riggs & Linder, 2016) and developing new such pedagogical strategies. Considering our own experiences as tutors in teaching such a course for the past four years, we recognized our role shifting from that of a subject matter expert, a course developer and a tutor to that of: (i) a technology trainee, to ensure we were familiar ourselves with various digital tools, (ii) a trainer, to support our students in their interactions with these digital tools and (iii) a facilitator or moderator, to manage our students' online contributions and interactions with their peers in online discussion forums. In particular, our role in promoting students' active and meaningful engagement in online discussion forums has been one of our greatest challenges. To identify strategies that support and maintain such engagement throughout the duration of the course, while at the same time evaluating and revisiting the design of our course, we carried out an exploratory study.

In this paper, we present our online asynchronous master's course on digital technologies for mathematical learning, followed by a description of the methodology of our exploratory study that investigated the extent to which and how the asynchronous online experiences impacted on our taught postgraduate students' learning in this course. The initial analysis from this exploratory study data follows. Some conclusions are then drawn, while the key findings of our study are put forward as key recommendations for nurturing active learning opportunities in any online asynchronous course.

## **Our online asynchronous course**

In 2014, we designed a brand new course *Digital Technologies for mathematical learning*, the first and only online course of the University College London (UCL)'s MA in Mathematics Education master programme, which uses the UCL Moodle platform for its delivery. There are two e-learning aspects of this course: (1) its online delivery and (2) the focus on digital technologies of the course itself, consisting of (i) familiarisation of the students with a wide range of digital tools and resources (graph plotters, dynamic geometry environments, statistical software, fully interactive online packages) and (ii) critical reflection on the implications of using such tools in the learning and teaching of mathematics mainly at secondary school level (11-18 years old students).

The main aim of this 10-week course is to encourage students to reflect critically on the potential and limitations of digital technologies for the learning and teaching of mathematics by providing opportunities for students to apply knowledge of relevant research and theory in practice. Besides

getting familiarised with digital tools and reflecting upon their use as ‘learners’ and ‘users’ themselves, students are also encouraged to design activities to use with at least three different digital tools and then evaluate them by trialling them with learners. In this process they carry out mini-research studies and reflect upon the use of digital technologies for mathematical learning. The course is delivered in 10 weeks and each week the tutors upload on the UCL Moodle platform: (1) the learning objectives and a description of the week’s content, (2) the key readings: one essential and two indicative ones and (3) the offline and online weekly tasks, which are tightly structured towards the course aims and the learning objectives. Instead of direct teaching, learning is designed to take place as the result of doing short, manageable offline and online tasks. The *offline tasks* include (1) familiarising with a piece of software and going through scaffolded activities using specific software, and (2) designing and trialling mathematics activities involving the specific software that bridge learners’ interactions with digital media and the mathematical concepts. The *online tasks* include: (1) engaging with the ideas in the key readings and writing a response about the points they agreed or disagreed with or by contributing to online discussion forums with written observations on views and perspectives of fellow students; (2) reflecting on the application of the ideas encountered in the key readings in specific learning contexts such as the offline tasks they designed and trialled. Every week, the students are required to carry out the reading and the weekly tasks, then post their reflections online, and respond to their peers’ posts. There are three themes covered in our course: (a) Visualising, (b) Generalising and Expressing and (c) Modelling. In these three themes, the students interact with many digital tools (DT), such as Excel, GeoGebra, Autograph, the eXpresser microworld, Logo, Scratch and a variety of modelling applications and online digital platforms. Research (e.g., Dixon, 2010) indicated that it can be helpful for instructors of online asynchronous courses to create an architecture for their own engagement, too. As tutors, we made sure that we had social presence demonstrated on a weekly basis through: uploading materials, posting messages, guiding student learning, providing feedback according to set times, sending reminders, contributing to some online discussions.

## Methodology

For the four years we have run this course, we have conducted end of theme, as well as end of course evaluations and while the vast majority of our students showed ‘online’ presence by posting their work and occasionally posting questions to tutors regarding practical issues about the work, we have recognised that they were not engaging in online collaborations with their peers as much as we wanted them to, for a full learning experience. In our efforts to encourage our students’ active and meaningful engagement in online collaborations, informed by findings of research (e.g. Dixon, 2010), we trialled some actions, which included: tasks that formed the basis of an online group discussion; collaborative tasks with tutor-nominated groups; pick-a-paper tasks, i.e. ‘choose one paper and its commentary from a member of your small group and post your comparative remarks and reflections’. While these strategies worked in terms of increasing the likelihood of students contributing online, we also became interested in why some students were more engaged than others, why they displayed a higher degree of learner autonomy, evidenced in their inquiring further, seeking assistance and generating new threads of discussion, than others. As such, we became interested in enquiring into *our students’*

*perceptions of the extent and the way their asynchronous experiences contributed to their active and meaningful engagement on this course.*

To address this research question, we decided to carry out an exploratory study focusing on data collected from our latest cohort of students. This data comprises 20-min interviews with a sample of 10 of the 17 students enrolled on this course and their online contributions throughout the delivery of the course (January-March 2018). Of the 10 students who volunteered for the interviews, three were English native speakers, while seven were international students, for whom English was an additional language. The interview questions focused on students' mode of study and students' experiences of online asynchronous learning, in particular their experiences of participating in online discussion forums. Our intention is to use the outcomes of this exploratory study to inform our thinking and identify issues to research further, but also rethink our practices in terms of communicating with our students and providing effective instructional strategies for improved student communication and collaboration. This will lead to the re-design of our course in its next presentation, focusing on encouraging active learning and engagement with the online course resources.

The interview data was analysed in conjunction with the students' online contributions and written assignments, following the grounded theory approach (Strauss and Corbin, 1990) and using NVIVO to organize, manage and analyse this data. Our students' social processes regarding their mode of study and online contributions were analysed by going through the interview transcripts and coding their comments using labels (i.e. short phrases or sentences) that described what they said. This process was repeated a number of times until there were no more issues identified in the data, no improvements to the current codes were needed and no more codes were produced. At the end of this iterative process, these labels had become analytical representations of the data and turned to the identified categories we share later in the Results section. By doing a constant comparative analysis of the emerging categories, we were able to identify two emerging themes and finalised the categories. Next, we present the emerged themes and categories in the way we linked and integrated them aiming at capturing all the variations in our data and allowing a theory to emerge, that of students' motivation and challenges they faced regarding online contributions in an online asynchronous course.

## Results

The two main emerging themes grounded in students' responses are: **Motivation to contribute in online asynchronous learning** encouraged and sustained through *Learning from others*; *Peer Assistance*; *Peer students' online study patterns*; *Interest in and enjoyment of topics*, and **Challenges to contribute in online asynchronous learning** such as *Non-participation*; *Visibility of learning*; *Style and Etiquette of communication*; *Feeling at ease with your peers*. For each of these two emergent themes, students had commented upon the tutors' influence in their learning.

**Motivation to contribute in online asynchronous learning: *Learning from others*** Those students who engaged with the online activity felt that they benefitted as a result. One international student, Jennie, who enrolled on this course following her undergraduate studies, admitted feeling comfortable to participate in the online discussion forum as she learned a lot from reading the contributions of what she thought of as 'her more experienced and older than her' peers. She admitted looking specifically for their contributions and trusting their views.

Yvette felt that reading research papers, reading other students' work and having to give feedback and comment on others' contributions helped her with her own learning: gaining a deeper insight into the key readings, thus learning about how to engage with research and how to use it to reflect on mathematical learning when digital technologies were used. Similarly, John reckoned he learned from his peers: "I felt like you were in a classroom with other students in a way. Obviously with it being asynchronous it's a lot slower than that, but you kind of need it to be asynchronous so you can actually go and read what people have written. And then it was easy to find again what you've written and how other people have responded", while Jack said that seeing other students' contributions triggered him to respond, hence explicitly engaging with the knowledge base of this course.

Mary and Anne mentioned the opportunities to learn from others, which were facilitated by the tutors' collated feedback on all students' contributions per theme; they would revisit this feedback often, which helped them be more aware of the expectations of this course and improve their future work.

**Motivation to contribute in online asynchronous learning: *Peer assistance*** All 10 students commented on how useful the UCL Moodle Discussion Forum was for sharing ideas, for reading other students' contributions and reflecting upon their own thinking and understanding of the course material, tasks and resources. "Sometimes if I had no idea how to start my work and I saw how my classmates did it, then I had some directions" (Janet). Having an online record of the peers' contributions enabled the students to revisit aspects of the course at any point throughout the course. One student, Frances, extended this argument by comparing the online contributions to those of a face-to-face learning environment, where "you can only hear a few people's ideas" and mentioned how useful it was to have the time to read and reflect upon them before responding and/or asking questions, which wouldn't have been the case in a time constrained face-to-face interaction: "You have all these online resources to access and explore, and you can ask directly the creators".

Even though there was some peer support offered in Discussion Forums, many students told us that they needed "immediate feedback". For example, Mary argued for the importance of having a tutor 'close by' when learning about and interacting with a new DT. She felt that she needed to ask questions that needed immediate answers in order for her to make progress. Similarly, Patricia and Helen argued about their preference for face-to-face sessions when familiarizing themselves with a new DT, as in that scenario the help was immediate and support was always there (we offered two optional face-to-face sessions as part of this course).

**Motivation to contribute in online asynchronous learning: *Peer students' online study patterns*** The variance in the students' online presence depended on many factors, such as their interest in the topic, their other commitments (work, studying, deadlines to assignments, etc.), but also their preferred style of studying. All the 10 students agreed they liked the flexible mode of study this course offered, as most of them found it very convenient to choose their own time to study.

Six of the 10 students (Janet, Anne, Patricia, Jack, Frances, Mary) admitted that time management was a challenge in this course. In some cases, it was as result of their own struggle at times to self-manage their work and not because of the structure of the course. But in other cases, it was due to 'wait-time' for others to contribute online to Discussion Forums. Anne agreed that timing is very important even if the course is asynchronous and flexible in that sense. She would never read any

postings that were uploaded too late in the week, as she would have already finished her work by then. Similarly, Patricia argued: “I can’t be bothered to respond to that now, because I’m on to the next one. It’s not fresh in my mind anymore”. Frances, too mentioned how important it was for peers to post on time otherwise “You are delaying your partner’s work too”.

**Motivation to contribute in online asynchronous learning: *Interest in and enjoyment of topics & tasks*** Looking at the patterns of *all* students’ online participation on a weekly basis throughout the course, we noticed that there were weeks when their online presence was much higher than in others. The 10 students we interviewed argued that this was due to their own interests in certain *topics* covered during certain weeks. For example, Janet said that being interested in a topic encouraged her to work on the task earlier in the week than when she didn’t like the topic or she was not very familiar with it, e.g. programming, and she would engage with others’ online contributions too.

All 10 students valued the *task* which required them to design and trial an activity with learners, then reflect on the mathematical learning. John and Jack argued how great it was to reflect on pedagogical issues regarding students’ learning mathematics with DT. They all commented about learning not only new DT, but also learning how to utilize them in the classroom and use them effectively with learners. Jennie felt that this course was indeed a great preparation for her future career as a mathematics teacher. She felt she got more time to think about the relationship between the DT and mathematics and how it could be used in her own way in mathematics classrooms.

**Challenges to contribute in online asynchronous learning: *Peer students’ non-participation*** Lack of sustained participation from students seemed to be a key factor for disengagement from online discussion forums. As the course progressed, Jack noticed that not many of his peers participated nor did they respond to his comments. He felt de-motivated and as a result lost his keenness for ongoing online participation. Similarly, due to the lack of peer participation, Anne found it difficult to contribute online, as there were no contributions from others that she could comment on. Even if there were contributions, if too few, there were only so many opportunities to comment on them.

**Challenges to contribute in online asynchronous learning: *Visibility of learning*** Amongst the reasons mentioned by our students as holding them from contributing online included being afraid of showing their insecurity and lack of confidence in their own expertise with DT or subject matter of the course. Mary confessed: “I know they won’t say are you stupid, how can’t you not know this? But I still feel people get the impression that you don’t know anything and they would hesitate comparing or checking your contributions”.

Visibility of online contributions was even more of a challenge for the non-native English students, who were also worried about the clarity of expressing their thinking in written format. Six out of seven of our international students admitted that they were reluctant to submit comments online. Mary admitted that she would probably hesitate to make a contribution in a face-to-face session for that same reason, but online her contributions remain visible to others for the duration of the course. This was also a concern for Vicky, who commented that she preferred the online mode of communication to the verbal one as it gave her time to think through what she wanted to say, with the advantage that she would ‘correct her English and grammar before posting anything’.

### **Challenges to contribute in online asynchronous learning: *Style and Etiquette of communication***

Helen mentioned the challenge of communicating in the Discussion Forums; when asking a question, she would need to spend time thinking and articulating the question accurately and in a concise format, whereas a face-to-face scenario is more like having a chat and the question might be formed by itself. The formality of the Moodle discussion forum was mentioned by Anne too. She was put off by the formality of such communications and the fact that tutors would see such contributions and that their posts would also be assessed. Her perception of the role of online contributions led to her being reluctant to upload anything that she hadn't thought through very carefully. Being a native English speaker did not make it easy to adhere to the more formal style of communication; Patricia too admitted feeling occasionally reluctant to post any comments as she had to make them formal.

However, all 10 students admitted that this formality required in all of their online contributions did lead to clarity and coherency of arguments that they were trying to put forward. Having tried to set up a group chat on Facebook Messenger (the seven international students) Jennie found the communications were very informal, with far too many details which she didn't need to read, and with ideas that lacked clarity, although she, like all the others liked the instant feedback.

### **Challenges to contribute in online asynchronous learning: *Feeling at ease with your peers***

Another reason for being disengaged from the Moodle Discussion Forum was the lack of familiarity with their peers, having not met them in person before the start of the course, which led to a lack of a sense of being part of a community. For example, for Helen it was difficult to post on the forum discussion and comment on work from students she never met face-to-face. Anne thought that her peers who she was not acquainted to were too 'polite' in their comments to her work, so as not to hurt her feelings. This familiarity and friendship with the people on Messenger allowed them to share comments freely, not thinking that they would be upset or offended. Another disadvantage of posting feedback to a peer in a forum is that the way the feedback is articulated might be considered bad criticism and upset their peer, whereas in a face-to-face situation, they could see that the feedback is expressed in a positive manner and their peers can recognize that a student is trying to help and give constructive feedback. For example, in Messenger you can put a smiley face too, and so no matter how the feedback was articulated (as a criticism, for example) the receiver would not see this as a negative comment.

### **Some conclusions and our key findings**

Some of our findings are similar to the ones by authors we referred to earlier in the introduction. All students were very appreciative of the flexible mode of study of our online asynchronous course and the time given to reflect upon peers' contributions, which are similar results to Riggs and Linder's (2016) work. Our students' learning did depend on the quantity and quality of peers' postings (Dixson, 2010) and the tutors' feedback and their trust in their peers (Haythornthwaite, 2002).

However, our study brought to the fore two important aspects not mentioned in the literature we reviewed. We learned from our data analysis that online communication was perceived by our students as a double-edge sword; on one 'edge' they all liked the flexible mode of study, managing their own time, taking time to think through their responses or others' contributions, but the formality of their contributions deterred them from engaging in conversations with peers more fully. We also

learned that we needed to orchestrate better the timing of online contributions in an asynchronous course: while having the flexibility to contribute at their own convenient times, deadlines are even more important to be set and met, in order to ensure an active and meaningful engagement and exchange of views. We thus conclude this paper by putting forward these two key findings as recommendations to designers and tutors of online asynchronous courses, with the aim of nurturing active learning opportunities.

### Acknowledgment

This work was supported by UCL Grand Challenge of Transformative Technology, which funded our project: *Supporting active and meaningful engagement in an asynchronous online course*.

# Dynamic vs. static! Different visualisations to conceptualize parameters of quadratic functions

Lisa Göbel and Bärbel Barzel

University of Duisburg-Essen, Germany; [lisa.goebel@uni-due.de](mailto:lisa.goebel@uni-due.de); [baerbel.barzel@uni-due.de](mailto:baerbel.barzel@uni-due.de)

*Keywords: Visualisations, parameter, technology.*

## Background

The technology has gotten faster over the last years; students became more proficient in the use of smartphones etc. But is the power of speed with a quick visualisation when dragging a slider bar or grabbing a graph really beneficial while learning and understanding the concept of parameters? The study presented here uses a guided discovery approach (adapted from Mosston, 1972) to investigate different visualisations to conceptualize parameters of quadratic functions as it is the first non-linear function taught and can serve as a prototype for the conceptualization of parameters of higher polynomial functions. To specify the intended learning process in the study, the core elements for a conceptual understanding are presented: For this study in the frame of quadratic functions the two mathematical objects variables and functions and their “Grundvorstellungen” (as defined in vom Hofe & Blum, 2016) are important for the conceptualization. For functions it is important to develop the ideas of a function as mapping, covariation and object (vom Hofe & Blum, 2016). All these three aspects are crucial, when learning how a graph is changing when one of the parameter changes. Parameters can be classified as a specific type of variables. While many authors distinguish the Grundvorstellungen of variables as unknown, generalized number and changing variable (e.g. Malle, 1993), Drijvers (2003) applies these specifications on parameters. The role of parameter is not fixed to one aspect, but can be placeholder, unknown, changing quantity or generalizer. All roles are crucial to understanding the concept and the conceptualization can be supported through technology. Another important aspect to understand the concept of a function is to be aware and to be able to change between different representations of functions (algebraic-symbolical, numeric-tabular, graphic-visual, situative-linguistical, e.g. Duval, 2006). Duval (2006) describes it as the critical threshold for learning. This can be supported by technological tools (Drijvers et al., 2016). It is still an open question whether the conceptualization differs when different visualisations are used when learning. These points lead to our research questions: How can technology-assisted guided discovery support the conceptualization of parameters in the field of quadratic functions?

## Methodology

In a control-group design intervention study with one control- and three experimental groups a total of 14 Year 9 classes worked on a series of tasks designed using a guided discovery approach, which was implemented through hints on the tasksheet how to investigate the influence (for information on the tasks see Göbel, Barzel, & Ball, 2017). The different control- and experimental groups differed only in the kind of visualisation used. The control group had no technological visualisation while the three experimental groups used different types of digital environments (standard function plotter tool, pre-programmed file with the possibility to drag the graph, pre-programmed file with sliders for the parameters) to investigate the influence of parameters in the vertex form of quadratic functions

$f(x) = a \cdot (x - b)^2 + c$ . Students designed a summary sheet of their findings during the intervention, which was collected. For an overview on the intervention and the differences between the four groups see Göbel et al. (2017). A paper-pencil test was given to all students to collect baseline data for the comparison between classes. As well as the summary sheets collected a focus group in 13 classes was filmed. The summary sheets were analysed using a coding manual developed by qualitative content analysis. The videos transcripts were analysed with regards to the role of parameters, as well as using technology to explore and validate students' own hypotheses.

## Results

Overall it can be said that the dynamic visualisations seem to support the students learning better than the static visualisations. Dynamic groups design significantly more overall appropriate summary sheets. Students in the dynamic visualisations groups, so students using sliders (SL) or drag mode (DM), found out more details about the influence of the parameters than students in the control group or students using a standard function plotter (FP). While in the control group 70,4% of students identified the influence of parameter  $c$  adequately (FP 46,3%, DM 76,5%, SL 73,8%), this number drops to 52,1% while identifying the influence of parameter  $b$  (FP 40,3%, DM 68,2%, SL 72,3%). Analysis of the summary sheets show that students in the dynamic groups seem to view parameter more as a changing quantity compared to students in the static groups who view parameter as placeholder. The video analysis shows that students use the technology to explore on their own, explain something to each other or to check their hypotheses even though they worked on their own in a guided discovery. Technology-assisted guided discovery can support the learning, but the pre-structuring and dynamic manipulation of the visualisation is crucial for benefiting the learning.

*Research on reading indicates that visual attention is different when using digital media or print. This study aims to explore whether the choice between paper and GeoGebra influences visual attention during collaborative geometry problem solving. We measured eight students' fixation durations during different lesson phases: teacher instruction, individual work, pair work, group work, students presenting on the board, and whole class discussion. During all phases except teacher instruction we observed a difference in the fixation distributions as indicated by Kolmogorov-Smirnov tests. The use of GeoGebra is related to a slight shift from median length fixations to short fixations, suggesting lower cognitive load when students work with computers.*

*Keywords: Attention, computers, cooperative learning, eye movements.*

## Introduction

Paper and pen is a different medium than computer and screen and dynamic geometry environment (DGE) is very different from paper when solving a geometry problem. It is well documented that technology in general (Chauhan, 2017) and DGE in specific (Chan & Leung, 2014) have positive effects on mathematics achievement. There is much research on the specific affordances of DGE in learning and problem solving. For example, Christou, Mousoulides, Pittalis, and Pitta-Pantazi (2005) argue that DGE as a mediation tool encourages students to use modeling, conjecturing, experimenting, and generalizing in problem solving. Healy & Hoyles (2002) claim that DGE can scaffold the solution process and help students move from argumentation to logical deduction, while for less successful students the DGE may prevent them from expressing their mathematical ideas.

One way to examine how the learners' experiences are different in DGE and paper is eye-tracking. Human gaze consists of approximately three to four fixations (maintaining of the visual gaze on a single location) in a second (Rayner, 1998). Hartmann and Fischer (2016) compare eye-tracking information to mind-reading: the target of a fixation usually tells what we think about and the fixation duration corresponds with processing time. Fixation duration is an established indicator for perceptual or cognitive processing difficulty, also in the context of mathematics (Rayner, 1998). Glöckner and Herbold (2011) summarize research evidence to suggest that gazes related to more automatic processes would have shorter fixations (below 250 ms) and more elaborated information processing generally requires long fixations of more than 500 milliseconds.

Visual attention has been studied mostly in the context of reading and research on mathematics is much less frequent (Hartmann & Fischer, 2016; Rayner, 1998). In a systematic review on reading on paper and digitally, Singer and Alexander (2017) found out that reading comprehension is influenced by the text presentation. However, in the context of mathematics, we did not find any comparative eye-tracking studies between digital and non-digital learning environments.

Existing eye-tracking research on mathematics shows that the method is relevant. Andr , Lindstr m, Arzarello, Holmqvist, Robutti, & Sabena, (2015) investigated how students read mathematical texts. In their study, fixation durations were typically in the range from 190 to 250 milliseconds. Fixations were longer for formulas than for graphs or text, but graphs attracted more fixations, leading to longer time spent looking at the graphs. In Lin and Lin (2014) study students were solving problems on tablets, and they suggest fixation counts, time on target, and run counts as relevant measures, because these differentiate successful from unsuccessful solvers and correlate with perceived difficulty.

We find the dominant methodologies for eye-tracking problematic. So far, most studies have been conducted in laboratory situations. We believe that problem solving needs to be studied in ecologically more valid contexts. We are interested in problem solving in contexts, where multiple modalities are present (Arzarello, Paola, Robutti & Sabena 2009) and multiple goals need to be addressed (Hannula, 2006). Most importantly, we are interested in problem solving in collaborative situations. Our earlier studies show that mobile eye tracking provides interesting data on attentional behavior in real classroom situations (e.g. Garcia Moreno-Esteva & Hannula, 2015; Haataja, Garcia Moreno-Esteva, Toivanen, & Hannula, 2018).

While we have not found studies examining the visual attention in digital and non-digital mathematics learning environments, it seems likely that a digital tool would have an effect on visual attention even in the context involving collaboration. We formulate our research question as follows: Does the choice of learning environment (paper vs. GeoGebra) have an overall effect on student attentional processes as indicated by fixation durations when students are solving a geometry problem.

## Method

### Participants

We examined fixation durations for one teacher and her eight students. The teacher taught the same problem solving session twice in two different Finnish grade nine classrooms. The first lesson was recorded in May 2017 and then the students solved the task using paper and pencil. We call this Paper lesson, even if at the end of the lesson the students continued examining the same problem using computers. The second lesson was recorded in May 2018 and then the students solved the task using GeoGebra software. This lesson we call the GeoGebra lesson, even if the students used also pen and paper to some extent. The ethics review has approved our research procedures.

The mathematics teacher Joanne was an experienced teacher. The students were four girls (using paper) and three girls and one boy (using GeoGebra). The students were selected among volunteers. Data from the first lesson has previously been analyzed from the perspective of student and teacher eye-contact (Haataja, Garcia Moreno-Esteva, Toivanen, & Hannula, 2018; Haataja, Salonen, Laine, Toivanen, & Hannula, forthcoming). The focus in this paper is to examine whether use of computers has an influence on students' fixation durations as an indication of an effect on their visual attention.

In both of the lessons, the teacher first introduced the lesson structure and when students got their respective tools (i.e. paper and rulers or laptop and GeoGebra) ready, the teacher posed the geometry problem to the class. Students first worked individually, then with a pair, then four together, and finally the students' solutions were collected on the board and discussed. During the first lesson, the

teacher also posed an extension problem and during both lessons they continued to examine the problem with a GeoGebra application after discussion. However, that end part of both lessons is beyond the current paper's analysis. The relevant lesson phases are summarized in Table 1.

Lesson phase	Paper and pen (s)	GeoGebra (s)
Teacher gives instructions regarding the lesson structure (1)	44	38
Students fetch papers and rulers	139	
Teacher gives instructions for GeoGebra		92
Teacher poses the problem (1)	273	111
Individual work (2)	373	387
Teacher gives instructions for pair work (1)	45	22
Pair work (3)	205	513
Teacher gives instructions for group work (1)	30	40
Group work (four) (4)	1210	570
Teacher poses task extension	362	
Students come to the board (5)	190	130
Whole class discussion (6)	106	244

**Table 1: Lesson phases and their durations. The numbered phases were analyzed in this study**

The teacher was instructed to provide encouragement and to ask questions that require students to explicate their thinking but to not provide hints for how to solve the problem. When students were working individually, in pairs, or in groups of four, the teacher's activity consisted of roaming in the classroom and stopping for scaffolding one group at a time.

For the analysis, we included only those lesson phases that took place during both lessons. Moreover, we grouped together four separate instances when the teacher was giving instructions to the class or posing the problem. This way, we have identified six lesson phases that captured altogether 41 minutes and 16 seconds of the paper lesson and 34 minutes and 15 seconds of the GeoGebra lesson. Our analysis will focus on these parts of the lesson.

### Apparatus

We recorded the actions and conversations of the problem-solving session using audio recording and three stationary video cameras in the classroom. In this paper, we analyze data from five gaze-tracking glasses that recorded eye movements of the teacher and the target students. The gaze-tracking device consisted of two eye cameras, a scene camera, and simple electronics attached to 3D-printed frames (Figure 1). The devices and software were self made (see, Toivanen, Lukander, & Puolamäki, 2017). The camera frame rate depended on lightning conditions, and maximum rate in optimal conditions was 30 frames/second. Data was recorded on laptop computers that were carried in backpacks allowing subjects to move freely in the classroom.

**Figure 1: The gaze-tracking equipment.**

## Procedure

The recorded data was first analyzed to identify all fixations for all subjects. The fixation durations were estimated from the eye image difference between consecutive cropped eye image frames and setting a threshold for the average pixel-wise difference. This results in more accurate measure, compared to using gaze coordinates which might fluctuate due to algorithmic miscomputations. The information of fixation onsets and durations was then combined with information about timing of lesson phases from a video following teacher actions in the class. After this preliminary organization of data in Excel, the data was imported to SPSS 24 for statistical analyses.

First we analyzed the descriptive statistics of fixation durations. As the distributions were non-normal, we used non-parametric tests in our consequent analyses. When comparing fixation durations of two samples, we decided to use the Kolmogorov-Smirnov Z-test rather than Mann-Whitney's *U*-test, because it has more power to detect changes in the shape of the distributions. We analyzed the variation of gaze durations across the different lesson phases separately for students and the teacher for both the paper lesson and the GeoGebra lesson.

We predicted that the gaze behavior might be different across different lesson phases and, therefore, we analyzed the data separately for different lesson phases. Our expectation was that the fixation durations would on average be similar across those lesson phases where the use of tool would not be central (i.e. teacher instruction, students to the board, and discussion) while the possible effect of computer as a tool could be seen during individual work, pair work, and group work.

To check for sufficient similarity of visual behavior of compared individuals in the two conditions, we made pairwise Kolmogorov-Smirnov Z-tests for fixation distributions between individuals. For this analysis we selected the lesson phases where we expected the effect of computers to be minimal, i.e. teacher instruction, students to the board, and discussion. We used the information of pairwise differences to identify individuals whose fixation distribution was not comparable with other subjects' distribution. We then removed from future analysis those students whose fixation distribution deviated from other students the most. Finally, we made a comparison between student and teacher fixation distributions for the two lessons (paper and GeoGebra) for the different lesson phases using Kolmogorov-Smirnov Z-test.

## Results

The total number of fixations during the analyzed lesson phases for all participants was 41,119. The shortest possible fixation to observe was 80 ms (two frames). The observed fixation durations varied from 80 ms to 15066 ms ( $Mdn = 234$  ms,  $M = 430$  ms,  $SD = 654.00$ ). The durations were non-normally distributed, with skewness of 6.52 ( $SE = 0.012$ ) and kurtosis of 69.62 ( $SE = 0.024$ ).

We then analyzed the similarity of fixation durations for both sessions for the teacher and all students for the lesson phases that were less tool dependent (i.e. teacher instructions, students at the board, and discussion). The Kolmogorov-Smirnov Z-tests showed that the teacher fixations over both sessions were similar across the two sessions and different from all but one students' fixations. All but one compared student pairs had statistically significant differences for at least one of the lesson phases. However, it was possible to identify two students, who stood out more strongly from the group as having a different distribution of fixation durations. We removed these students from the analysis. After this removal, we had three female students from the paper lesson and two female and one male students from the computer lesson.

We then made Kolmogorov-Smirnov tests for each lesson phase to compare fixation durations between the two conditions (working with paper or working with GeoGebra) (Table 2). The results show that during pair work and group work the distributions differ statistically very significantly. The medians indicate that students using GeoGebra had shorter fixations during pair work than students using pen and paper, while the difference was small and opposite during group work. Differences for the other lesson phases were statistically significant ( $p < .01$ ) for pair work and group work.

Lesson phase	Tool	<i>n</i>	<i>Mdn (ms)</i>	<i>Z</i>	<i>p</i>
Teacher instruction	Paper	933	269	.75	.627
	GeoGebra	1826	269		
Individual work	Paper	1775	269	1.38	.045
	GeoGebra	1918	267		
Pair work	Paper	2692	264	3.10	.000
	GeoGebra	1151	204		
Group work	Paper	2880	240	2.17	.000
	GeoGebra	5611	250		
Students at the board	Paper	786	233	1.57	.015
	GeoGebra	923	240		
Discussion	Paper	1177	268	1.59	.013
	GeoGebra	464	233		

**Table 2: Kolmogorov-Smirnov Z-test results for tool effect on fixation durations.**

To further explore the difference between paper and GeoGebra for visual attention, we looked at the distributions of different fixation lengths. We used the whole session for these students to identify the cut points for deciles. These cut points were then used to divide the distribution of fixation durations for the two lesson phases for paper and GeoGebra condition. We see that the GeoGebra condition had more deviation from the expected distribution of ten percent in each category. For pair work (Figure 2), the students using GeoGebra had more fixations in the time range 100 ms to 200 ms and fewer fixations of longer duration in comparison to paper condition. For group work (Figure 3), students using GeoGebra had fewer gazes in the time range 200 ms to 300 ms and more very long fixations. While the two distributions in the GeoGebra condition are somewhat different, there seems to be a trend for somewhat more short fixations at the cost of average duration fixations.

**Figure 2: The distribution of fixation durations (ms) for the selected students for pair work**

**Figure 3: The distribution of fixation durations (ms) for the selected students for group work**

## Discussion

The results show an effect in student fixation durations for the choice between computer and paper as a media to solve a geometry problem. Use of GeoGebra is related with slight shift in fixation durations towards short fixations during collaborative phases of the problem solving. During this phase, students are comparing their individual solutions and discussing for alternative options. With respect to visual attention, this phase should include attention to other students and their drawings.

Shorter fixations usually indicate lower cognitive load. In this context, it might mean that students who worked interactively with GeoGebra, executed more often simple search tasks, such as searching for cursor on screen, which have a low cognitive demand. Alternatively, it might be related to easier extraction of information from neat GeoGebra drawings in comparison to peers' hand written solutions. Thirdly, the computer screen has a lot of visual attracters (e.g. menus) that may lead to short fixations on distracting elements. We provide one more possible explanation. In our earlier studies we have noticed that during interpersonal interaction in class, short fixations at the other person's face are frequent. It may be that the students working with GeoGebra have more short fixations on peers' faces, either because they have longer discussions or as it is more difficult to share screens than notebooks, they have less time for looking at solutions. These possible explanations can't be answered before we have analyzed student behavior during these events and annotated the targets of the fixations.

These results need to be taken with caution. There is significant variation in fixation durations between individuals and even within an individual across time. Although we tried to control for this variation and removed students with obviously deviating fixation duration distributions, the remaining students are by no means identical in their gaze behavior. Future studies should address larger variation of individual and situational differences. A larger sample of students would allow us to identify clusters of students whose visual attention follows a similar pattern and then compare these groups with different attentional profiles across digital and non-digital contexts. There is also need to examine qualitatively the nature of visual attention where a difference has been found. For example, what are the targets of longest fixations when solving the problem with GeoGebra and not? We also need additional data with different types of tasks. Perhaps some of the differences identified here are specific to the task used? Overall, this is just a beginning of a long journey.

# An Exploration of the effect of Bray's Activity Design Heuristics on Students' Learning of Transformation Geometry

Aoife Harrison, Aibhín Bray and Brendan Tangney

Trinity College Dublin, The University of Dublin, Ireland; [aharrison@mountanville.ie](mailto:aharrison@mountanville.ie),  
[brayai@tcd.ie](mailto:brayai@tcd.ie), [tangney@tcd.ie](mailto:tangney@tcd.ie)

*Keywords: transformation geometry, contextual mathematics, technology-mediated, active learning.*

## Introduction

The Irish Mathematics Curriculum, Project Maths, which was introduced into all post-primary schools on a phased basis from 2010, aligns with the core principles that underpin the Programme for International Student Assessment (PISA) mathematical framework (Merriman, Shiel, Perkins, & Cosgrove, 2014). However, there is evidence to suggest that teachers have been slow to move to the more constructivist teaching and assessment style required by the new curriculum (Jeffes et al., 2013; Merriman et al., 2014). In particular, in comparison to other participating countries, students in Ireland performed relatively poorly on the transformation geometry items in the PISA tests in 2003 and 2012.

One approach that has been proposed to address this issue is the use of Bray's Heuristics (Bray, 2016); a set of guidelines for designing technology-mediated, cross-curricular, collaborative and contextual mathematics learning activities. The theoretical framework that underpins Bray's Design Heuristics combines Realistic Mathematics Education (RME) and a particular constructivist model of 21<sup>st</sup> Century teaching and learning – Bridge21 ([www.bridge21.ie](http://www.bridge21.ie)). Participation in activities of this kind have been shown to have a positive effect on students' conceptual understanding and engagement with mathematics (Bray, 2016; Tangney, Boran, Knox, & Bray, 2018). The research presented in this paper extends previous work by focusing on student attainment in exam-type questions, asking: How might participation in a transformational geometry activity created using Bray's Design Heuristics, help participants to achieve higher levels of attainment in the topic?

## The Activity

Following a number of classroom-based, technology-mediated, exploratory activities designed to provide students with a foundation in basic transformational geometry concepts, participants were presented with a laminated orienteering map of the school campus overlaid with a square grid. An orienteering circuit with 5 bases, each labelled as a set of coordinates from A to E, was set up on the school grounds, with QR codes fixed at each base. Scanning each QR code generated the geometrical transformation required to locate the next base.

The class group was divided into five teams of 4/5 students. Each team was given a card with the coordinates of their team's starting point (e.g. A (-3,5)). Teams were timed from the moment they began to discuss the location of their starting base on the map. The teams dispersed in different directions to locate their first QR code. In order to scan the codes and receive the geometrical transformation, students used a built-in feature of the Snapchat app, which they had on their mobile phones. The geometrical calculations, needed to navigate to the next location, involved Axial

Symmetry, Central Symmetry and Translations and were carried out by the students using white board markers on the laminated maps of their school grounds.

## Methodology

The results presented in this paper focus on the quantitative aspect of the overarching exploratory study, exploring changes in attainment in written exams pre- and post-intervention. Participants in this research were 63 students, aged 14-15. The treatment group consisted of one class ( $n = 22$ ) of students and the control group was made up of two classes ( $n = 41$ ) graded at the same level of mathematical ability. The first author was mathematics teacher to the students in the treatment group, and the control group classes were taught by two other mathematics teachers within the school. The transformation geometry module was presented as outlined above to the treatment group while the control group were taught in a traditional, classroom-based fashion. The module took place in 10 x 40-minute single class periods over two weeks, within the normal school timetable. In an attempt to ascertain the impact of the learning experience on the students' ability to apply their knowledge of transformation geometry, the treatment and control cohorts sat the same written exam at the end of the module. This exam consisted of five exam questions, focused on transformation geometry, drawn from past papers of the state examination that Irish students sit at the end of grade 10.

## Results

Average scores of the treatment group were 3% lower than the control groups in a pre-intervention, mid-year exam whereas in the post-intervention exam their results were 9% higher than those of the control group (Treatment:  $M = 71\%$ ,  $SD = 18$ ; Control:  $M = 62\%$ ,  $SD = 15$ ). Results of a one-tailed independent samples  $t$ -test indicated a statistically significant difference in performance between the participants in the treatment group and the control group ( $t(61) = 2.021$ ,  $p = .029$ , one-tailed).

## Conclusion

This paper provides a small sample of the results of a more significant exploratory study into the possible effects of participation in collaborative, technology-mediated, active learning experiences. The quantitative results described here are limited but have furthered the development of the hypothesis that this approach to activity design has the potential to positively impact on student learning in mathematics in general, and in transformation geometry in particular.

# Didactical resource purposes as an aspect of students' decision making regarding resources used to learn mathematics

Eivind Hillesund<sup>1</sup>

University of Agder, Norway; [eivind.hillesund@uia.no](mailto:eivind.hillesund@uia.no)

*Keywords: Resources, documental approach to didactics, university mathematics.*

Link to poster: <https://drive.google.com/open?id=1T4MJccfGPJBrQASWcav8BxB7KryYBqdQ>

## Introduction

In my ongoing PhD project, I investigate first year engineering students' use of resources to learn mathematics. The project focuses on resource use from a student-centered perspective. Rather than focusing on any particular resources, I look at the use of resources as whole. In my data collection, I aimed to uncover all the resources the students used to learn mathematics, some of their strategies for how to use them, how the strategies evolved over time and what factors influenced which resources they used and how at any given time. I later added students' decision making to my focus based on its prevalence in the collected data. For the poster, I restrict myself one of the themes I uncovered in my thematic analysis of interview data, which I have named didactical resource purposes (DRPs).

Based on a literature review of leading journals in mathematics education, going back to 2010, there are very few studies about resources at university level, with a broad focus and a student-centered perspective. The few that exist (i.e. Gueudet & Pepin, 2016), still cover different aspects of the resource use than I do. Hence, my data is more relevant to didactical resource purposes.

## Theoretical framework

I use the documental approach to didactics (DAD) by Gueudet and Trouche (2009) as my theoretical framework. It is focused on how teachers use resources, both for teaching and professional development. Trouche and Pepin (2014) argue that the documental approach may also be used to look at students' learning and suggest university mathematics as a good place to experiment with the approach. I hope my research can help expand upon the documental approach to include perspectives on how students use resources to learn mathematics. I use an inductive approach with a deductive component. After identifying themes, I consider whether it can be related to an aspect of the documental approach. I derived the term 'didactical resource purpose', from DAD's view that a resource has a material component, a mathematical component and a didactical component. The didactical component of a resource is tied to the organization of activity. DRPs can be considered phases of learning that structure students' use of resources.

## Methodology

The study involves nine students from introductory mathematics courses for engineers at three different universities in Norway (here called Alpha, Beta and Charlie). The universities were chosen on the basis of courses that I considered having a different focus (Alpha on material resources, Beta on digital resources and Charlie on social resources). Beyond that, I used convenience sampling. All volunteers from each course were accepted (4 from Alpha, 2 from Beta and 3 from Charlie). They

were interviewed three times, near the beginning middle and end of the semester. The interviews were semi-structured, starting with open questions (i.e. “can you say a bit about how you use resources to learn mathematics”) and moving on to more specific questions (i.e. how many do you usually study with when you study with fellow students). I analyzed the interviews using a thematic analysis approach (Braun & Clarke, 2006), including open coding; test of intercoder reliability; creating themes; reviewing themes; and then naming and defining them. While codes were numerous and often quite specific, themes were fewer and more general. When identifying themes, I took care to count the number of statements from each student that related to the theme and keep track of the extent to which these statements were in response to open or narrow questions. I also compiled a list of related quotes. Both numbers and quotes related to each DRP feature in the poster.

## Results

The didactical resource purposes I identified in my analysis can be considered phases of the students’ learning process. Each DRP related to statements from at least seven out of the nine students:

- Introduction. Some resources were commonly used for students’ first encounter with mathematical topics, including lectures, textbook and lecture videos.
- Practice. After introduction, students work mathematically, mostly using resources emphasized in the courses. The textbooks and learning platforms were used to find exercises and calculator, pencil and paper and fellow students were employed to solve them. At University Beta, the program MyMathLabs was used to find and solve exercises.
- Evaluation. Students often checked whether their answers were correct or their work processes were constructive. Resources included answers in the textbook, Wolfram Alpha, GeoGebra, and discussion with fellow students, the lecturer or a parent.
- Explanation. After introduction, during practice or after evaluation, students would look for elaborations on the topic at hand to solidify their understanding or ‘fill gaps’. This process involved a more active search for information than introduction did. Resources for this included textbook, fellow students, student assistants, lecturer, parent, Google, lecture videos, YouTube, Khan Academy, course pages and worked examples in MyMathLabs.

# Guidelines for design of didactic sequences utilizing dynamic geometry affordances related to mathematical reasoning competency

Ingi Heinesen Højsted

Aarhus University, Danish School of Education, Denmark; [ingi@edu.au.dk](mailto:ingi@edu.au.dk)

*Keywords: Dynamic geometry environments, reasoning competency, research-based guidelines.*

Identifying guidelines for fruitful teaching with technology in mathematics education is an important research objective. However, technology, such as dynamic geometry environments (DGE), can be used for different purposes. Therefore, to make sense of guidelines for teaching with DGE, it is necessary to clarify the mathematical aim of the teaching. To this end, the notion of mathematical competencies (Niss & Jensen, 2011), which includes the reasoning competency (RC), can be used. Research on DGE affordances has found potentials regarding development of students' mathematical reasoning (e.g. Leung, 2015), which is promising, because students' inadequate abilities in reasoning is well documented (e.g. Hoyles & Healy, 2007). However, students' accessibility to DGE, does not guarantee greater learning outcome. The manner in which the DGE is used is essential (Jones, 2005). Therefore, to support the utilization of the potentials of DGE regarding RC, it is important to investigate: which research-based guidelines may be formulated for using DGE to support students' development of RC?

An extensive review was conducted using the hermeneutic circle approach (Boell & Cecez-Kecmanovic, 2014), to map out potentials of DGE described in the literature. Initial searches were made with search words such as "dynamic geometry", "geometry software", "geometry technology", "interactive geometry" and "proof", "reasoning", "conjecture" in MathEduc and ERIC databases, as well as reading CERME technology TWG proceedings. After reading literature acquired from the primary search, interesting references were followed and if suitable, added to review. In addition, after reading and gaining some insight into the area of interest, adjusted search words were used in new searches. 136 publications were included. The definition of the RC played a decisive role in the review process. It influenced the choice of search words and was the optic used to decide which DGE potentials described in the literature were deemed relevant for this study.

In synthesizing the review findings, three categories of guidelines were identified: students' cognition, task design and teaching practices. The guidelines emerge from the utilization of four types of DGE affordances: feedback, dragging, measuring and trace. Theoretical constructs from two predominant theoretical frameworks, the instrumental approach (Artigue, 2002) and the Theory of Semiotic Mediation (Bartolini-Bussi & Mariotti, 2008), were found to be suitable in the design of guidelines. Specifically, the notion of semiotic potential is useful in the consideration of what dimensions guidelines might entail. Furthermore, a description can be made of the instrumented techniques to be appropriated along with the utilization schemes needed. The role of the teacher can be described in supporting the mediated signs of the students towards mathematical meanings in order to support their development of RC. The guidelines are considered a priori in an ongoing project, in which the next step is to implement them in practice and refine them through a design-based research approach. To illustrate, table 1 below shows a segment from the a priori guidelines.

Instrumented techniques	Utilization schemes	Tasks	Teacher's role	Reasoning competency
Constructing direct invariants, which induce indirect invariants because of Euclidean theory.	Understanding the difference between direct and indirect invariants, and the connection between them.	Construction tasks with direct invariants, where dragging free points in the construction unveils (surprising) indirect invariants.	Instruction, discussion and feedback: focus on mathematical meanings - Address that direct invariants can induce indirect invariants because of Euclidean geometry governing the environment.	Prerequisite for working on conjecturing tasks.  Some initial conjecturing tasks.

**Table 1: Example from a priori guidelines**

# Issues in modelling terms involving subtraction in a manipulative environment for linear equations—and a possible solution

Thomas Janßen, David Reid & Angelika Bikner-Ahsbahs

University of Bremen, Germany; janssent@uni-bremen.de

*In this paper, we present and utilize theories about interface design and didactical models to evaluate how existing manipulatives models for linear equations represent terms involving subtraction. We then outline a redesign of subtraction zones for algebra tiles that can be implemented on a screen. The presented work is intended to serve as an example case for theory-guided design of digital or digitally enhanced didactical models, anticipating the all-important learning activities with the resulting models.*

*Keywords: Equations (mathematics), educational technology, instructional systems, instructional design, design requirements.*

## Introduction: Manipulatives environments for linear equations

To help students understand equations and how to solve them, different tangible models are in use. Each consists of material objects or manipulatives (standing for numbers and variables) and an environment that specifies the relationship between the variables and numbers represented by the manipulatives placed in the environment. Probably the best-known model is the balance scale, where known and unknown weights on both sides of a scale are supposed to be kept in balance. Another model uses two sets of objects, some hidden in containers. The two sets are stated to have equal numbers of objects and the equation is framed as a puzzle, to find the number of hidden objects. Affolter et al. (2003) have used matches in matchboxes, Radford and Grenier (1996, p. 184) cards in envelopes. In this model the equality, which had a physical parallel in the balance model, is an abstract social convention. A further abstraction is made when *algebra tiles* (or blocks) are used. Known quantities are represented by squares (or cubes) and unknowns by oblong rectangles (cuboids). They are placed on a mat divided into two sides and students are informed that the amount represented by the tiles on the left side is the same as that on the right side. This model was developed because it is applicable to manipulating quadratic expressions, but has since also been used for linear equations.

We are involved in a research project with the goal of developing an “intelligent” system of algebra tiles with the ability to give feedback to its users (Reinschlüssel et al., 2018). The algebra tiles model was chosen because it can be used as the concepts of algebra are developed further; avoiding the need to introduce a new model for manipulating quadratic expressions, etc. Furthermore, the model allows the representation of terms involving subtraction (such as “ $x - 3$ ”) differently from additive terms involving negative values (“ $x + (-3)$ ”). In the design process, however, shortcomings in the representation of subtraction in the algebra tiles environment became apparent, offering a chance to reconsider its design. The considerations guiding this redesign, specifically describing how a concrete model can sensibly represent equations involving subtraction, are the focus of this theoretical paper.

Theories on (educational) interface design as well as experiences from early design cycles are used to answer the following research questions:

- What are the specific disadvantages of the ways different models represent subtraction?
- How can subtraction be represented in a way that preserves advantages of existing designs but avoids the identified problems?

## Line of argumentation

This paper aims to advance the understanding of the design of technology for teaching and learning mathematics. For a theoretically informed discussion of the two questions, approaches from human-computer interaction studies and mathematics education are introduced and set into relation with each other. The subsequent section probes existing models' representation of subtraction. We argue that there are advantages in representing subtraction as in the algebra tiles model but that there are certain specific shortcomings. We show how these shortcomings can be addressed in a screen-based redesign of the algebra tiles model. The discussion will be used to highlight the relevance of the presented work for the design of digital or digitally enhanced didactical models and to point out possibilities how activities can be designed around the layout that we claim solves the identified problems.

## State of the art and existing theoretical approaches

There has been little rigorous research regarding the representation of subtraction in manipulative models for equations (see Vlassis, 2002). Thus, it is all the more advisable to take notice of the rich theory around (educational) interface design in general.

Goguen (1999) builds his theory for user interface design on the claim that “user interfaces are representations, that their quality is determined by what they preserve, and that this can be an effective basis for design” (p. 243). To investigate the quality of user interfaces, Goguen defines and investigates *mappings* between *sign systems*, indicating the possibility for mathematics educators to do so for the representation of a given mathematical sign system (such as linear equations) through a certain manipulative environment (such as algebra tiles).

The focus on mappings has been elaborated with regard to teaching models in mathematics education by English and Halford (1995), who name four principles of learning by analogy that can help to analyze (and to design) didactical models (pp. 100–102):

- Learners need to be able to understand the structural properties of the model.
- The mapping between model and concept to be learnt shall be unambiguous to the learners.
- The attributes of objects of the model that are relevant to the concept to be learnt form a cohesive conceptual structure—other attributes shall be designed to not disturb this structure.
- A model shall be applicable to a range of instances.

Taking up the language of mappings, Vlassis (2002), with regard to the balance scale model, goes so far as to claim that “the isomorphism between the object itself and the mathematical notions implied allows students to form a mental image of the operations that they have to apply” (p. 355). However, investigating and optimizing the characteristics of a model will not suffice, and claims that ascribe the success of material models to their alleged relationship to the mathematics to be learnt may be premature. English and Halford (1995) are very clear that a model “will fail miserably if the accompanying explanation is unclear” (p. 99). Gravemeijer (2011) criticizes denoting models as transparent on the grounds that it may suggest transparency to be a feature of the model, not taking

into account that instruction may nevertheless fail to offer students a help in seeing mathematical meaning beyond the mathematics they have already learnt. Meira (1998) argues that transparency should not be seen as an inherent feature of objects used in a model but as a *process* “mediated by unfolding activities and users’ participation in ongoing sociocultural practices” (p. 121). A model that properly illustrates the mathematics to be taught is nothing but a necessary first step.

These considerations let us return to Goguen’s work. With its reliance on semiotics it avoids the epistemological problem of what form of existence is ascribed a) to the representation and b) to the mathematics to be represented. Regarding the former, he writes: “what ‘really exists’ (in the sense of physics) are the photons coming off the screen; the structure that we see is our own construction” (Goguen, 1999, p. 271). Therefore, the models created “are definitely not adequate in certain respects, some known and some unknown” (p. 271). What is then needed in order to learn with such necessarily imperfect models is illuminated by a range of approaches in mathematics education that take learning processes with technology to be thought of—and therefore designed—as processes of semiotic mediation (Mariotti, 2002; cf. Meira, 2008; Duval, 2017).

In the subsequent discussion of existing models, we will follow Goguen’s view on interface design, focusing on the mappings between the interface and the mathematics to be represented, which both are taken as sign systems. This view makes our approach compatible with semiotic theories of learning that may later be helpful regarding learning processes around the designed model. Where appropriate, we enrich this approach by referring to the principles devised by English and Halford.

## **Discussion of existing manipulatives models representing subtraction**

We are particularly interested here in the mapping between negative integers and the operation of subtraction in algebra, and negative tiles and various representations of subtraction in the algebra tile model. In algebra, numbers are distinct from operations, it is possible to subtract from an unknown quantity, it is possible to subtract negative integers, and it is possible to divide a term involving subtraction (i.e.,  $3x - 9$ ). Here we discuss ways in which these aspects of the sign system of algebra map onto aspects of the sign system of algebra tiles.

### **Representing subtraction only by action**

The basic implementations of the balance scale and container models do not allow for terms involving subtraction as part of an equation. The only way students experience subtraction with these models is as an action carried out on one representation to produce an equivalent representation. One cannot represent  $x - 3 = 6$ , but one can represent  $x + 3 = 6$ , and then subtract three on both sides (i.e.,  $x + 3 - 3 = 6 - 3$ ). The subtraction on each side would not be represented by material objects, but by actions of taking away. Only the result of the subtraction, i.e.  $x = 3$ , is materially represented. Thus, the distinction between an operation (represented as an action) and a number (represented by objects) is preserved, but at the cost of not being able to represent subtraction from an unknown quantity. When progressing to equations that cannot be represented in this way, students are expected to accept that the rules that applied to positive numbers and variables connected by addition and multiplication similarly apply to terms including negative numbers and fractions, subtraction and division. Some students, however, may find this difficult. Vlassis (2002) found that students instructed with the balance scale model had problems as soon as subtraction and negative integers were present in

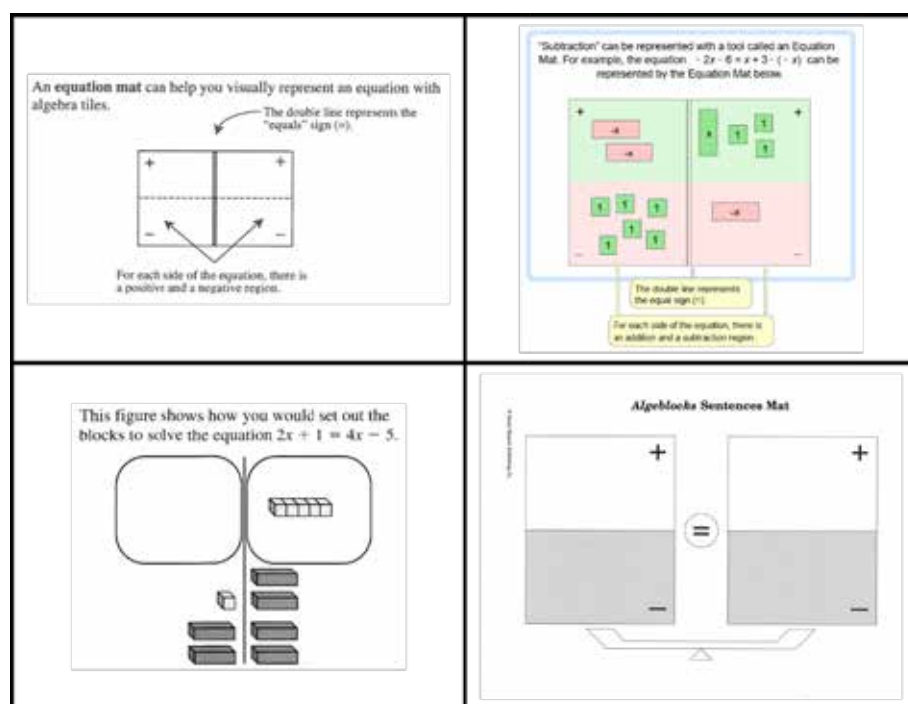

symbolic equations to be solved. She reasoned that “the negatives place the equation [...] on an abstract level. It is no longer possible to refer back to a concrete model or to arithmetic“ (p. 350).

### Representing subtraction with objects that stand for negative integers

An alternative is to introduce objects that stand for negative integers and to define subtraction of positive integers as addition of negative integers. In some virtual implementations, the balance model is amended with “negative weights”, e.g. represented by helium balloons. Unbound by problems of physics, the algebra tiles model allows the introduction of opposite tiles for both the unit tiles and the variable tiles. However, what is then represented are *negative numbers* and *variables with an opposite sign*. All terms in the equations are still *added*. Subtraction from an unknown quantity like  $x - 3 = 6$  can be represented (e.g., Balka & Boswell, 2006) but the distinction between operations and numbers is blurred. However, subtraction of negative integers is not possible in such a model, except by accepting a priori that this would mean addition. Hence it is clear that these models, as sign systems, do not involve elements that directly represent terms involving subtraction in linear equations.

### Representing subtraction with a fixed subtraction zone above or below an addition zone

Many algebra tiles models introduce a “subtraction zone” to allow terms involving a subtraction (such as “ $x - 3$ ”) to be distinguished from additive terms involving negative values (“ $x + (-3)$ ”). Tiles representing subtracted terms are placed in the subtraction zone. In all models that we are aware of, the subtraction zone is placed below or above the addition zone (see examples in Fig. 1).

**Figure 1: Layout of subtraction zones in different algebra tiles environments, clockwise from top left (disregard the texts): textbook *Algebra Connections* (Dietiker & Baldinger, 2006, p. 69), implemented in an applet under <https://technology.cpm.org/general/tiles/>; applet developed at the Freudenthal Institute (<https://app.dwo.nl/dwo/apps/player.html#202852>, step 8); Algeblocks® mat with an iconic scale; textbook *Algebra* by Wah & Picciotto (1994, p. 212) with so-called minus areas above.**

The use of subtraction zones has the potential to provoke fruitful thoughts and discussions. For example, they can help illuminate the relationship between subtraction and negative integers: by placing representations of  $a - b$  on both sides (i.e.,  $a$  tiles in the addition zone and  $b$  tiles the subtraction zone), students can add  $b$  negative tiles to both zones on one side to make sense of the identity  $a - b = a + (-b)$ . The spatial juxtaposition of a zone for addition and one for subtraction highlights the basic concept of subtraction as comparison and may already be familiar to students from arithmetic (e.g., English & Halford, 1995, p. 157–159). According to Stacey, Helme, Archer, and Condon (2001), such familiarity with an idea from earlier studies can promote engagement with a model. However, there are still some shortcomings that shall be discussed in the following paragraphs.

First, subtracting a term that itself involves subtraction (e.g.  $3 - (4 - x)$ ) and therefore discussing the rules of dealing with bracketed terms is not possible.

Second, the traditional design of the subtraction zone may lead to misunderstandings about division as an equivalent transformation. Dividing the expression on each side by the same number can be represented with algebra tiles in the last step by evenly assigning the number of unit tiles to the remaining unknown tiles (see Fig. 2). This suggests that as long as some tiles are in the subtraction zones, division is not possible. Unlike in the algebra sign system, it is not possible to divide a term like  $2x - 6$  involving subtraction. As Goguen points out, not all aspects of the original sign system can and should always be represented in the sign system of the model. However, the limitation that an equation like  $2x - 6 = 0$  can only be divided by 2 after it has been transformed into  $2x = 6$  seems arbitrary—and can be avoided, as we will show later.

The remaining blocks (those that cannot be matched with blocks on the other side) can then be rearranged to make it easy to see the solution to the equation.

**Figure 2: The equivalent transformation of division as even assignment of unit tiles to unknown tiles (Wah & Piciotto, 1994, p. 212).**

Third, the primary distinction between left and right can become submerged. The designs of the environments shown in Figure 1 all visually distinguish between the vertical boundary (between the left and right side of the equation) and the horizontal boundary (between the addition zone and the subtraction zone on each side). However, an analysis of how well the first principle of English and Halford—clarity of the model—is met, shows some differences: In two of the models the vertical boundary is more marked (top left: double solid line vs. single dashed line, bottom right: gap vs. no gap, balance scale as framing image), corresponding to the primacy of separation of the sides of the

equation: However we parse the expressions on each side, it is their relation to each other as a whole that is most important (see Fig. 3). The bottom left model in Figure 1 highlights this by having only one real boundary that suggests two sides; the boundary of the subtraction zones seem to lie within their respective side. Only in the top right model some observers may find the continuously colored fields to suggest a stronger connection between the zones on both sides than within each side.

**Figure 3: Structure tree for linear equations highlighting that any operation on each side of the equation should be less prominent than the distinction between the two sides**

### Addressing the shortcomings of existing models

In the design of Wah and Piciotto (1994, see Fig. 1, bottom left), the subtraction zone can be interpreted as lying within the addition zone on each side. When the environment is shown on a screen, one can start with the addition zone only and allow students to draw the subtraction zone whenever they need it, and to change its size and position as circumstances require. Furthermore, nested subtraction zones are possible, representing nested expressions (see Fig. 4, left). This can be helpful in modelling realistic situations without referring to learnt rules for subtracting negative integers at the outset. So for example, an equation like  $3x - (3 - x) = 3$  can be modelled without using negative integers, which is desirable if the equation models a situation where all quantities are positive. The subtracted terms are eliminated by adding their equivalents to both sides, reinforcing the concept that subtraction and addition are inverse operations.

The possibility of drawing the subtraction zone anywhere also solves the problem of division. It is now possible by drawing the subtraction zone(s) in a way that allows setting up groups horizontally across addition and subtraction zones (see Fig. 4, right).

**Figure 4: A flexible subtraction zone allows representing nested expressions (see left) and to arrange tiles so that the result of a division becomes perceptible ( $x - 1 = 1$  is equivalent to  $3x - 3 = 3$ , see right).**

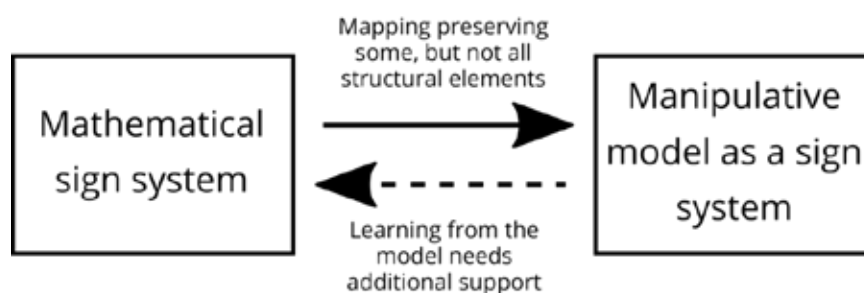

### Discussion and outlook

Quite regularly, instructional designs have such a long use history that it is hard to find their origins, let alone the thinking behind them. Their popularity and success may well be a result of the intuition of experienced teachers. However, as this paper shows, even models used in textbooks may have

significant shortcomings. The redesign of familiar models for new technologies offers a chance to reconsider their foundations: Are the models the best way to represent the mathematics we want students to become aware of? This paper presents a set of theoretical ideas that have helped us to identify problems with how subtraction is modelled in different manipulative environments. Moreover, we do not only highlight shortcomings; the theories presented here positively offer a methodology to think of better designs. This theoretical analysis complements the experience and intuition that have guided the development of models hitherto. We understand mathematical knowledge to be learnt, and models to be designed, as sign systems that need to be linked by a mapping with certain qualities that preserve important aspects of the mathematics. Considering these qualities gives us a way to argue why a certain design should be preferred over a traditional approach.

A well-designed model is nothing but a necessary first step. As noted above, no model is transparent; like any sign system it must be interpreted. Moreover, as Goguen notes, the mapping from one sign system to another cannot be one-to-one, something must be lost. Both the learning *of* the model and learning *from* the model must be facilitated. We diagram this situation in Fig. 5.

**Figure 5: The mathematical sign system (here: linear equations) is mapped to the model sign system (here: the algebra tiles model) in an incomplete manner, necessitating additional support.**

To support learning with a model sensible instructional approaches need also to be designed. The focus of this paper does not allow us to go beyond some suggestions: The algebra tiles model can and should first be used without negative tiles or subtraction zones to introduce the initial equivalent transformations (subtracting and dividing). In this way, confusion about the meaning of subtraction zones is avoided as long as they are not needed (see third principle of learning by analogy quoted above). The need to represent equations including terms involving subtraction may then come from a problem situation that is modelled, in which something must be taken away from an unknown quantity. Representing the not-yet-possible subtraction as a set of tiles in a subtraction zone can make a link between the well-established concept of subtraction as taking away and the concept of subtraction as comparison. As can be seen from these suggestions for teaching practice, the application of theories in this paper has the potential to be followed upon by research that explores “how technology mediates knowledge and the consequences of mediation on the knowledge itself” (Trgalová, Clark-Wilson, & Weigand, 2018, p. 152).

### Acknowledgment

The research reported on in this paper is part of the ongoing project “Multimodal Algebra lernen” (MAL), which is funded by the German Federal Ministry for Education and Research in the grant program “Erfahrbares Lernen” (experienceable learning) (grant number: 16SV7550K).

National and Kapodistrian University of Athens [myrtokrvk@math.uoa.gr](mailto:myrtokrvk@math.uoa.gr); [kynigos@ppp.uoa.gr](mailto:kynigos@ppp.uoa.gr);

*Trigonometry consists of a multifaceted mathematical field whose fundamental concepts, sine and cosine, have many different representations, some of them approached throughout secondary education. Unfortunately, many of its aspects are taught individually, leading students to make isolated, unconnected meanings on them. This empirical study discusses an alternative view towards trigonometry, in an attempt to create connections among the different aspects, under the scope of one meaningful context; that of periodicity. The use of digital media enables the application of this unconventional proposal, through a set of specially designed activities. In this paper we present a brief description of the main study-in-progress, as well as the results gained by its first implementation to 9<sup>th</sup>- Grade students, in terms of their meaning making on trigonometric concepts.*

*Keywords: learning trigonometry, periodicity, digital tools, meaning making*

### Periodicity for meaning making in Trigonometry

Research on teaching and learning trigonometry has been given surprisingly little attention in relation to, say, algebra or calculus. Studies regarding this field show that students develop weak and narrow understandings on the fundamental concepts of sine and cosine. They also develop a fragmented, disconnected view of the various related representations, such as the triangle model, the unit circle model and Cartesian graphs (Weber, 2008; Gür, 2009; Moore, 2010; Demir & Heck, 2013). The problem is not unrelated to epistemological debate on the nature and functionality of trigonometry in mathematics. Newson and Randolph (1946) argue that the problem has its origins in the predominant definition of sine and cosine in terms of angles, something which they perceived as related to a narrow application of trigonometry. They compare this to the attempt to define arithmetic as the “science of money”, as it is based on one of its limited applications. They instead proposed defining trigonometry as the mathematical science concerned with the trigonometric functions, whose arguments may denote time, or any other magnitude, or just a real number without any connotation. Hirsch, Winhold and Nichols (1991) characterize traditional trigonometry instruction as “memorization of isolated facts and procedures” that is unable to support a robust understanding of the subject. They also suggest a shift in emphasis towards trigonometric functions themselves and their applications at modeling periodic phenomena. Weber (2008) stresses two additional important obstacles that students deal with when learning trigonometric functions: they are initially familiar to sine and cosine as algorithms of ratios within the right-triangle context rather than as procedures regarding any given angle. The right-triangle model consists of a restriction on perceiving any other representation of trigonometric functions, as no links are ever made to this initial approach. Further, trigonometric functions are typically among the first functions that students cannot evaluate directly by performing arithmetic operations; that makes them even more complicate in order to be deeply understood. The literature focus is thus two-fold. Firstly, on posing

the problems that reside in learning trigonometry as currently portrayed from an epistemology perspective mainly emphasizing the right-triangle sine and cosine constructs (Blackett & Tall, 1991; Breidenbach et al., 1992). Secondly on fostering one representation of trigonometric functions as more important over another, while proposing a certain type of exercises (Kendal and Stacey, 1997; Weber, 2008). A fresh alternative look towards this field is presented by Demir and Heck (2013) and focuses on promoting integrated understanding of trigonometric functions by connecting their three representations within a dynamic geometry environment. In this paper we address trigonometry as a field for generating meanings around periodic covariation placing it at the centre of pedagogical focus, in line with with Demir and Heck's idea and Newson and Randolph's epistemological arguments. We follow on from prior research on the use of digital resources for students to develop understandings of periodicity through trigonometric functions (Gavrilis and Kynigos, 2006), but expand the idea of periodicity beyond the right-triangle context.

## **Design considerations**

In our Lab, we have a history of employing two constructs which for us have been fundamental to the generation of new ideas to exploit various affordances of expressive digital media for mathematical meaning making (Kynigos, 2015). The first is that of 'restructuration' coined by Willensky and Papert in 2010, where the designer questions the existing structure and emphasis of a mathematics curriculum allowing for a fresh look for meaning making opportunities in new structures and perspectives of mathematical ideas, given the new expressivity affordances of digital media. The second is that of 'conceptual field' (Vergnaud, 2009), where these new structures are perceived as an integral part of re-configuring sets of closely related concepts, using a diverse but connected set of meaningful representations for these and creating a set of problem situations where these play a central role for their resolution. So, for us, periodicity was a central characteristic of a special kind of mathematical function such as sine-cosine and tangent connected to diverse representations and part of physical phenomena such as tide. Adopting this perspective, we perceived the design of the tasks we prepared for students under the scope of the conceptual field of periodicity. Into this field, notions of trigonometry, geometry, algebra and physics are linked together so as to strengthen their embedded meanings. Trigonometric functions can be approached through different situations within the meaningful context of periodic phenomena, where students have the opportunity to derive their properties and their actual value. Our assumption is that in that way, we enhance the meaning-making process on these concepts and their various representations within meaningful situations (Noss and Hoyles, 1996) and provide flexible connections between them, as they all share the feature of periodic nature. We saw our perspective and design principle as uniquely enabled by special digital simulations and microworlds which we developed for students to use as media for expressing mathematical ideas. Firstly, we used an available Dynamic Geometry System, Geogebra, to create a simulation of the periodic phenomenon of tide connected to the representation of both the graph of the trigonometric functions and the one of the unit circle that model the phenomenon. Then, we developed a programmable microworld with the MaLT2 tool, which integrates programming and dynamic manipulation of variable values (Kynigos and Zantzos, 2017), to provide opportunities for students to make connections between periodicity and trigonometry of angles through a code-editing task. Our aim was to shed light on what meanings of

the trigonometric field can be produced by students, who engage with the designed tasks around periodicity.

## Research setting and tasks

The tasks designed for this study reflected the ideas described above. They were separated into two phases, each of which corresponded to different but complementary intentions by the designers. The first phase was related to the phenomenon of tide (in a non-realistic yet close to students' perception way) simulated in the dynamic environment of Geogebra in order to be modeled in any way possible by students. The second one was dealing with the periodic change of the vertical lines of a right triangle in the programmable media of MalT2, requiring correlation of periodic functions with the trigonometric ones and leading to formalization.

## Modeling Periodic Phenomenon

We designed a model in Geogebra that visualizes the periodic rise and fall of sea levels according to the sinusoidal function  $f(t)=\sin t$ , where the variable  $t$  stands for the time passing in hours (Figure 1a). This phenomenon was simulated so that the sea would cover and uncover periodically the surface of an island. It could be observed by moving the cursor of the variable  $t$  till it reached the value of 30 hours and then it would start over. The initial task students would be challenged with was to make a schedule for future most suitable time for visits to the island; ones that would last the longest in order to collect its valuable shells. The final task was the construction of a math formula that would receive a value of any future time and export the exact height of the sea levels. The available digital tools were split into two representations which were given to students during the first phase along with a worksheet directing the above exploration process. The first one involved the “trace-leaving” point  $M(t,y)$  available for dragging into a Cartesian system (Figure 1b). By following the height that corresponded to every time value, starting from 0 and moving forwards, the trace would form the sinusoidal graph. The second representation was that of the unit circle. Adopting the “wrapping function” model (Podbelsek, 1972), we made a cursor that enables the wrapping around the unit circle of a segment whose starting point is the  $(1,0)$  and has the length of the exact same value as the time paused (Figure 1c). When the segment was fully wrapped, the stopping point's coordinates revealed the sine and cosine of that value as well as a corresponding arc/angle. The tasks required the specification of the relationship between time and the height of sea levels in order to find a convenient way to predict the island's uncovered surface at any future time. The particularity of this phase is the fact that the words sine or trigonometry were not mentioned anywhere so as for students to proceed to formalization.

## Formalization of the Trigonometric Functions

The second phase interfered in order to “fill” the gaps that the first phase left uncovered; those are the formalization that the functions responsible for the periodic change are the trigonometric ones and their possible reference to angles or any other magnitude. For this matter, we designed an artefact in the programmable environment of MalT2. The code that produced the turtle's trace for this artefact was hidden from the students, whose task was to discover it and reproduce it. The only accessible source was the product of the code: the artefact that represented a right triangle (Figure 2) and the periodic changes of its shape while manipulating the value of its unique variable through

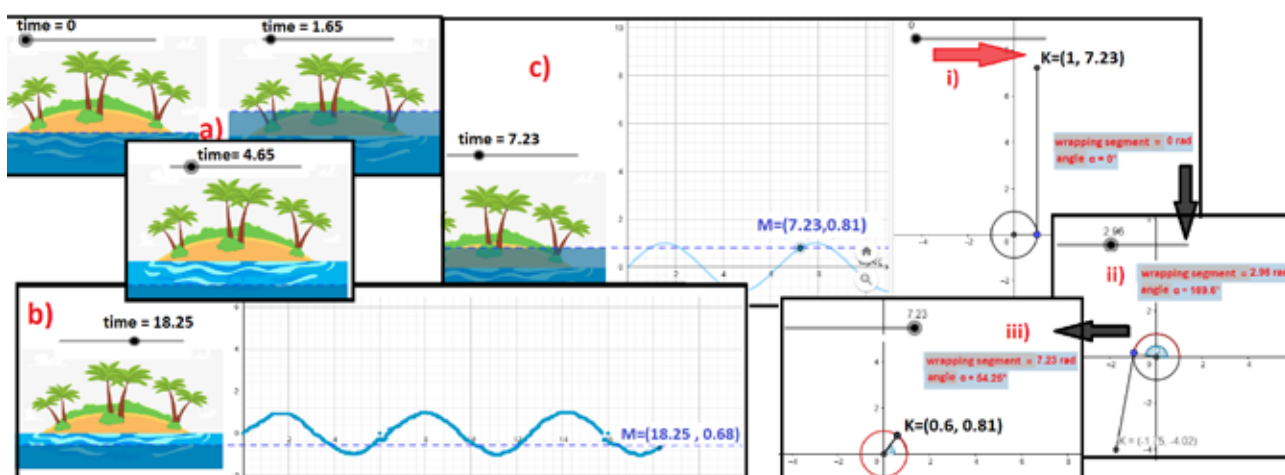

the uni-dimensional variation tool. An additional output that students had access to was the values of the length of every triangle's side. The relations that needed to be "unmasked" were the sinusoidal and cosinusoidal covariation between the visible variable  $t$  -that corresponded to a triangle's angle- and a triangle's vertical side.

## Findings

The study described above was an educational intervention designed according to the methodology of "design experiments" (Collins et al., 2004). The focus was both on the meaning-making process by students and their interaction with the digital tools. Three small groups of 9<sup>th</sup> Grade students from a public Experimental School in Athens participated in a first implementation of this study. It took place in the pc-lab of the school during after-class mathematics courses for totally six teaching hours within two weeks.

### Phase 1

All three groups engaged with the tasks described above generated rich meanings on the embedded concepts. We analyze below some representative dialogues that help us perceive aspects of this meaning making process.

**Figure 1: The phenomenon of tide and its two representations at Geogebra**

At first, students studied the phenomenon of tide and the way it was affecting the represented island. While studying the simulation and the questions of the worksheet, they all followed a similar thinking flow, presented in this discussion:

Student 1: Well, we could say that the sea levels are going up and down in a steady rhythm. There is a highest and a lowest point the levels reach within a standard period of time; almost 6 hours? In order to predict it, we need to know the relation between time and height, but we don't know the function formula.

Student 2: The best time for visiting the island is when the height is at level 0 and goes downwards. This level is reached many times, maybe even infinite ones. But I can't say their exact value after the 30<sup>th</sup> hour. But I am sure there is a way to find out because there is a standard pattern. It's like a circle repeated endlessly.

In our understanding, these lines indicate a first approach of the trigonometric functions based on their periodic nature. Dragging the point M helped them express the relation between time and height until the 30<sup>th</sup> hour. That way they constructed the sinusoidal graph, which inspired them with ideas for predicting accurately the future evolving of the phenomenon:

- S1: The most suitable moments for visiting are at 3.14, 9.42 and 15.7 hours.
- S2: These numbers are odd multiples of 3.14. Therefore we can determine the most suitable for a visit future moments by computing as many multiples as we can. But I can't think of a way to determine the exact height level at any future time.

The graph provided them with the conception that the phenomenon follows a specific pattern defined by its period. What concerned them is the fact that they were unable to find a way to predict the exact correspondence between sea levels and any future time. This enlightenment came during their interaction with the second representation; that of the unit circle. By wrapping the segment - that equals with the time value- around the circle, students realized that the stopping point reveals the height of the sea levels by its ordinate. This procedure improved the way they perceived the periodic nature and led them to discover a convenient way for predicting the phenomenon at future time. They counted the times the segment was wrapped to a full circle and determined the height according to the wrapping of the remaining segment. A possible interpretation of this achievement is the fact that the circle model reminded them of a familiar concept; that of division.

- S4: We must find how many times this whole segment will be wrapping a whole circle. Let's divide it with 6.28.<sup>1</sup> The remainder gives the length of the segment that will determine the height.
- S5: Yeah, all we have to do is wrap the remainder value segment and see the ordinate of K where it stops. The remainder is always lower than 6.28. We can use that as a formula to predict the exact height of sea levels at any future time.

This realization came when they were asked to predict the height of the sea levels at the 300<sup>th</sup> hour since the beginning of the observation. That led them to the modeling of the phenomenon and the conquest of the wider challenge of the study. A strong link was thus established between the trigonometric function and the notions of periodicity and predictability. However the study is incomplete; no student made the connection between the trigonometric representations and trigonometry itself. As a result, the meanings they produced were rich in trigonometric features but, not surprisingly, they did not correspond to formal trigonometric labels.

## Phase 2

As mentioned above, this phase aimed to establish links between periodic covariation and formalized trigonometry. Students started their exploration by manipulating the cursor and observing the changes happening to the triangle. The following parts of their conversation represent their initial thoughts and their completion:

---

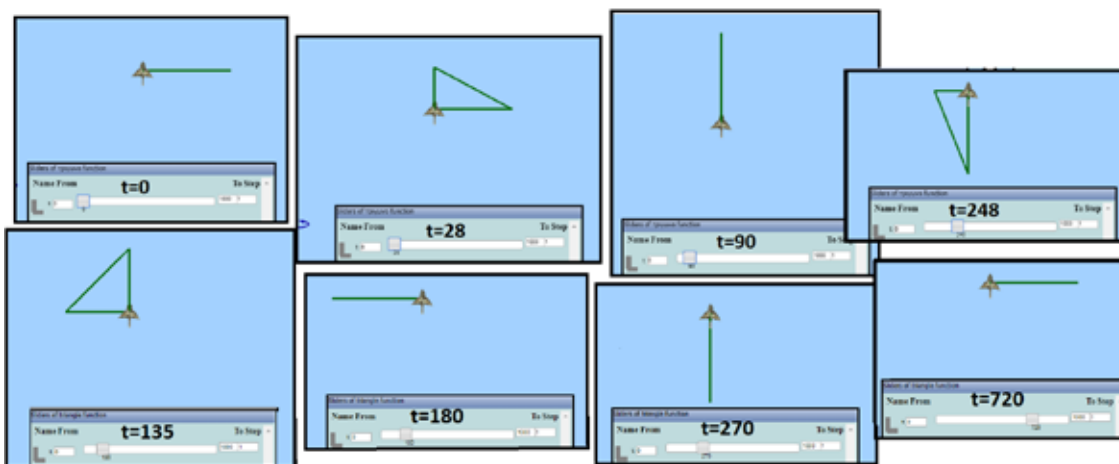

<sup>1</sup> They had already pointed out that an exact circle is fully wrapped when  $t=6.28$ ; thus its perimeter equals to 6.28.

S1: The things here that remain stable are a right angle and the length of the hypotenuse, which is always 100, no matter what value the (variable)  $t$  takes.

S2: Yes, except from 0. Oh, and 90. And 180, too. Bet it's 0 at every multiple of 90.

Students S1 and S2 were seeking for regularities in order to find the “unaffected” from the cursor’s movement magnitudes and start the code writing from these constants. Then, while trying to figure out the nature of the observing variation and decode it, many trigonometrically interesting things emerged:

S3: It’s weird because while one vertical side grows, the other one shortens. I think they grow with a steady rhythm. (...) It repeats itself after a period of time. Just like the sea levels did.

**Figure 2: Manipulating the value of the variable  $t$  causes changes to the artefact**

S1: In order to make a right triangle that remains right, we know that this angle is 90 degrees, so the other two must sum up to 180. Now, can we find the vertical sides based on these constant elements?

S2: Guys! What if we use the variable  $t$  as angle and not as length? That way we can find that side by the relation “sine  $t$  equals the ratio of the opposite side to the hypotenuse”. That way we find the opposite side!

S1: YEAH! Genius! We can do the same thing with the last side, but using cosine instead.

```

TO triangle :t
  fd 100*sin(:t) rt 90+:t fd 100 rt 180-:t
  fd 100*cos(:t) rt 90
END

triangle 30 |

```

**Figure 3: The code producing the artefact made by the students**

These students followed the right conceptual path in order to conceive the idea that led them to the interpretation of the artefact. Being familiar with the right triangle model, they easily discovered the

trigonometric relation by thinking of the variable  $t$  as an angle. Based on that realization, they managed to correspond each unknown element of the triangle to a functional relation with the known ones. Thus, considering sine and cosine as functions, they got to the discovery of the right code. (Figure 3)

Student S3 made a crucial comment on the completion of the meaning-making process; he realized the resemblance to the phenomenon of tide examined at the previous phase. After the discovery of the functional code, he completed his thought with an even more remarkable comment:

S3: Therefore sine and cosine are responsible for the growing and shortening of the segments. It depends on the angle; when an angle grows the one side, it shortens the other one with the same period. I think it's the first time I realize that.

He expressed the connection between trigonometry and periodicity, building a strong conceptual link between them. We found it quite interesting that he intuitively he connected variability in sine and cosine with segment length rather than angle. This signified the mental abstraction that trigonometric functions can be used in order to express periodic change of the value of a segment. As a result, the completion of this phase came along with the awareness that the value of trigonometric functions goes far beyond the right triangle model.

## Conclusion

The students seemed to find periodicity as a familiar concept and to be able to think about functional relations and trigonometric functions to gradually see the mathematical underpinning of periodicity. The tasks allowed them to observe and to express trigonometric functions as elements representing periodicity. They first produced meanings on various trigonometric notions and afterwards they established links between them. They approached sine and cosine as functions and not as just numbers and they listed many of their properties based on their periodic nature. They finally realized that trigonometry is strongly connected with periodicity and thus it can be exploited for modeling periodic phenomena which are of great scientific importance. The role of the digital media was integral during the students' meaning making progress. They managed to interpret periodicity using trigonometric terms, thanks to their exploration with these digital tools. They provided an alternative dynamic and constructionist way to visualize, model and manipulate dynamically periodic situations. It is very difficult to represent periodicity in an alternative way open to exploration. So, this study indicates that it might be interesting to further research the potential of using digital representations of trigonometry so that some constituent elements can be understood through the fertile conceptual field of periodicity rather than the curriculum based focus on angles within a triangle. Maybe this could provide a solution to the constant problem of connectivity among trigonometric concepts and representations and, as a consequence, a promising proposal for learning trigonometry.

# Moving fingers and the density of rational numbers: An inclusive materialist approach to digital technology in the classroom

Doyen Kim<sup>1</sup> and Oh Nam Kwon<sup>1</sup>

<sup>1</sup>Seoul National University, Department of Mathematics Education, Seoul, South Korea;  
[dk0209mathed@snu.ac.kr](mailto:dk0209mathed@snu.ac.kr), [onkwon@snu.ac.kr](mailto:onkwon@snu.ac.kr)

*This study aims to examine the relationship between the body and the meaning-making process in mathematics classroom with digital technologies. We investigate a mathematical activity in which students explore the meaning of the concept 'density' of rational numbers with a multi-touch dynamic digital apparatus. A case of elementary school students is studied from the inclusive materialist perspective through microethnographic analysis. The result indicates that students' finger movements toward the digital apparatus played a critical role in developing the meaning of density throughout the activity.*

*Keywords: Touchpad, GeoGebra, Density, Body, Inclusive materialism.*

## Introduction

Contemporary digital technologies have become more 'body-friendly' (Sinclair, 2014) with the widespread adoption of haptic input devices. In a haptic technological environment - such as that with touchpad or touchscreen - users interact with technologies through more direct body movements compared to the keyboard-and-mouse environment, and hence a more powerful status is granted to the user's body. This change in the interaction asks the studies concerning the technologies in mathematics classrooms to include our body as one of the central interests (Ferrara, Faggiano, & Montone, 2017).

On this basis, this paper aims to examine the dynamic relationship between the body and the meaning-making process in mathematics classroom with digital technologies. We study a small group of grade 5 students exploring the meaning of density of rational numbers using multi-touch dynamic digital apparatus. We take the inclusive materialist perspective (de Freitas & Sinclair, 2014) to focus on the body movement in mathematical activity with digital technologies. Through a microethnographic analysis, we pay attention to the bodily movement toward the given technology and the development of meaning during the activity.

Our specific research question in this paper is as follows: *In a multi-touch dynamic digital technology environment, how does the meaning of the density of rational numbers evolve in relation to the students' body movements toward the technology?*

## Theoretical framework: Inclusive materialism

### Existing theoretical approaches

When theorizing the relation between the meaning-making process and technological environment in the mathematics classroom, two theoretical perspectives have been dominant in recent studies, namely the instrumental approach and the semiotic perspective (Drijvers, Kieran, & Mariotti, 2010). These two perspectives together seize the material, social and psychological nature of mathematical

activity with tools. Nevertheless, they do not leave much theoretical room to embrace the role which the body plays. The inclusive materialism, based on the new materialist ontology in which the physical and the mathematical reside on the same ontological realm, reexamine the role the material elements - including the body - play in mathematical activity. In recent years, the studies concerning the multi-touch digital technologies started to adopt this approach to investigate the relationship between the hand movement on touchscreen and mathematical thinking (e.g., de Freitas & Sinclair, 2017).

### Inclusive materialism

Breaking with anthropo-centric views, the inclusive materialism argues that all human and non-human elements partake varying degrees of agency and power during a mathematical activity. Therefore, de Freitas and Sinclair (2014) redefine body so that the theory fuses the physical and psycho-social dimensions of the bodily interaction in mathematical activity. They expand the concept of the body and propose the body be "an assemblage of human and non-human components, always in the process of becoming " (p. 25). Here, the boundaries are flexible and porous, and agencies are distributed across the environment of the mathematical activity. By proposing such a comprehensive definition of the body, they suggest that we pay delicate attention to the matters and their material configuration - the physical bodies, utterance, artifacts, signs, representations, and their dynamic relationship - in mathematical activity.

What does the material configuration have to do with the meaning of a mathematical concept? The inclusive materialism takes an ontological turn by which mathematical meanings are not abstract or disembodied, but rather material and concrete. That is, the meaning of a concept is ontologically entangled with specific physical arrangements. In a mathematical activity constructing a circle with a compass, for instance, it is not the case that the compass is a disposable medium for some transcendental, determinate and a priori meaning of the concept 'circle'; instead the meaning of a circle is performed through the process where the circle and the compass are assembled. In other words, meanings emerge through mathematical activity and entail all the material specificity implicated in the activity.

In terms of research, the practical goal of the inclusive materialism lies in capturing the emergent and creative aspect of the meaning-making process. Drawing on the insights from the history of mathematical inventions, de Freitas and Sinclair (2014) deem *mobility* to be critical for such inventiveness. Moving mathematical objects or attending to how they are determined in terms of movement—rather than logically—configure the material elements in new ways. In short, movement actualizes the potential mobility of mathematical objects, creates a new material assemblage, and hence a new meaning as well. In that respect, the design of a mathematical activity should encourage learners to attend to the mobility of material elements and hence new senses that were previously imperceptible, instead of passively following the procedures which already seem possible or logical.

**Figure 1: The initial setup of the activity**

## Research context and method

### Participants and the activity

Participants involve a group of grade 5 students (age 10-11) in elementary schools at Seoul, South Korea. Through preliminary oral interview of a class ( $N=20$ ), we selected four students in each school who had exhibited mid-level achievements in mathematics from the previous semester and, at the same time, displayed low-level understandings of the density in their responses to a questionnaire based on Vamvakoussi and Vosniadou (2007). This paper reports an episode of students A, B, C, D from one of the schools.

The activity is a game called 'point-and-name.' It was a part of a teaching experiment that the authors designed for students to explore the number line for the density of rational numbers using GeoGebra and spanned three lessons. In the beginning, on the screen was a horizontal line with three points on it, each named 0, 0.5, 1 respectively. On the background lied grid lines: In between two adjacent thick grid lines, four equidistant thin lines were placed and divided the space into five parts [Figure 1]. Students sat facing each other and were given touchpad keyboards that were connected simultaneously to a single GeoGebra environment on a shared monitor screen. Split into two teams (AB vs. CD) and taking turns, each team was asked to place a point anywhere on the line in between the two Xs on left and right; name it with a rational number in reference to the previously placed points and their names. To achieve the goal, students could move the points on the line horizontally, and zoom in and out. Once students zoom in, the gaps between the grid lines widen, and new grid lines appear filling the gap. The game ends when a team fails to place a point or give an appropriate name to their points. One of the researchers took the teacher's role only offering technical help.

### Data collection and analysis

All three lessons were video recorded and transcribed. We conduct a microethnographic analysis (Streeck & Mehus, 2005) which is effective for the in-depth examination of the interplay among speech, gesture and artifacts in a mathematical activity (e.g., Nemirovsky, Kelton, & Rhodehamel, 2013).

Thereby, we pay particular attention to the following elements to understand the interaction between the learners' physical body and the digital apparatus: (a) the hand motion on touchpads, (b) the cursor movement on the screen, (c) the movement of screen itself (e.g. zooming in/out, panning), (d) the speech of students, (e) the hand gesture in the air. We must watch the hand motions on the touchpad since they are the primary means of manipulating the apparatus for students. The cursor and screen movements are also important for they embody the learner's attention and its shift. Furthermore, in a multi-touch digital technology environment, the gestures in the air are specifically important not only because they communicate meanings coupled with the speech but also they are part of a gestural continuum together with the gestures toward the haptic input device, preserving senses from one to the other (de Freitas & Sinclair, 2017).

On the cognitive side, Vamvakoussi and Vosniadou (2007) had identified various aspects of understanding of the density of rational numbers. Their result suggests that a critical cognitive action in developing the meaning of density is to find a smaller unit than the least common unit of numbers

in an interval in order to conceive a number with the smaller unit which would locate in somewhere 'in-between' the existing numbers (e.g.,  $\frac{3}{4}$  in the interval  $(\frac{1}{2}, 1)$ ). Understanding that this action could be implemented in any interval of two rational numbers is considered as indicating a sophisticated development of the meaning of density.

## Result and discussion

Our major findings are drawn from three notable sequences of the episode. As students carried out the activity through these sequences, the meaning of density had become more and more sophisticated. Each sequence is thematized by a significant development of the meaning of density that had come to the surface. We present each sequence through transcription or a brief depiction that highlights key events, then follow up by discussion.

### Sequence 1: “You must follow the rules.”

Shortly after the beginning, students started to establish collectively a set of implicit rules of engagement (*First-rules*) and eventually all began to abide by them to play the game: **First-rule 1.** *A new point must be 0.5-away from an existing point and named accordingly;* **First-rule 2.** *A new point must be placed on a thick grid line.* The highlight of the first sequence is presented below.

- 1 C: (C drags his index finger to the left and then gently taps.) [C’s cursor moves to the left side of '0', and a point appears on the left side of the line.] [Figure 2 (a)]
- 2 D: Why are you putting it there?
- 3 C: You don’t like it?
- 4 D: No. You can’t just do this in whatever way you want.
- 5 C: Then, how?
- 6 D: You must follow the rules. See, it goes from 0 to 0.5, then to 1. What do you think will come next?
- 7 C: 1.5, it is. Let me throw this away. (C right-clicks with his middle finger) [C opens the menu on the point and deletes it.]
- 8 D: (D spread her index and middle fingers away on the touchpad, then double-taps the pad, and drags with her index finger to the right.) [The screen zooms in. The point appears on the line and is dragged right to the place where a thick grid line adjacent to '1' meets the line.] [Figure 2 (b)]
- 9 C: Now you name the point.
- 10 D: (D tabs and then types ‘1.5’) [The name ‘1.5’ appears above the point.] [Figure 2 (c)]

Figure 2: The establishment of First-rules

After Team CD pointed '1.5', A began to led Team AB' turn. A zoomed in, and '0.5' and '1.5' got off the thick grid line because of that. A started counting the number of thick grid lines - including newly appeared ones - between '1' and '1.5' with his cursor. After expressing confusion about how far they should zoom in, A zoomed out, coming back to the scale at which they were. Then A placed '2' on a thick grid line as far away as the distance between '1' and '1.5'. From then on, every new point ended up on a thick grid line, 0.5-away from the point either at far-right or far-left, subsequently producing '2.5', '3', '3.5' and so on [Figure 3].

Figure 3: The screen capture at the end of Sequence 1

Although the students did not articulate the rules explicitly, we could infer the First-rules from their discourse and actions in this sequence. Line 6 and Line 10 are good examples where they defined the way the game should be played and complied. These rules suggest that 0.5, the least common unit of numbers given in the initial setup, remained indivisible to students and they did not conceive any smaller unit by which they could play the game. The multiples of 0.5 (e.g., 0, 0.5, 1.5) are treated as if they were successive.

We must note that these rules are neither given by the teacher nor randomly established by the students. Rather, they resulted from the structure consisted of the salient perceptual features of the initial technological terrain: the three points on the line with names '0', '0.5', '1'; evenly distanced from each other; all aligned with the thick grid lines [Figure 1]. This regulation was not included in the instructions from the teacher. Students could have laid their point anywhere in between the Xs and claim its legitimacy by naming it with a proper rational-number. Instead, their attention was captivated by the given structure and, as a result, their subsequent practice began to adapt to it. Although Team AB had zoomed in and thus had a better chance to place their point in between the existing points, they were only *looking closely* at the line to measure the distance between 1 and 1.5. Instead, having their attention fixed only at the thick grid lines, they failed to obtain the measure they wanted since 1.5 was not on one of the thick grid lines. Eventually, they zoomed out so that they could place '2' one thick-grid-line away to the right.

### Sequence 2: “We can’t go beyond X.”

In the following sequence, to resolve the problem on hand, students devised new rules (*Second-rules*): **Second-rule 1.** A new point must be 0.1-away from an existing point and named accordingly; **Second-rule 2.** A new point must be placed on a grid line, either thick or thin. The highlights of this sequence are described below.

Once Team CD placed '4', the last point in Figure 3, students encountered an issue: There is no available place for new points. According to the First-rules, they were only supposed to point on the thick grid lines between the two Xs. Zooming in at the interval (3.5, 4), frustrated, A commented, "We can't go beyond X." Instead of giving up, however, Team AB then decided to seek a new place for '0.1'. B zoomed in and started counting thick grid lines between '0' and '0.5', of which she counted eight [Figure 4 (a)].

However, students therein encountered the second issue: No thick grid line corresponded to the proper location of '0.1'. While B was having a hard time finding a thick grid line corresponding to '0.1', A started to notice the use of thin grid lines and suggested B to make use of them. Not long after, B agreed on A. There, they began to count, finding out the interval (0, 0.5) comprised 20 thin grid lines and thus 0.1 corresponded to four of them. At last, a new point appeared near 0 and got dragged slowly to the fourth thin grid line and so did the name '0.1', shortly [Figure 4 (b)]. From then on, students unanimously followed Team AB's method with little verbal exchange, counting four thin grid lines to the right and pointed '0.2', then '0.3' [Figure 4 (c)]. The activity had to stop there since the lesson time was over.

**Figure 4: The establishment of Second-rules**

After Team AB had devised a solution to place '0.1' in violation of the First-rules, Team CD simply followed their solution for '0.2' with no dispute at all, and Team AB repeated the action for '0.3' in the same way. Even though we were not able to observe further after '0.3', it is reasonable to assume they would have continued to play in the same manner judging based on their previous performance.

This new set of rules suggests the students became able to conceive a smaller unit (e.g., 0.1). Moreover, it shows that they could come up with the numbers which can be placed in between two once-seemingly-successive numbers. At this point, 0.5 was not the indivisible least common unit, and the multiples of 0.5 were not successive for students any longer.

Throughout this sequence, the body movements were at the center. Especially, the act of zooming in and out, rendered by spreading and pinching fingers on the touchpad, eventually evoked the change in students' perceptual habit and made them recognize the potential of thin grid lines – which was imperceptible earlier.

Another noteworthy thing is that the same perceptual change did not occur in the first sequence even though they zoomed in/out in precisely the same manner. The fundamental difference here lies in the degree of X's agency-in-play in the two situations. Once the students reached the barricades, unlike the first sequence, X became a major player in this student-technology-concept assemblage, which dismissed the students' propensity to go further outward according to the First-rules. Instead, it turned their attention to the intervals in between the points. It was not until the formation of this particular configuration that spreading fingers catalyzed such a dramatic shift in practice. Only then, students were *stretching* the number line and space rather than merely *looking closely* at them.

### Sequence 3: "We keep stretching."

After the activity was over, the teacher conducted an ill-structured group interview with students on-site. Through students' discourse and gestures, it became apparent that the meaning of density had evolved further, and it was indeed inseparable from the technological environment of the activity.

- 11 T: Let's say we already have placed like, so many points and, say, y'all are really smart people. Then, can we place another point at this time?

- 12 All: Yes.
- 13 B: By stretching more and more (*palm facing forward and all fingers open, B spreads her thumb and index and close them in repeatedly*) [Figure 5 (a)].
- 14 T: Then, until when?
- 15 A, B: Forever.
- 16 B: We do **zero point zero, zero, zero, zero, zero, zero, zero, one [0.0000001]**
- 17 A: **Zero point zero, zero, zero, zero, zero, zero, ... zero, one [0.00000001]**<sup>1</sup> (...)
- 18 C: The further you stretch (*palm facing downward and only index and middle finger open, C spreads them away and close in quickly and repeatedly*) [Figure 5 (b)], the more lines you will have (*palm facing forward, C repeats to spread and squeeze all of his fingers swiftly*) [Figure 5 (c)].
- 19 T: Then, let's say, I would place my points at all the empty place on the line there, and now we don't see any empty place. Can we still lay another point?
- 20 A: We can.
- 21 B: Yes. We keep stretching (*palm facing downward, B spreads her index and middle finger away and bring them in repeatedly*) [Figure 5 (d)].

**Figure 5: The students' hand gestures in the air**

The students realized that no matter how many points are on the line and how dense they appear to be, they could always find a place for another point in between them. B was enumerating zeros in 0.0000001 out loud (Line 16) to imply that the game could go on by finding a number with a sufficiently small unit in response to the teacher's question (Line 11). Moreover, while enumerating zeros out loud simultaneously with B, A noticed that he could find an even tinier unit if he continued to add zeros before finishing with one. This made A take a brief halt when B finished and then quickly added one more zero and one (Line 17). Also, Line 13, 18 and 21 indicate that students became able to conceive a room to put such numbers by virtually stretching the line and space.

As we have observed from the episode, the body movement is a crucial factor in the invention of new meanings. Students' hand gestures on and off the touchpads demonstrate the catalyzing role of the mobility in the meaning-making process or, in other words, becoming the assemblage of fingers-touchpads-number line-space-'density'. No one possessed the emerged meaning from the beginning. No one was able to produce it by only repeating what seemed possible. The meaning did not exist until the finger movements actualized the latent material configurations and allowed the new senses

<sup>1</sup> This bolded and underlined part in the transcript indicates the moment when speeches of A and B were overlapping. Note that B deliberately continued to add a zero even after A stopped.

in unanticipated ways. It is this emergent nature what makes the meaning genuinely new and inventive.

## Concluding remarks

We have scrutinized a case of mathematical activity to examine the relationship between the body movement and the meaning development in a multi-touch digital technology environment. Through the inclusive materialist lens, we could observe how the finger movements toward the digital apparatus played a crucial role in developing the meaning of the density of rational numbers. As Sinclair and de Freitas (2014) note, movements of the hand bring about new material reconfigurations and hence new hand gestures, which participate in the process of communication as well as the invention of meaning. We hope this study will contribute both to the embodied cognition theory and the studies on the integration of digital technologies in mathematics education by encouraging to incorporate the body and the material as central foci of investigation.

# Investigating students' use of dynamic materials addressing conceptions related to functional thinking

Edith Lindenbauer

University College of Education Upper Austria, Linz, Austria; [edith.lindenbauer@ph-ooe.at](mailto:edith.lindenbauer@ph-ooe.at)

*This paper reports on a qualitative case study about the use of dynamic worksheets addressing typical difficulties and misconceptions concerning functional thinking. The dynamic worksheets designed in this project visualize the transfer between iconic situational and graphical representations and were utilized during an intervention with students in a 7th grade Austrian middle school class. In addition to observational data, diagnostic tests and interviews regarding students' conceptions in the field of functional thinking were conducted. The case study particularly pays attention to the intuitive conceptions of students, the influence of the dynamic worksheets on these conceptions, and whether or not these materials are able to support students in developing appropriate mathematical conceptions. In this paper, an overview of the study and the part of the results related to students' use of dynamic worksheets are presented.*

**Keywords:** Functional thinking, technology, representational transfer, lower secondary school.

## Introduction

Functional thinking is an important concept in mathematics education and various students' problems and (mis-)conceptions have been widely researched in this context. The development of technology and technology-based resources now offers new opportunities with regard to multiple, dynamically linked representations. The question arose, whether such materials are able to support students in an early stage of learning functions as well as whether and in what ways they may influence students' conceptions. Based on these considerations, I developed several dynamic worksheets that visualize the representational transfer between iconic situational and graphical representations and integrated them into a qualitative case study to investigate this question.

## Theoretical background

Literature review reveals various problems and misconceptions in the field of functional thinking; for example, illusion of linearity (De Bock, Van Dooren, Janssens, & Verschaffel, 2002), problems related to representations of functions such as graph-as-picture errors and slope-height confusions (e.g., Clement, 1989), and difficulties related to aspects of functional thinking whereby particularly the dynamic co-variational aspect is difficult for students to comprehend (Goldenberg, Lewis, & O'Keefe, 1992). These problems can cause misinterpretations of functions and particularly of function graphs. In this study, I follow Vollrath's (1989) description of functional thinking mainly including relational and co-variational aspects, because it best fits for the purpose of my study.

Dynamic Mathematics Software (DMS) allows to examine multiple, dynamically linked representations because changing one representation immediately affects the other(s). Therefore, it may support students' development of functional thinking because it is suitable to emphasize relational as well as co-variational functional aspects, the latter providing a dynamic perspective on functional dependencies (Falcade, Laborde, & Mariotti, 2007). So far, quantitative studies in the field

of technology reveal at best moderate effects on students' achievement, but research related to dynamic representations appears to be more promising (Drijvers et al., 2016; Hoyles, Noss, Vahey, & Roschelle, 2013).

At present, Cartesian coordinates seem to be dominant for representing function graphs in mathematics learning and teaching. Another way to represent functional dependencies is based on a software called DynaGraph providing two parallel lines instead of perpendicular axes (Goldenberg et al., 1992). According to Goldenberg et al. (1992), dynagraphs are powerful tools to examine characteristic properties of functions, to analyze functions qualitatively and therefore to support the understanding of functions. For instance, it is not possible to perceive graphical representations as static “images”, which could lead to graph-as-picture misinterpretations. Dynagraphs are able to complement static representations by adding dynamic perspectives, thus enriching the conceptual development of students. However, we need to examine in more detail the influence of dynamic materials (utilizing Cartesian as well as parallel coordinates) on students' conceptions.

Several researchers (e.g., Vosniadou & Vamvakoussi, 2006) suggest introducing mathematical concepts at an earlier stage in mathematics education in order to help students building a diverse concept image and to avoid that intuitive conceptions develop to misconceptions. This led to my research interest in students in an early phase of learning functions. In Austria, this group is represented by students in grade 7 and in the beginning grade 8 (age 12 to 13), because they have already learned how to interpret Cartesian coordinates. Therefore, they are able to study graphical representations, but they are not accustomed to the concept of the function and have only little experience with different functional relationships.

## Dynamic materials

For creating dynamic worksheets, I decided to use the DMS GeoGebra, because it provides the possibility of dynamically linked, multiple representations, it is widely used in Austrian schools, and it is an open-source and free software. Moreover, I focused on the representational transfer between iconic situational and graphical representation due to the age and prior knowledge of the participating students, and additionally because it is particularly problematic (Bossé, Adu-Gyamfi, & Cheetham, 2011). An English version of the worksheets can be retrieved here: <https://ggbm.at/ftqpETqJ>.

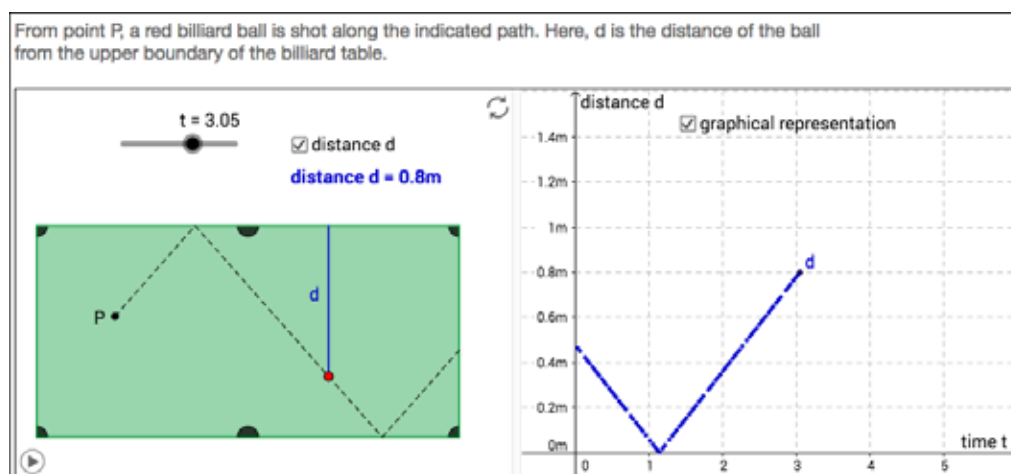

Figure 1: Dynamic worksheet “Billiard”, <https://ggbm.at/Dyf9Pwxj>

Figure 1 is based on a task by Schlöglhofer (2000) and illustrates a typical example of the dynamic materials designed for this project. Each dynamic worksheet concentrates on problems concerning functional thinking described in literature and consists of an interactive GeoGebra applet, which presents an iconic situational model and a graphical representation of a specific example (Cartesian coordinates or dynagraphs). Dynamically linked and interactive representations should address aspects of functional thinking.

## Research design

The literature review drew my attention to several research questions (Lindenbauer & Lavicza, 2017). In this paper, I discuss a part of the results related to the following aspect: What kinds of influences of dynamic materials exist on lower secondary students' conceptions concerning functional thinking?

Two 7th grade classes of a middle school in Austria including 28 students with a broad range of different achievement levels participated in the study. I chose a qualitative inductive approach, more exactly Eisenhardt's (1989) approach that integrates features of Grounded Theory in a case study design in which the students represent different cases. Several types of data were collected in this study by diagnostic tests, diagnostic interviews, students' worksheets on paper, and observations during the intervention. These methods were arranged to a research design including five data collection stages: (1) diagnostic test 1, (2) diagnostic interviews, (3) intervention, (4) diagnostic test 2, and (5) diagnostic interviews (Lindenbauer & Lavicza, 2017). During the three-lesson-intervention, students worked in pairs with the designed dynamic worksheets without teacher guidance, because first I wanted to examine the influence of these interactive materials. Ten students were audio- and videotaped when working and the screens of their laptops were recorded, and I supervised these students in my role as researcher. The other students were working in another school's computer lab supervised by their mathematics teachers. Both teachers were instructed before the intervention process in order to guarantee that the participants were not influenced in their learning processes by the teachers' help.

## Results concerning dynamic materials

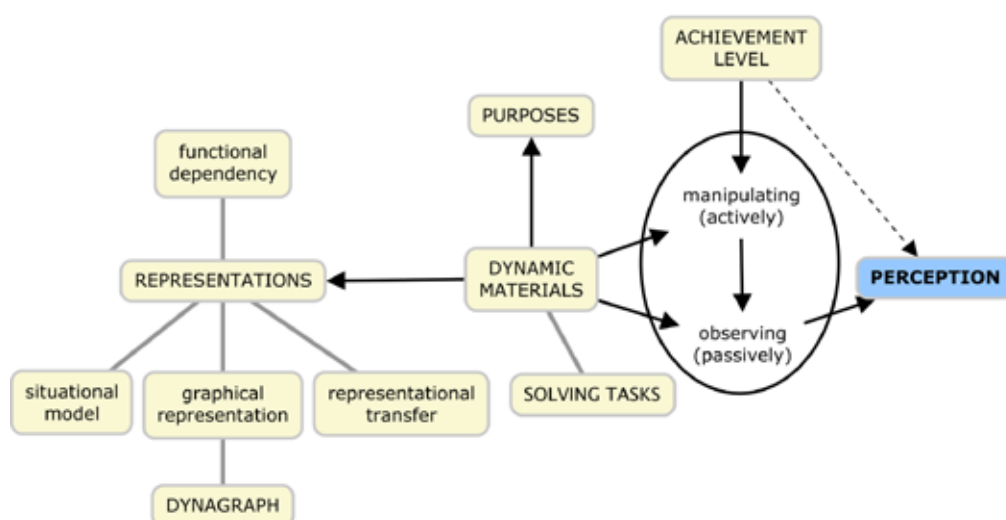

For analyzing data, I followed coding procedures related to Grounded Theory (initial, focused, and theoretical coding). Various categories emerged from the common analysis of data from the second diagnostic tests and interviews as well as observation data. For this paper, I chose to outline results concerning students' use of dynamic materials and representations. Further results will be presented in upcoming papers.

As can be seen in Figure 2, when students worked with dynamic materials, they observed what happened within the dynamically linked representations, either more actively when *manipulating* dynamic representations (e.g., by moving sliders) or more passively by *observing* an animation. The variety and number of codes assigned to data imply an influence of students' *achievement level* on how different students utilized dynamic worksheets; in essence, higher achieving learners appear to use dynamic materials in more diverse ways. For instance, only Harald<sup>1</sup> and Wolfgang, the highest

---

<sup>1</sup> All student names are pseudonyms to preserve anonymity.

achieving students who I grouped together during the intervention, utilized the trace mode to mark extrema of the functional dependency within a dynagraph representation (“Billiard dynagraph”, see <https://ggbm.at/hSP3H9wv>) and to compare with other function values. Lower achieving students Konstantin and Mario, however, mainly worked with the same dynamic worksheet passively by watching the animation. Possibly, such students’ behavior could be related to the use of visual representations in problem-solving processes. Stylianou and Silver (2004) compared experts and novices and found out that the former utilize visual representations in more diverse ways.

**Figure 2: Dynamic materials and related issues**

The way of utilizing dynamic worksheets influenced what students observed and consequently what they perceived. *Perception*, which in this context means that students consciously observe a feature and further consider or interpret it, evolved as main category when analyzing data related to the research question (see Figure 2). In brief, data analysis indicates an intention-reality discrepancy between the mathematical content the dynamic materials are intended to visualize and what students really perceive, especially when students focus on visual features of dynamic worksheets (Lindenbauer, 2018). Due to space limitations this issue will not be outlined further in this paper.

As the dynamic materials designed for this project address the transfer between iconic situational and graphical *representations* and visualize functional dependencies, these topics also emerged during the data analysis (see Figure 2). They mainly contain several students’ activities such as manipulating and observing dynamic representations, describing variables or functional dependencies, relating variables and representations, and interpreting graphical representations. Results suggest that for solving tasks, students tend to rely on the more familiar representation – the situational model – if possible. Particularly higher achieving students utilized representations more flexibly while lower achieving learners seemed to focus on one representation. Research results about connections between a flexible use of representations and students’ achievement levels and experience support these observations (Acevedo Nistal, Van Dooren, & Verschaffel, 2014; Stylianou & Silver, 2004).

### **Potentials and difficulties of working with dynagraphs**

During the intervention, students discussed two dynamic worksheets that first utilized Cartesian coordinates and within a second version dynagraph representations instead (“Billiard dynagraph”, see

<https://ggbm.at/hSP3H9wv>, and “Triangle dynagraph”, see Figure 3). At this time, they were not used to dynagraphs, and included paper worksheets only provided a brief explanation.

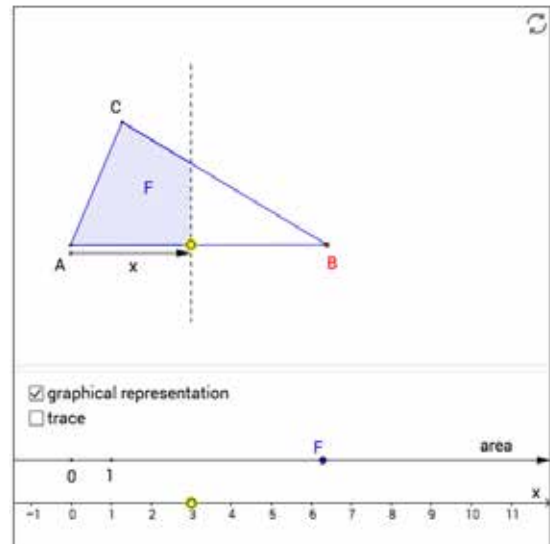

Intervention data reveals that *dynagraphs* are intuitive for students to work with when solving tasks addressing relational as well as co-variational aspects of presented functional dependencies (e.g., to describe co-variational behavior of functional dependencies, to read off function values) and, thus, provide easy access to graphical representations. For example, during an interview Hannah applied the dynagraph representation within worksheet “Triangle dynagraph” (see Figure 3) correctly for answering questions addressing relational aspects (e.g., minimum of the function) while she had difficulties in answering similar questions by interpreting Cartesian coordinates (Lindenbauer, 2018).

Furthermore, dynagraph representations appear to emphasize co-variational aspects of the presented functional dependency probably because the function value  $y$  “moves” along the upper axis when the  $x$  value changes. Participants repeatedly described the dependency of function values from arguments in terms of speed and similarly observed the speed of the points representing  $x$  and  $y$  values relative to each other. Additionally, data implies that this representation also stresses rates of change, which can be experienced directly from changing speed of these moving points. One example provided by Pia, a student between average and low achieving level with lack of understanding of Cartesian coordinates, who rather described the functional dependency in dynamic worksheet “Billiard dynagraph” focusing on co-variational aspects than she did when interpreting Cartesian coordinates. However, students’ focus on speed could also lead to a confusion of variables, especially the  $x$  variable with time. In sum, dynagraph representations actually appear to provide a more dynamic perspective on functional dependencies than Cartesian coordinates and enable a more profound examination of the co-variational aspect of functional dependences as already outlined by Goldenberg et al. (1992). In addition, dynagraphs emphasize specific properties of functions including inflection or fixed points. Several students implicitly recognized such points without being asked. When asked to describe how the function value changes when  $x$  is increased within dynamic worksheet “Triangle dynagraph” (see Figure 3), Franziska, for instance, implicitly observed the inflection point of the presented functional dependency. She replied:

- 56 Franziska: Here it [area] is increasing faster (she moves the  $x$  value from  $x = 0$  to  $x = 1$ ) . . . and then slower again.
- 57 Interviewer: Do you have any idea from where it slows down?
- 58 Franziska: So, from here on (She moves dashed line to vertex C).

As the dialogue reveals, Franziska identified the inflection point from which on the change of rate decreases. Apparently, the “speed” of the point representing the function value relatively to those

The dashed line can be moved left and right.  $F$  indicates the area of the blue shaded figure. The graphical representation uses two parallel coordinate axes - a so called dynagraph representation - in the lower graphics window.

**Figure 3: Dynamic worksheet “Triangle dynagraph”,** <https://ggbm.at/wrVPlwHE>

representing the argument  $x$  can be easily perceived. For these reasons, characteristic features of dynagraphs could be utilized in mathematics teaching to support students in accessing graphical representations, possibly in scaffolding the representational transfer to Cartesian coordinates.

Although students had no difficulties in recognizing dynamic properties of dynagraphs, they did not always interpret them correctly. Konstantin, a lower achieving student, recognized the inflection point as position where the increase of speed changes similar to Franziska (see previous paragraph). However, he related this change of speed to the decreasing non-colored area within the triangle (see Figure 3) when dragging the dashed line from vertex  $C$  to the right. In addition, students tried to interpret visual features, such as the denseness of points created by trace mode on the  $y$ -axis, similar as they did when working with Cartesian coordinates.

A further student problem, which I call a “projecting error”, appeared when reading off function values. Following solution from Tina when working with dynamic worksheet “Billiard dynagraph” exemplifies this error. Tina described when trying to answer the question about the distance of the ball at  $t = 1$  second:

Tina: At one second it [the distance] is about 0.2.

**Figure 4: Screenshot of students’ work with dynamic worksheet “Billiard dynagraph”**

Figure 4 illustrates that Tina correctly adjusted the value for time on the lower axis to  $t = 1$ . However, she did not identify the correct function value of about less than 0.1 m (possibly due to the distracting influence of the trace). Instead, as the yellow shaded cursor indicates, she replied the function value exactly above  $t = 1$ , which would actually be about 0.2 meters.

### Dynamic materials

Data related to dynamic worksheets was additionally analyzed separately from other intervention data to provide further insight. On the one hand, in essence the structure of categories manipulating, observing, and interpreting perceived features also evolved from this data analysis and thus triangulates the results. On the other hand, data revealed further typical students’ activities when solving tasks and purposes of dynamic worksheets (see Figure 2). As these results are not specific for this research project but typical activities when working with computer-based materials or technology in general (e.g., Artigue, 2002), I will not provide further details.

### Potentials and problems of dynamic materials

This issue summarizes further potentials and problems of working with these dynamic materials. First, they can be supportive within the first steps students have to conduct when translating from iconic situational to graphical representations, namely for understanding and visualizing a situation as well as for identifying and describing the dependent variable. Second, results related to another research question in this project revealed a comprehension gap as obstacle for students to overcome during this transfer. Data analyses indicate that if students are basically not able to understand and

interpret graphical representations in Cartesian coordinates, without teacher guidance students could rather not manage to overcome this comprehension gap by working with the dynamic worksheets alone. Apparently, they would profit from teachers' assistance to help them reflect and reconsider their perceptions and interpretations.

Third, for students who are basically able to make representational transfers, dynamic materials seem to be helpful, because they appear to induce adaptations of students' conceptions. When first confronted with the dynamic worksheet "Triangle" (for situational model see Figure 3), Wolfgang and his colleague represented the functional dependency by a piece-wise linear function (see Figure 5). After the second test, in which both students solved a corresponding task correctly, Wolfgang resumed:

Figure 5: Students' solution

76 Wolfgang: . . . because at first, I thought that it [the area] regularly becomes larger, but then I found out that it grows increasingly.

Apparently, this dynamic worksheet supported Wolfgang in adjusting his conception from regular to irregular increase of the function value and, consequently, from a linear to a curved graph.

## Conclusions

The data analyses reveal *perception* as main category of working with dynamic worksheets. In particular, students appear to focus on visual or structural features of iconic situational and graphical representation. Perception seems to depend, among others, on students' achievement levels and their prior knowledge. Therefore, the problem remains how to draw students' attention to those features that are relevant for mathematical learning.

Dynagraphs provide an intuitive access to graphical representations and seem to be easy for students to interpret. Minor difficulties have to be considered when introducing dynagraphs in school, mainly concerning reading off function values. Finally, these results could be influenced by the order of dynamic worksheets utilized during the intervention. Possibly letting students first work with dynagraph representation and then with Cartesian coordinates would provide further insight.

Depending on students' prior conceptions and their understanding of Cartesian coordinates, the dynamic materials utilized in this project have an adaptational influence on students' conceptions. In other words, they appear to support students in improving descriptions of functional dependencies (e.g., leading to qualitative correct ideas about changing slopes of function graphs). However, these materials could also generate new misconceptions, especially when only superficially perceived. Lower achieving students in particular would profit from teachers' assistance to reflect their perceptions and interpretations.

Additional questions arose from this project, for example, how to improve these materials and how to utilize them in regular teaching to support students. Design experiments and instrumental approach respectively could be suitable frameworks to investigate these questions further in other studies.

# A virtual environment dedicated to spatial geometry to help students to see better in space

Xavier Nicolas and Jana Trgalova

University of Lyon, Claude Bernard University Lyon 1, S2HEP (EA4148), France;

[xavier.nicolas@uca.fr](mailto:xavier.nicolas@uca.fr); [jana.trgalova@univ-lyon1.fr](mailto:jana.trgalova@univ-lyon1.fr)

*We report about an experiment carried out in a school context of teaching spatial geometry with a dynamic geometry environment, based on gesture-based interface for use with immersive, room-scale virtual reality. The work reported in this paper is the first iteration of a research cycle involving teachers, researchers and developers to help high school students better “see” in space and propose principles for the design and use of such environments in a school context. Our study focuses on the impact of “dimensional construction” techniques on the way students perceive a geometric figure represented in a cavalier perspective. Our first results show a significant improvement of students’ performance, demonstrating the appropriation and transfer of these dimensional construction techniques to 2D supports as well as the transition from an iconic to a non-iconic vision of figures, which is an essential condition for geometric activity.*

*Keywords: Mathematics, learning, geometry, visualization, technology*

## Introduction

Teaching geometry in space is considered difficult because it is necessary to “see in space,” objects or situations most often represented by drawings in cavalier perspective. In geometry, dynamic geometry environments (DGE) have revolutionized not only the way geometric objects are created and manipulated, but also allowed new didactic situations and modified our very relationship to geometric objects (Laborde, 2003). However, DGE are constrained by a 2D representation mode (screen), which poses perception and usability problems (Dimmel & Bock, 2017). In the domain of technology in education, unlike the professional world, virtual reality (VR) has made a timid entry. A DGE in VR could be relevant to better see in space or at least avoid the problem, but what will happen once the HMD (Head Mounted Display) is removed and the students are back on their tables? An interesting aspect of virtual worlds that can be exploited is their modes of interaction and assistance that are impossible in the physical world as a way of approaching learning differently (Burkhardt, Lourdeaux, & Mellet-d’Huart, 2006). VR can reveal and make tangible concepts or information normally outside the field of human perception (Winn, 2003). This leads us to question whether concrete and intelligible manipulation of geometric objects performed by students in a VR environment can change the way they later see them in cavalier perspective drawings? In this paper, we present a research aiming to evaluate the potential of VR environment in geometry in space, but also to set some benchmarks for academic learning.

## Theoretical framework

### Seeing in space in geometry

In the context of geometry, the act of seeing involves complex perceptive and cognitive processes. For Duval (2005), a major cognitive problem is how to move from discriminative recognition of

shapes to the identification of objects to be seen. This transition can take two paths: an iconic and a non-iconic path. The iconic path is based on the similarity of the shapes with the object and is not specific to geometry. Seeing in space in an iconic way can also be considered from the perspective of spatial skills as "the ability to generate, preserve, recover and transform well-structured visual images" (Lohman, 1996, p. 98). The non-iconic way relies on considering a representation of figural units linked by relations as a whole. Most of spatial geometry tasks imply this flexibility of vision. The dimensional deconstruction (Duval, 2005), i.e., considering the figural units of smaller dimensions in a geometric object, is the central point for the geometric processing of representations. Following Duval, we start from the premise that getting students to mobilize dimensional deconstruction on a 3D object represented in 2D can help them better "see in space".

According to Chaachoua (1997), to be efficient in geometry, the representations must fulfill three functions: illustration, supporting assumptions and allowing the heuristic change of point of view like the dimensional deconstruction. In spatial geometry, the drawings in cavalier perspective are the most commonly used representations. Mithalal (2014) notes that drawings in perspective struggle to fulfill these functions, and that dynamic geometry environments (DGE) allow them to be partially restored.

In order to tackle our initial question, we need to identify different ways of seeing in space students mobilize in a geometric activity. This involves modelling the ability to "see in space" in an ecological approach, which leads us to choose the anthropological theory of didactics.

### **The anthropological theory of didactics**

The anthropological theory of didactics (ATD, Chevallard, 2012) provides an epistemological framework aiming at the understanding of the ecology of mathematical knowledge. In ATD, any human activity is modelled through the notion of *praxeology* represented by so called "4T-models ( $T, \tau, \theta, \Theta$ )". A *type of task* ( $T$ ) and the relevant *techniques* ( $\tau$ ) for solving tasks  $t$  of the type  $T$  constitute a practical block or *praxis* (know-how). The technologico-theoretical block or *logos* (know why) covers a *technology* ( $\theta$ ) explaining and justifying the technique and a *theory* ( $\Theta$ ) justifying the underlying technology. In the case where the type of tasks  $T$  relates to the field of mathematics, we use the term of *mathematical organization* (MO) rather than praxeology. For Duval, "the way of seeing a figure depends on the activity in which it is mobilized" (Duval, 2005, p. 8). From the ATD perspective, we consider the different ways of seeing as intrinsic *elementary praxis* (EP) because, on the one hand, they only exist through their mobilization within techniques of prescriptible types of tasks and, on the other hand, they are present at a level of granularity that the didactics of mathematics can no longer exceed. We propose the following elementary praxis to describe the possible transitions from a figure to a geometric object. EP1 and EP2 follow the iconic way (Chaachoua, 1997), EP3 the non-iconic way (Duval, 2005).

- EP1: Associate the recognized shapes with the appearance of a physical object seen from a certain point of view (identification by natural observation and resemblance).
- EP2: Associate the recognized shapes with a prototypical image of the object available in a mental catalogue (identification by prototypical shapes).

- EP3: Identify figural units and their relationships (identification by processes supported by dimensional deconstruction).

### *The relationship to knowledge*

In ATD, the notion of *relationship to knowledge* (Chevallard, 1992) leads to considering the didactics from the anthropological perspective. An individual's relationship to particular (piece of) knowledge may be different from the relationship that the educational institution has with that knowledge. In the case of the ability to see in space, the student develops his/her personal relationship within and outside the school walls. The analysis of student productions, and in particular of their mistakes with regard to the different EPs mobilized in the techniques used to solve a geometric task, can provide us with information on the student's personal relationship with the notion of seeing in space. At the secondary level, in geometry, as well as more broadly in mathematics, the curriculum clearly aims to develop a deductive approach. From the point of view of the institutional relationship to "seeing in space", EP1 and EP2 are non-compliant and error-prone relationships. It is the EP3 that is targeted by the teaching of geometry in space.

### *The concept of ostensive/non-ostensive*

The implementation of a technique involves manipulation of *ostensives*, i.e., tangible and manipulable objects, regulated by *non-ostensives*, i.e., theoretical objects as concepts, notions, ideas (Bosch & Chevallard, 1999). Ostensives can belong to different registers: graphic, gestural, discursive and scriptural. The performance of an ostensive can be evaluated according to two criteria: its *instrumental valence*, which is its ability to act, to work and its *semiotic valence*, which is its ability to see, to appreciate in a sensitive way the work done or to plan the work to be done.

According to Chevallard (1994, p 8), "one of the factors of progress in mathematics is the creation of ostensives that are effective from both an instrumental and a semiotic point of view." (our translation).

We have seen in the introduction that drawings in perspective are ostensives whose instrumental and semiotic valences are not sufficient to develop a non-iconic way of seeing in space.

### **Analysis of *Handwaver*, a DGE in virtual reality**

The *Handwaver* application is developed by a research team at the University of Maine to exploit the modes of representation and interaction available in virtual environments to create experiences where learners use pseudo natural gestures to observe, create and manipulate mathematical objects (Dimmel & Bock, 2017). In *Handwaver*, the "stretch" and the "extrude" operators allow to generate geometric objects of  $n$  dimensions from an object of  $n-1$  dimension (Figure 1).

**Figure 1. Different cases of the “stretch” operator: a point is stretched into a line segment, the segment is stretched into a polygon, and the polygon is stretched into a prism (Dimmel & Bock, 2017)**

As we focus on 3D objects, we consider the generation of a polyhedron from a polygon as a type of task T, made up of several punctual mathematical organizations (PMO), i.e., relating to a single subtask of T. We describe these praxeologies and the involved ostensives in Table 1.

Type of task T	Construct a polyhedron from a polygon	
Punctual Mathematic Organization	Dimensional construction of prisms PMOdim_prism	Dimensional construction of pyramids PMOdim_pyramid
Subtype of task T	Construct a prism from a polygon	Construct a pyramid from a polygon
Technique	Make a translation of a polygon and join corresponding vertices of the two polygons by segments generating faces of the prism	Extract an apex from the polygon, pull it out of the plane and join it with all vertices of the polygon generating faces of the pyramid
Technology	Definition of a prism: a polyhedron with two polygonal faces lying in parallel planes and with the other faces parallelograms	Definition of a pyramid: a polyhedron with a polygonal base and three or more triangular faces that meet at a point, called apex
Theory	Euclidean geometry	Euclidean geometry
Ostensives	The stretch operator	The extrude operator
Graphical register	Virtual model of the prism reacting in real time to the manipulation of polygonal bases	Virtual model of the pyramid reacting in real time to the manipulation of the apex and the polygonal base
Gestural register	Grasp and stretch (with hands apart) the polygon	Touch the polygon with the extrude tool and move away the apex created (with hands apart)
Discursive register (later introduced by the teachers of our experiment)	"I stretch the polygon"	"I pinch the polygon"

**Table 1: Two examples of Punctual Mathematical Organizations related to the type of task T**

The a priori analysis of the stretch and extrude ostensives leads us to make the following observations:

- From the point of view of their instrumental valence, the mobilization of pseudo natural gestures makes the techniques easy to apply and retain.
- From the point of view of their semiotic valence, the environment provides immediate feedback on the manipulation of objects in the form of visualization of the polyhedron being generated. This enables the student to control the process of generating polyhedrons, and thus makes the techniques, and more generally the continuity of the process leading from the polygon to the polyhedron, readable and intelligible.

With regard to these two considerations, we hypothesize that these techniques have a strong reversibility potential, i.e., they allow a dimensional deconstruction of the polyhedrons enabling to identify the starting polygon. This leads us to reformulate our initial questioning:

To what extent the use of Handwaver to solve tasks involving dimensional construction techniques help students to move from an iconic (EP1 & EP2) to a non-iconic (EP3) way of seeing drawings in a cavalier perspective?

## Methodology

Our methodology relies on a teaching experiment involving two grade 6 classes and their mathematics teachers. Our aim was to design and test activities with *HandWaver* involving the above mentioned techniques. The methodology comprises several phases outlined below.

### Phase 1: Identification of errors related with seeing in space

We interviewed six secondary school mathematics teachers through two focus groups in two schools to determine types of tasks where seeing in space is problematic for students. We present here two errors that are widespread according to the teachers at the beginning of secondary school and that persist throughout compulsory schooling:

- Error 1 (E1): The student does not consider cubes or rectangular cuboids as prisms.
- Error 2 (E2): The student does not identify properly the base of a prism or a pyramid in a non-prototypical position.

From the point of view of our theoretical framework, E1 and E2 are characteristic of a relationship of knowledge that does not conform to the one expected by the institution. EP1 leads for example to difficulties with perceiving geometric properties shared by different solids as this requires identifying components or figurative units and their relationships, which EP1 does not allow. EP2 comes from observation of real objects and leads for example to always identify the base of a solid as a face on which the solid sits on. E1 and E2 errors prove the non-mobilization of EP3.

### Phase 2: Diagnostic assessment

To investigate these statements, we analyzed the outcomes of a diagnostic assessment administered to 40 grade 6 students (11-12 years old, two classes) who have not had yet teaching of geometry in space. The test consisted of two exercises: classify given solids by family and identify a base for each of the given solids. The solids are represented by drawings in cavalier perspective. E1 and E2 errors were present in all students, confirming the statements collected from the focus group teachers. We note that only EP1 and EP2 are present in students' personal praxeology for these types of tasks. We assume that we can evaluate changes in ways of seeing in space with respect to the presence of these errors in students' productions. We can therefore test the following hypothesis:

The dimensional construction technique makes it possible to develop the EP3 praxis in the students' personal praxeology.

### Phase 3: Design and implementation of tasks in Handwaver environment

With the two teachers, we have designed a scenario to allow students to implement the dimensional construction PMOdim\_prism and PMOdim\_pyramid (Table 1). The scenario outlined below was implemented by each of the two teachers in their 6th grade class of 20 students who passed the diagnostic assessment and whose results are reported above. It should be noted that this was the first session where the notions of prisms and pyramids were introduced at this level of class.

**Figure 2. The classroom setting and the generation of a prism using the stretch operator**

The implementation went through the following phases in the classroom setting shown in Figure 2 (left):

- Introduction of the activity and demonstration of the environment by the teacher
- Generation of solids in the environment by students with the stretch or the extrude operator - one student manipulated at a time, the others observed the screen (Figure 2, right)
- Classification, by each student, of the solids generated on the basis of the techniques used by the group (mental re-mobilization and reversibility of techniques)
- Discussion, argumentation, validation of the students' classifications (development of a discourse on techniques) - whole class
- Institutionalization by the teacher of prisms and pyramids in relation to the techniques used
- Mental reinvestment of the techniques considering a disc (to generate either a cylinder or a cone) - whole-class discussion

#### **Phase 4: Post-test**

A post-test was administered to the students 10 days after the session. As the students were on a school trip during these 10 days, they did not have any mathematics lessons during this period.

**Figure 3. The set of solids from the post-test**

The post-test includes the following two exercises:

- Classify the solids in the families of prisms, pyramids, or other.

- Color a base of the solid on each figure (if possible).

In terms of MO, the type of task underpinning the first exercise is “Identify prisms and pyramids in a set of solids in cavalier perspective” (T1) and the type of task underpinning the second one is “Identify the base of solids in cavalier perspective” (T2). The test includes 12 solids represented in cavalier perspective whose visible faces are colored to avoid perceptual aberrations. Among the solids are 5 prisms including a cube and a rectangular cuboid, 4 pyramids, 1 cone, 1 cylinder of revolution, and 1 sphere (Figure 3). A particular attention was paid to draw some of the solids in a non-prototypical position.

## Findings and discussion

In the analysis of the post-test results, we focus on those that are relevant to the types of tasks T1 and T2. We obtain the following success rates:

- 79% of students correctly solved T1 (68% for prism and 93% for pyramids).
- 75% of students correctly solved T2

If we consider only the object in the post test who can generate the errors E1 and E2:

- Error 1 (E1) 70% of students correctly solved T1 (Fig:1, 2)
- Error 2 (E2): 59% of student correctly solved T2 (Fig: 3, 4, 7, 9, 10, 12).

Even if we have not submitted a real pre-test, only a diagnostic assessment, the very significant decrease in the presence of E1 and E2 in student production seems indicate the non-mobilization of EP1 or EP2. The new technique used by student is more relevant, that could indicate the mobilization of EP3 and could be link to the PMOs used in the VR environment. This seems to confirm our hypothesis and the a priori analysis of stretch and extrude ostensives in terms of their instrumental and semiotic valence. However the solids generation by extrusion is not new, it is often used in an imaginative way by teachers or in CAD software used by students in technology teaching. Yet mistakes persists. The novelty in VR lies in the use of a behavioral interface that affects the graphical and gestural registers of the ostensive. We must consider how cognition operates within constraints imposed by our physiology. First about the graphical register, artificial environments can use computer technology to create metaphorical representations in order to bring to students concepts and principles that normally lie outside the reach of direct experience. (Winn, 2003). Secondly about the gestural register, in the embodied cognition approach, the mathematical concept of dimensional construction that we mobilized in our experiment, could be considered as a conceptual metaphor (Nunez, 2009), grounded in bodily-based mechanisms : the stretch gesture like stretching gum from a ball to a thread (from a 0D to 1D object), or pulling a blind down (from a 1D to 2D object). So we can suppose in our case that students can easily accept that stretching a polygon makes a 3D object so they can mobilize spontaneously this technique later.

## Conclusion

The VR activity implemented seems to have helped students develop a heuristic understanding of drawings in cavalier perspective, based on the identification of figurative units of smaller dimensions, and thus helping to better see in space. In a VR environment we call presence the belief that you are “in” the artificial environment, not in the laboratory or classroom interacting with a

computer. The coupling effect leads to a permeability at the cognitive level between the real world and the artificial world. An environment considered as real by users but where we program the interactions and rules, open a field of great opportunities for learning.

# Students' perceptions in a situation regarding eigenvalues and eigenvectors

José Orozco-Santiago<sup>1</sup>, Carlos-Armando Cuevas<sup>1</sup> and Luc Trouche<sup>2</sup>

<sup>1</sup>Center for Research and Advanced Studies of the National Polytechnic Institute (Cinvestav-IPN), Mexico; [jorozco@cinvestav.mx](mailto:jorozco@cinvestav.mx), [ccuevas@cinvestav.mx](mailto:ccuevas@cinvestav.mx)

<sup>2</sup>Institut français de l'Éducation, ENS de Lyon-, France; [luc.trouche@ens-lyon.fr](mailto:luc.trouche@ens-lyon.fr)

*In this study we investigate conceptualization processes among university students in solving a problem involving concepts of eigenvalues and eigenvectors in a linear algebra course for engineering. In the pilot phase of the study, we examined a case study of two first-year linear algebra students and analyzed the data through the theory of instrumental genesis in a dynamic geometry paper-and-pencil environment.*

*Keywords: Linear algebra, Eigenvalue, Eigenvector, Scheme, Instrumental genesis.*

## Introduction

Linear algebra is one of the first abstract mathematics courses engineering students take in their early years in college. According to Robert and Robinet (1989), when first encountering linear algebra, students express concern about the use of formalism, the overwhelming number of new definitions and the lack of connection between this new field and their existing knowledge of mathematics. Dorier and Sierpiska (2001) distinguish two inseparable sources of difficulty for students in learning processes: the nature of linear algebra itself (conceptual difficulties) and the kind of thinking necessary for the understanding of linear algebra (cognitive difficulties).

After the Linear Algebra Curriculum Study Group (LACSG) recommended the use of technology in early linear algebra courses (Carlson, Johnson, Lay, & Porter, 1993), some teachers began to incorporate Computer Algebra Systems (CAS) into their classrooms. At the same time, several researchers studied the reflexive use of technological tools in classroom teaching/learning processes (involving both the tool and the mathematical content), which gave rise to the *instrumental approach to didactics* as a central theoretical framework (Artigue, 2002; Guin, Ruthven, & Trouche, 2005; Trgalová, Clark-Wilson, & Weigand, 2018).

Eigenvalues and eigenvectors are important concepts in the study of linear algebra (Gol Tabaghi, 2014; Meel & Hern, 2005), and they require an understanding of other concepts such as vector spaces, linear transformation, bases and dimension, among others. In this paper, we present the preliminary results of our doctoral research, whose objective is to orchestrate a teaching situation appropriate for introducing the concepts of eigenvalues and eigenvectors in a traditional course on linear algebra. For this part of our research, we pose the following question: what utilization schemes does the student experience / develop when faced with a geometry task involving the concepts of eigenvalues and eigenvectors?

## Theoretical framework

The French mathematics education community (Artigue, 2002; Guin et al., 2005) has extended the instrumental approach (Rabardel, 2002) to the learning of mathematics through the reflexive use of technological tools. Rabardel thus defines an instrument as a “mixed entity made up of an artifact

and a scheme” (p. 37), retaining Vergnaud’s notion of scheme, as “the invariant organization of behavior for a certain class of situations” (Vergnaud, 1998, p. 167). To understand the function and dynamic of a scheme, we must take into account its components. These include one or several goals, each with its sub-goals and anticipations; rules to generate action, information seeking and control; its operational invariants (concepts-in-action and theorems-in-action); and the possibilities of inferences within the situation. Artifacts are associated with two kinds of utilization schemes: usage schemes and instrument-mediated action schemes. Two different users can approach the same artifact differently, develop different utilization schemes, and create two different activities and instruments (Alqahtani & Powell, 2017, p. 14). For a subject, the artifact becomes an instrument through a process, called *instrumental genesis*, “involving the construction of personal schemes or, more generally, the appropriation of social pre-existing schemes” (Artigue, 2002, p. 250). According to Trouche (2004), instrumental genesis is a complex process that requires time, and is related to artifact’s characteristics and the subject’s activity. In instrumental genesis, two processes coexist: instrumentalization and instrumentation. “*The instrumentation process is the tracer of the artifact on the subject’s activity, while the instrumentalization process is the tracer of the subjects’ activity on the artifact*” (Trouche, 2014, p. 311). In a technological environment, interactions between student and artifact must be organized with specific didactic intentions. The crucial role of teachers in this process was soon recognized. To characterize the teacher’s role in guiding students’ mastery of tools and their learning processes, Trouche (2004) introduced the notion of *instrumental orchestration*. An instrumental orchestration consists of two main elements: didactical configuration and exploitation modes.

## Methodology

In this paper we present the results of a single task, part of a larger study whose objective is to design an orchestration of a situation to introduce the concepts of eigenvalues and eigenvectors in a first course on linear algebra for engineering students. The task was designed by the teacher, in conjunction with the researcher. The study was carried out in the spring of 2018 and included a case study. The research involved eight volunteer students averaging nineteen years old, all enrolled in a "Fondamentaux des Mathématiques II" class at a public university in France. The session lasted 120 minutes. The students had experience in matrix calculation, vector spaces, and linear transformations, but they had not yet addressed eigenvalues and eigenvectors. They also mentioned having some previous experience with the Dynamic Geometry Environment (DGE), in this case GeoGebra. The students were told that we would be studying the way they solved the problem, or the techniques used, and that they would not be graded. Each student was given the paper assignment and each group (of 2 or 3) was provided with a laptop with GeoGebra and Internet access. The data was collected from observation and field notes by a researcher external to the experiment, and lasted about 120 minutes. For our analysis, we selected two students: Cécile and Henry.

## Mathematical context and task design.

An eigenvector of an  $n \times n$  matrix  $A$  is a nonzero vector  $\vec{x}$  such that  $A\vec{x} = \lambda\vec{x}$  for some scalar  $\lambda$ . A scalar  $\lambda$  is called an eigenvalue of  $A$  if there is a nontrivial solution  $\vec{x}$  of  $A\vec{x} = \lambda\vec{x}$ ; such an  $\vec{x}$  is called an eigenvector corresponding to  $\lambda$  (Lay, Lay, & McDonald, 2016). Here we consider  $n = 2$ ,

by the availability of a DGE (GeoGebra), considering the potentiality of the *dragging* tool “wandering dragging” (Arzarello, Olivero, Paola, & Robutti, 2002).

The task (see figure 1) was not designed to evaluate the student’s progress in the course. Rather, it was restricted to having the students to work on  $\mathbb{R}^2$  in order to study their conceptualization of eigenvalues (real) and eigenvectors of 2x2 matrices, specifically in solving the first two points in a single class period of 30-50 minutes.

Given the following two rectangles.

1. Find a process to build a linear application  $f$  that sends the rectangle OABC to the rectangle ODEF.
2. Apply this process when the points have the following canonical coordinates:  $A\left(-\frac{1}{2}, 1\right)$ ;  $B\left(\frac{3}{2}, 2\right)$ ;  $C(2, 1)$ ;  $D\left(-\frac{3}{4}, \frac{3}{2}\right)$ ;  $E\left(\frac{13}{4}, \frac{7}{2}\right)$ ;  $F(4, 2)$   
And build the matrix  $M$  of  $f$  in this basis
3. In GeoGebra, we code a matrix with the braces  $M = \{\{a, b\}, \{c, d\}\}$ . We can create a  $u = \text{Vector}((1, 1))$  then move its end and apply the matrix  $M$  by  $\text{Vector}(M * u)$ . Model the previous situation and check the values.
4. Can we find a vector  $v \in \mathbb{R}^2$  such that  $f(v) = \lambda v$  for a certain real  $\lambda \in \mathbb{R}$ ? What are the possible values of  $\lambda$ ? What are the possible vectors for a given  $\lambda$ ?
5. Let  $v_1 = \overrightarrow{OC}$  and  $v_2 = \overrightarrow{OA}$ . Give the matrix of the linear application  $f$  in this database.

**Figure 1. The task discussed in this document**

The students are invited to develop intuitive notions of eigenvalues and eigenvectors associated with the matrix  $M$ , in the environment of GeoGebra, by means of a draggable vector  $\vec{v}$  and its vector image  $M\vec{v}$ , as the vector  $\vec{v}$  is dragged around the screen, the vector  $M\vec{v}$  moves accordingly. To find an eigenvalue of the matrix  $M$  geometrically, the student will have to drag a position where  $\vec{v}$  and  $M\vec{v}$  are collinear, in order to explore the relationship involved in the equation  $A\vec{x} = \lambda\vec{x}$ , and to recognize that there is an infinite number of eigenvectors associated with each eigenvalue.

### Instrumental orchestration of the class

The main objective of the orchestration is to introduce and use the concepts of values and eigenvectors in a first course on linear algebra. The secondary objective is to analyze a geometric problem in a paper-pencil environment and in a DGE to explore the problem and validate the solutions proposed by the students. It is defined by a didactical configuration (students organized in heterogeneous working groups, with access to GeoGebra) and exploitation modes (each group

analyzes the problem and proposes solutions using a combination of paper-and-pencil work and GeoGebra; the group is free to ask questions of the teacher and each participant's role is identified).

## Data Analysis

The students followed the steps given in the task. Question # 1 can be identified as the phase of data selection, solution strategies and operation to be performed to solve the task:

- A transformation (matrix) that stretches the rectangle horizontally and another transformation (matrix) that stretches it vertically, then a composition of transformations;
- Display a matrix  $M$  of  $2 \times 2$  that  $M\overrightarrow{OC} = \overrightarrow{OF}$  and  $M\overrightarrow{OA} = \overrightarrow{OD}$  (matrix-vector);
- Display a matrix  $M$  of  $2 \times 2$  that  $M\overrightarrow{OC} = 2\overrightarrow{OC}$  and  $M\overrightarrow{OA} = \frac{3}{2}\overrightarrow{OA}$  (matrix-vector-scale),
- Discover the matrix  $M$  by trial and error with the help of GeoGebra (trial-and-error).

### First Case: Cécile.

The components of Cécile's "matrix-vector" scheme were:

Goal: find a linear transformation, such that $T(OABC)=ODEF$	Sub goals: -Identify the possible relations of parallelism and collinearity -Recognize the proportionality constant $k$ ( $k \in \mathbb{R}$ ), such that $\overrightarrow{OF} = k_1\overrightarrow{OC}$ and $\overrightarrow{OD} = k_2\overrightarrow{OA}$ -Check that the result fulfills the conditions of the problem.
Anticipations	Know that you have more than one way to solve the problem--either DGE or paper-and-pencil.
Rules of action	-If I find a matrix that when multiplied by $\overrightarrow{OC}$ , gives $\overrightarrow{OF}$ , then that same matrix must when multiplied by $\overrightarrow{OA}$ , give $\overrightarrow{OD}$ . -If I find a matrix and enter it into GeoGebra, I can test the solution.
Operational invariants	<i>Concepts-in-action</i> - Two vectors are collinear if they can be placed one on top of the other or they are on the same straight line <i>Theorems-in-action</i> - TA1 If when moving the vector $\vec{u}$ both clockwise and counterclockwise, the opening (angle) between the vector $\vec{u}$ and the vector $\vec{v}$ decreases so that the vector $\vec{u}$ superimposes the vector $\vec{v}$ , then the matrix $M$ has an eigenvector - TA2 If the opening (angle) between the vector $\vec{u}$ and the vector $\vec{v}$ does not decrease when the vector $\vec{u}$ moves both clockwise and counterclockwise, then the matrix $M$ does not have an eigenvector.
Possibilities of inference	-If I find a matrix $M$ that when multiplied by $\overrightarrow{OA}$ gives $\overrightarrow{OD}$ , there is a $3/2$ relation.

**Table 1: Elements of Cécile's utilization scheme**

Cécile began by using the paper-and-pencil technique. From the rectangle OABC, she identified  $\overrightarrow{OA}$  and  $\overrightarrow{OC}$  as the vectors:  $\overrightarrow{OA}$  and  $\overrightarrow{OC}$ . In the rectangle ODEF, she also identified  $\overrightarrow{OD}$  y  $\overrightarrow{OF}$  as the vectors:  $\overrightarrow{OD}$  y  $\overrightarrow{OF}$ . She defined a  $2 \times 2$  matrix which multiplied by the vector  $\overrightarrow{OA}$  must give the vector  $\overrightarrow{OD}$ , and which multiplied by  $\overrightarrow{OC}$  must give the vector  $\overrightarrow{OF}$  (see figure 2). From the two systems of linear equations obtained, Cécile grouped the equations with the same unknowns into two  $2 \times 2$  systems and, after solving the two systems, built the matrix  $M = \begin{bmatrix} -19/10 & 39/5 \\ 1/5 & 8/5 \end{bmatrix}$ .

$$M = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$M * OC = OF \rightarrow \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 2 \\ 1 \end{bmatrix} = \begin{bmatrix} 4 \\ 2 \end{bmatrix} \rightarrow \begin{cases} 2a + b = 4 \\ 2c + d = 2 \end{cases}$$

$$M * OA = OD \rightarrow \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} -1/2 \\ 1 \end{bmatrix} = \begin{bmatrix} -3/4 \\ 3/2 \end{bmatrix} \rightarrow \begin{cases} -\frac{1}{2}a + b = -\frac{3}{4} \\ -\frac{1}{2}c + d = \frac{3}{2} \end{cases}$$

**Figure 2. Cécile's working to find the matrix M**

Cécile said she had rarely used GeoGebra in her previous courses, so she requested support from a partner to be able to input the matrix. Afterwards, she input the operations  $M * C$ ,  $M * B$  and  $M * A$ , creating points G, H and I (names automatically assigned by GeoGebra). When entering the operations, she observed that the points obtained did not coincide with the points D, E and F. In fact, she observed that two of the three points did not coincide. She first checked her notes to see if she had made some arithmetic error but was still unable identify the problem, so she turned to the teacher for support. The teacher reviewed Cécile's worksheet and pointed out an arithmetic-algebraic error. Cécile then corrected the solutions to the equation system, obtaining the matrix  $M = \begin{bmatrix} 19/10 & 1/5 \\ 1/5 & 8/5 \end{bmatrix}$ . Cécile entered this matrix in GeoGebra and performed the operations  $D' = M * A$ ,  $E' = M * B$  and  $F' = M * C$ . This time the points coincided, so the matrix M obtained was considered acceptable.

Proceeding on to question 3, Cécile focused her attention on the edges of the rectangles, mentioning that "while I drag the vector  $\vec{u}$  towards the base of the rectangle, the vector  $\vec{u}$  follows the vector  $\vec{v}$  and reaches it at the base" and "while I drag the vector  $\vec{u}$  towards the height of the rectangle, the vector  $\vec{v}$  pursues the vector  $\vec{u}$  and reaches it exactly at the top." She continued, "when the vector  $\vec{u}$  is exactly the same as the base OC, the vector  $\vec{v}$  is twice  $\vec{u}$ , i.e. if  $\vec{u} = (2,1)$  then  $\vec{v} = (4,2)$ , but when  $\vec{u}$  is approximately the base OC, there is a difference of hundredths, between  $\vec{v}$  and twice  $\vec{u}$ , i.e. if  $\vec{u} = (1.13, 0.57)$  then  $\vec{v} = (2.27, 1.13)$  (indicated in the Algebraic View). Cécile is able to observe that  $\vec{v} = 2\vec{u}$  when  $\vec{u} = (2,1)$ , and that only then is  $\vec{v} = 2\vec{u}$ ; with other values, she notes,  $\vec{u}$  fails to reach twice  $\vec{u}$ , due to decimals. Cécile fails to calculate the other eigenvalue and fails to intuit the concepts of eigenvalue and eigenvector.

At this point, we observe that in Cécile's instrumentation process, the tool guides her attention and the instrumentalization process is recognized by the "wandering dragging" functionality. Gol Tabaghi called this dragging modality "*intentional dragging*--which involves dragging a point with the intention of producing a certain configuration" (p. 234).

### Second Case: Henry.

The components of Henry's scheme are:

Goal: find a linear transformation, such that $T(A)=D$ , $T(B)=E$ , $T(C)=F$ .	Sub goals: -Identify the possible relations of parallelism and collinearity -Verify that the result fulfills the conditions of the problem.
Anticipations	Know that you have more than one way to solve the problem--either DGE or paper-and-pencil.

Rules of action	- If you succeed in matching point E' with point E, you will have found the matrix M.
Operational invariants	<i>Concepts-in-action</i> - Two vectors are collinear if they can be placed one on top of the other or they are on the same straight line <i>Theorems-in-action</i> - If the vectors $\vec{v}$ and $M\vec{v}$ are linearly independent, then the matrix M does not have an eigenvector - If the vectors $\vec{v}$ and $M\vec{v}$ are linearly dependent, then the matrix M has an eigenvector.
Possibilities of inference	- If the vectors $\vec{v}$ and $M\vec{v}$ are dependent, then $\lambda = \ M\vec{v}\ /\ \vec{v}\ $ .

**Table 2: Elements of Henry's utilization scheme**

Henry used a trial-and-error scheme with DGE. Since Henry had experience with GeoGebra, he created four sliders-- $x_1$ ,  $x_2$ ,  $x_3$  and  $x_4$ --and then, with the sliders, he created a  $2 \times 2$  matrix  $M$ :  $M = \{\{x_1, x_2\}, \{x_3, x_4\}\}$ . The interval that he defined for the four sliders was -5 to 5, increments of 0.1; finally he introduced the three points E', D' and F' (see figure 3).

Henry commented that if he could match point E' with point E, the other points (D' and F') would be superimposed as well. On his first attempt, Henry managed to match point E' with point E (see figure 3), but contrary to what he thought, the other two points (D' and F') did not overlap. Subsequently, through trial and error, by moving the sliders, he managed to obtain the matrix M. Henry mentions that the elements of the matrix are decimals, which could cause the points to "overlap, but they are not equal." At this point we believe that Henry saw points E and E' overlapping, and noted that their values were the same in Algebraic View (3.25, 3.25), but the E and E' do not overlap exactly, i.e., they show a slight offset. Henry then turned to the GeoGebra *Relation*<sup>1</sup> tool to verify that they were in fact the same. He did not use paper-and-pencil.

To resolve question 3, since Henry had already entered the matrix M in GeoGebra, he entered only the vector  $u = \text{Vector}((1,1))$  and  $v = \text{Vector}(M * u)$ . Then he began to drag  $\vec{u}$  clockwise. Henry used the "Algebraic View" in GeoGebra to observe the numerical values and relied on the Relation tool to explore the relationships between  $\vec{u}$  and  $\vec{v}$ . As the vector  $\vec{u}$  was brought closer to the  $\overline{OC}$  segment, he used the Zoom tool to make sure that they were able to overlap, and continued until the two vectors  $\vec{u}$  and  $\vec{v}$  lay one on top of the other. Henry said: "of course,  $\overline{OC}$  and  $\overline{OF}$  are collinear," and to avoid further approximation he modified the vector  $u = (2,1)$ . "When  $\vec{u}$  is (2,1)," Henry continued, "the vector  $\vec{v}$  is twice  $\vec{u}$ ." He then wrote  $M\vec{u} = 2\vec{u}$ , stating that 2 is  $\lambda$ . With this same analysis he once again modified the value of  $u = (-0.5,1)$  and said: "uff, they're decimals, I think the value is....I'd better check it..." Henry then used the *Distance or Length* tool to calculate the norm of  $\vec{u}$  and  $\vec{v}$ . And after calculating the rules he said that in fact  $\lambda = 1.5$ .

<sup>1</sup> This command shows, in a message box, the relationship between two objects. It allows you to verify whether two lines are perpendicular/parallel, two (or more) objects are equal, or three points are collinear, among others. ([https://wiki.geogebra.org/en/Relation\\_Command](https://wiki.geogebra.org/en/Relation_Command))

**Figure 3. Henry's technique for finding the matrix M**

Once finished, Henry began working with the "matrix-vector-scalar" scheme using paper-and-pencil. In obtaining the linear equation systems, Henry represented the systems as lines in the plane and obtained the values through their intersections, concluding satisfactorily with the matrix M. We conclude that Henry displays a good level of instrumentation and instrumentalization of the DGE.

### Preliminary conclusion

Using the above tasks, we were able to observe the schemes that students develop, and the difficulties they may encounter, when using the concepts of eigenvalue and eigenvector before formally addressing them in class and when the problems arise outside the context in which they have been taught (given a matrix, obtain its eigenvalues and eigenvectors). The conceptualization of eigenvalues and eigenvectors is a long and continuous process, in which the teacher plays an important role by carefully choosing situations that allow the mathematical knowledge to be meaningful. We believe that the success of Henry's scheme was possible because the elements of the matrix M are exact, and they lay within the interval that he had defined from the beginning (-5 to 5). When dragging  $\vec{u}$  and observing the change in  $\vec{v}$ , the participants were prompted to look for relationships between these two objects and relate them to the matrix obtained. The use of GeoGebra helped Henry with his conceptual difficulties, while Cécile showed a better conceptual knowledge, relying on geometrical thinking. In this experience we were unable to determine whether the students recognized the existence of an infinity of eigenvectors associated with each eigenvalue. Our future research will study two questions: What orchestrations can help the teacher foster the students' development of conceptual knowledge? And, how can students be helped to recognize how many different eigenvectors are associated with a given eigenvalue?

### Acknowledgment

We are grateful to Prof. Christian Mercat and the students of the University Claude Bernard Lyon 1, for allowing us to conduct this research.

# Why digital tools may (not) help by learning about graphs in dynamics events?

Sonia Palha

Amsterdam University of Applied Sciences, Centre for Applied Research on Education (CARE),  
Amsterdam, The Netherlands; [s.abrantes.garcez.palha@hva.nl](mailto:s.abrantes.garcez.palha@hva.nl)

*Understanding graphs representing dynamic events is a challenge for many students at all levels. And technological tools can provide support in overcoming some of these difficulties. In our research we developed a digital tool that enables students to create, modify and improve graphs from dynamic events using interactive animations and intrinsic feedback. In order to get insight about why the tool helped (or not), the students we conducted a qualitative study in which we interviewed nine students who used the tool. The results offer insight in students' learning and thinking about dynamic graphs and how digital feedback can afford that. These results are useful for researchers, developers and teachers.*

*Keywords: visualization, intrinsic feedback, graphs, interactive tool, learning with technology.*

## Introduction

Dynamic graphs remain an essential subject at all levels of High School in mathematics, but it remains a challenging topic for students and even for teachers (Carlson, Larsen, & Lesh, 2003; Moore & Carlson, 2012). Reasons behind students' difficulties frequently involves problems in visualizing change and variation, limited understanding of functions and co-variational reasoning. Moreover the construction of a global graph from a realistic situation and stretch is similar to mathematical problems solving and requires mathematical thinking (Moore & Carlson, 2012; Thompson, 2011). Digital tools can support students to deal with these difficulties in several ways. Dynamic software as Geogebra and applets can support students in visualizing relations through enabling them to draw, move and modify graphs within different representations. And interactive applications that connects animations and graphs can be used to explore relationships between phenomena, and it's graphical representation. The learning potential of dynamic tools can be highly improved by including possibilities for students interaction with the tool like students' own productions and incorporated feedback-features (Laurillard, 2013). However, this also put more demands on the tools' design especially when they build upon students free-hand productions. More knowledge and research on students learning with this type of tools are needed to inform tool-developers and teachers.

Interactive Virtual Math (IVM) is an example of such a tool. It generates and builds upon students free-hand graphs, and it has incorporated feedback. The tool was developed through developmental research (Palha & Koopman, 2016) with the aim to improve students' learning about graphs by dynamic events. The tool creates opportunities for students to experience the thinking and reasoning that is needed to generate, revise and modulate a graph from themselves. When entering the tool they get tasks that encourages them to imagine two variables changing simultaneously. The tool requests the students to produce the graphical representation and the verbal explanation for this relation, which requires students to represent their concept image graphically and verbally. With the

help of the incorporated feedback, the student is challenged to think, reason and act upon his own construction. This is an innovative pedagogical feature of the tool that requires deep knowledge to be developed properly. The tool also includes the use of Virtual Reality (sound, movement, interaction), which is however very limited, but it is expected to improve the experience of the graphic situation.

Previous research (Palha, 2017) about IVM shows that students (age 13-17) find the tool useful because it assists them to improve graphs and/or to gain a more thorough understanding of the subject. The study was a teaching experiment involving three classes at secondary and one class at tertiary education in The Netherlands that used IVM during one lesson (45-50 minutes). Seventy-nine students reported through questionnaires about their experience with the tool and what supported them the most. However, this data didn't provide us much in depth knowledge about the way students improved their graphs and why. During the experiment we also interviewed nine students, and we collected their backlog files in the tool. This data has been analyzed recently, and it provides us with new insights on learning with the tool.

In this paper we report the results of these qualitative analyses. We use the framework for covariational reasoning of Carlson, Oehrtman, & Engelke (2010) and the notion of intrinsic feedback (Laurillard, 2013) to interpret and evaluate the way students utilized the tool. The guiding research question is: how does the tool enable students to improve their graphical representation and/or understanding about dynamic events?

## **Theoretical background**

### **Learning about dynamic graphs**

An example of a dynamic event is the following situation: imagine a bottle filling with water. Sketch a graph of the water's height in the bottle (Carlson et al., 2010). To solve the bottle-task, the students will need considering how the dependent variable (height) changes while imagining changes in the independent variable (volume). The coordination of such changes requires the ability to represent and discern relevant features in the shape of the graph. These mental actions are in the core of covariational reasoning and are clearly defined in the framework of Carlson et al., (2010). The authors define covariational reasoning as entailing five mental actions: (M1) coordinating the value of one quantity with changes in the other; (M2) coordinating the direction of the change; (M3) coordinating the amount of change of one quantity while imagining successive changes in the other quantity; (M4) coordinating the average rate of change of the function with uniform increments of change in the input variable; (M5) coordinating the instantaneous rate of change of the function with continuous changes in the independent variable for the entire domain of the function.

Several researches (Thompson, 2011; Saldanha & Thompson, 1998; Castillo-Garsow, Johnson, & Moore, 2013) reported students' difficulties in engaging with the mental activities M4-M5. These students also have difficulty explaining why a curve is smooth and what is conveyed by an inflection point on a graph. According to Carlson et al., (2010). Students should have opportunities to experience the covariational nature of functions by dynamic events. Thompson (2011) too states it is critical that students first engage in the mental activity to visualize a situation and construct relevant quantitative relationships prior to determining formulas or graphs. Ellis (2007) suggests

that learners should be helped to focus on quantities and generalizations about relationships, connections between situations and dynamic phenomena.

### **Intrinsic feedback**

Technological tools can be designed to help to create a learning environment that fits the characteristics mentioned in the previous section. The learning environment that we have in mind involves learning from experience and by reflection on ones' own productions. These are underlying ideas in theories that account learning as an active and social process. With the use of specific type of tasks, students can translate their concepts into practice. They can compare and evaluate how well they achieve some learning goal. And employ this to improve their initial concept and practice and develop knowledge (Laurillard, 2013).

Digital tools with capability to provide intrinsic feedback can assist students with learning because they: (i) enable the students to modulate their concept image and generate actions that brings them nearby a goal and; (ii) use the feedback of the tool to modulate their practice and revise their actions. According to the framework of Laurillard learning occurs when students engage in a successive cycle involving these actions. Actions and feedback drive the internal modulate-generate cycle that links the students' conception to their repertoire of actions as practice. Through reflective observation students can modulate the abstract concept in the light of concrete experience and generate new actions as active experimentation (p.168).

The prototypical tool IVM aims at creating a practice environment for the learning about graphs by dynamic events, in which student engage in the internal successive cycles described above. Moreover, the tool incorporates features designed to engage students in modulate-generate-revise actions that foster the development of covariational reasoning Carlson et al. (2010). With the tool there is a sequence of trials, mostly with a cyclic character that need to occur and be repeated to assure learning (see table 1 with the description of the tool).

<i>Self-construction -task</i>	
Task	the tool sets a task to construct a graph from a non-trivial dynamic event
Learner	the learner draws a graph by the dynamic event and explains his/her thoughts
<i>Compare -task</i>	
Task	The tool displays a second task with a dynamic event that corresponds to the more common mistake made by learners with regard to this type of task
Learner	The learner uses the comparison to draw (if needed) an improved graph and/or adapt the explanation
Task	The tool offers a menu in which students can choose between seeing help or to submit their graph
<i>Help 3D-animation (optional)</i>	
Learner	The learner chooses help 3D-animation
Task	The tool displays an animated version of the dynamical event in which the same amount of water is added each time student presses a button
Learner	The learner notices that the height of the water increases in the jar and that, for the same amount of added water, the incremented heights are different and depending on the form of the jar; the learner reflects on these relations and becomes aware that the increment of the height is smaller when the jar is broader -in the middle and larger in the extremities. The learner uses the visualization to draw (if needed) an improved graph and/or adapts the explanation
<i>Help interactive animation (optional)</i>	

Learner	The learner choose help interactive animation
Task	The tool displays an animation of the dynamical event and an empty cartesian graph in which the learner can move given dots to the estimated height every time the same amount of water is added; both actions, adding the water by pressing a button and moving the dot are performed by the learner.
Learner	The learner moves vertically the first dot to the position he/she thinks that the height of the water will reach and then press the button. The water fills in the jar at a certain height. The learner compares the estimated and the reached height and uses the comparison to move the dot to a more precise location.
<i>Feedback at the end- reward feature</i>	
Learner	The learner submits his/her solution
Task	The tool displays the figure of the jar corresponding to the learner drawings
Learner	The learner compares the form of the jar with the initial form and reflects on the differences and similarities and on the relation between the graph and the shape of the jar. The learner can go again through the tool and use the visualization to draw an improved graph and/or adapt the explanation

**Table 1: description of the tool Interactive Virtual Math (IVM)**

## Method

We interviewed nine students from 10th and 11th grade who utilized the tool in the classroom: two boys (Niels and Abel) and two girls (Miriam and Jenny) from school A, 11th grade, 16-17 years-old; two girls (Olivia and Anne) from school B, 10th grade, 15-16 years-old and two boys (Gerry and Arion) and one girl (Manon) from school C, 10th grade 16 years old. In schools A and B students utilized a computer and construct the graph with the mouse. In the school C school students used a Iphone and draw with the finger. The interviews were semi-structured and focus on the way students used the tool and the reasons to modify or not the original graph. The interviews were performed by the author of this paper or by the teacher. They took about 5-10 minutes per student and were recorded in audio. Additional data included the results of a survey conducted during the lesson and the students productions registered in the tool self (backlog of the tool). The data analysis was qualitative and based on the covariational framework van Carlson et al. (2010) and the notion van learning cycles from Laurillard (2013).

## Findings

### Students transformed an incorrect graph into a correct graph with the tool (n=5)

To draw a correct graph students need to coordinate the average rate of change of the height as function of the volume and imagining it changing instantaneously with continuous changes in the independent variable (levels MA4 and M5 of the covariation framework). Analysis of the backlog of the tool showed that five from the nine students generated a correct graph, but only after a second or third trial. In their first trial these students sometimes draw straight lines instead of curves or draw a concave up-down graph instead of a concave down-up or an inaccurate global shape. This suggests that the students could reason at the levels MA2 or MA3 of the covariation framework at the start of the assignment. In the interview students were asked to explain how they transformed their graph and why they transformed it. Table 2 provides an overview of the way students engaged in the learning cycle and generated, modulated and revised their initial graph with the tool.

Students	How and why the graph was transformed and which tool-features enabled this
Jenny	Jenny <i>modulated her concept image</i> and <i>generated a better-shape graph</i> after two trials. The student used the feedback from the reward-feature to <i>revise</i> and <i>modulate the steepness</i> of the curves.
Niek	Niek <i>modulated his concept image</i> in two trials. The student used the feedback from the reward-feature to <i>revise</i> and <i>modulate</i> a concave up followed by a concave down graph into a correct graph.
Abel	Abel <i>modulated</i> his concept in two trials. The student used the feedback from the reward-feature to transform part of the graph (an increasing straight line) into a concave down curve.
Gerry	Gerry <i>modulated</i> his concept in three trials. The student used feedback from the reward-feature and help 3D-animation to <i>revise</i> and <i>modulate</i> three increasing straight lines into a concave down followed by a concave up curve and to improve the shape of the graph.
Manon	Self-construction of the graphs (with no formula) enabled Manon to reflect before drawing the graph and therefore <i>modulate her concept image</i> ; feedback from the reward-feature enabled her to <i>generate and revise</i> actions as she improved her graph. Both help-features were consulted but not used.

**Table 2: the tool enables students to produce a correct graph with the tool (n=5)**

All five students realized that their graph was not correct because of the feedback from the reward-feature. One student, Niels explained:

"when I saw the feedback at the end (...) you can work towards a nice graph and you know how it really should look like, because you know that at a certain point will be slower than elsewhere (...) " when your vase is inside you know that then you have to go to the other side (...) so first slowly and then faster instead of first faster and then slower "

Manon found the tool very instructive especially because the self-construction- task that challenged her to generate an action from her practice repertoire and reflect on it:

"I was already ready to put something in the Graphic Calculator or to do something like that. But this was not possible in this case and I really had to think: ok, what is happening here? what happens in the middle? what happens there ... and that I found very instructive"

Also Gerry, mentioned the self-construction task as a useful feature to visualize the graph.

"You start without having an idea of what looks like; you try to imagine yourself and then when you see the film you realize that it is very different from what you had thought up"

Gerry felt also helped by help 3D-animation and he explained why:

"you saw in the animation (3D) the round shape of the bowl and you saw better how the water was distributed. In the beginning that a lot more space had been taken and in the middle there is much wider and because of that the graphs were very different "

Further, all the students with exception of Abel considered that because of the tool they understand the subject better; Abel considered that he already understood the subject.

### **Students realized they had an incorrect graph and did not succeed in transforming their graph into a correct one with the tool (n=3)**

Three of the nine students (Olivia, Anne and Arion) have done two, sometimes three trials with the tool but were unsuccessful to generate a correct graph. Analysis of the backlog of the tool showed

that the students initially generated a graph with one or more straight lines, which corresponds to M2 in the covariational framework. Interviews with the students provided us with more insight about how students revised and modulated their graphs (Table 2).

Students	How the graph was transformed and which tool-features enabled this
Olivia	The first trial is an increasing straight line, the second trial is a concave down line and third trial is a concave up. The comparison-task and the feedback from the reward-feature enabled student to <i>modulate</i> her concept in the sense that the lines should not be straight. Olivia <i>generates</i> and <i>revise</i> actions when she produces new graphs with curves. She <i>revised</i> and <i>modulate</i> her graph but <i>she could not generate</i> a correct graph
Anne	In the first and second trial the graph is an increasing straight line and the slope of the second trial is smaller. The feedback from the reward-feature and help-3D animation enabled Anne to ( <i>partially</i> ) <i>modulate</i> her concept as she realized that the lines should not be straight. She <i>revised</i> and <i>modulate</i> her graph but <i>she could not generate</i> a correct graph.
Arion	In the first and second trials the graph has three increasing straight lines. The feedback from the reward-feature enabled student to <i>modulate</i> his concept: that the graph should not have straight lines. However, for technical reasons the student could not work with the tool and use the feedback to improve his graph.

**Table 3: the tool enables students to realize their mistake but not to improve it (n=3)**

Olivia considered that the tool helped her to improve the graph and she explained why:

“it really helped that in the end I converted my drawing into that shape, as a sphere because I saw a bit connection” (...) “If there is no straight line then there must be a concave up line or a concave down line – I will try both.

Olivia didn’t used the help-features because she doesn’t think that it would be useful to achieve her goal of drawing a correct graph. The visualization of the context is not the problem according to the student but the fact that she can’t draw the graphical representation:

“I went very often trying the tool because I was curious (...) with the movies I do not know much what I had to show”

The other two students did not consider that the tool helped them to improve the graph. Anne because the straight line remained a straight line and Arion because the tool didn’t work well and he could not keep trying (there were in some smartphone technical problems). For these students the intrinsic feedback provided by the tool enabled them to engage in the modulate-generate cycle and modulate their initial concept image towards a more sophisticated one (although not yet correct).

### **Students realized they had an incorrect graph but did not do nothing about it (n=1)**

Miriam was the only student who produces an incorrect graph and did not invest effort to improve it with the tool. In her initial trial she constructs an incorrect graph with three straight increasing lines, which corresponds to the mental action M3 in the framework covariational reasoning. She didn’t consult the help-features. In a second trial Miriam worked with a peer-student who produced a similar graph to her but with curves instead of straight lines. Noticing the difference enabled the student to *revise* and *modulate her concept image*. Additionally, her graph was discussed by the teacher in the classroom. This student only engaged in the learning cycle when the intrinsic feedback of the tool was combined with extrinsic feedback of a peer student and from the teacher.

## Conclusions and discussion

Learning dynamic graphs at secondary school represent a challenge for many students. In this study we investigate how and why the IVM-tool enabled students to improve (or not) their graphical representation of a dynamic event. We have seen that all nine students failed to produce a correct graph in a first trial with the tool. Five of these students could improve their initial graph and produced a correct graph in their subsequent trial. The features of the tool that supported them the most were to see the bottle-form correspondent to their graph at the end (reward-feature) and the opportunity to self-construct the graph, because it challenged them to think and try to imagine how the graph it would be. One student referred also to the animation 3D, which have encouraged him to imagine better “how the water was distributed” in the bottle and with relation to the graph. Three other students have tried improving their initial graph with the tool and although they could not produce a correct graph the tool seemed to have helped them to improve their thinking, as they became aware that the graph should not be linear or contain linear parts. They conclude this because of the reward-feature and in combination with other features (comparison-task or with the animation help-3D). One student only improved her graph when this was combined with extrinsic feedback from peer-student and the teacher.

Reflecting upon these results, we realize that even though the tool showed potential to engage students in thinking about mathematical graphs this was insufficient for all the students to generate an appropriate representation. These students realized with the help of the tool what they have done wrong and the feedback maintained them on the task. But the students did not successfully use these and other features of the tool to move forwards. Why did the tool not help the students? Analysis with the covariational framework suggests the three students possessed a limited understanding of covariational reasoning. What can seem to be a reason for students' difficulty in imagining the change of the height varying as function of the volume and (Thompson, 2011; Carlson et al., 2010). The tool contains two animations that were explicitly designed for students to engage in covariational thinking: the animation 3D and the interactive animation. But as our results showed none of the students consulted it or they only did it superficially. We cannot therefore comprehend how these features could have supported the students. Another feature of the tool that we had expected to help the students was the reward-feature and, in a certain way it did. The feedback assisted students to realize they were not constructing the correct graph but did not provide other directions or explanations that help them forwards. This is an aspect that requires further thought and investigation. In addition, expanding the tool with more tasks and different contexts is needed in order to offer students enough opportunities for exploring and practice covariational thinking and reasoning.

This study extends previous research about learning dynamic graphs and covariational reasoning. It adds knowledge about students thinking in contexts of change and their difficulties in constructing graphs from themselves. The results provide directions to improve the instructional environment of IVM that can be useful for teachers and researchers interested in using the tool. Further research is needed to gain more insight in the help-features and to improve the intrinsic feedback. We also need to investigate the learning with the tool in larger settings: with more students, teachers and

whole classrooms. The prototypical version of the tool presented at CERME 11 is available at <https://app.dwo.nl/dwo/apps/player.html#570660>.

# Learning environments applying digital learning tools to support argumentation skills in primary school: first insights into the project

Melanie Platz

University of Siegen, Department of Mathematics, Mathematics Education, Germany;

[platz@mathematik.uni-siegen.de](mailto:platz@mathematik.uni-siegen.de)

*Based on a cooperative project between the Europe University Flensburg, the University of Koblenz-Landau and the University of Siegen (Germany) on the development of an open source electronic mathematical proof system (cf [e-proof.weebly.com](http://e-proof.weebly.com)), a new project has evolved with a focus on primary education. The aim of this project is to support argumentation skills through the iconic and enactive visualization of reasoning processes. The focus is on supporting classical teaching and learning processes in primary education with digital learning environments. Grounded in the philosophy of pragmatism, Design Science research is performed for creating learning environments applying digital learning tools to support argumentation skills in primary school as artifacts. In this paper the first developed learning environment is presented and insights into the results of an empirical pilot study investigating the learning environment are given.*

*Keywords: Educational media, primary schools, argumentation.*

## Introduction

The demand of the Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany (KMK) is supposed to be addressed in this research project, that in dealing with the digitization of education the “primacy of the pedagogical” (KMK, 2016, p. 51) has to be followed and must be incorporated into educational concepts in which learning is in the foreground (KMK, 2016). Consequently, the potential of digital media for teaching can only unfold, if it is used in a meaningful and an educational reflected way. In this sense, a project on the development of learning environments applying digital learning tools to support argumentation skills in primary school is performed. The scope of this project is to identify opportunities and possibilities, as well as challenges and limitations of learning environments including digital media to support argumentation skills through the iconic and enactive visualization of reasoning processes and their influence on student learning. “In mathematics education, the teaching of reasoning skills plays a major role. These skills form the basis for proofs of mathematical statements and contexts dealt with in higher school-grades in different contexts. It is especially logical reasoning that supports the formation of understanding.” (Platz et al., 2017, p. 2). Wuttke (2005) performed a study, comparing different forms of educational communication in relation to their influence on the generation of knowledge and understanding among the pupils. This study has shown that it is in particular the argumentation in that a variety of connection possibilities to the students’ prior knowledge is provided through the exchange of different and well-founded perspectives, which therefore contributes particularly to understanding (cf. Budke & Meyer, 2015). In the present paper, a first draft version of a learning environment including an applet to be run on a hand-held device with internet-connection and touch-screen, e.g. a tablet PC, is presented. Design Science is performed for learning environment creation. The TPACK-Framework (cf. Koehler & Mishra, 2009) is applied to analyze the developed

learning environment and first insights into the results of an empirical pilot study investigating the learning environment are given.

## **Objectives**

The aim of the overall project is to create learning environments to support argumentation skills through the iconic and enactive visualization of reasoning processes. A central media aspect is to make the handling with teaching and learning material computer-detectable and thus, to infer optimized learning environments. The focus is on supporting classical teaching and learning processes in primary education with both digital and non-digital learning environments.

The objectives of this paper are to

1. employ the TPACK-Framework (cf Koehler & Mishra, 2009) to analyze the developed first draft of a learning environment applying digital learning tools to support argumentation skills in primary school.
2. give an insight into the results of an empirical pilot study investigating the first draft learning environment.

## **Research Method**

In order to optimize the learning environment, Design Science is applied. Design Science is grounded in the philosophy of pragmatism and creates artifacts which is something created by humans usually for a practical purpose. The learning environment applying digital learning tools to support argumentation skills in primary school is a method (artifact) (cf. March & Smith, 1995) to support pupils in gaining argumentation skills. Within the meaning of the Design Science Research Methodology Process according to Peffers et al. (2006), a problem was identified and an objective for a proposed solution was formulated (see sections “Introduction” and “Objectives”) for the first run of the process. Furthermore, an initial prototype was generated (see section “The developed Prototype and the TPACK-Framework”). For demonstration, the prototype (learning environment applying digital learning tools to support argumentation skills in primary school) was tested in an empirical pilot study (see section “The Empirical Pilot Study”) and first evaluation results are presented. The results are communicated among others through this paper. Through the first iteration of the process the prototype will be optimized.

## **The developed Prototype and the TPACK-Framework**

Koehler and Mishra (2009) describe the TPACK (Technology, Pedagogy, And Content Knowledge) framework as a complex interaction between three sets of knowledge: content, pedagogy, and technology. The interaction of these sets of knowledge, both theoretically and in practice, generates the kind of flexible knowledge needed to successfully integrate technology into the classroom (Koehler & Mishra, 2009). In contrast to the original purpose the TPACK framework was designed for, i.e. to be used as an analytical framework for a teacher’s different types of knowledge, it is used in a broader way as a framework that refers to knowledge in general. Taking a closer look at the developed first draft of a learning environment applying digital learning tools to support argumentation skills in primary school, an interaction of technology, pedagogy and content knowledge becomes visible. In the following sections, the learning environment is analyzed

concerning the Pedagogical Content Knowledge (PCK), the Technological Content Knowledge (TCK) and the Technological Pedagogical Knowledge (TPK).

### **Pedagogical Content Knowledge (PCK): Mathematical Proofs in Primary School**

The main task the pupils are concerned with in the empirical pilot study is the following<sup>1</sup>:

**Task:** *If you add two odd numbers together, you always get an even number.*

*Is that correct? Give reasons!*<sup>2</sup>

With respect to the argumentation chain developed by Bezold (2009) by formulating the task in this way, the pupils have to question the special attributes and find reasons or respectively reasoning ideas to solve the task. Krummheuer and Fetzner (2005) hold the opinion that proofing in the strictly deductive sense is not yet possible in primary school, but substantial mathematical argumentation (cf Toulmin, 1958, p. 116) can be implemented. Due to Kothe (1979), primary school children have fun on problem solving with appropriate instructions. Here, proof need is: “I want to show the teacher or classmates that my approach is right” (Kothe, 1979, p. 276). The awakening of a need for proof in primary education requires long-term didactic planning to seek opportunities for local sensitization to mathematical thinking, (Kothe, 1979). Semadeni (1984), describes an action proof as “a simplified version of a recommended way in which children can convince themselves of the validity of a statement; in practice, an action proof will require some preliminary or additional exploration”, (Semadeni, 1984, p. 32). In this study, the preformal proof according to Blum and Kirsch (1991) is focused with the aim to find a way to include proofs in primary education: In accordance with the concept of action proofs (cf Semadeni, 1984), a preformal proof can be defined as a chain of formally represented conclusions which refer to valid, not formally represented conclusions which refer to valid, non-formal premises. In contrast to the definition of an action proof, inductive arguments (“etc.”) and indirect arguments (“imagine that ...” or “what would happen if ...”) should not be excluded in this context. The conclusions must be capable of being generalized directly from the concrete case. If formalized, they have to correspond to correct formal-mathematical arguments. To accept a preformal proof it is, however, not necessary for such a formalization to be actually effected or even recognizable. Occasionally, the consensus within the mathematical scientific community is quite sufficient. Preformal proofs have to be valid, rigorous proofs, (Blum & Kirsch, 1991). The concept of a preformal proof is comparable to the concept of the operative or “intuitional” (or “inhaltlich-anschaulich”) proof (“see-proof”), (cf. a.o. Wittmann, 2014, p. 226). To describe the differences and relationships between proof and argument, Pedemonte (2007) refers to Peirce and Polya:

---

<sup>1</sup>The worksheet can be found at the following link: [http://www.melanie-platz.com/ES\\_1/Task\\_even-and-odd.pdf](http://www.melanie-platz.com/ES_1/Task_even-and-odd.pdf). In contrast to e.g. Wittmann & Müller (2013a), the formulation of the task is meant to be more open to enable more variety in the solution methods, as the structure of double rows is not unconditionally necessary, when operating with pairs of tiles.

<sup>2</sup>An example on how a preformal proof for the **Task** above could look like is made available at the following link: [http://www.melanie-platz.com/ES\\_1/Preformal-Proof\\_even-and-odd.png](http://www.melanie-platz.com/ES_1/Preformal-Proof_even-and-odd.png)

the logical connection between statements in an argumentation differs from the logical connection in a proof. Each step of a proof can be described as a deductive step. But argumentation structure is unlikely to be a deductive structure; it can be composed of steps of different nature, such as abductive steps or inductive steps. (Pedemonte, 2007, p. 29)

Pedemonte (2007) derives, that a structural change is required for the construction of a deductive proof, that is from abductive or inductive steps to deductive steps. To enable a support of argumentation skills, the pupils worked together in groups of two, to foster communication between the pupils. Communication is important to gain argumentation competences, as one aspect pupils should learn is to respond appropriately to reasoning in interaction with others (Budke & Meyer, 2015).

### **Technological Content Knowledge (TCK): reversible tiles as representation**

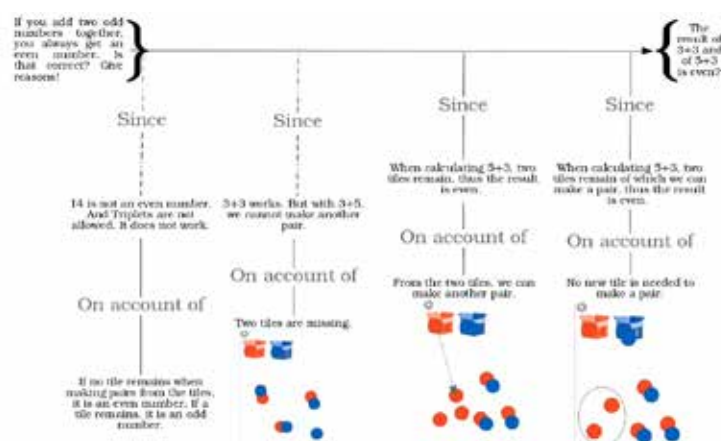

The reversible tile applet is a prototype of a freely available JavaScript-applet developed by the author of this paper, which allows the virtual laying of (reversible) tiles. The applet is available at <http://www.melanie-platz.com/WPA/>. Tiles are a fundamental means of representation in primary education (cf. Wittmann, 2014). Based on the categorization of Krauthausen (2018), the tiles are used in the function of working material and illustrations as argumentation and proving tool. Wittmann (2014), states that this material is from its origin not didactic, but of epistemological nature. The preformal proof stimulated by the *Task* mentioned above is not grafted from the outside, but deeply connected with the nature of numbers. Around 600 BC, Pythagoras and his students discovered and proved universal number-theoretic patterns when laying stones (Wittmann, 2014; Wittmann & Müller, 2013b). “It can be said without exaggeration that stones (tiles) form the cradle of number theory” (Wittmann & Müller, 2013b, p. 142).

### **Technological Pedagogical Knowledge (TPK): The reversible tile applet**

The developed applet is especially suitable for digital devices with touchscreen display (e.g. tablet PCs), which allow a control through touch gestures with the fingers. The tiles in the app are created similar to the analogue tiles. Because of the two-dimensionality of the screen, the tiles are also two-dimensional and cannot be lifted up, as it is the case with the analogue tiles. In the case of the present study, the tool is used in the sense of activist learning as an illustrative tool and to be given to the learners as tool of their own mathematical activity (cf. Krauthausen, 2018). In order to ensure a certain openness of the use of the applet, no structuring aids are given. The applet can thus be used in the function as a medium of argumentation and proof. Referring to the SAMR-Model (Puentedura, 2010), the first step of enhancement can be covered with the developed applet in the learning environment, which is substitution of the analogue material. The second step of enhancement, augmentation (technology acts as a direct tool substitute, with functional improvement), can be rudimentary covered. One advantage of the reversible tile app is that the organizational handling is more suitable for everyday use (to be quickly provided or put away in an orderly manner) than with analogue tiles, as single tiles cannot disappear within the app.

## The Empirical Pilot Study

In the framework of a school visit in May 2018 at the Maths Lab “MatheWerkstatt” at the University of Siegen (Germany), a fourth-grade school class of a local regular school containing 23 pupils took part in the empirical pilot study. The school class was separated into groups of six or respectively five pupils who worked at different learning stations during their two hours stay at the university. For the learning station three tablets were made available where pupils worked in groups of two using one tablet per group and discussing their ideas and results. In each of the four cases, one group of two pupils of the three groups of pupils was videographed and the tablet screen was screencasted, both with audio recording. This possibility of the screencast is an advantage of the technology use, because the touch-gestures performed by the pupils coming with their oral argumentation can be captured. Each group worked for 20 minutes at the learning station. The recorded material was transcribed and sections were extracted, where information on the argumentation process and on the User Experience (UX) could be discerned. From these sections, video vignettes were extracted and the argumentation process was represented in a model as it is described below (see Figure 1).

**Figure 1: Exemplary representation of an argumentation process in the pilot study; the diagram can be read like a timeline from left to right; the dashed lines mark refutation trials of the assertion; screenshots with markings visualize the action of the pupils while speaking**

To investigate and understand preformal proof and argumentation processes, a diagrammatic representation is developed and evaluated. This is in line with van Gelder (2005) who represents the opinion, that a diagrammatic representation of complex argumentation was developed, because

everyone knows that complex structure is generally more easily understood and conveyed in visual or diagrammatic form [...]. Interested in argument but dissatisfied with the tools offered by the logical tradition, Toulmin developed a simple diagrammatic template intended to help clarify the nature of everyday reasoning. (van Gelder, 2005, p. 4)

Nevertheless, Toulmin himself applied his layout to mathematics: as an example, Theaetetus's proof that there are exactly five platonic solids is visualized in Toulmin et al. (1979). Aberdein (2005) concerns with the application of Toulmin's layout to multi-step proofs. Pedemonte (2007) uses Toulmin's model as a methodological tool to compare proof and argument. "This model can be used to detect and analyse the structure of an argumentation supporting a conjecture (abduction, induction,

etc.) and the structure of its proof” (Pedemonte, 2007, p. 23). Reid et al. (2011) investigate the potentials of the refutation of arguments visualized in an adapted model of Toulmin’s layout. The ideas of Reid et al. (2011) are similar to the representation of arguments of Miller (1986). Miller (1986) works with structure trees in order to analytically grasp argumentation processes. A combination of these models is applied to represent the argumentation processes in the pilot study, see Figure 1. Furthermore, in orientation to a framework developed by Barendregt and Bekker (2003), the User Experience of the children while working within the learning environment, was investigated.

## Results

With regard to the User Experience, the applet itself seems to be intuitive and the pupils did not have problems in using the applet. No introduction on how to control the applet was needed. One pupil of the test group did not like to work with tiles, as this was found “childish being already in grade four”. The argument of the pupil was, that they had already learned to calculate until one million and tiles were only needed to calculate in grade one. From the conversation with the pupils, it seems likely, that the task was not really understood, i.e. no real need for proof (Kothe, 1979) was awakened. In the example visualized in Figure 1, it seems like the pupils did not understand the reason for making pairs of the tiles. This can be inferred from the interpretation of the pupils’ actions visualized in the screenshot of the third backing, when the pupils added new red tiles to build pairs instead of making pairs of the red tiles representing the number 5 which they already got out. As the need for proof did not seem to be awakened, it is not possible to reconstruct a structural change for the construction of a deductive proof (Pedemonte, 2007) from the conversation of the pupils.

## Discussion

The prototype (learning environment applying digital learning tools to support argumentation skills in primary school) was analyzed via the TPACK-Framework and tested in an empirical pilot study and needs to be optimized through the first iteration of the Design Science Process. Due to Kothe (1979), the awakening of a need for proof in primary education requires long-term didactic planning to seek opportunities for local sensitization to mathematical thinking. This is supposed to be reached with an optimized prototype of the learning environment. One important issue for an optimization is to give the pupils more time and instruction, to initiate an understanding of why a proof is needed. Due to Kothe (1979), primary school children have fun problem solving with appropriate instructions. Here, proof need is: “I want to show the teacher or classmates that my approach is right”, (Kothe, 1979, p. 276). To support this creation of proof need, a new prototype should incorporate the theory of discovery learning (cf. Winter, 1989). Discovery learning is based on the idea that knowledge acquisition and progress and the ability to work in problem solving skills happens “by own active action and recourse to the already existing cognitive structure, but usually stimulated and thus made possible by external impulses” (Winter, 1989, p. 3). Furthermore, a central media aspect shall be to make the handling with teaching and learning material computer-detectable and thus, to derive optimized learning environments. One research field is the investigation of “gestures” made by the pupils on a touch screen with relation to semiotics (cf. Peirce, 1931-1935). Huth (2013) states that gestures in particular, can at least temporarily take over the function of possibly unavailable or not possible inscriptions. Such “gestures” can be made detectable with the help of digital media, and automated evaluation and help selection are supposed to be provided. With implementation of these

functionalities, the first step of transformation according to the SAMR-Model (Puentedura, 2010) can be reached, which is modification, i.e. the technology allows for significant task redesign and enables other possibilities to handle heterogeneity in a school class.

## Acknowledgments

I especially thank the working group of primary school education of the Institute of Mathematics and Computer Science Education, Goethe University Frankfurt, around Prof. Dr. Rose Vogel for the very enriching meetings and discussions. Furthermore, I thank Dr. Eva Hoffart (Institute of Mathematics Education, University of Siegen) for the opportunity to perform the empirical pilot study in the framework of the “MatheWerkstatt-Seminar” and Kathrin Holten for her very helpful comments.

# Digital media support functional thinking: How a digital self-assessment tool can help learners to grasp the concept of function

Hana Ruchniewicz and Bärbel Barzel

University of Duisburg-Essen, Germany; hana.ruchniewicz@uni-due.de, baerbel.barzel@uni-due.de

*Developing functional thinking is a central objective in mathematics education. Students especially need to internalize three aspects of functions: mapping, covariation, and object besides learning to translate flexibly between various representations. However, many learners struggle to recognize and interpret functional relationships. To help these students, a formative self-assessment approach with digital media offers new possibilities. Technology can support understanding not only due to the use of multiple, dynamic, interactive, or linked representations, but offer a constraint-support structure to guide students' actions. We present two case studies in form of task-based interviews from the third cycle of a design-based research study that aims at the development and evaluation of the “self-assessment for functional thinking electronic” (SAFE) tool. The cases show how certain technological features of the SAFE tool support learners' self-assessment and functional thinking.*

*Keywords: Digital media, technology, functions, formative self-assessment, metacognition.*

## Why support functional thinking?

Many real-world phenomena, such as measuring the temperature at a weather station over a period of time, can be comprehended functionally. Because of this variety of applications and its importance to grasp further mathematical concepts, the discussion of functional relationships is central in many mathematics curricula. For example, it is one of five key content domains in lower as well as upper secondary mathematics education in Germany. Although the function concept is fundamental in the learning of mathematics, many students have difficulties in its comprehension. Thus, they need support to acquire ‘functional thinking’. For this reason, we use a formative student self-assessment approach as it has proven to enhance student learning (Stacey & Wiliam, 2013).

## Theoretical Background

### Formative self-assessment and metacognitive activities

According to Wiliam and Thompson (2008), formative assessment (FA) can be conceptualized in five key strategies. These regard mainly the teacher to be responsible for FA. Especially in computer-based assessment, features such as automatic feedback, a limitation of students' responses by e.g. multiple choice formats, or a focus on measuring achievements (Stacey & Wiliam, 2013), leave little room for students to recognize, reflect upon and react to their work. This is why, the FA framework by Wiliam and Thompson was refined in the EU-project FaSMEd to allow formative self-assessment to be understood as a process performed, observed and reflected on by students. It is conceptualized in these five key strategies (KS): 1) understanding learning intentions and criteria for success, 2) eliciting evidence of understanding, 3) providing self-feedback, 4) activating peers as instructional resources for one's learning, and 5) regulating one's learning process. However, strategy four is only relevant when observing formative self-assessment in classroom situations (Ruchniewicz, 2017). For

all these strategies, but especially for the fifth, learners need to use metacognitive activities. They describe the procedural component of one's metacognition. This means all actions of regulation of one's cognitive activities in learning processes. They include: 1) *planning* problem-solving steps with appropriate mathematical tools, 2) *monitoring* in form of controlling tool-use and comparing what is achieved to set goals, and 3) *reflection* on given problems or understanding of mathematical concepts (Cohors-Fresenborg, Kramer, Pundsack, Sjuts, & Sommer, 2010). To enable students to self-assess their functional thinking abilities, this mathematical content needs careful consideration.

### **Functional thinking**

Functional thinking is a didactical concept, that describes all mental images learners need to build and use when dealing with functions, their representations, and their applications in modelling and problem solving to gain a comprehensive understanding of the function concept. "Functional thinking is a way of thinking, that is typical for working with functions" (translated from Vollrath, 1989, p. 6). Three aspects, noticed in German didactics today as Grundvorstellungen (GVs), characterize this "typical" and allow for various views on functions (Vollrath, 1989): 1) *Mapping*: a function assigns exactly one value of a dependent quantity to the value of an independent one. As such a unique mapping, it is viewed in a local and static way. 2) *Covariation*: in a dynamic view, a function describes how two quantities change in relation to one another. While the independent quantity runs through a set of values from a domain, it causes the values of the dependent quantity to change accordingly. 3) *Object*: a function viewed globally is a mathematical object, that has its own specific properties (e.g. characteristic graph, symmetry) and can be operated upon.

Although the three GV's of functions apply for all forms of semiotic representation, they can appear variously according to a function's visualization. Usually, students interact with functions represented verbally, numerically, symbolically, or graphically. The mapping aspect, for instance, is highlighted when calculating a y-value by inserting the x-value into an equation. By contrast, the covariation aspect is of interest when looking at the change of a graph's values for an interval of x-values. Each representation emphasizes different properties of the function (Duval, 2006). Thus, it is central for functional thinking that students learn to work with and translate between various representations. This leads them to a comprehensive understanding of the function concept (Duval, 2006).

Due to the concept's complexity, such a comprehension and, thus, the acquiring of functional thinking is challenging. Numerous misconceptions are described in regards to learners struggling to conceptualize functions. For example, Clement (1985) states that many students falsely treat graphs as literal pictures of the underlying situations (graph-as-a-picture mistake). Others overgeneralize function types or properties, such as using linear functions in inappropriate situations (illusion of linearity). Further, students might swap the x- and y-coordinates or disregard the uniqueness of a function (e.g. Hadjidemetriou & Williams, 2002; Leinhardt, Zaslavsky, & Stein, 1990). To react to such misconceptions and support students' self-assessment, digital media offer new opportunities.

### **Digital media**

Digital media have the potential to enhance formative self-assessment by altering the assessment process due to changes in, e.g. the nature of tasks, types of feedback, or even assessed skills. What is more, they present new chances for learning by e.g. providing dynamic or interactive representations

of mathematical objects (Drijvers et al., 2016). Various studies examine if the use of technology improves achievements. In an ICME survey concerning lower secondary learners, Drijvers et al. (2016, p. 5) summarize: “[t]he overall image is that the use of technology in mathematics education can have a significant positive effect, but with small effect size.” The authors conclude that existing studies give hints for whether achievements can improve, but do not explain why (Drijvers et al., 2016). To answer why digital media can support functional thinking, it is necessary to consider their potential and appraise it against possible risks. Following, we list some of the most important arguments for teaching, learning and assessing functional thinking with digital media:

1) *Fast availability of representations*: Quickly available visualizations of functions leave time for examining functional relationships, generating examples, or checking one’s hypotheses. Yet, the large amount of representations and speed of their availability might lead to a complexity that hinders students to reflect on their actions (Barzel, Hußmann, & Leuders, 2005). Cavanagh and Mitchelmore (2000, p. 118), for instance, identified the tendency “to accept whatever was displayed in the initial window without question” as one of three typical mistakes of 10th and 11th graders asked to interpret linear and quadratic graphs on graphic calculator screens. Students did not reflect upon the visual image on screen or relate it to an inserted algebraic equation (Cavanagh & Mitchelmore, 2000).

2) *Multiple representations*: The aspect of fast availability plays a key role when it comes to screening various representations of the same function at once. Each one stresses different aspects of a function (Duval, 2006). Simultaneous visualizations can support the construction of mappings between those aspects and the translation between representations, which helps learners to solve problems quicker and conceptualize functions (van Someren, Boshuizen, de Jong, & Reinmann, 1998).

3) *Dynamic representations*: In static media, variations of a mathematical object need to be observed, interpreted, and projected upon its representation by the user. Dynamic representations let students experience these changes directly (Kaput, 1992). Especially the covariation GV of functional thinking can, thus, be supported by digital media as the investigation of changes in function values is easier.

4) *Interactivity and linked representations*: Digital media permit „not simply to display representations but especially to allow for actions on those representations“ (Ferrara, Pratt, & Robutti, 2006, p. 242). Moreover, it is possible to link representations so that the variation of one is automatically reflected in another. Such links enable learners to investigate functional relationships as they provide immediate feedback and encourage them to change between representations. Although interactive and linked representations offer great potential to support functional thinking, the technological speed entails the risk of students being overwhelmed by quick changes in visualizations and driven to act upon them without reflection (Zbiek, Heid, Blume, & Dick, 2007).

5) *Effecting student actions*: Student actions are effected by a digital tool’s design. If learners are asked to draw a function graph, the technology might supply them with a suitable coordinate system. Kaput (1992, p. 526) refers to a tool’s “constraint-support structure” stating that “whether a feature is regarded as one or the other does not depend inherently on the material itself, but on the relation between the user’s intentions and those of the designer of the material and the contexts for its use.”

In our study, these arguments for using digital media to support functional thinking guide the design of a digital self-assessment tool and offer hypotheses for the analysis of students’ learning processes.

## Methodology

We use design-based research that aims at developing and evaluating the SAFE tool (Ruchniewicz, 2017; Ruchniewicz & Barzel, in print). Several versions of the tool are designed, investigated, and re-designed. This cyclic process is guided by the following research question: *How do certain technological features of the SAFE tool support students' self-assessment and functional thinking?*

### Design of the SAFE tool

The SAFE tool's aim is for students to be self-assessors and, thus, no direct feedback is generated. For all tasks, users compare their answer to a sample solution and evaluate on their own whether it is correct or which steps to take next in their learning. The design means to create a balance of providing enough information and autonomy for learners. Therefore, the SAFE tool intends to assess and repeat basic competencies after they have been taught. The learning conjecture is the ability to sketch graphs based on given situations as this reflects a key aspect of functional thinking. The SAFE tool runs as an iPad application and consists of five parts: *Test*, *Check*, *Info*, *Practice*, and *Expand*. These are joined in a hyperlink structure and labelled with various symbols for easy user orientation (fig. 1).

**Figure 1: Hyperlink structure of the SAFE tool**

Students start by solving the *Test* task, which presents the story of a bike ride and asks them to draw a time-speed graph. They can label the axes using drop-down menus and sketch the graph directly on the screen using their fingers. Afterwards, they move to the task's sample solution. It consists of a simulation of the situation that is linked to one possible solution graph. The simulation can be started and stopped by the user and a qualitative speedometer can be viewed as well (fig. 3a). The learner moves to the *Check*, that provides five statements regarding important aspects about the graph in question alongside common mistakes that could arise. For each statement, the student decides whether it is true or false for his/her own solution. For this diagnostic step, the *Check* includes a pictorial visualization of the situation together with a static representation of the sample graph and the learner's own solution in the same coordinate system (fig. 3b). If an error is identified, the student can choose to read an *Info*, which entails a general explanation to repeat basic ideas about the function concept and specifies them in the time-speed context of the *Test* task, or work on a specified *Practice* task. If the initial graph is correct or a student checks all statements, he/she is presented with two more *Practice* tasks as well as an *Expand* task with a more complex context.

### Data collection and analysis

We use case studies in form of task-based interviews with individual students. The interviews are videotaped, transcribed, and analyzed qualitatively. Three subject groups are included: grade 7–9 students (aged 12–15) as they are novices regarding the function concept; grade 10 students (aged 15–16) as they have to repeat curricula contents of years 5–10 for a state-wide assessment; and 2<sup>nd</sup> semester university students in their bachelor in mathematics education (aged 19–22) as they are experienced, but often need to repeat basic competencies in the transition from school to university.

This paper presents two cases from the third design cycle, which give a first glance of the latest SAFE tool's potential as data collection is not completed. So far 3 interviews with year 9 and 5 with university students are recorded. One university student solves the *Test* and self-assessment without difficulties. One younger student shows poor knowledge of the content and does not recognize graphs as representations of functions. She is unable to identify her mistake on her own. Six learners show similar self-assessment processes. As the diagnostic step of assessing their solution to the *Test* occurs when viewing either the *Test solution* or *Check*, two of the (university) students were chosen as cases to represent both of these ways of self-assessment. As our focus is assessment, the learner's work with other tool parts (*Info*, *Practice*, *Expand*) is not included, as it portrays their next steps of learning.

For data analysis, we use qualitative content analysis with deductive categories. Additional inductive categories will be developed once data collection is completed (Mayring, 2000). In relation to our theoretical basis, three main categories with different subcategories were identified to guide analysis:

Student self-assessment	Functional thinking	Technological features (TF)
Key strategies (KS)	GVs	Linked simulation & graph (TF1)
Metacognitive activities (MA)	Change of representations (CR)	Multiple representations (TF2)
	Misconceptions (M)	Constraint-support structure (TF3)

**Table1: Categories guiding the case studies' qualitative content analysis**

## Results

The *Test* task, that students use for the diagnostic step of their self-assessment, asks them to draw a time-speed graph for this situation: "Niklas gets on his bike and starts a ride from his home. Then he rides along the street with constant speed before it curves up a hill. On top of the hill, he pauses for a few minutes to enjoy the view. After that he rides down and stops at the bottom of the hill." Paul and Ayse solve the task and describe their reasoning in the interviews (fig. 2). Thus, they elicit evidence of their own understanding (KS2). Afterwards, they both move to the sample solution (fig. 3a).

**Figure 2: a) Paul's and b) Ayse's *Test* solution and reasoning**

Paul starts the simulation, stops it when the bike starts to ride uphill and says: "The first thing I saw was that it is assumed that not - (points at the origin in the sample graph) so that he does not start

directly with constant speed (points along the first increasing graph segment) but that starting from home is also its own time period. That means that you also have to consider that he has to start first and that he is not at any speed at first.” Thus, the linked simulation encourages him to reflect his own solution. He identifies a mistake in his answer by realizing that he previously did not model the first part of the situation, namely starting the bike ride from home. Afterwards, he resumes the simulation and stops it again when the bike stops on top of the hill: “Okay, and then he becomes again, when he rides up the hill, that he does not reach the speed with which he rides uphill at once, but that the speed decreases in shifts.” Here, Paul reflects part of his answer (riding uphill) by comparing it to the sample graph. He recognizes that the speed and, thus, the graph cannot decrease suddenly, but that it slows down with time. Even if Paul does not realize that his graph disregards the uniqueness of the underlying functional relationship (vertical lines in his solution, fig. 2a), the simulation does inspire him to observe the covariation of the quantities time and speed more closely.

Ayse watches the entire simulation at once and directly moves on to the *Check*. Her screen shows the checklist and a multiple visualization of the bike’s path together with her own and the sample solution’s graph in one coordinate system (fig. 3b). Ayse reads checkpoint 2: “I realized correctly when the graph is increasing, decreasing, or remaining constant.” Relating to this, she assesses her solution: “Basically yes, but the duration! So with the variable with the time, so I should have much longer (points to the part of her graph that models the bike stopping on top of the hill) along zero – should have gone along the x-axis when he stops for a few minutes.” Thus, she denies the statement of the checkpoint for her answer and crosses it off (fig. 3b). The checkpoint together with the multiple representation of the functional relationship prompt Ayse to reflect on her solution and discover an error regarding her graph’s slope: while she depicted the bike stopping on top of the hill only as one point of her graph reaching the x-axis, the tool reveals that it should be a constant graph segment with the value of zero. Her reflection shows that Ayse did regard the variation and value of the dependent quantity (speed) while drawing her graph, but she missed to consider the change of the independent quantity (time) as well. The SAFE tool helps her to focus more on the covariation of both quantities.

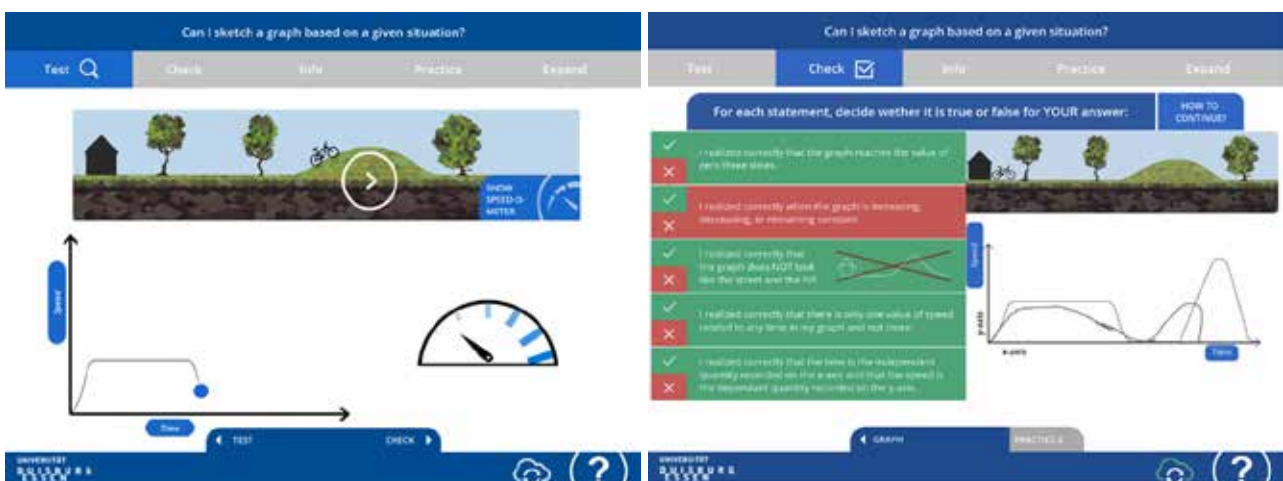

Figure 3: a) Linked simulation and graph as the *Test*’s sample solution, b) Ayse’s *Check* screen

## Conclusion

The two cases of Paul and Ayse show that the SAFE tool can support students' self-assessment and functional thinking. This becomes apparent when considering how the analysis' categories of self-assessment, functional thinking, and technological features interact with each other in the interviews.

Paul's case reveals that an interactive representation of a simulation linked to a graph (TF1) stimulates him to use the metacognitive activity of reflection (MA3). Further, he starts and stops the simulation several times in order to evaluate different aspects of the graph, which shows that his reflection is supported by this tool functionality (TF3). He evaluates his own graph by comparing it to the sample solution and identifies his own mistakes while regulating this process (KS5). Paul realizes that he missed to model part of the situation (start of bike ride) and translate it into its graphical representation (CR). For another part of the situation (riding uphill), he focusses on the covariation of both quantities. While he initially assumes a more prototypical graph with many constant segments (fig. 2a, M), he addresses a non-linear decrease of the graph's slope to model the bike slowing down when looking at the simulation (GV2). In his reflection, he shows an understanding of criteria for success, namely translating all parts of the situation and correctly sketching the graph's slope (KS1). Additionally, he describes how to change his initial work to correct it, thus, giving himself feedback (KS3).

Likewise, Ayse's case shows that the SAFE tool encourages a reflection of her solution (MA3) and points her attention towards the covariation of both variables (GV2). Her reflection is initiated by the *Check*'s multiple representation of the situation together with her and a sample graph (TF2) as well as a provided checkpoint (TF3). Ayse grasps that change in both variables needs consideration when sketching graphs (KS1). Finally, she formulates a self-feedback (KS3) and regulates her assessment process by reflecting her work, identifying a mistake and crossing off the checkpoint (KS5).

Both students use four key strategies of formative self-assessment and the metacognitive activity of reflection when working on technological features, such as multiple, interactive, and linked visualizations. This enhances their functional thinking by shifting the learners' focus towards the Grundvorstellung of covariation, paying attention to the graph's slope, and translating the entire situation into a graphical representation of the underlying functional relationship. Future investigations of students' work with the SAFE tool will reveal whether these findings can be generalized to inform the design of other digital media to support learners' conceptions of functions.

# Exploring pre-calculus with augmented reality. A design-based-research approach

Florian Schacht<sup>1</sup> and Osama Swidan<sup>2</sup>

<sup>1</sup>University of Duisburg-Essen, Faculty of Mathematics, Germany, [florian.schacht@uni-due.de](mailto:florian.schacht@uni-due.de)

<sup>2</sup>Ben-Gurion University of the Negev, Be'er Sheva, Israel, [osamas@bgu.ac.il](mailto:osamas@bgu.ac.il)

*This paper reports on the development of a learning design addressing pre-calculus concepts using augmented reality-technology. In a first step, both task- and technology design-principles are derived from the research literature and both elements – tasks and technology – will be described and discussed. Within a first design-research cycle, the paper reports on experimental difficulties with the technology used for the first version of the AR-tool and the needs for the development of a second version. By doing so, the paper addresses technological constraints experienced in experimental situations and discusses alternative ways.*

*Keywords: augmented reality technology, pre-calculus concepts, design research*

## Introduction

This paper describes a first cycle within a design-based-research project, which aims at a better understanding of pre-calculus concepts by using augmented reality tools. Specifically, we emphasize the capability of AR to merge dynamic features of a real phenomenon (e.g. a moving object along inclined plane) with those of its mathematical representations, which can be displayed graphically and numerically (e.g. plotting points of graph, ordered pairs in a table of values), as well as the learners' own perspectives with respect to the phenomenon. Within the DBR approach (Gravemeijer, 1994; Prediger et al., 2015) we distinguish between two different layers of design-principles, namely the task and the technology design principles. Hence, this paper aims to discuss the design principles of the tasks and the technological tools of such an environment.

## Exploring pre-calculus concepts

One of the main goals of teaching pre-calculus concepts is to initiate experiences with functional relations. In calculus, students use quantifiable methods to explore certain characteristics of functions. It is essential to allow pre-calculus explorations though, in which such characteristics are not yet experienced as being standardized, formalized and quantified. That means that students need activities, in which they explore pre-calculus concepts in qualitative learning settings. A detailed exactification by introducing the concepts of rate of change, accumulation or derivative is part of a later stage within the learning process.

One way to design such learning activities is the use of real experiments. Inquiry-based enactment of scientific exploration shows how students can be engaged in learning activities, in which they conduct real experiments and - by doing so - develop the mathematical concepts. One key feature of inquiry-based learning approaches is the shift from deductive ways of teaching to more inquiry-based approaches in order to increase the students' interest in mathematics (Rocard et al., 2007, p. 2; Artigue & Blomhøj, 2013). Within such inquiry-based situations students formulate conjectures based on experimental experiences and ask for reasons and try to prove them (Lakatos (1976) speaks of the quasi-empirical nature of mathematics). Furthermore, the role of physical action and of bodily

experiences is highly important for the genesis of mathematical concepts (e.g., Edwards et al., 2009; Radford, 2014; Roth, 2009). For the context of functional reasoning Duval (2006) points out that different representation modes (like graph, table, symbolic expression) are necessary in order to grasp mathematical concepts in general and especially the concept of function.

On the basis of this very dense discussion we formulate the following content-specific design-principles:

- P1: Enable students to conduct their own experiences.
- P2: Use different representations to foster the mathematization.
- P3: Ensure enough room to verbalize the individual conjectures and to interact with other students in order to prove them.

## **The role of augmented reality**

In a mathematical representation of real phenomena, the correspondence between the original phenomenon and the mathematical representation is usually not acquired directly as an effect of a natural similarity (as in analogies and often in diagrams). For example, considering the function that models the fall of a ball, the graph that represents the relation between time and space does not provide a direct, sensory similarity between the actual position of the ball and the shape of the graph; rather, the analogy is between the numerical expression of the respective phenomenon and its graphic representation, which is spatial.

Within the design-research project described in this paper, we use an augmented reality technology to experience and explore the pre-calculus concepts described above. AR technology uses a wide spectrum of techniques for projecting computer-generated materials, such as text, images, and video, onto users' ordinary unaided perceptions of the real world (Kaufmann et al., 2005). Johnson et al. (2011) observe that AR can be especially used in order to support inquiry-based learning. Despite some educational suggestions, Wu et al. (2013) point out that the use of AR in educational settings still remains in its infancy. AR is commonly used by science educators to help students visualize scientific processes, such as chemical reactions, which cannot be observed easily in the real world (e.g. Wu et al., 2013). Importantly, Cheng and Tsai (2013) conclude that while research on the use of AR in educational settings has examined issues such as development, usability, and initial implementation (Blake et al., 2009; Sayed et al. 2011), students' inquiry skills and the learning processes within AR environments have largely been ignored in the scientific literature.

For mathematics education, Sommerauer and Müller (2014) found that most studies on mathematics education using AR examined the effect of this technology on learning spatial abilities (e.g., Kaufmann et al., 2005); this finding is not surprising, as 3D is one of the key affordances of AR. For example, Kaufmann and Schmalstieg (2003) developed a learning environment that allows students to act on and interact with geometrical objects in space. Similarly, Oronzco and colleagues (Orozco et al., 2006) developed an AR-rich learning environment to assist students in visualizing multivariable function curves and reported that it helped develop spatial reasoning and visualizability of 3D mathematical objects.

Within the research project, we will examine the way how a learning environment based on AR, given its ability to combine real-world experiments, real-time data regarding these experiences, and

symbolic systems that model them, may help to create the conditions whereby inquiry-based learning will be set into motion in a natural and productive way. This paper reports on the first design-cycle in developing an AR-tool and a learning environment. On the basis of the discussion of the technological aspects of using augmented reality and with reference to the design-principles P1-P3 we formulate the following technology-specific design principles:

- P1\*: The digital tool is used within a real experiment conducted by the students.
- P2\*: The digital tool augments the students experiments with different representations.
- P3\*: The provided data allows students to formulate conjectures and make qualitative experiences with pre-calculus concepts.

## **The Method of Variation inquiry**

This study is guided by the method of the Varied Inquiry (MVI) approach, which is a combination of two theoretical perspectives: the logic of inquiry (Hintikka, 1999) and the variation theory (Marton et al., 2004).

The main idea behind the logic of inquiry involves seeking rational knowledge by questioning (Hintikka, 1999). Hintikka (1999) conceived the process of seeking new knowledge as an interrogative process between two players. The first player (the inquirer) has the role of asking questions, and the second player has the role of answering and is called the verifier (or oracle). The former is the seeker of knowledge who tries to prove a conclusion to be reached from prior experiences or even from theoretical premises. The latter is considered the source of knowledge.

In order to design educational situations that may promote inquiry processes, Arzarello (2016) refers to the variation theory. The variation theory (Marton et al., 2004) defines learning as a change in the way something is discerned, i.e., seen, experienced or understood. According to this theory, meaning emerges as the learner focuses his awareness on the object of learning. In this case, some aspects of the object appear at the forefront of his attention. Yet, not all aspects are discerned at the same time or in the same way. In order to understand an object of learning in a certain way, various specific critical aspects must be discerned by the learner. To facilitate the discerned object of learning, Marton et al. (2004) proposed four interrelated functions (or patterns) of variation to be taken into account when designing educational tasks: (a) contrast: "...in order to experience something, a person must experience something else to compare it with"; (b) generalization: "...in order to fully understand what 'three' is, we must also experience varying appearances of 'three'..."; (c) separation: "In order to experience a certain aspect of something, and in order to separate this aspect from other aspects, it must vary while other aspects remain invariant"; and (d) fusion: "If there are several critical aspects that the learner has to take into consideration at the same time, they must all be experienced simultaneously" (Marton et al. 2004, p. 16).

In the MVI approach, Arzarello (2016) proposes that drawing students' attention to critical aspects, asking to vary them, and observing their effects on the phenomena may foster students' inquiry processes. The main idea of the MVI is creating challenging situations by varying some aspects of the phenomena (real-world or mathematical) while keeping the others invariant. Exploring various aspects of the same phenomena may lead the students to grasp the intended object of learning.

## Design and Tasks

This paper reports on a first design-cycle of a learning environment and a digital tool using augmented reality in order to develop a learning design for pre-calculus concepts. Such iterative design-cycles are essential within design-based-research approaches (van den Akker et al., 2006; Gravemeijer, 1994; Gravemeijer & Cobb, 2006; Prediger et al., 2015). Within this research paradigm, research and development are strongly connected (Bakker, 2018). A mathematical design consists of learning activities embedded in certain tasks. Hence, the role of the design-principles concerning the tasks is crucial and they should contain “several representations, several kinds of sensory engagement, and several question types” (Watson et al., 2013, p. 10).

<b>Galileo Experiment</b>	
<b>Task 1</b>  Release the cube from the upper side of the inclined plane. Observe the movement of the cube and answer the following questions. What drew your attention when you observe the cube? Write as many observations as you can. Make a conjecture, which one of the observations will change if the plane inclination changes! Make a conjecture what will change if the time is reduced and give reasons?	<b>Task 2</b>  Your task is to explore how the change of the plane's inclination may affect the movement of the cube. <ul style="list-style-type: none"> <li>A. How will the change of the inclination affect the movement of the cube?</li> <li>B. Change the plane inclination in order to verify or refute the conjectures you raised in (A). Do your conjectures change? If yes, why? If not, prove your conjecture.</li> <li>C. Can you find an equation that describes the movement of the cube movement? Why or why not? Justify your answer.</li> </ul>
<b>Task 3</b>  Your task is to vary the plane inclination in order to explore the motion of the cube. You are requested to explain and justify your answers using the graphic and numeric representations. <ul style="list-style-type: none"> <li>A. Explain the shape of the curve when the plane inclination changes?</li> <li>B. How do the differences between the y-values of the points on the graphs change when varying the plane inclination?</li> <li>C. Compute the differences of the distance differences. What can you observe? Why? Is your conjecture always true? Can you prove it?</li> </ul>	

**Figure 1: Learning environment to explore the Galileo experiment with Augmented Reality**

Based on the formulation of the design-principles above we have developed both elements (task and tool) in a first version. The design principles of the tasks were motivated by the MVI approach. Each task contains a real-world phenomenon and mathematical representations of the dynamic aspects of the phenomenon. The main idea of the design is to create different situations by varying some aspects of the phenomenon while keeping the others invariant (see table 1). For example, the first task may request students to explore the mathematical model of a ball rolling on inclined plane (as in the well-

known Galileo experiment). In this situation, the time elapsed and the spaces traversed of the ball vary, and the inclination plane angle is invariant. Hence, the crucial aspect of this task is the time-distance relationship. The second task requests students to explore the same situation as in task 1, but this time the angle of the plane is varied, and the students explore how this new situation affects the mathematical model. In this case, the students explore quadratic functions based on their graphs and numeric values. Exploring various aspects of the same phenomenon may lead the students to grasp the intended object of learning, namely, quadratic function and its properties.

Task	Mathematics	Crucial aspects
1	Non-propositional relationship	Time-distance relationship
2	Quadratic functions based on their graphs	Parabola, time-distance relationship
3	Quadratic function based on the second differences	Second differences of the space traversed, parabola, time-distance relationship

**Table 1: Mathematical ideas, the crucial aspects of the phenomenon**

### First design-cycle: prototype and discussion

This section describes the development of two different prototypes. Based on experiments with the first version of the developed AR-tool we identified various disadvantages of the technology in use. The discussion below highlights some of the features of both versions and discusses the reasons for the technological changes within the developmental process.

**Figure 2: (left side figure, version 1) coded color method for recognizing dynamic object; (right side figure, version 2) Cube movement augmented with graph and table of values**

*First Prototype:* We used MATLAB software in our first attempt to design the AR prototype. MATLAB has the ability to identify the dynamicity of an object and to present it graphically or numerically. To activate this option, the use of a video camera with high resolution is required and the dynamic objects should be color coded. In this way, the specific color given to the dynamic objects is traced and the dynamicity of the physical object is recognized. For example, a mass hanging on a spring was wrapped by yellow coloured paper as well as the beginning and the end of the spring are

coded by another colour (figure 2, left side). In this case, a camera followed the coded-colour papers. To recognize the coded colour paper, the users must calibrate and define the color to be traced in each new experiment. For recognizing the color properly—as a result to collect the data of the dynamic object correctly—a uniform distribution of light in the room is required. In fact, small changes in the light conditions changed the results significantly so that the values and graphs in the different augmented representations showed different results depending on the light conditions of the specific point of view.

*Second Prototype:* The several constraints that are required for the AR prototype to function properly, which are very difficult to ensure, obliged us to look for a new tool to design the AR prototype. We especially looked for tools that are insensitive to light and friendly for users. Therefore, in the second round of the designing, we decided not to use MATLAB in favour of using ARtoolKit library. ARtoolKit is an open-source computer tracking library for creating augmented reality applications that overlay virtual imagery on the real world. The developer's mission was to write an AR code to detect a moving cubic over an inclined plane. The cubic detection is done by using fiducial values or markers. The ARtoolKit provides several methods for tracking and detecting objects in the real world. The most primitive one is the marker-based tracking and detection. We used a specific marker from the markers-collection called “Hiro”. The marker is treated as a pre-defined input. The program extracts features from the input marker. Additionally, the program detects these features of the marker in each frame. The markers are attached to the cube in our experiment (figure 2, right side version), so that it allows the detection of the cube movement in real-time (presenting the distance vs. time function) while using a camera. The data is then displayed on the eyeglasses (see figure 2, right side). The type of eyeglass used is HTC VIVE Pro (<https://www.vive.com/eu/product/vive-pro/>). The data of the dynamic object is displayed graphically and numerically. Hence, one sees the real experiment augmented with the data. The data itself is displayed in different representations. Within the evolving graph, one can see a distance-time function graph. The graph itself can be displayed a set of discrete points, or as a continuous function graph. The table shows three columns: time, distance and the difference between two consecutive distances. Both the graph and the table of values are displayed, so that the students can relate and reflect on the relation of the different representation modes.

## Conclusion and Outlook

Based on both task- and technological design-principles we discussed a first cycle of the development of a learning design addressing pre-calculus concepts using AR technology. We have reported on the features of an AR-tool with disadvantages in the experimental situations and a second version, which is much more stable in the experimental situations. The outcome of the described iteration is an AR prototype that can be used in order to explore a dynamic real-life situation with mathematical concepts in the field of pre-calculus. The user wears eyeglasses and the data is displayed in different representation modes simultaneously.

The next step will be to conduct empirical experiments with students in order to study their conceptual developments when using the technology and to empirically evaluate the chosen design-principles.

*Although teaching according to a flipped classroom approach is being increasingly used in schools, it is still the case that this type of education is often teacher-driven, and that teachers play a dominant role in terms of determining learning objectives and materials. Recently, the definition of flipped classrooms is being changed, accordingly the approach is becoming more student-driven and teachers mostly start to play supportive roles. Thus, this new approach is currently referred to as the flipped learning approach. The aim of our research is to identify central elements for students when learning mathematics in flipped learning environments. Therefore, teaching scenarios were developed, applied at a higher secondary level and written feedback from pupils were obtained. The grounded theory based analysis of feedback suggests that it is crucial for students to work together, jointly generate knowledge, become active in determining learning paths and selecting materials.*

**Keywords:** *Flipped classroom, Flipped learning, Mathematics education, Student centred learning.*

## Introduction

Flipped Classroom Approaches (FCA) have been gaining popularity in education and in most cases, digital technologies are used to facilitate creating a flipped environment. Digital technologies include mathematics specific software products such as GeoGebra as well as communication and collaboration platforms such as Moodle or Mahara. In general, modern technologies have been becoming increasingly important in mathematics education. Nevertheless, using technologies should always improve students' learning process, and not simply appease them (Klein, 2002). Even though many scientists and practitioners describe education according to an FCA as progressive, there is already a development of this approach – the flipped learning approach (FLA). However, the terms Flipped Classroom and Flipped Learning are used synonymously in some scientific articles (e.g. González-Gómez et al., 2016; J. Lee, Lim, & Kim, 2017). But the approaches differ regarding their definitions and characteristics. The fact that the two approaches are still used synonymously may indicate that education according to an FLA has not been fully integrated into research and teaching. This can also be observed in the STEM education field, since recent publications use the approaches interchangeably and without differentiation (e.g. Gnaur & Hüttel, 2014; Ponikwer & Patel, 2018).

The first section will discuss the differences between an FCA and an FLA. Here, a special focus is placed on students learning mathematics and how these approaches are linked to social constructivism. Then, we will focus on our actual research question: Which components of an FLA are crucial for both students' well-being in such environments and students' motivation to participate in mathematics education? In order to achieve the research aim, data were collected and evaluated according to a grounded theory approach and action research. Finally, the thesis will discuss the results of the research and, from this, draw conclusions.

## Theoretical Background

This section defines the singularities and differences between FCA and FLA. Additionally, relations of these approaches to mathematics education and to the theory of social constructivism are described.

### Defining flipped classroom approaches

Even though FCA has been dealt with often at an academic level in recent years this form of education can be found in many classrooms, there is still no uniform definition of this educational approach (Enfield, 2016; Wasserman et al., 2015). But most FCA descriptions have common elements. The fact that direct instructions and passive learning activities take place outside classrooms characterizes many definitions of an FCA. The classroom time is then used for student-centred and active learning activities. This means that in pre-class phases of an FCA, mainly simple learning objectives are pursued and in in-class phases learners and a teacher try to achieve higher learning objectives (Wasserman et al., 2015).

In mathematics education it is quite common utilizing videos in pre-class phases and lessons are used for active, group-based or problem-solving activities. Recently, more and more research projects (e.g. Esperanza, Fabian & Toto, 2016) demonstrate that flipped classroom education can improve students' achievement in learning mathematics.

### Defining flipped learning approaches

Many assume that *flipped classroom* and *flipped learning* are similar terms used to describe more or less the same approach. To counter misconceptions, the Flipped Learning Network (FLN) (2014) composed a formal definition of the term “flipped learning”, as follows: “Flipped Learning is a pedagogical approach in which direct instruction moves from the group learning space to the individual learning space, and the resulting group space is transformed into a dynamic, interactive learning environment where the educator guides students as they apply concepts and engage creatively in the subject matter” (FLN, 2014). According to the FLN, an FCA does not necessarily lead to flipped learning. However, FLA can be considered as a development of FCA.

Implementing FLA into mathematics education should lead to flexible learning environments in which students could achieve higher cognitive goals, for instance by tackling real-world problems. Moreover, for the construction of different mathematical meanings, learners can be given the opportunity to make their own experiences and feel the need for an introduction of concepts or terms.

Although many studies have already explored implementing an FCA in mathematics teaching, there is a lack of research investigating flipped learning in mathematics education. In a few mathematics education research studies some elements of an FLA can be found (e.g. Weidlich & Spannagel, 2014). However, these learning environments are often not described according to an FLA.

### Social constructivism's influence on flipped learning environments

Social constructivism (SC) (Vygotsky, 1978) is a student-centred learning theory that emphasises importance of the social environments in which learners generate their knowledge themselves. According to SC, students are becoming more active to determine their learn path and teachers' role change from knowledge providers to supporters of the learning environments. FLA has already

incorporated SC in its initial development as in flipped learning environments learning is self-directed and seen as an active process. Moreover, students are also encouraged to learn through social interactions within their groups (Green, 2015).

## **Research design**

This section outlines the participants, the mathematical content and the procedures of our flipped learning experiments.

### **Framework of our flipped learning educational experiment**

The educational experiment was conducted with four classes (students aged from 14 to 16 years) at two different schools in Vienna – an urban college of business administration and a humanistic high school with a focus on classical languages. All four classes were already taught in a traditional flipped classroom setting. The educational experiment lasted between 6 to 7 teaching units and more than 110 students took part in it in total. The centre of education was formed by square functions and their applications. Since students from different types of schools were involved, the experiment was carried out according to the respective curricula of the 9th and 10th grade.

### **Proceedings of our flipped learning educational experiment**

At the beginning of the learning sequences, all students were informed about the tasks to be performed, the goals to be achieved and the deadline. In the college of business administration, students had to solve different tasks, which were made available via an online learning platform. There were also short interactive videos with integrated questions provided to check students' comprehension. Therefore, watching a video became an active process. In the high school, students had to research Leonardo bridges, build such a bridge themselves, and finally mathematically examine this self-built bridge. Students were able to use tablets (college of business administration), their own notebooks (high school) and other learning materials according to their preferences.

In all settings it was essential that learners were given tasks and objectives. However, the availability of time and technological tools enabled the students to self-determine the learning path. This availability should make it easier for learners to individualise learning processes themselves. The provision of modern technologies, as well as databases and communities on these technologies, should enable students to tackle higher mathematics.

Since experimental conditions in education in general, and in a flipped setting in particular, are difficult to produce (Reinmann, 2005) and our research interest focuses on exploring crucial aspects for students when learning mathematics in flipped learning scenarios, we decided on qualitative oriented research methods. Thus, approaches and methods of action research and grounded theory were used to collect and evaluate data.

## **Research aim and research methods**

Exploring which components are significant for students when learning mathematics according to an FLA is the aim of our research. In order to develop these new hypotheses and theories concerning FLA mathematics education, our research is designed according to qualitative research approaches.

The education sequences described above were planned and carried out by us, the authors. We had to assume both the role of a teacher and the role of a researcher. This should help to ensure that both practical and academic knowledge could be gained through the research process. For the action research McKernan's iterative model (McKernan, 1991) was chosen. This model is based on Lewin's four original action research phases: plan, act, observe and reflect (Lewin, 1946).

Additionally, a grounded theory approach (GTA) was applied to develop an FLA mathematics education theory. This theory is based on teaching records and on student feedback forms. Both data collection and evaluation follow GTA principles according to Strauss and Corbin (1990, 1997). Since both perspectives of researchers and the educational environment are of central importance, many elements of a constructive GTA according to Charmaz (2006) can also be found in the present research design. After the last lesson of this sequence, learners were asked to provide open written feedback on the FLA mathematics education experiment. The learners were asked to evaluate the positive and negative experiences and aspects. The feedback guidance was formulated openly and broadly, as on the one hand new hypotheses and theories were to be developed based on feedback forms. On the other hand, precise guiding questions were omitted in order to reduce the risk of students answering as they think teachers would like them to. We were able to achieve a complete survey of all students, which provided 110 feedback forms. First, feedback forms were fully transcribed and openly coded. This led to 30 codes. The comparison of the codes and corresponding transcript passages led to four new codes with an added level of abstraction. The new codes were then mutually examined, axially coded and a synthesis of findings was produced. This led to two central concepts described below according to our research interests.

## Results

In the following paragraphs, the two central concepts mentioned above are explained in more detail. The inserted quotations of the learners were translated by us, the authors.

### Working together and in groups

The feedback from students shows that they found it positive when learning products were created together and when different tasks could be solved as a group. Learners also appreciated that mathematical knowledge was created collaboratively and that they could support each other in this creative process. Here, certain students also took on the role of coaches, which reduced the time taken to receive help, and was emphasized positively by the learners.

Student: I found it a very good and useful opportunity to teach and support other students. It was all positive. When there was a question, immediate help was given.

Student: It was good to work on topics together and to discuss and debate these topics together.

It was also noted that working with friends was always fun and enjoyable. Moreover, this had a positive effect on the motivation of the learners and led to the mathematics class turning into a more positive place compared to teacher-centred lessons.

Student: By creating the mind map [on the blackboard, concerning a catenary] together, the lesson became funnier and the math was treated in more detail.

In this context, it was important for the students to be involved in the formation process of the groups and to be able to decide which students would form a group. Furthermore, the learners emphasized that it is just as important to be able to work individually (temporarily) in such a setting.

Student: I liked it because we could also work alone.

### **Active and self-directed learning process**

Feedback from learners demonstrates that it was positively received that students themselves could choose the approach and how to tackle a problem. They highlighted that it was exciting to be able to work out a problem and that the answer is not immediately given.

Student: I think it was a good exercise, because you learn to work independently and try to find a solution on your own.

Furthermore, data from the feedback forms show that students liked the speed and intensity of learning as well as the focus of the learning process being chosen by the students themselves. This also means that the learners liked that some of the places of learning could be chosen by them and that the lessons could therefore be better adapted to their needs.

Student: [...] that we actually built the bridge was great and that we had lessons in roof rooms was also great.

Student: [...] I liked it [flipped learning], because everyone could work at their own pace.

In their feedback on the teaching sequence the learners commented that it was perceived as helpful that they themselves could switch between the real world with real problems and mathematical concepts. In line with student feedback, this made it possible to improve the idea of mathematical concepts and to make the significance of mathematics easier to grasp.

Student: It wasn't just numbers, we built the bridge ourselves and the real meaning behind the calculations was better understood this way.

### **Discussion and further considerations**

This section will discuss the findings and contributions and attempt to establish a connection to current literature as well as to school practice. According to sub-codes, further considerations are made in the conclusion, not only regarding isolated and/or non-cumulative feedbacks from learners, but also missing feedback on certain topics.

### **Working and learning in groups**

Since an FLA is characterised by students working in groups and thus exploring the subject matter, it is not surprising that this classroom mode was preferred by students. But it is still rare that mathematics lessons are taught in groups. This applies both to academic discourse and to everyday school practice. Only a few authors (e.g. Bell & Pape, 2012 or Lee & Johnston-Wilder, 2013) have dealt with group work in mathematics lessons. Future research on mathematics education, especially on linking mathematics education and an FLA, should also look at how group work can be integrated into this synthesis and which framework is important here. In this context, on the one hand, it would be important to investigate how mathematics can be learned in a flipped scenario, and, on the other

hand, how learning outcomes achieved in FLA mathematics education can be both secured by students and assessed by teachers. This is because it could be shown that learning actions which are not graded are considered meaningless by pupils and their parents (Häcker, 2011).

Nevertheless, some feedback from learners and literature (e.g. Harkness & Stallworth, 2013) demonstrates that there are students who (also) prefer to work on their own. When group work is integrated into flipped mathematics, it is of paramount importance that these learners are not forgotten. Hence, it would be necessary to expand the students' learning space and options.

### **Active and self-directed learning process**

The feedback data show that students perceived it positively that active learning was possible and that a learning path could be co-determined by them. Already Leonard et al. (2014) demonstrated in this context that different learners have different interests. If the interests of pupils are at the centre of the learning process, it increases the probability can be increased that active and sustainable learning takes place and that the pupils strive to plan their own learning path. For the purpose of creating a learning environment in which the interests of the students dominate and are therefore often self-directed, some basic conditions must be provided. One possibility is that the teacher offers a wide range of tasks from which students themselves can choose. Another possibility would be for tasks to be designed in such a way that they can be modified by learners. The fact that these tasks are present in a self-directed learning process is therefore important, since only then can one count on the fact that learners seriously attempt to solve a problem. This puzzling is necessary to achieve sustainable learning and consequently a better understanding of mathematics among students.

In contrast, the feedback data also revealed that there are students who struggle with taking control of their learning process. With regard to this, the learners mentioned that they missed structure in the teaching units and that a lack of structure hindered their learning process. As a result, a balance between freely selectable tasks as well as a given structure will have to be struck so that the majority of students can benefit from a pupil-active and self-directed learning environment.

### **Further considerations and conspicuous features**

Although modern technologies were of central importance in our teaching experiments and learners made intensive use of them, working with technologies was rarely addressed in the feedback forms. On the one hand, this could be a consequence of the fact that it is not new for students that technologies are used in the learning process. On the other hand, it is very probable that modern technologies are an integral part of the everyday lives of young people in the 21st century and it is therefore not worth mentioning to learners that these technologies are also used in school contexts.

With relations to the desire for a possibility of individual work, some students also addressed discipline and collegiality in the teaching experiment. For this purpose, future research should identify relationships between freedom and discipline that is conducive to the well-being of most learners.

For some students, time management in the teaching experiment was as challenging as its structure. It can be concluded that some students have a high need for such meta-competencies. Future research will also need to examine how learners can be supported in a flipped learning setting so that these skills can be acquired.

## Conclusions and further research

The research data indicate that for students it is more important how mathematics is learned according to an FLA than which tools are used and how complex the learning content is in such a setting. From this we conclude that it might be most critical for students to be able to determine their learning paths as well as goals, and to set their own priorities in education. It was surprising to us that neither technology-enhanced learning environments nor tackled content, which was sometimes challenging for students, were stressed. This is particularly true of the content, because certain mathematical concepts are not covered in the curriculum until later (limiting value and complex numbers) or are not included in the secondary curriculum (catenary and hyperbolic cosine).

For learning mathematics according to an FLA, our research has drawn that the amount of direct instruction could be reduced in the individual learning space. Instructions could either be offered just in time, or students could acquire new learning content in a constructivist way. Here, it could be significant, both in an individual and in a group learning space, that a teacher is available to pupils as a guide if pupils learn mathematics in a self-determined way according to an FLA.

Since the research corpus for learning mathematics following an FLA is still weak and undifferentiated from an FCA, this paper could help to initiate further research in this direction. Here, it would be important that characteristics of an FLA (FLN, 2014) are taken into account and that further mathematics education FLA research is clearly distinguished from respective FCA research.

## **‘Practicing place value’: How children interpret and use virtual representations and features**

Axel Schulz<sup>1</sup> and Daniel Walter<sup>2</sup>

<sup>1</sup>University of Bielefeld, Germany; axel.schulz@uni-bielefeld.de

<sup>2</sup>University of Münster, Germany; daniel.walter@uni-muenster.de

*The tablet-app ‘Stellenwerte üben’ (Practicing place value)<sup>1</sup> was developed to provide a software for practicing place value concept. There are two goals associated with this project: 1) Developing the app and 2) Investigating how children interpret the given non-symbolic representations and how they use the implemented features. This article presents the underlying theoretical background, a short description of selected features, and a sketch of initial empirical findings on the interpretation and use by primary school children in their second and third school years. First findings suggest that previous experience with concrete physical material overlaps and influences the intended use of the implemented virtual features.*

*Keywords: Place value, digital media, representational change, primary mathematics education*

### **Place value understanding**

The development of the understanding of place value and therefore of the composition of multi-digit numbers is one of the most important goals in mathematics education in primary school (Wittmann, 1994). In addition to that, lack of understanding of the concept of place value is a main indicator for learning difficulties in arithmetic (Scherer et al., 2016, p. 636). Understanding of place value can be assumed when someone 1) knows that the place value system is based on continually grouping by tens (powers of ten), 2) knows about the meaning of place value: The quantity of the value is determined by its position represented by the digits – the values of the positions increase in powers of ten from right to left, 3) knows about the meaning of face value: The digits have to be multiplied by the power of ten assigned to its position, 4) knows that the quantity of the whole numeral is the sum of the values represented by the individual digits and 5) knows the rules and structure of number word formation corresponding to the written number (e. g. Fuson et al., 1997).

In the literature, we can find numerous appropriate activities to foster the development of students’ place value understanding and to strengthen it in practice phases. Some of these activities are the following: Bundle and unbundle unstructured sets of objects according to the power ten (van de Walle, 2004; Hiebert & Wearne, 1992), arrange the bundles according to the place value to introduce and practice the place value system and name the bundles to compile and practice the rules of number word formation (van de Walle, 2004; Gaidoschik, 2003). In addition to these activities there are several manipulatives and representations that seem to be appropriate to work with: Unstructured objects such as linking cubes and tiles, pre-structured objects, for example base-ten blocks (Dienes-Blocks), ‘place value mats’ for sorting or trading base-ten material (e. g. van de Walle 2004, pp. 165–

---

<sup>1</sup> The German version of the tablet-app is provided on Google Play. An English version is in progress.

169, Gerster & Walter, 1973) and place value charts with tiles or digits for a standardized and conventional representation.

## **(Virtual) representations and their potentials**

Theoretical analyses and empirical findings suggest that there are several features *of virtual representations* that have the potential to support mathematical learning processes. Some examples for these features are the following: Multitouch-Technology (e.g. Sinclair & Heyd-Metzuyanim, 2014), support in structuring an unsorted set of objects (Walter, 2018), reducing an extraneous cognitive load by the means of computational offloading (Rogers, 2012) and informative feedback (e.g. Harrass, 2007). For the present study, we focus on the following two features (see below): *Fitting between virtual representations and mathematical ideas* (e.g. Peltenburg, van den Heuvel-Panhuizen & Doig, 2009) and *synchronously linked representations* (e.g. Ainsworth, 2006). However, it must be pointed out that the existence of the features mentioned above does not automatically lead to an intended use (e. g. Walter, 2018).

### **Fitting between representations and mathematical ideas**

Mathematical objects can not be empirically observed (like for example astronomical or biological objects) and therefore mathematical knowledge can not be developed through this observation. “The only way to have access to [...] [mathematical objects] and deal with them is using signs and [...] representations” (Duval, 2006, p. 107). These representations can be symbolic (e.g. written or spoken numbers “30”, “three tens”) or non-symbolic such as iconic or concrete representations (e.g. three ten-rods of the base-ten blocks; thirty apples in a picture), or something in between (e.g. three tiles in the tens place in a place value chart). In addition to that, these representations can be ‘material/external’ or ‘mental’ – for example three dots in a place value chart or *thinking* of three dots in a place value chart (Duval, 2006, p. 105). In this context, there are (among other things) two aspects that have to be taken into account: 1) The intended way from external representations to mathematical ideas ‘is not straight, easy or clear’ (Söbbeke, 2015, p. 1499) and these representations are not self-explanatory (Dreher & Kuntze, 2015, p. 91). 2) Mathematical ideas are abstract concepts and the representations must not be confused with the mathematical idea or object (Duval, 2006, p. 107).

Nevertheless, the structure of a given non-symbolic representation (no matter if these are concrete, virtual or mental) should ‘fit’ with the structure of a given mathematical idea (e.g. Sarama & Clements, 2016). On the one hand this fitting should be provided by an ‘intended structure’ built in by the manufacturer (Söbbeke, 2005, p. 135; Sarama & Clements, 2016, p. 82), on the other hand this fitting is the result of an epistemological process (Steinbring, 2015, p. 288). These aspects and conditions are taken into account through developing the tablet-app and analyzing its interpretation and use (see section “Design research and study design” below).

### **Synchronously linked representations**

“Comprehension in mathematics assumes the coordination of at least two registers of [...] representations” (Duval, 2006, p. 115). On the one hand this coordination is a learning goal in mathematics education. On the other hand, it is a challenge because representations can be misinterpreted and the representations of different registers do not have to be congruent and,

therefore, a translation between registers is not simple, obvious or self-evident (Duval, 2006, pp. 115–120). An appropriate method to foster the ability to coordinate and translate between different registers and to realize what is mathematically relevant is to analyze *representation variations in at least two registers* (Duval, 2006, p. 125). In contrast to non-virtual representations, virtual representations can automatically be linked so that changes to one representative have a direct effect on another representation. This feature has the potential to support children in overcoming difficulties in switching between different representations (e.g. Ainsworth, 1999; Goodwin & Highfield, 2013).

## Design research and study design

There are two goals associated with the presented project: 1) Developing the app considering the described theoretical background and 2) Investigating how children interpret the given non-symbolic representations and how they use the implemented features. To give an insight into the process of this design research project, we give a short description of the implemented features, a short description of the study design and in the next section a sketch of initial empirical findings on the interpretation and use by primary school children.

### Implemented features

There are numerous apps focusing on place value (e. g. Burris, 2013; Ladel & Kortenkamp, 2016; Utah State University, n. d.). Though, none of these focus on the practicing phase of the learning, which provide self-generating tasks and informative feedback after entering a result. In addition to that, the implemented features of the app ‘Stellenwerte üben’ as described below can also be found in these apps. However, there is no app that combines all of these features.

**Bundle and unbundle:** The module ‘Bundle’ requests the bundling of *exactly* ten objects (ten ones or ten tens) to create a bundle of the next higher value (ten ones  $\rightarrow$  one ten; ten tens  $\rightarrow$  one hundred). To this end, one has to ‘activate’ exactly ten objects (e.g. by using the lasso-function) and to push the bundle-button. Then the ten objects assemble automatically into the next higher bundle and this slides to the respective column of the place value sorting map (see Fig. 1). An essential aspect of this assembling is the transparent value preserving: Even after bundling ten objects, these objects are still apparent (a ten is made of ten ones, a hundred is made of ten tens). In reverse, unbundling is possible, for example, by sliding one hundred in the tens (or ones) column. After doing this the hundreds automatically split into ten tens (or hundred ones). This feature is implemented in all modules with virtual representation of the base-ten material. Sarama and Clements point out that these virtual bundling activities are “more in line with the *mental actions* that we want students to learn” (Sarama & Clements, 2016, p. 85, emphasis in original) than activities with concrete-physical base-ten blocks.

**Sorting bundles:** The module ‘Sort’ requests the sorting of an unorganized set of ones, tens and hundreds in the place value sorting map. By sliding the objects in the respective columns, the students practice the assignment of a given bundle to the appropriate place value column. In this context, the

Figure 1: Bundling ten ten-rods

sorting is aligned to the visible quantity of a given bundle. This visual assignment is supposed to strengthen the integration of the ‘quantity’ value aspect and the ‘column’ value aspect of place value understanding (Sayers & Barber, 2014, pp. 24–25).

It has to be taken into account, that these practicing activities (virtual bundling and sorting) *do not only by themselves lead* to a sustainable place value understanding, but there have to be several prior activities and accompanying instruction (e. g. van de Walle, 2004). In addition to this, it has to be taken into account that the described activities are based on representations that are visually clearly distinguishable by their quantity. These activities can be interpreted as didactic stages on the way to an abstract understanding of place value. A rigid adherence to these stages and an unreflected use of this representation could lead to common errors (as described by Ladel & Kortenkamp, 2016, p. 297).

**Figure 2: Sorting objects**

The research interests arising from these considerations are the following:

- Research question 1 (RQ1): In which ways do students interpret and use the intended fitting between representations and mathematical ideas?
- Research question 2 (RQ2): How do students interpret the non-symbolic representation particularly with regard to the hundred-squares, ten-rods and unit-squares in the place value sorting mat?

**Synchronized linked representations:** Changes in the iconic register (e.g. unbundle a ten rod) lead to changes in the nonverbal-symbolic register at the bottom of the surface ( $0+10+2$  changes into  $0+0+12$ , see Fig. 3).

**Figure 3: Synchronously linked representations in ‘Stellenwerte üben’**

- This leads to research question 3 (RQ3): Do children notice the synchronously linked representations and in what ways do they use this feature?

### Study design

One focus of our research is to analyze students’ *methods of usage and interpretation* while working with the tablet-app ‘Stellenwerte üben’ (see the research questions developed above). To this aim individual clinical interviews with  $n=29$  German second and third graders have been conducted. All children knew the physical base-ten material from classroom. Main tasks have been, among other

things: 1) the creation of non-symbolic representations: “Please show me the number two-hundred-forty-five using the tablet-app.” (RQ1), 2) the explanation of a created non-symbolic representation: “How do you know this is the number you are looking for?” (RQ1 and 3), 3) an interpretation of 2 ten-rods in the tens place: “Another child has told me this is a representation of twenty tens. What do you think?” (RQ2), and 4) taking away two tens from two bundled hundred-squares “Can you please remove two tens.” (RQ1). All interviews have been transcribed (obtaining both speech and actions) and analyzed using a qualitative content analysis (Mayring, 2015).

## Initial empirical findings

It was examined whether and how children *make use* of digital media’s features implemented in the developed tablet-app. Furthermore, we wanted to evaluate how children *interpret* the given non-symbolic representation. These findings might lead to implications for further development, research and for lessons using the described app.

### Using the fitting between representations and mathematical ideas

As expected, we found different types of usage. On the one hand, there are children who use the implemented features (here bundling and unbundling by sliding and lassoing) independently and are aware of what they are doing (for an example see the following transcript).

Interviewer: What would you have to do to remove twenty?

Student: I know, I know. Like this. (*Unbundles a hundreds-square by sliding it to the tens-column. Swipes away two ten-rods.*)

Interviewer: Ok, and what is your result?

Student: Hundred-and-eighty.

On the other hand, there are children who imitate the action with concrete base-ten blocks (namely trading). These children erase a given hundred-square, create ten ten-rods instead and take away two of these ten-rods. This finding suggests that previous experience with concrete physical material overlaps and influences the intended use of the implemented feature. This assumed interdependence between virtual and concrete actions is worth a closer look in further investigation.

### Interpretation of the non-symbolic representation

The non-symbolic representation of the tablet-app was developed to integrate both the quantity value aspect and the column value aspect of place value understanding (Sayers & Barber, 2014, pp. 24–25). To examine children’s interpretation of this representation (two ten-rods in the tens-column) we asked explicitly for this interpretation (“Another child told us... What do you think?”, see above). By doing this we found two different types of explanation: 1) Children who are aware of the fact that there are exactly two tens. Some of these children referred explicitly to the intended integration of quantity value and column value. 2) Children who mix up the naming of the given representation (“There are twenty tens”). Through further analyses and interviews we want to find out if these answers have their roots in an inaccurate use of mathematical vocabulary or if they are indicators for a conceptual misinterpretation of the intended structure.

## Using the synchronously linked representations

As expected, our findings indicate that not all children consider the linked representations *independently* in their methods of use. Most children only focus on and refer to the non-symbolic representation. There are at least two possible explanations for this finding: 1) in the surface's graphical proportioning there is much more room for the non-symbolic representation than for the symbolic representation and 2) the main tasks requested actions with the non-symbolic representation. Nonetheless, it can be stated that there are both low- and high-achieving students who do independently use the linked representations, and all students use this feature when asked for an explanation. In these cases, the linked representations are used to support children's argumentation and as self-monitoring.

Interviewer: Please show me the number two-hundred-fourty-five.

Student: (*Creates two hundreds in the hundreds-column, four tens in the tens-column, five ones in the ones-column.*)

Interviewer: Ok, and how did you know, how many hundreds, how many tens and how many ones you needed?

Student: One square is hundred ones (*points at the hundred-square*) and there are two, thus, two-hundred. You can read this here, too (*points at the symbolic representation*).

## Conclusion

The described study investigates children's *usage* and individual *interpretation* concerning a virtual practicing material. The tablet-app was developed to foster and strengthen children's place value understanding and it provides several features which are supposed to support mathematical learning processes. The implemented features are based on mathematical didactic theories and findings. In the following, we summarize the main results and draw some conclusions for teaching and further research.

The described findings validate the previous assumptions (Walter, 2018) that the existence of the described mathematical didactic features of virtual representations does not automatically lead to an intended use. Especially instead of using the synchronously linked representations children mainly focused on the non-symbolic representation, which is quite explainable. Nevertheless, we found that some children (both low- and high-achieving) used the linked representations *independently* and others used them for argumentation when asked for an explanation. This knowledge gives teachers the opportunity to discuss the connection between the different representations in the context of 'math conferences' with all students. In these settings students may become aware of the possibility to change between and use different representations, which they do not yet do independently. Another feature which was not used as intended by some children is the fitting between the virtual actions and the intended mental actions (Sarama & Clements, 2016, p. 85). Some students traded a hundred for ten tens and vice versa, instead of bundling or unbundling. These different types of usage (trading vs bundling and unbundling) could be used for constructive discussions in class: Do these different actions lead to the same results? What aspects of these actions are the same, what are different? This

discussion about actions, representations and the underlying mathematical ideas might lead to a better understanding of some basic aspects of the place value concept.

As mentioned above, some of the reported findings lead to further research interests like the investigation of an interdependence between using concrete and virtual representations. Also of interest is the question if the different interpretations of the non-symbolic representation ground merely on inaccurate use of mathematical vocabulary or if they are indicators for a conceptual misinterpretation of the intended structure. Since the tablet-app was developed for practice, further investigations also might focus more on autonomous usage (without an interviewer) and ways of practicing.

# Exploring non-prototypical configurations of equivalent areas through inquiring-game activities within DGE

Carlotta Soldano<sup>1</sup> and Cristina Sabena<sup>2</sup>

<sup>1</sup>University of Torino, Italy; [carlotta.soldano@unito.it](mailto:carlotta.soldano@unito.it)

<sup>2</sup>University of Torino, Italy; [cristina.sabena@unito.it](mailto:cristina.sabena@unito.it)

*Inquiring-game activities are inspired to Hintikka's semantical games and are designed within a Dynamic Geometric Environment (DGE). In this report, we focus on inquiring-game activities on the equivalence of quadrilaterals areas, which were proposed to primary school students in Italy. The goal of these activities is to exploit the dynamicity of semantical games and of DGEs to foster students' geometrical thinking. Through a design-based approach and a case-study, we highlight how the double dynamicity of the didactical design allows the students to i) explore non-prototypical configurations and ii) reinvest their geometrical knowledge to make sense of the observed relationships between the figural and the numerical register.*

*Keywords: Non-prototypical figures, inquiring-games, area equivalence, primary school, DGEs.*

## Introduction and theoretical framework

In primary school the concept of area and its measurement are among the main goals of learning in all countries. Area measurement is usually the first case in which students encounter numerical computation in geometry (Smith & Barrett, 2017): first by counting units, and then by multiplicative computations. Comparing areas of different regions can be perceptively difficult when the shapes are different or they are not prototypical. Usually, students learn to establish the equivalence of figures both by using measurements and by decomposing them into congruent polygons, by cutting and pasting figures, folding papers, and drawing in paper and pencil environment. In this context, algebraic formulas are also introduced. However, research and international tests show that formulas often remain obscure or even 'black boxes' to many students (*ibid.*). Furthermore, students show difficulties in distinguishing between area and perimeter (D'Amore & Fandiño Pinilla, 2006).

In our study, we explore how inquiring-game activities within Dynamic Geometric Environments (DGEs) may foster students' geometrical reasoning, in particular on area and area equivalence. The study is part of a larger research project in which theorems of elementary geometry are transposed into inquiring-game activities inspired to semantical games (Soldano & Arzarello, 2018). These games are connected with a new form of logic, called 'logic of inquiry', developed by the Finnish logician J. Hintikka (Hintikka, 1999). In this logic, Hintikka made use of games of verification/falsification, known as *semantical games* (Hintikka, 1998), through which he reversed the recursive definition of truth given by Tarski.

For reason of space, we will refer only to the semantical games associated to statements expressed in the form " $x \text{ } \$y \text{ } S(x, y)$ ", since we took inspiration from them to design our games. To this end, we can imagine a situation in which a verifier (V) has the goal of showing the truth of the statement while a falsifier (F) has the opposite goal of showing that it is false. F controls variable  $x$  and V controls variable  $y$ . F starts the game by choosing a value  $x_0$  for the variable  $x$  and then the turn moves to V,

who should find a value  $y_0$  for  $y$  such that  $S(x_0, y_0)$  is true. In this game, F tries to create difficulties to V by choosing non-typical cases (such as extreme cases). According to Hintikka, the choice of the  $y_0$  by V is a reliable test of truth if the  $x_0$  chosen by F forces V to play in the worst-case scenarios. This game between V and F hence creates a dynamic interplay between them, paralleled by a dynamism at the cognitive level. Such dynamism is assumed to trigger students' inquiring process and foster their understanding of the mathematical situation.

Within DGEs, variables  $x$  and  $y$  are thought as base-points of geometric constructions. Since dragging preserves the critical attributes of robust constructions (Healy, 2000), by moving the base-points new configurations of the same robust shape can be explored. As it is well known from the literature, students tend to identify shapes with the prototypical examples representing the category (Rosch, 1973), e.g. they easily recognize figures when one of their sides is horizontal. Goldenberg and Mason (2008) underline the importance for students of dealing with many and different examples, since they are “a major means for ‘making contact’ with abstract ideas and a major means of mathematical communication” (p.184) and “the variation in examples can help learners distinguish essential from incidental features” (*ibid.*). Variation can also produce the enlargement of students' *personal example space* (Watson & Mason, 2005), namely the “set of mathematical objects and construction techniques that a learner has access to as examples of a concept while working on a given task” (Sinclair, Watson, Zazkis & Mason, 2011, p.1). DGEs may facilitate students' accessibility to non-prototypical examples, thanks to the dynamic exploration of the figures. Non-examples serve to clarify “the boundaries or necessary condition of a concept” and can play the role of counterexample if they are used to “show that a conjecture is false” (Watson & Mason, 2005, p. 65). If a geometric property is not robustly constructed, namely the construction does not retain the critical attributes of the properties, DGE offers the possibility to produce both *examples and non-examples of the considered property*.

Generally, DGEs provide tools for computing an approximate value of the area of the constructed figures. If this value is made visible in the environment, dragging the base-points of a figure produces a double change: one within the figural register of representation and the other within the numerical one. Duval (2006) highlights two different operations with registers of representation, which he calls *treatment* and *conversion*. Both are fundamental for the understanding of mathematical concepts: treatments deal with transformations within the same register of representation, while conversions consider more than one register and the relationships between them. Revisiting Duval theory within DGEs, dragging of a robust figure can be interpreted as a treatment made within the figural register, while the coexistence of figural and numerical registers of representation may engage students to inquire their links by making conversions.

## Methodology

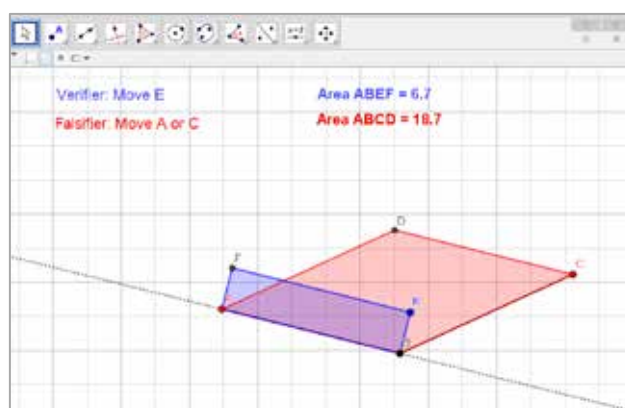

Following a design-based perspective (DBRC, 2003), we carried out a teaching-experiment in two Italian 5<sup>th</sup> grade classrooms with the collaboration of their school teachers and of a master's degree student. We designed a sequence of five DGE inquiring-game activities centered on area equivalence and on the area/perimeter relationship of quadrilaterals. In each activity, pairs of students are invited to play a game in DGE, and to answer to specific questions that guide the inquiry of the geometric

concepts. After all students write their answers to the questions, a classroom discussion is developed under the teacher's guidance. Usually, two hours are dedicated for each inquiring-game activity (including discussion), for an amount of 10 hours.

In this contribution we present a case study from the first activity, focusing on the area equivalence between rectangles and parallelograms. The inquiring game and the worksheets for students are presented below. In previous lessons, students have explored the area and perimeter of quadrilaterals using paper models (cutting and pasting) and in paper&pencil environment. The collected data consist of the audio and screen capture of one pair of students (that we will call Rose and Lily) during the DGE inquiring-game activity, the completed worksheets from all the pairs of students and the video-recording of the classroom discussion. The collected data are analysed according to a semiotic multimodal approach to mathematics (Arzarello, Paola, Robutti & Sabena, 2009), which focuses on students' speech, gestures, drawings and actions within the DGE. Through the produced signs it is possible to grasp how students discover and make sense of the geometric property on which the game is based. More precisely our interest is to explore the potentials and limits of the didactic design based on the double dynamicity provided by the game and by the DGE affordances, with respect to students' geometrical reasoning in non-prototypical configurations.

### The inquiring-game activity on parallelogram-rectangle area equivalence

The activity focuses on the relationship between the area of a rectangle and a parallelogram that share one side (named AB): the corresponding game starts from the configuration shown in Figure 1.

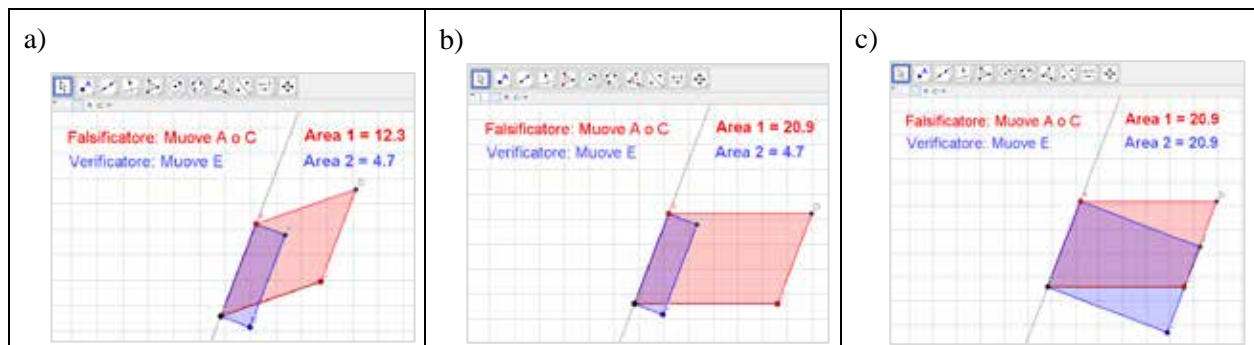

**Figure 1: The initial configuration of the parallelogram-rectangle game**

Both the parallelogram and the rectangle figures are robust constructions; by moving the free point A, it is possible to change the length of AB and rotate it around the fixed-point B (see Fig. 2a). This move changes also the values of the area of the figures, which are displayed on the screen. By moving point C, it is possible to drag the parallelogram and vary its area while the side AB remains fixed (see Fig. 2b). By dragging point E it is possible to vary the length of EB and the area of the rectangle ABEF. Since the figures share the same side AB, if the heights relative to AB are of the same measure the two figures are equivalent. A key-feature of the design is that this property is not constructed in a robust way, so to allow students to produce examples and non-examples of the property, through the verifier and falsifier's moves. The dotted straight line (the extension of the side AB) is inserted to

help students to visualize the correct position of the height relative to AB of the parallelogram. All draggable points can be moved in either half-plane identified by the line.

**Figure 2: The effects of dragging point A, C and E**

The following table contains the English translation of the rules of the game:

Within your pair, choose a verifier and a falsifier.

- The falsifier can move point A or C,
- The verifier moves point E.

Each match is made of two moves and the first one is always made by the falsifier.

**GOALS:**

The goal of the verifier is to make Area EBEF equal to Area ABCD, while the goal of the falsifier is to prevent the verifier from reaching the goal.

The player who reaches her/his goal at the end of the verifier's move wins the match.

**Table 1: Rules of the parallelogram-rectangle game**

According to the rules of the game, the verifier and the falsifier play a semantical game on the following statement: 'For all positions of point A and C there exists a position of point E such that Area ABEF is equal to Area ABCD'. The verifier can always win, by transforming any non-example of equivalent figure (i.e. rectangle non-equivalent to parallelogram, as in Figure 1) into an example of equivalent one (as shown in Figure 3). In agreement with the teacher we decided to round the area measure to the first decimal place.

**Figure 3: Examples of game configurations showing equivalent areas**

The players' moves produce a *double simultaneous treatment*: one in the figural register, since each figure is transformed into another one of the same category, and one in the numerical register since also area values change. The following inquiring questions are proposed to students:

Answer these questions trying to use geometrical language:

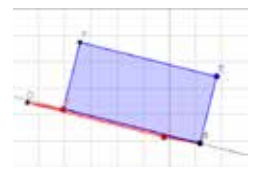

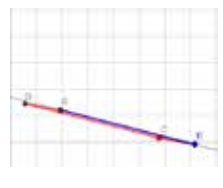

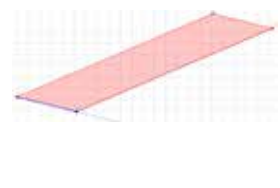

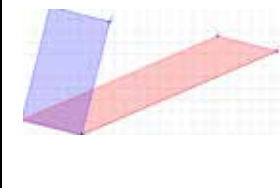

1. Consider the case in which the verifier is winning. Write here your observations.
2. Explain why each time the verifier reaches the goal area ABEF is equal to area ABCD.
3. While playing, have you ever found a situation in which the two areas are zero? If not, play a new match to get it and describe what happened to the figures. If you like, make a drawing.

**Table 2: Questions proposed to students**

The guiding questions are meant to shift students' attention from the game to the geometric properties on which the game is based. Through the first one we collect students' observations, without giving them any hint. The second question focuses on area equivalence, that is the geometric property on which the game is based. It is meant to know whether students are able to convert the results observed in the figural and in the numerical registers using the known geometric properties. More precisely, students can provide two mathematically correct explanations: the first relies on the geometric interpretation of the area formula, the second one is made by showing that the two figures are made by the same congruent polygons (decomposition). Primary students are not expected to completely justify the congruence of the figures in a rigorous way, but chunks of arguments are expected to emerge. Finally, the last question requires students to produce a degenerate configuration and is meant both to investigate their conceptions of these cases, and to foster geometrical reasoning in non-prototypical configurations.

## Data analysis

We report about Rose and Lily's inquiry in the game and in answering the worksheet questions. According to the teacher, they are medium-level students; Rose is reflective and her mathematical knowledge is a little bit higher than Lily, who is less reflective and is smarter in more practical activities. They play the game for about 40 minutes and then they turn to answer the worksheet questions. During the game it happens that Lily wins all the matches both when she plays the verifier's role and when she plays the falsifier's. While playing as falsifier, Lily produces non-prototypical configurations (very big and stretched or very small, see as examples matches 3 and 4 reported in Fig. 4) in which it is very difficult for the verifier reaching the goal (sometimes it is impossible for approximation reasons).

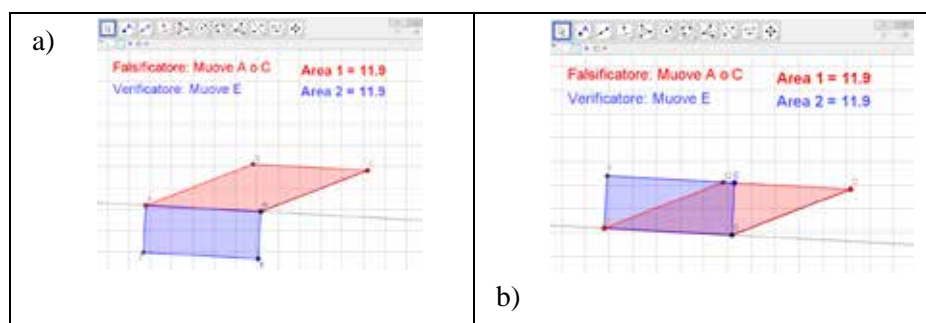

3 <sup>rd</sup> match		4 <sup>th</sup> match	
			
Area ABCD = 0,5 Area ABEF = 14,1	Area ABCD = 0,5 Area ABEF = 0,1	Area ABCD = 62,4 Area ABEF = 0,1	Area ABCD = 62,4 Area ABEF = 54,4

**Figure 4: Falsifier 'winning' configuration (3<sup>rd</sup> and 4<sup>th</sup> matches in Rose and Lily's game)**

While playing the verifier's role, Rose notices that her defeats depend on technical aspects of the DGE, namely on the fact that after zooming out many times area measures are expressed by quite big number, even if the figures look as big as usual (see Fig. 4). In this condition, a little dragging produces a huge variation in the numerical values and it is very difficult for the verifier to win. Students' first observations relate to tool affordances rather than geometric properties. They do not even call the figures with their names until the researcher (who is videotaping them, first author) asks them to do it. In doing so, Rose immediately answers correctly, but Lily needs to drag the configuration and to produce prototypical examples of rectangle and parallelogram. From this moment on, Lily and Rose focus on geometrical features. We report an excerpt in which students are discussing the configuration contained in Fig. 5a:

1. Lily: This (*pointing to the parallelogram in Fig. 5a*) is bigger than this (*pointing to the rectangle in Fig. 5a*) but they have the same area
2. Rose: You mean that it has a bigger shape?
3. Lily: Yes, but they have the same area, they are equivalent with different measures.
4. Rose: With different sizes. And why do you believe it happens?
5. Lily: I have no idea... Or maybe here it's called area, but it means the perimeter... no it's impossible...
6. Rose: But Lily, if you look at this side here, the one overlapped (*pointing to AB*), it is equal to this side here (*pointing to CD*), but this is slopped. This one (*pointing to EF*) is equal to this one (*AB*) and this one (*CD*). Do you think that this height (*with her finger on the screen, she is tracing the height relative to AB of the parallelogram, from C to the dotted line*) is equal to this one (*pointing to AF*)?

**Figure 5: Configurations discussed by Lily and Rose**

Lily and Rose highlight a perceptual problem that creates a contradiction: the parallelogram looks bigger than the rectangle and this perceptual observation collides with the fact that they have equivalent areas (lines 1-3). Namely, Lily and Rose observe a contradiction between the figural and the numerical registers (Duval, 2006) due to a visualization problem. In order to solve the contradiction, Rose relies on the algebraic formulas of the areas, which she interprets geometrically on the figures (see her words and gestures in line 6, Fig. 5).

Being the figures in opposite half-planes, it is difficult to visually compare their heights relative to AB (see Rose's last question, line 6). Hence, the researcher suggests considering configurations in

which both figures are in the same half-plane. Following the researcher's suggestion, the students make a treatment in the figural register and discuss the configuration shown in Fig. 5b:

7. Rose: What does it happen? This one (*pointing to the rectangle*), the rectangle...
8. Lily: Is the half of the other [the parallelogram]
9. Rose: How is it possible? If we put this triangle (*pointing to BCE*) here (*pointing to ADF*), we make the whole rectangle. Instead here we have only a piece of parallelogram (*moving her finger on BE*). This triangle which lies outside (*pointing to ADF*) is this triangle (*pointing to BCE*)! Do you understand, Lily?

When looking at Fig. 5b, Rose does not continue in discussing the heights relative to AB, rather she observes that areas are equivalent since they may be obtained by the same congruent polygons (line 9). The imagined treatment in the figural register, based on decomposing and rearranging the figures, allows Rose solving the previous contradiction between the numerical and the figural register. In this way, she avoids referring to the parallelogram height relative to AB, which is not drawn and is not perceptually easy to seize (because the figure is slanted) nor to compare with the rectangle height. Having shown the equivalence of the figures, Rose moves back to the previous height observation and concludes that “if the area is the same then heights should be equal”.

## Conclusion

As highlighted in the analysis, it took time for the videotaped students to start a geometric discussion of the game and the researcher had to prompt it through some questions. Anyway, the provided chunk of argumentations revealed that the design worked well: the students made sense of the equivalence between parallelogram and rectangle with arguments that exploited both the areas' formulas and the decomposition of the figures into congruent polygons.

While playing, students produced non-prototypical examples of parallelograms and rectangles. The non-prototypicalities can be related to different aspects: the figures orientation (the produced configurations do not have the base in a horizontal position); the figures size (the explored area values are very big or very small non-integers); the figures proportions (the produced configurations are stretched and the ratio between their sides is unusual). Moreover, a second order of non-prototypicalities should be considered. It refers to configurations of parallelogram-rectangle equivalence in which the figures belong to opposite half-plane (with respect to line AB) or in which the height of the parallelogram referred to side AB lies on the extension of AB. In these cases, it is more difficult or even impossible for students to imagine the decomposition and rearrangement of the showed figures into each other.

Some non-prototypicalities were not considered in the design and they actually did not help students in linking the game situation and the mathematical property at stake. Rose and Lily do not perceive that the parallelogram is equivalent to the rectangle in a case of second order non-prototypicality: the parallelogram, which was not overlapped by the rectangle, looks bigger than the rectangle (lines 1-3). On a design-based perspective, this result will be considered in the second cycle of experimentation.

The exploration of non-prototypical configurations is the effect of the *double dynamicity* characterizing the inquiring-game activity, namely the one provided by the verifier/falsifier game and the one given by the DGE affordances. Implications of this double dynamicity seem promising with respect of developing students' critical thinking and argumentation competences.

### Acknowledgment

We wish to thank the teacher Ezio Scali and the master's student Michelina Pitrelli for their fruitful collaboration in the teaching-experiment.

# The graphing calculator as an instrument of semiotic mediation in the construction of the function concept

Manuela Subtil<sup>1</sup> and António Domingos<sup>2</sup>

<sup>1</sup>Agrupamento de Escolas Fragata do Tejo, Escola Básica 2º, 3º ciclos Fragata do Tejo, UIED<sup>1</sup>, Moita, Portugal; mm.pedro@campus.fct.unl.pt

<sup>2</sup> Universidade Nova de Lisboa, Faculdade de Ciências e Tecnologia, UIED, DCSA, Monte da Caparica, Portugal; amdd@fct.unl.pt

*Keywords: Artefact, graphical calculator, semiotic mediation, utilization schemes.*

## Introduction

According to some authors, the graphing calculator facilitates the students' ability to reflect and generalize, when involved in performing exploratory tasks, leading them to the construction of mathematical knowledge (Doorman, Drijvers, Dekker, Heuvel-Panhuizen, Lange e Wijers, 2007). We present the resolution of the task: "My hand", with the graphing calculator, whose purpose was to consolidate the concept of function and to understand when a cartesian graph corresponds to the representation of a function. On the other hand, looking at the artifact, the graphing calculator, as a instrument of semiotic mediation, we intend to analyze how the transition from personal meanings to mathematical meanings (Mariotti, 2018) was developed, in the resolution of the task.

## Theoretical Framework

The use of an artifact in solving a mathematical task can provide the emergence of pre-existing student knowledge, which relates to the mathematical knowledge essential to the teaching-learning activity. The teacher can intentionally exploit the semiotic potential of an artifact that translates into the facility that the artifact possesses in associating mathematical meanings evoked by its use, culturally determined, with personal meanings that each subject develops in its use (instrumented activity) in the completion of specific tasks. In this way, the process of semiotic mediation is developed around the notion of the semiotic potential of an artifact and a didactic cycle (Mariotti, 2012, 2018).

## Methodology

This study is framed in a broader qualitative research, following an interpretative approach. The experiment was conducted in the school year of 2016/17, in a class of the 7th grade, with 29 students. In this poster we present the performance of two students, Berta and Maria. The techniques used to collect the data were based on students' written reports, direct observation of the researcher, images of the graphic representations of the graphing calculator screens and logbook (Creswell, 2012).

---

<sup>1</sup> This work is supported by national funds through FCT - Foundation for Science and Technology in the context of the project UID/CED/02861/2016

## The task presented to the students: "My hand"

The task consisted in drawing the outline of a hand using paper and pencil, in a cartesian referential and placing points at choice. The first point had to be equal to the last point, for the line to be closed. Subsequently, each student represented in the graphing calculator, the polygonal line that had as vertices the coordinates of the chosen points. The students had to justify whether the visualized representation was a function and to conclude under what conditions a cartesian graph represents a function. Previously, the students had learned the concept of function and the representation of a function through diagram of arrows and tables. The students individually performed the task with the artifact, the graphing calculator. Afterwards, the individual productions were analyzed, and the collective discussion, managed by the teacher, was developed, promoting the evolution of students' personal meanings towards mathematical meanings (Mariotti, 2018).

## Analysis of Results

The graphing calculator, allowed them to visualize another form of representing a function, its graphical representation. The semiotic potential of the graphing calculator, inherent in the visualization capacity and dragging technique (Mariotti, 2012), as well as the collective discussion, fostered the emergence of personal meanings related to mathematical meanings. The student Maria showed evidence that she had mobilized mathematical knowledge learned previously. The personal meanings that arose were related to mathematical meanings learned earlier.

The student Berta showed a certain difficulty in distinguishing the difference between object and image, as well as formally constructing the concept of function. However, these aspects "seem to us" to have been filled with the collective discussion and the insistent orchestration of the teacher. In the poster, the results will be presented in detail.

## Conclusion

When learning takes place in the social environment of the classroom, in which individual productions are promoted, resulting from the accomplishment of tasks, using the graphic calculator and later collective discussion, orchestrated by the teacher, it can generate a greater ease in the transition from personal meanings to mathematical meanings.

## Drawing topology using *Ariadne*

Moritz L. Sümmerrmann<sup>1</sup>

<sup>1</sup>University of Cologne, Germany; [moritz.suemmermann@uni-koeln.de](mailto:moritz.suemmermann@uni-koeln.de)

*Keywords: Topology, Learning environment, Mathematics education, Computer software.*

### Research overview

The focus of this work is to build a learning environment, making it possible to learn about paths and homotopies without the use of formalism. Here, learning environment means a microworld given through a software in the sense of Papert (Papert, 1987). To help achieve this goal I have developed *Ariadne*, a software tool for the visualization of and interaction with paths. These paths can be constructed on a wide variety of surfaces, from the plane to manifolds of arbitrary genus, and punctured versions thereof. A more detailed account of *Ariadne*'s capabilities is given in (Sümmerrmann, 2019).

**Figure 1: The Pochhammer Contour, a non-nullhomotopic green path starting and ending at the magenta dot with winding number zero around both black punctures, constructed in *Ariadne*.**

Topology in general is not present in the school curriculum, which limits the extent of research in the field of topology education. It is, however, a very important part of modern mathematics, so there have been some attempts to visualize topology, either without (Strohecker, 1996; Sugarman, 2014) or with software (Culler, Dunfield, Goerner, & Weeks, n.d.; Scharein, 1998). There has been no attempt to implement interactive continuous deformations as represented by homotopies, which is the focus of *Ariadne*. It also follows a different approach didactically, as its purpose is not only to visualize concepts already known to the user, but to teach the user these concepts by letting him interact with the visualization. The theoretical framework behind the design of *Ariadne* is based on the design principles of Devlin, 2013 and the Artefact Centric Activity Theory from (Ladel & Kortenkamp, 2013).

*Ariadne* is split into a two- and a three-dimensional mode. Both are usable on any touchscreen device, such as tablet-PCs or smartphones. In 2D, the user can construct points, paths and homotopies of paths on the plane with an arbitrary number of punctures, as well as compute the winding number around these punctures. This allows the user to tackle questions on the existence and equivalence of paths, and thus the treatment of the fundamental group. The same can be done for closed orientable surfaces of genus  $g$  in three-dimensional mode.

For the 3D-mode, a mixed reality environment is implemented. This mode facilitates the interaction with two-dimensional surfaces in three-dimensional space, such as the sphere or the torus, and thus alleviates handling issues inherent to the two-dimensional touchscreen. The three-dimensional mode also allows the construction of paths on the universal cover of the chosen surface, which is for

most surfaces the hyperbolic plane. *Ariadne* is being evaluated through individual interviews with students from all age groups, in which they are being posed questions to assess their understanding of the used concepts. Further research directions are a didactical analysis of the topological notions involved in *Ariadne* to ensure that the answer quality is representative for the understanding of the content, planned to be implemented as a qualitative empirical study with mathematicians. The questions can then be refined based on this analysis.

## Poster contents

The poster contains a short summary of the mathematical objects involved using some formulas and pictures, so it is clear what mathematics are conveyed with *Ariadne*. This is by no means exhaustive, but intends to sensitize the audience to the subtleties of the concepts involved. In the center of the poster is a tablet-PC, which the conference participants can use to test *Ariadne* for themselves. Another part of the poster is a list of sample questions which can be answered with the help of *Ariadne*, as a demonstration of *Ariadne*'s capabilities. The last part is a short overview on the technicalities of the program for those interested in the mechanisms of action behind *Ariadne*.

*In this paper, we report on a research study that aims to understand the ways students transit between the simulation of real phenomenon and the mathematical representation, as the modelling activities are introduced by dynamic digital artefacts. The study took place in a high school in Turin, in which 9th grade students were introduced to the quadratic function through a task to be accomplished with the use of a dynamic digital simulation of a rolling ball on an inclined plane - the Galileo experiment. The semiotic mediation approach guided this study to carefully analyze the modelling activity, enhanced by the use of the digital artefact, in terms of meanings that evolve. Our results identify the signs which refer to the simulation of the real phenomenon and those which refer to the mathematical representation and bring to the fore the evolution from the artefact signs to the mathematical signs.*

**Keywords:** *Modelling activity, digital artefacts, semiotic mediation, signs, quadratic function.*

## Introduction

Mathematical modelling (the process of translating between the real world and mathematics in both directions) is one of the topics in mathematics education that has been discussed and propagated most intensely during the last few decades (Kaiser, 2014). Mathematical modelling is now a compulsory part of the mathematics curriculum in many countries worldwide and one of the main skills within international educational standards. Over the last two decades, a considerable variety of models (Borromeo Ferri, 2006) that explain the interplay between the real phenomena and the mathematical representations have emerged and processed (e.g. Blomhøj & Jensen, 2003; Blum & Leiß, 2007; Voskoglou, 2007). Despite the differences between the variety of models, the transition from the real phenomenon to the mathematical world is considered to be a common point among them. For example, to model this transition, Blum and Leiß (2007) distinguished between the mathematical world and the rest of the world. The transition from the real model to the mathematical model happens through a mathematising process, while the transition from the mathematical world to the real results happens through an interpreting process (Figure 1, taken from Blum & Leiß, 2007). These two processes are complex and require careful analysis in order to avoid useless oversimplification (Blum, 2011). This complexity is also valid when the real phenomenon is simulated by digital artefacts which connect the real phenomenon with mathematical representation. Digital artefacts are widely used to design and develop modelling activities, especially, to simulate complex real phenomena. Digital artefacts, indeed, allow linking multiple representations simultaneously. With their use, data concerning the real phenomena can be precisely displayed and mathematically interpreted. In the context of using digital artefacts, modelling activities are designed by using several kind of signs that are embedded in the artefact. Some of these signs are iconic (they have a great similarity with the real object), others are symbolic (they have a meaning in a specific culture). Bridging the gap between the iconic and symbolic signs is a serious challenge and should be taken into account (Arzarello & Sabena, 2011). Therefore, in addition to the traditional complexities of the transition between the real phenomenon and the mathematical one, the affordances and constraints of the digital artefacts, and

the design principles of the tasks, should be taken into account when analyzing the learning processes of modelling activities (Naftaliev, 2017).

Herein, we assume that the construction of mathematical meanings throughout a modelling activity can be achieved through the mediation of dynamic digital artefacts. Moreover, we believe that the semiotic mediation approach could provide a suitable framework to carefully analyze the transition between the real world and the mathematical representations, identifying the evolution of personal meanings, emerging through the modelling activity, towards mathematical meanings, which are the objectives of the teaching intervention. In this paper, we will report on a research study that aims to understand the ways students transit between the simulation of real phenomenon and the mathematical representation, as the modelling activity is introduced by a dynamic digital artefact. We exemplify our approach by analyzing a teaching experiment concerning the quadratic function. For this purpose, we describe a designed and implemented modelling activity, which is based on the simulation of a rolling ball over an inclined plane – Galileo experiment – through the use of a dynamic digital artefact. We have chosen the Galileo experiment because the mathematical model of the spaces traversed by the ball is quadratic. We have chosen to simulate the real phenomenon using a dynamic digital artefact because it has the potentiality to precisely display the mathematical representation of the model and the real phenomenon using multiple-linked representations. The teaching experiment has been analyzed with the aim of revealing how the use of the digital artefact contributes to the construction of mathematical meanings, and to show how the semiotic mediation approach may help us to shed some light on the students' twofold transition between the real world and the mathematical world.

**Figure 1: The Blum's modelling model (Blum & Leiß, 2007)**

**Figure 2: The semiotic mediation approach**

## Theoretical Framework - Semiotic Mediation Approach

In the context of using artefacts, Bartolini Bussi and Mariotti (2008) have modelled learning process by taking advantage of the potential of artefacts. The model aims to describe how meanings related to the use of a certain artefact can evolve into meanings recognizable as mathematical. The semiotic mediation approach assumes that social interaction and semiotic processes play a key role in learning, particularly in situation in which learners are encouraged to use the artefact in order to solve a given task. This approach considers learning to be an alignment between the personal meanings arising from the use of a certain artefact for the accomplishment of a task and the mathematical meanings that are deployed in the artefact. The relationship that the artefact has with the personal meanings emerging from its use and the mathematical meanings that might be evoked by such use is described

as a double semiotic relationship and defines the *semiotic potential of the artefact*. On one hand, we concentrate on the use of the artefact to accomplish a task, recognizing the construction of knowledge within the solution of the task. On the other hand, we analyze the use of the artefact, distinguishing between the construction of the personal meanings arising in individuals from their use of the artefact in accomplishing the task (top part of Figure 2) and the mathematical meanings; meanings that an expert recognizes as mathematical (bottom part of Figure 2) when observing the students' use of the artefact in order to complete the task (left triangle in Figure 2). Personal meanings emerging from the activities carried out with an artefact may evolve into mathematical meanings, objectives of the teaching intervention. This evolution can occur in the peer interaction during the accomplishment of the task and in the collective discussions conducted by the teacher. In this long and complex construction process of shared mathematical meanings, it is possible to identify evolution paths (called *semiotic chains*) which are described by the appearance and enchainment of different types of signs: artefact signs, mathematical signs and pivot signs. The *artefact signs* refer to the artefact and its use, are produced through the social use of the artefact (upper right vertex in Figure 2) and may evolve into signs (called mathematical sign) that refer to the mathematics context. The *mathematical signs* are related to the mathematical meanings shared in the institution to which the classroom belongs (right side of Figure 2). Through a complex process of evolution of the artefact sign into a mathematical sign, other types of signs, which Bartolini Bussi and Mariotti called *pivot signs*, play a crucial role. The authors suggest that the characteristic of these signs is their shared polysemy: the pivot signs with their hybrid nature, both referring to the use of the artefact and to the mathematical domain, are characterized by their function in the evolution process, fostering the move from artefact to mathematical signs with their intrinsic ambiguity. An a-priori analysis of the semiotic potential of the artefact with respect to the given task has a double role: it can help the teacher in her important role to foster the evolution of signs during the class discussion; it can also be the basis on which researchers can identify students' construction of meanings through the evolution of signs.

## Method

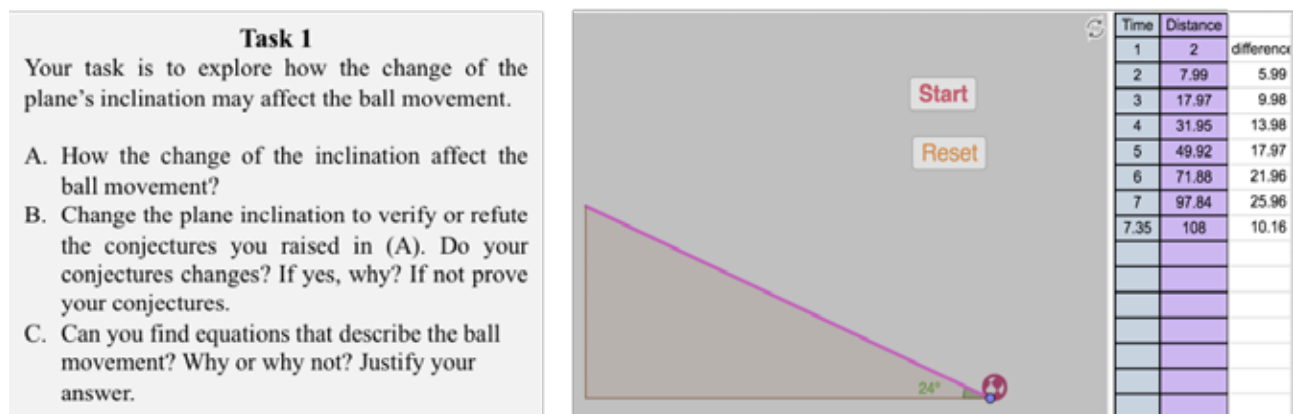

### Setting and procedure of the teaching experiment

The study took place in a high school in Turin (Italy), in which a senior teacher introduces the Galileo experiment with her eighteen 9th grade students. A short introduction to the activity and its design principles were previously given to the teacher. The teacher was followed by the researchers as she taught one lesson of 1.5 hour. In order to introduce the students to the chosen topic, a short video clip ([Inclined plane experiment](#)) concerning the Galileo experiment about a ball rolling on an inclined plane is provided, and students were asked, before the lesson, to watch the video at their home, to observe and make conjectures concerning what they have observed. The students were initially required to work in small (triads or four students) groups, sharing a worksheet containing the task and a computer for the simulation of the Galileo experiment. The teacher walked around and interacted with the students, when she believed it was needed. As soon as the students accomplished the task in the small groups, the teacher conducted a general discussion with the whole class.

### Task given to the students and a-priori analysis of the semiotic potential

The design principles of the tasks are motivated by mathematical modelling approach and by the choice to exploit the potential of digital artefacts. The task presents a simulation of the real world phenomenon and, through the use of a dynamic digital artefact, offers mathematical representations

of the dynamic aspects of the phenomenon to be analyzed. The main idea of the design is to create different situations by varying some aspects of the phenomenon while keeping the others invariant. Figure 3 shows the written modelling task given to the students. It blends the simulation of the rolling ball on the inclined plane with the numerical representation. At the beginning of the lesson the task was given to the students requesting them to explore the mathematical model through the dynamic digital artefact (Figure 3). In the default situation of the simulation, the inclination plane angle is invariant, while the spaces traversed by the ball, when the “Start” button is clicked, vary as the time elapsed. Then, according to the task, students are asked to conjecture and then verify how the plane inclination affects the ball movement and the mathematical model. This can be done, in particular, focusing on the differences of the distance and looking for the equation that describes the movement. These insights may lead the students to grasp the intended object of learning, namely, the quadratic function and its properties.

**Figure 3: The Galileo experiment task**

An a-priory analysis of the semiotic potential of the artefact with respect to the given task (Tab. 1) is fundamental in order to identify the appearance and evolution of signs during the teaching-learning activity, as it describes what is expected to emerge in the classroom.

**Table 1: The semiotic potential of the artefact with respect to the task**

Mathematical meanings	Semiotic potential
<ul style="list-style-type: none"> <li>- The table represents a correlation between two sets of values (time vs distance).</li> <li>- The third column represents the differences between the distances.</li> <li>- The differences between two consecutive differences in the third column are constant.</li> <li>- The model of spaces traversed by the ball is a quadratic function of the form <math>s(t) = at^2</math>.</li> </ul>	<ul style="list-style-type: none"> <li>- When clicking on the start button, the ball rolls down on the plane and the table is filled: this may evoke the idea that there is a correlation between the time and the spaces traversed by the ball and that there is also a constant correlation between two consecutive differences in the third column.</li> <li>- When changing the angle, the values in the second column (except for the last), the last value in the first column, and the values in the third column change as well, but the differences between two consecutive values always remain constant: this may evoke the idea that the inclination affects the ball's movement and that the model of the spaces traversed by the ball is a quadratic function.</li> </ul>

## Data collection and method of analysis

To collect the data, the learning experiment was entirely video recorded. The students and their actions on the computers were captured. The collective discussion conducted by the teacher, after the students completed the task, was video recorded as well. Segments of the recorded clips of the students' transition between the real-world phenomena and the mathematical representation were identified and analyzed at a macro level according to the Blum's model. Thereafter, to have an in-depth insight into the learning processes, a micro level analysis was done using the semiotic mediation approach. At this level, the artefact signs and pivot signs used in the transition processes were identified and their evolution toward mathematical meanings were also considered and analyzed. In particular, the analysis was developed with the aim to identify semiotic chains in order to reveal the unfolding of the semiotic potential of the artefact throughout the modelling activity and the collective discussion.

## Results and discussion

Herein we present results coming from the students' interactions in one of the small working groups and from the subsequent whole class discussion conducted by the teacher.

As students were asked to see the Galileo experiment clip at home, when the first lesson starts they already have their own personal conjectures on the phenomenon. According to the task, they are asked to explore if and how the change of the plane inclination may affect the ball movement, to share their hypotheses and verify them. According to the observations done at home, they agree on the hypothesis that the more the plane is inclined the faster the ball moves. In order to verify their conjecture, they use the provided digital artefact and take notes of the values of the spaces traversed as the time elapses. That was obtained when they started the simulation with the given ( $24^\circ$ ) inclination plane angle. They realize that the difference between two consecutive numbers in the third column is always 4. Then, they change the angle to  $40^\circ$  and realize that the numbers in the third column are the differences between the corresponding two consecutive numbers in the second column. They take note of the values and change the angle to  $45^\circ$ . At this point, they are watching the first value in the second column and, while the others are comparing it with the one obtained before, one of the students, A., observes that:

00.26.27 A.: Yes, true, look, I told you that in one second it [the ball] always makes more distance.

But it seems that this observation is not useful for them to look for the relation among the variables - time and distance - so A. focuses on the last row and then a pressure of speeches and gestures follows:

00.26.51 A.: Here [*pointing to the last number in the first column*], if you see, instead of being 5.8, it's 5.5... changes... it is faster.

00.27.07 B.: Yes, true, because...

00.27.08 C.: The more it is inclined [*she moves her hands in the collective space in front of the screen: the left hand, raised with the palm facing up, would represent the final point they are focusing on and the right hand, waved up and down, would represent the increasing of the plane inclination*], the faster it [the ball]

is... than this here [*pointing on the screen and on the paper on which they have copied the data before*].

- 00.27.12 B.: The distances increase but this last datum [*pointing on the last difference on screen*] is not useful for us because it [the ball] arrives down before... let's try 50°.

Finally, when the angle is 50°, as the last number they find in the first column is smaller, they are convinced they have verified their hypothesis and then start writing their shared conclusion: “increasing the plane inclination and keeping the same time, distances increase and the ball moves faster if the plane is more inclined; the example shows that to reach the same final distance, 108, if the plane inclination is 40° it takes 5.8 seconds, if the plane inclination is 45° it takes 5.5 seconds”. In the students’ interaction described above it is clear how they are trying to interpret the artefact signs, obtained when accomplishing the task with the digital artefact, in order to give meanings to them in terms of the situation under study. In the following part of the lesson they attempt to find the way to mathematically express the relationship which describes the ball movement. They recognize that the graph of the distances, as times elapsed, cannot be modelled by a straight line. The work at this point is stopped by the teacher who decides to start the whole class discussion.

At a macro level, it is worth noting how in this initial phase of the activity students’ discourses move from the real world to the mathematical world. As a matter of fact, the teacher then needs only four minutes to summarize the situation. And when she asks if there is something that changes when passing from the video clip to the digital artefact the students immediately, and with judgment, answer negatively. The students’ answer reveals that the students consider the artefact as a mean for verifying the conjecture raised when they watched the clip. At this point, it is not clear what is the added value of the digital artefact in constructing meanings. However, the micro level analysis, as we will present below, highlights the specific contribution of the artefact in the process of the construction of meanings.

A micro level semiotic analysis, indeed, reveals how through the use of the digital artefact during the transition phase of the modelling activity, the signs emerge and evolve. The word “faster” referring to the ball when the inclination is increased, for instance, is a pivot sign which evokes, on the one hand the increasing of the numbers in the second column, on the other hand the decreasing of the last number in the first column, which represents the time needed to traverse the distance until the arrival, “to reach the same final distance”.

Hereinafter, the teacher (T.) conducts the class discussion with the aim of focusing on identifying the variables to be used to describe the situation:

- 01.00.20 A.: If when you incline the plan you increase the time... you take less time... the ball takes less time to traverse that distance...
- 01.00.34 T.: the ball takes less time to traverse that distance...
- 01.00.36 A.: the same distance, but as the plane is more inclined, the ball is faster.
- 01.00.42 T.: ok, so, to the same distance... [*she use her hands making an iconic gesture to represent a given quantity for the distance*].
- 01.00.48 A.: but time is smaller.

- 01.00.49 T.: Time is smaller [*she moves on her right as to represent a shifting on something else, namely what changes in the time*] And the same time?
- 01.00.52 A.: the distance... the distance is bigger.
- 01.00.58 T.: the distance is bigger...
- 01.02.20 T.: How can we read the table?
- 01.02.25 D.: when the time is 1 the space is 2.13, when the time is 2 the space is 8.51 and so in a given time the ball traverses a given space.
- 01.02.58 T.: and this space always increases more... as it happens in the video... and so how can I write a relation between this space and the time? Is it a line?
- 01.03.25 E.: No. Because otherwise it would have had all the same differences.
- 01.03.26 T.: and here?
- 01.03.27 E.: And here the differences are not the same.

From the modelling point of view, it is evident here that A. is trying to figure out what he has observed varying the inclination of the plane using the digital artefact in terms of movement of the ball. He is in the transition phase from the mathematical world to the real world. However, A. and his classmates still need to understand how to mathematically express the movement of the ball. The request to interpret the table, and to express the relationship between the time and the distances, allows them to focus on the third column, namely on the differences between the distances.

A semiotic analysis of the episode reveals some more details of the learning processes. Worthy of note is, for instance the semiotic chain in Figure 4 (identified in the transcript above) which highlights the unfolding of the semiotic potential of the digital artefact, through the emergence and enchainment of signs, and will bring to the quadratic function.

**Figure 4: An identified semiotic chain**

While students face the real world situation accomplishing the task through the mediation of the digital artefact, indeed, the signs they use are evolving. The focus on the difference of the distances would allow them later on to conjecture that the spaces traversed are proportional to the squares of the times according to a factor which depends on the inclination of the plane.

## Final remarks

Literature about modelling mainly focuses on the transition between the real world and the mathematical world. However, in our view, the way students move throughout the transition is not sufficiently addressed. This study attempts to deeply focus on the transition processes between the real and the mathematical worlds. Although these transitions are crucial in order to understand the overall modelling process, we believe that they are challenging and need a detailed analysis. Our

results suggest that a macro level analysis, based on the Blum's model, is not sufficient to reveal the contribution of technology in modelling activities. However, a semiotic micro level analysis can bring to the fore the role of the digital artefact in the complex students' transition processes. The semiotic mediation approach, indeed, helped us to highlight the complexity of the evolution from the artefact signs to the mathematical signs. In this evolution process the students used a variety of signs, some of them refer to the real phenomena while the others refer to the mathematical representation. Through this process the students also produce pivot signs which have a polysemy of meanings, namely they may refer both to the real situation and at the same time to the mathematical representation. Revealing the evolution of signs has not only a theoretical importance but also a practical one: the semiotic chain which bridges the gap between the real situation and the mathematical representation, indeed, can help teachers in their mediating process of the students' learning. This happened, for instance, in the episode we analyzed when the teacher fostered A.'s thought and signs to emerge and to be shared. In this way she guided the class to move from considering the final "real" effect - the ball is faster - to focusing on the distances (traversed) and the "mathematical" information given by their differences.

*Understanding the structure of the hypothesis testing procedure is challenging for many first-year university students. In this paper we investigate how providing automated feedback in an Intelligent Tutoring System can help students in an introductory university statistics course. Students in an experimental group (N=154) received elaborate feedback on errors in the structure of hypothesis tests in six homework tasks, while students in a control group (N=145) received verification feedback only. Effects of feedback type on student behavior were measured by comparing the number of tasks tried, the number of tasks solved and the number of errors in the structure of hypothesis tests between groups. Results show that the elaborate feedback did stimulate students to solve more tasks and make fewer errors than verification feedback only. This suggests that the elaborate feedback contributes to students' understanding of the structure of the hypothesis testing procedure.*

### Introduction

Hypothesis testing is widely used in scientific research and is therefore covered in most introductory statistics courses in higher education (Carver et al., 2016). This topic is challenging for many students, due to the large number of complex concepts involved (Castro Sotos, Vanhoof, Van den Noortgate, & Onghena, 2007). Students struggle to understand the logic of hypothesis testing and the role and interdependence of the concepts in the testing procedure (Vallecillos, 1999). Appropriate feedback might support students in comprehending this structure and understanding the line of argumentation in hypothesis tests (Garfield et al., 2008). Since group sizes in introductory statistics courses are often large, automated feedback in an online system seems a promising direction.

Carrying out a hypothesis test requires several steps, which have to be performed in a particular order. To address the structure of hypothesis tests, feedback should address all aspects of a solution: not only the content of individual steps, but also the relations between steps. An Intelligent Tutoring System (ITS) can provide such sophisticated feedback on the level of steps and can provide detailed diagnostics of student errors (Nwana, 1990). Such feedback on the step level is generally more effective than feedback on the level of complete solutions (VanLehn, 2011).

Although ITSs vary considerably in design, they generally contain the following four components: an expert knowledge module, a student model module, a tutoring module, and a user interface module (Nwana, 1990). Of these four, the expert knowledge module is the most domain-dependent. It contains information about exercises that students can solve in the ITS and about domain knowledge required to solve these exercises (Heeren & Jeuring, 2014), and is therefore also referred to as *domain reasoner*. Two important paradigms for constructing domain reasoners are model-tracing, in which the ITS checks that a student follows the rules of a model solution, and constraint-based modeling, in

which the ITS checks whether a student violates constraints. There exist ITSs that support hypothesis testing based on either of these approaches (Kodaganallur, Weitz, & Rosenthal, 2005). We combined the two paradigms in a single ITS supporting hypothesis tests, and in this paper we evaluate the feedback by this ITS. The research question guiding this evaluation is: does the feedback provided by the ITS contribute to student proficiency in producing well-structured hypothesis tests? Before describing the design of the ITS and the study design, we briefly discuss the two paradigms; for a more extensive overview, see the work of Kodaganallur and colleagues (2005).

### **Model-tracing**

The model-tracing paradigm concentrates on the solution process. The domain reasoner contains a set of expert rules: rules that an expert would apply to construct solutions to exercises in the domain. It can also contain buggy rules: incorrect rules that arise from incorrect domain knowledge. Finally, the domain reasoner contains a model tracer that can identify which expert and buggy rules a student has applied to arrive at a (partial) solution. After this identification, several actions can take place. If a buggy rule is recognized, a diagnosis of the student's error can be given. Otherwise, a hint for a next step can be provided, or just feedback that the current solution path is correct.

### **Constraint-based modeling**

Constraint-based modeling concentrates on partial solutions, rather than on the solution process. The underlying idea is that incorrect knowledge emerges as inconsistencies in students' partial solutions (Mitrovic, Mayo, Suraweera, & Martin, 2001). Domain knowledge is represented as a set of constraints, consisting of a relevance condition and a satisfaction condition. For instance, in the domain of hypothesis testing a relevance condition might be that the partial solution contains an alternative hypothesis and a rejection region, and the corresponding satisfaction condition that the position of the rejection region (left side, right side or two sides) matches with the sign of the alternative hypothesis. Errors in student solutions emerge as violated constraints, that is, as constraints for which the relevance condition is satisfied, but the satisfaction condition is not. If a student's solution does not violate any constraint, it is diagnosed as a correct (partial) solution.

## **Methods**

### **Design of the domain reasoner**

The technical design of the domain reasoner evaluated in this study is based on the Ideas framework (Heeren & Jeuring, 2014), which uses a model-tracing approach to calculate feedback. However, for the domain of hypothesis testing the constraint-based modeling approach was also considered useful, because of its capability to identify inconsistencies in solution structures. Addressing these inconsistencies might contribute to student understanding of the relations between steps, and hence of the structure of hypothesis tests. Therefore, the domain reasoner designed in this study combines elements of the two paradigms. It contains 36 expert rules, 16 buggy rules, and 49 constraints. Every time a student adds a step to a hypothesis testing procedure, for example defines an alternative hypothesis or calculates the value of the test statistic, the domain reasoner checks the student's solution so far. First, all constraints are checked, and if one is violated, the domain reasoner determines whether a buggy rule was applied. If so, a specific feedback message corresponding to

this buggy rule is displayed to the student, and otherwise a general message for the violated constraint is reported. For example, a student solution that does not contain an alternative hypothesis, but does contain a rejection region, violates the constraint with relevance condition “the solution contains a rejection region” and satisfaction condition “the solution contains an alternative hypothesis”. The corresponding feedback message addresses the role of the hypotheses: “To which hypotheses does this rejection region correspond? First state hypotheses”.

If no constraints are violated, the domain reasoner tries to identify the rule the student applied to arrive at the current partial solution. A feedback message corresponding to the identified rule is shown to the student, for example: “Your rejection region is correct”. If no rule is identified, the student’s partial solution is marked correct (“This is a correct step”), since no constraints are violated. Besides checking partial solutions, the domain reasoner can also provide hints on what next step to take.

The design of expert rules, buggy rules and constraints was informed by discussions with three teachers of introductory statistics courses in various disciplines about the structure of hypothesis tests and common errors by students. Furthermore, textbooks were consulted. Based on this input, we decided to support two methods for structuring hypothesis tests: the conclusion about the hypotheses can be drawn based on comparison of the test statistic with a critical value, or based on comparison of a p-value with a significance level. In each method, a complete solution should contain four essential steps: (1) state hypotheses, (2) calculate a test statistic, (3) either find a critical value or find a p-value, and (4) draw a conclusion about the hypotheses. Although crucial for the logic of hypothesis testing, stating a significance level was not regarded as an essential step, since it was always specified in the task description. Besides these four essential steps, students could include several other steps in their hypothesis tests, such as a summary of sample statistics and an explicit specification of whether the test was left sided, right sided or two sided.

### **Participants and study design**

The domain reasoner was used in a compulsory Methods and Statistics course for first-year psychology students at Utrecht University. In five weeks of this ten-week course, students received online homework sets consisting of 7 to 13 tasks that were selected by the teachers of the course. These homework sets were designed in the Freudenthal Institute’s Digital Mathematics Environment (DME; see (Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013), which supports various interaction types, such as formula input and multiple choice tasks. To enable intelligent feedback on hypothesis tests, a connection was set up between the DME and the domain reasoner.

The third, fourth and fifth homework set concerned hypothesis testing. Each of these three homework sets contained two tasks that specifically challenged the students’ proficiency in carrying out hypothesis tests, by asking the students to select steps from a drop-down menu and to complete these steps. An example is shown in Figure 1: after selecting a step from the drop-down menu called “Action”, it appears as next step in the step construction area. Next, the student can complete the step by filling in the answer boxes and use the check button to check the hypothesis test procedure so far. After finishing the construction of the hypothesis test, the student should state the overall conclusion in the final conclusion area, below the drop-down menu with steps.

To evaluate the effects of the domain reasoner feedback, students in the course were randomly divided into an experimental and a control group. This allowed for a comparison of student work between both groups, and differences in student behavior and learning effects could be ascribed to the only difference between both groups, the domain reasoner feedback (Cohen, Manion, & Morrison, 2011). From the 310 students in the experimental group 226 students worked on the hypothesis testing tasks, of which 154 gave consent for the use of their work in this study. From the 309 students in the control group 216 students worked on the tasks, of which 145 gave consent. The participants were on average 19.3 years old ( $SD = 1.7$  years) and 77% were female. To reduce the Hawthorne effect, i.e. the effect that students might behave differently because they were part of an experiment (Cohen et al., 2011), students were not told about the different conditions and whether they were in the experimental or in the control condition.

**Exercise 7**
**MTS1 HS 9 and 11**

How would you react if the grade you received for an exam is much lower than you had expected? Research suggests that most students think they can handle such situations better than their peers, but some students think their coping is worse than that of their peers.

In this study, participants were asked to read a scenario of a negative event and indicate how this event would influence their well-being (-5: worsen much, +5: improve much). Next, they were asked to imagine this same event from the perspective of a peer. The difference between both judgments was noted.

Suppose that for the sample of  $n = 25$  students the mean difference score was  $M_D = 1.28$  points (own judgment minus judgment peer) with standard deviation  $SD = 1.50$ .

Round off answers to two decimals, if necessary.

**Formulas**

**a** Based on these data, can you conclude that there is a significant difference between the own judgments and judgments of peers? Use a test with  $\alpha = .05$ .

**1** Step: State null hypothesis and alternative hypothesis

$H_0: \mu_D = 0$

$H_1: \mu_D \neq 0$  Check

**2** Step: Determine whether the test is left sided, right sided or two sided

The test is two sided Check

**3** Step: Find critical value

$t_{crit} = 2.064$  Check

**4** Step: Determine rejection region

$t < t_{crit}$  Check

**Action:** Choose ? ↩

**✗** Does the sign you use in the rejection region match with the direction of the alternative hypothesis?

Conclusion: There Choose significant difference between the judgments of ones own reaction and the reaction of a peer.

Partial scores

**Figure 1: Digital Mathematics Environment displaying one of the hypothesis testing tasks (translated)**

The homework sets were equal in both groups, except for the six tasks in which students constructed complete hypothesis tests by selecting and filling in steps. Students in the experimental group received feedback from the domain reasoner, whereas students in the control group only received verification feedback. Hence students in the experimental group received elaborate feedback on errors in the structure of their hypothesis tests, while students in the control group only received feedback on the correctness of their current step, irrespective of previous steps. As a consequence, for solving a task completely, students in the experimental group needed to include all four essential steps, since otherwise one or more constraints would be violated. For students in the control group, tasks were already marked as solved once they contained a correct conclusion about the null hypothesis. A final difference between the two groups was the hint functionality of the domain reasoner, but in this study we did not take the students' use of hints into account.

## Data and data analysis

Data for this study consisted of the students' work on the six hypothesis testing tasks in the DME, that is, all their attempts at constructing steps and drawing final conclusions in these tasks. After exporting log files with the students' attempts from the DME, work from students who did not give consent was deleted and all other attempts were anonymized.

Two measures served as indicators for feedback effectiveness: skipping vs. trying behavior and solving vs. failing behavior (Narciss et al., 2014). Skipping vs. trying concerned the number of students who skipped constructing steps and only filled in a final conclusion versus the number of students who tried constructing steps. This can be regarded as a measure of feedback effectiveness, since students who filled in a final answer without constructing steps apparently did not perceive the feedback on the steps as helpful. Solving vs. failing concerned the number of students who produced complete hypothesis tests versus the number of students who failed to produce complete tests. Since feedback was more elaborate in the experimental group than in the control group, we expected the proportion of solving students to be higher in the experimental group.

To find the number of students who tried constructing steps, for each task the number of students who made at least one step using the drop-down menu was counted. The total number of trying students over all tasks was calculated as the sum of these counts. Next, the total number of all trying and skipping students was found by summing the number of students who used the final answer boxes over all tasks. For both groups the proportion of trying students was found by dividing the number of trying students by the number of trying and skipping students. For solving vs. failing, we considered a task solved if a student had correctly included all four essential steps in the solution. The number of solving students was calculated over all tasks, and divided by the total number of trying students, to find the proportion of solving students. Chi-squared tests were used to evaluate whether the two proportions (trying as proportion of all students and solving as proportion of trying students) were significantly larger in the experimental group than in the control group.

The second part of data analysis concerned errors in the structure of hypothesis tests. Structure errors could be missing information, such as stating a rejection region before stating hypotheses, or inconsistent information, such as a rejection region that did not match with the alternative hypothesis. For the first few tasks, we expected an equal number of structure errors in both groups, since students had not received feedback on their errors yet. In later tasks we expected fewer structure errors in the experimental group than in the control group, and we especially expected that fewer students would make the same structure error in multiple tasks in the experimental group. For each task, the proportion of students who made at least one structure error was calculated and the proportions were compared using Chi-squared tests. Next, for each structure error that the domain reasoner could diagnose, the number of students who made it in only one task and the number of students who made it in multiple tasks were counted and these counts were summed. Again, a Chi-squared test was used to compare the proportions between groups.

## Results

Table 1 contains the proportion of students who tried using the stepwise structure in the experimental and the control group, and the proportion of students who completely solved the tasks, as proportion

of all students who tried the task. As can be seen in the table, students in both groups tried to construct steps almost 80% of the times, and there is no significant difference between these proportions in both groups:  $\chi^2(1, N = 1558) = 0.09, p = .759$ . This implies that the domain reasoner feedback did not impact the students' decision to try or skip using the stepwise structure to solve tasks.

	Experimental group	Control group	$\chi^2$	$df$	$p$ -value	Effect size
Total number of final solutions in six tasks	802	756				
Proportion of students who tried (vs. skipped)	0.77	0.78	0.09	1	.759	
Proportion of students who solved (vs. failed)	0.52	0.40	19.18	1	< .001	0.13

**Table 1: Proportions of students who tried vs. skipped, and who solved vs. failed, in experimental and control group, over all six tasks**

The proportion of students who included all essential steps in their solutions does differ significantly between the groups: in the experimental group, this proportion was 0.52 and in the control group it was 0.40 ( $\chi^2(1, N = 1208) = 19.18, p < .001$ ). The effect is regarded small ( $\phi = 0.13$ ). This result suggests that the feedback from the domain reasoner did support students in producing more complete hypothesis tests. Although positive, this result is not very surprising, since the domain reasoner feedback explicitly notified students of missing steps. To find out how much the domain reasoner really contributed to the students' proficiency in producing well-structured hypothesis tests, we also considered the errors students made in the structure of their hypothesis tests.

**Figure 2: Proportion of students with errors in solution structure in both groups**

Task	$N$	$\chi^2$	$df$	$p$ -value	$\phi$
3.4	297	0.345	1	.557	-
3.6	216	0.501	1	.479	-
4.7	207	5.086	1	.024	0.16
4.8	194	6.665	1	.010	0.19
5.3	158	4.936	1	.026	0.18
5.6	136	7.663	1	.006	0.24

**Table 2: Errors in solution structure in both groups for each of the six tasks**

Figure 2 shows the proportion of students with errors in their solution structure for both groups, compared to the number of students who attempted the tasks. The total number of students who attempted each task is given in Table 2. The graph in Figure 2 shows that for the first two tasks, 3.4 and 3.6, the proportion of students who made structure errors were quite similar in both groups, and above 0.70. This similarity between groups was to be expected, since students just started working with the feedback. For the latter tasks, however, the proportion of students who made structure errors decreased strongly in the experimental group, and remained higher in the control group. Table 2 displays the results of a series of Chi-squared tests which confirmed this finding: in the first two tasks,

the number of students who made structure errors did not differ significantly between groups, whereas in the latter four tasks, in the experimental group significantly fewer students made errors in solution structure than in the control group. This suggests that the feedback contributed to the students' proficiency in producing hypothesis tests without making structure errors. Considering the numbers of students who made the various structure errors just once and the number of students who repeated the same structure error in multiple tasks corroborates this finding: a Chi-squared test on these numbers yielded  $\chi^2(1, N = 1053) = 38.29, p < .001, \phi = 0.19$ , indicating that students in the experimental group repeated the same structure error in multiple tasks significantly less often than students in the control group. This confirms that the domain reasoner feedback was effective in reducing students' mistakes with respect to the structure of hypothesis tests.

## Conclusion and discussion

In this paper we have evaluated the influence of feedback from an Intelligent Tutoring System that supports hypothesis testing on student behavior in six hypothesis testing tasks. Our aim was to evaluate whether this feedback contributes to student proficiency in producing well-structured hypothesis tests.

Students who received domain reasoner feedback did not use the stepwise structure for producing hypothesis tests in more tasks than students who received verification feedback alone, but they did produce more solutions that included all four essential steps in hypothesis testing. Hence, as a consequence of the domain reasoner feedback, students in the experimental group had more opportunities for valuable practice on these essential steps (Narciss et al., 2014). Students in the control group tended to use the steps more as "isolated checkers", rather than as building blocks for producing complete hypothesis tests. By only selecting the steps they wanted to check and omitting the other steps from their solutions, these students missed out on opportunities to practice with the line of argumentation that is important for understanding hypothesis testing (Garfield et al., 2008).

Not only did the domain reasoner feedback encourage students to produce more complete hypothesis tests, it also supported students in doing this more independently. In the first two tasks the number of errors in solution structure was similar between groups, and hence students in both groups relied equally on the feedback to help them correct their errors. In the final four tasks, however, students who received domain reasoner feedback made significantly fewer structure errors than students in the control group. This indicates that domain reasoner feedback did more effectively support students in resolving their misunderstandings than verification feedback alone, which is in line with earlier findings that elaborate feedback is more effective than verification feedback (van der Kleij, Feskens, & Eggen, 2015).

In this paper, we just examined direct effects of the domain reasoner feedback on student behavior; we have only considered tasks in which domain reasoner feedback was provided and no subsequent work. Future work will focus on longer term learning effects of the domain reasoner feedback; do we see the same effects for other hypothesis testing tasks in which students do not receive feedback on their solution structure? Results from the study discussed in this paper are promising; students demonstrate proficiency in structuring their hypothesis tests and hence seem to have gained understanding of the roles of the different steps in this complex procedure.

## Acknowledgments

We thank teachers Jeltje Wassenberg-Severijnen and Corine Geurts and software developers Noeri Huisman, Martijn Fleuren, Peter Boon and Wim van Velthoven for the valuable collaboration.

# Problem-solving techniques in the context of an educational video game: the Mudwall puzzle in Zoombinis

Georgios Thoma<sup>1</sup> and Irene Biza<sup>2</sup>

<sup>1</sup>Ormiston Victory Academy, Norwich, United Kingdom; [g13thoma@gmail.com](mailto:g13thoma@gmail.com)

<sup>2</sup>School of Education and Lifelong Learning, University of East Anglia, Norwich, United Kingdom; [i.biza@uea.ac.uk](mailto:i.biza@uea.ac.uk)

*This paper aims to highlight the problem-solving nature of video games by examining problem-solving techniques in the context of the educational game Zoombinis. Using screen-capturing software, the gameplay of an 8-year-old participant was recorded and analysed in relation to his strategies towards solving the implicit Mudwall problem in the game, from a global-local perspective. Findings indicate the development of techniques — ‘stepping-stone’ and ‘probable-exclusion’ — that through Polya’s problem-solving steps, the game’s design and participant’s experimentation, can be used to solve the Mudwall puzzle, illustrating such game’s potentiality as a problem-solving environment.*

*Keywords: Problem-solving, video games, techniques, global-local problem.*

## Introduction

Compared to other media, video games offer interactivity to the player. As this unique attribute is constantly explored and worked upon by game designers, educational researchers examine the role video games can play to learning. Playing video games, for example, can create highly motivational and engaging environments for players (Van Eck, 2015). Devlin (2011) and Monaghan (2016) view video games as ideal means of presenting and learning mathematics, which, through their design, can potentially represent mathematics by overcoming the symbolisms used in paper. Literature has focused on ways video games could influence mathematical learning, either be played during students’ spare time (Lowrie, 2005) or be included in traditional classrooms (Moore-Russo et al., 2015) or other classroom settings (Calder & Campbell, 2016). However, even when researchers are optimistic about the future, they are still reserved on what has been realized so far by video games (Ke, 2008). Video games have been studied in many mathematics education research studies mainly as motivational and engaging educational environments (Kebritchi et al., 2010; Chang et al., 2015). Nevertheless, few studies focus on how mathematical content is presented in these games. The study (Thoma, 2017), part of which is presented in this paper, examined the educational game Zoombinis as a mathematical problem-solving environment for young children. Zoombinis has been viewed as engaging, challenging and motivational by previous studies (Yelland, 2002; Moss, 2004). The aim of this study was to examine how the problems are presented in Zoombinis, how young players interact with the game, and how they form techniques to deal with said problems. In this paper, we focus on the techniques developed by one participant in a specific puzzle of the game, called Mudball Wall (Mudwall thereafter). After presenting the theoretical framework of the study, a description of the game—and then the Mudwall puzzle—will be offered showcasing the key features that make it a problem-solving environment. Next, the analysis is presented using excerpts of the participant’s playthrough highlighting his techniques, followed by a discussion with concluding remarks.

## Theoretical framework

Downs and Mamona-Downs (2007) propose two perspectives on mathematical problem: the *local* and *global*. The authors argue that every problem's structure implies a global system of principles and assumptions that are related to this and other similar problems. However, the structure of a certain problem remains highly local and specific. Problem-solving approaches and arguments can develop at a local level, that in turn might be generalised from a global perspective, namely a meta-level of similar problems. According to Downs & Mamona-Downs (2007) the “switch” (p.2271) between the two perspectives might happen in two ways: by viewing problem-solving as an amalgamation of both global and local perspectives, or by examining strategies emerging from a local perspective, that become important in the global. One construction that could emerge through the interrelationship of the local-global could be a *technique*. In this paper, the term technique is used based on the definition offered in Mamona-Downs and Downs (2004):

A technique, as does a method, conveys a mathematical argument that can be extended over a variety of tasks. Our convention is that a technique splits the argument into pre-determined stages, each of which addresses a specifically formulated aim. For a method such explicit structuring is not stressed. (p. 236)

While techniques can be linked with a specific mathematical theory, some techniques can be formed as “products of problem-solving activities” and “successfully completed solutions” (p. 237). After formed, techniques can be used as problem-solving tools. This way one technique could deal with many problems, as well as objects, that share similar attributes, very often without the problem-solver being aware of this technique. Additionally, Mamona-Downs and Downs (2004) view each solution as a construction, which can guide a problem-solver towards understanding the technique as a response to past problem-solving experiences. Finally, techniques could be viewed as existing between heuristics and algorithms (Mamona-Downs & Papadopoulos, 2017).

## Video games as problem solving environments

Video games generally have an overarching theme, story or goal that create a setting for the player-problem solver. This is what we consider as the global perspective of the problem (*global problem* thereafter). The global problem is not always explicit, but rather it is experienced through solving problems from a local perspective that players face at each puzzle (*local problem* thereafter). Most of these local problems in games hint or build towards a solution of a global problem, either explicitly, shared with the players, or hidden from them until they make the connection themselves. We see video game problem-solving endeavour, having similarities to Polya's basic steps of problem solving (1973, pp. xvi-xvii): trying to understand the problem; making connections between available data to devise a plan; carrying out said plan; and reflecting on actions. Since video games are interactive media and usually offer real-time feedback the player may be guided by the game's design towards the steps mentioned. Additionally, variations of the same problem can guide the development of certain techniques. However, for the above to happen a player must have experience and a clear understanding of the games rules. Thus, the understanding for this paper is that techniques can be formed only once an initial exploration phase has past, when the player has some awareness of the actions they are allowed to perform and has formed an idea or expectations on what results said

actions might yield. Therefore, experimentation is important in these early stages and is usually the first step of a developing technique. In its mathematical essence regardless the problem, experimentation has the following elements:

“Locate the variables, the key-elements of the problem. Keep all except one constant, and start experimenting with this one to understand its role towards the solution of/solving the problem. Afterwards, keep this one constant and experiment using another one. Do the same for each element of the problem until you can understand the role each one plays towards solving the problem.” (translated from Greek, Mamona-Downs and Papadopoulos, 2017, p. 81)

Based on the above, a game can be defined as a collection of global problems, that through experimentation and consecutive playthroughs of local problems, can lead players into reflecting on their actions, and developing techniques that lead them to a solution.

### **The participant and data collected**

The participants of the study were four children aged 6 to 8 years old. A requirement for the study was participants had never played the game before. This way, the exploration and the formation of problem-solving techniques could be captured from their first stage of development. Data were collected by the first author through video captured from participants' gameplay, recording their on-screen actions, exclamations, inquiries, ideas as well as conversations between them and the researcher who is the first author of the paper. To enrich audio data, participants were advised to express their thoughts and actions verbally as has been done in similar studies (Ke, 2008). Additionally, suggestive and encouraging prompts were used by the researcher in an effort to produce more data, while creating a comfortable and game-friendly environment for the participants. The 8-year-old participant presented in this paper, with pseudonym Damian, played the game in four hourly sessions, in different days in a week.

For each participant, the screen recordings were categorized to short segments of playthroughs, namely successful or unsuccessful attempts of the same game puzzle. Then, the data were analysed according to participants' actions to go through the puzzle (experimentation); approaches to understand what works or not (local problem); being able to see the underpinning rules (global problem); being able to transfer what they have learned in one playthrough to the next one (shift from the local to the global); development of techniques. The total amount of time allocated in each stage and the gameplay session were also taken into account.

### **Zoombinis<sup>1</sup>: the game and the global-local problems**

Zoombinis are creatures that try to find a new home. Guided by the player in groups of 16, they visit and must go through a total of 12 puzzles before reaching their goal. Each Zoombini has four attributes: hair, eyes, nose and feet, and these are often the variables used in each game puzzles (three Zoombinis can be seen in Figure 2). Each puzzle has a penalty system that stops Zoombinis from progressing, thus forcing the player to backtrack, collect any Zoombinis left behind, and try the puzzle again. This way, players are encouraged to work towards more efficient and effective solutions,

---

<sup>1</sup> <https://external-wiki.terc.edu/display/ZOOM/The+Game>

improving them through continuous playthroughs of local problems. Based on the above, we define local problems of a puzzle the individual attempts of this puzzle. The puzzle has an underpinning rule that is controlled by variables that are not known to the player, which we call global problem. However, in each of player's attempts the values of these variables change randomly as we explain in the context of Mudwall in the next section. That means the player begins a new attempt with new values of the variables, which justify a new local problem. However, the global problem remains the same and the solver has to unpack it, often working unknowingly towards its solution. While a local problem might be solved by chance, this solution will not work the next time the player visits the puzzle, due to the randomization mentioned before. In order to be effective problem solvers, players need to find techniques for the global problem that corresponds to this puzzle that will allow them to solve every local problem they will encounter at this puzzle. Considering the specific penalty of each puzzle, the global problem is the search for an optimal solution with minimum and ideally zero Zoombinis left behind after the problem is solved.

### **The Mudwall puzzle**

In the Mudwall puzzle, the Zoombinis are faced with a tiled wall that obstruct their journey. The player tries to get the Zoombinis to go over the wall using a mudball launcher machine. This machine fires mudballs onto the  $5 \times 5$  tiled wall and the player needs to hit the marked tiles that have dots in them (a double-dotted marked tile can be seen in Figure 2). The number of dots on each marked tile corresponds to how many Zoombinis will go over the wall successfully. The machine has buttons of five colours (blue, red, yellow, purple and green) and five shapes (square, triangle, star, circle and rhombus). In each playthrough the  $5 \times 5$  matrix (named A for the purposes of this paper) is a permutation of five shapes on one axis, and a permutation of five colours on the other axis, which is not known to the player. Each cell of this matrix corresponds to a unique combination of shape and colour. Additionally, there is a hidden permutation of the two axes as well, as the colours or the shapes can either be on the horizontal axis or the vertical one. These random permutations allow for:  $5! \times 5! \times 2! = 28800$  possible different  $5 \times 5$  matrices. Furthermore, on each such matrix, marked tiles are distributed randomly. The number of marked tiles can be from one to eight, based on the number of Zoombinis the participant has at the beginning of this puzzle. We consider the local problem of the Mudwall as: "Are you able to find the coordinates (i.e. shape and colour combination) of all the marked tiles, on this specific wall?". The player does not have an unlimited amount of mud due to the penalty system of the game. Essentially, the player's aim is to use the least possible amount of mudballs to the player to locate the coordinates of the marked tiles. We consider the underpinning global problem: "Can you find the coordinates of the marked tiles, in each possible wall (out of the 28800 that might appear), by firing the least amount of mudballs every time?". In the following section, we describe Damian's playthroughs of the Mudwall puzzle and illustrate the development of his problem-solving techniques.

### **Analysis of Damian's Mudwall puzzle playthroughs**

Damian visited the Mudwall puzzle six times, spending 2 to 4 minutes in each playthrough, for a total of 15 minutes. It is important to highlight that due to the linear progression of the game described above, Damian was engaged with other puzzles in Zoombinis between playthroughs of the Mudwall.

Thus, a considerable amount of time has passed between each of the events described below, ranging from ten-minute gaps up to days. In his playthroughs he was mostly quiet and engaged, and only spoke about any of his strategies when he was sure of their results. In the following pages, matrices (Figures 1 and 3) created by the first author as part of the analysis demonstrate Damian's sequence of actions. Additionally, a screenshot (Figure 2) of the overall playthrough is offered where a step-by-step summary is not necessary.

At his first encounter with the Mudwall puzzle Damian is mostly exploring and experimenting, trying to understand how to interact with the puzzle. He located and used the available buttons of shapes and colours but he was not able to identify the goal of the problem and subsequently solve it. This experimentation phase was expected, as the Zoombinis video game constantly enforces an exploratory attitude through gameplay and narration, where players have to identify the variables, the goal and finally the solution of the problems they come across. Before ending his first playthrough, without having successfully launched any of the Zoombinis over the wall, he noticed that he run out of mud, which marks his first realisation of the penalty system of this puzzle.

**Figure 1: Damian's second playthrough, where he hit his first marked tile #9, the yellow-rhombus marked with a '+' sign in its center**

On his second playthrough, Damian shot four times consecutively the same yellow-star mudball (Figure 1, #1 to #4). During his shots, his cursor movements indicated how he was trying to hit adjacent tiles to yellow-star, by point-and-clicking on the tiles themselves, then firing the mudball. After his fourth shot, he stops trying to direct his mudballs this way, and explores different combinations of shape and colour. In his last two shots (Figure 1, #10) a pattern can be seen, the process of keeping one variable unchanged. This will be explored by Damian on his next playthrough. Finally, he managed to hit one marked tile  $A_{4,3}$  (Figure 1, #9). After conversing with the researcher, he became aware that this is his aim on the Mudwall puzzle, to aim for the marked tiles.

In the third playthrough (Figure 2), Damian focused on keeping the colour constant and changing the shape. Once the column with the yellow shapes was completed, he tried to complete the blue column until his mud finished. During this playthrough, Damian identified the relationship of colour and shape to columns and rows of the tiled wall.

**Figure 2: Damian's third playthrough, one Zoombini has made it over the wall successfully**

In his fourth playthrough (Figure 3) Damian found the coordinates of all the marked tiles, getting all his Zoombinis over the wall. This is his first totally successful playthrough, and from this point onwards he was able to develop techniques which he then uses on his last recorded playthroughs. We present this playthrough in detail, aiming to illustrate the techniques Damian developed. His first shot (#1) is a yellow-circle and the second (#2) a red-square (Figure 3). He changed both variables keeping neither colour nor shape constant. The current information does not allow him to relate the shapes and colours to the rows and columns of the matrix. With his third shot (#3) of a red-triangle, Damian keeps one variable constant (colour) and changes the second (shape). This creates a connection between the two mudballs: both share one variable, in this case the red colour (Figure 3, #2 and #3). These two mudballs now reveal that the matrix has colours in the columns and therefore shapes in the rows as illustrated below (Figure 3, #3-known data). We can see the approach of keeping one variable unchanged as systematic experimentation, which we name the *stepping-stone technique*.

**Figure 3: Damian's fourth playthrough and his first fully successful one**

Our interpretation is that Damian used the stepping-stone technique with the aim of landing on a marked tile. However, as the colours are in the columns he did not manage to land on the marked tile  $A_{5,1}$  and lands instead on tile  $A_{2,3}$ . By observing that the colours are arrayed on the columns, he can deduce that shapes are on rows. With the new information gained, Damian now focuses to hit either the tile  $A_{3,1}$  or  $A_{4,5}$  which are marked. He knows that the first row will be circles, the second triangles and the fifth squares. Thus, he eliminates all shapes except rhombus and star, as well as the colours red and yellow, as they belong on the third and fourth column respectively (Figure 3, #3-known data). Finally, he chooses the colour blue, and the shape of a rhombus, both choices for which he has no information yet. His fourth mudball is blue-rhombus that lands on  $A_{4,5}$  with success. We see this

elimination of available options as another type of systematic experimentation, which we call *probable-exclusion technique*.

For his fifth (#5) mudball, Damian uses again the probable-exclusion technique and fires a pink-star (Figure 3). This time his shot lands on  $A_{3,2}$ . He finally finds both tiles  $A_{3,1}$  and  $A_{5,1}$  using both the probable-exclusion and stepping-stone techniques.

On his fifth and sixth playthroughs Damian employs the strategies shown in his fourth playthrough. He begins by keeping one of the two variables constant in his first two mudballs. From that point he uses interchangeably the stepping-stone and the probable-exclusion techniques, aiming for marked tiles whenever he gains some new information. Both his last playthroughs were successful as he managed to get all his Zoombinis through with mud to spare.

## Discussion and conclusion

The aim of this paper was to examine the development of problem solving techniques in the context of the educational video game Zoombinis. We analysed Damian's experimentation approaches in relation to solving the local and global problem of the Mudwall puzzle, a problem he had no experience with. During his first local problem, he explored Mudwall by locating the variables, both colour and shape; as well as the penalty system of the mud decreasing after each shot. In his second local problem, he explored the machine's controls showing awareness of its function and managed to hit a marked tile thus experiencing a successful result, indicating his global problem goal. On his third local problem, he worked with only two colours, minimizing the variety of his choices, but establishing the connection between colour-shape to row-column. Finally, in his fourth playthrough he used the two techniques of stepping-stone and probable-exclusion, that combined lead him to his first successful solution in terms of the game. It is at this stage that Damian can be considered as having simultaneously solved the global problem of finding all the marked tiles without his mud running out. Thus, we identified strategies that go beyond random trial and improvement.

However, not every participant of the original study was as successful as Damian with the Mudwall puzzle. For the limited time of less than five hours of gameplay, all participants showed examples of experimentation, formed techniques and adapted them, some successfully reaching a global solution in the various in-game problems. It was also interesting how similar patterns emerged from the different participants' data, leading to the suggestion that due to carefully crafted game's design, players can be smoothly guided to a specific form of problem solving approaches.

This paper examined the video game Zoombinis as an environment used to learn problem-solving techniques. In their study Mamona-Downs and Downs (2004) highlight some issues regarding teaching techniques, such as students not wanting to use a technique after they had been taught it, and the difficulty to identify the underlying technique through the mathematical tasks which were provided for that reason. In my view, in the context of the video game, the first issue potentially could be resolved as students are the ones discovering and adapting the technique themselves. Problem-solvers implicitly guided by a global problem, they have the agency to interact and experiment in a story-driven and challenging environment and thus find the need for a more efficient solution. Along the way, techniques and other constructions formed from this process, would be something players developed on their own and something that is efficient at providing a solution.

*Drawing statistical inferences (SI) is essential in a society where data are of increasing importance. Understanding the relation between data and chance, necessary to understand statistical inference, is however challenging for students. Technological innovations – such as the Sampler in TinkerPlots (TP) – enable students to investigate this relationship by modeling a population and simulating repeated samples. Along this line, the research reported here presents the results of a pilot with fourteen 9th-grade students, inexperienced with sampling, in a Learning Lab. The pilot focuses on how students use TP as a digital environment for exploring data and chance – i.e. what strengths and constraints they encounter – and how they subsequently use this information for SI. The results suggest that the participating students encountered difficulties in modeling the population, however, they were able to simulate, explore and reason inferentially through repeated sampling in TP.*

*Keywords: TinkerPlots, repeated sampling, (informal) statistical inference, modeling, statistics education*

Drawing statistical inferences (SI) is essential in a society where data play an increasingly important role. However, the handling of variation and uncertainty involved in drawing inferences based on sample data, is challenging for students (Castro Sotos, Vanhoof, Van den Noortgate, & Onghena, 2007; Konold & Pollatsek, 2002). New technological innovations – such as the Sampler-option in TinkerPlots – enable students to model and investigate the interaction between data and chance in order to gain insight into variation and uncertainty (Biehler, Frischemeier, & Podworny, 2017; Pfannkuch, Ben-Zvi, & Budgett, 2018). Following this approach, Van Dijke-Droogers, Drijvers, and Bakker (2018) suggested an approach of repeated sampling with a black box filled with colored balls to introduce students, inexperienced with sampling, to the key statistical concepts of sample, frequency distribution from repeated samples and the simulated sampling distribution. This approach with a black box seemed promising to invite students to investigate the intertwined relationship between data and chance. As a follow-up to this study, the research reported here investigates *how* activities in the digital environment of TinkerPlots can strengthen the statistical insights of students, i.e. the interrelation between data and chance.

## Theoretical background

### Statistical inference

Statistical inference includes making statements about an unknown population based on observed sample results. In contrast to descriptive statistics, which concerns describing the data under

investigation, inferential reasoning includes the handling of sampling variation and interpreting the role of chance.

### Digital environments for statistical modeling

Recent digital environments that use dynamic visualizations and offer opportunities to create statistical models, enable students to investigate the intertwined relationship between data and chance. Tools such as TinkerPlots that have both data analysis and sampling capabilities, support young students to think about the modeling process. Creating statistical models to simulate data from repeated sampling can be helpful to develop key statistical ideas of distribution and sampling variation (Konold, Harradine, & Kazak, 2007). In an instant of time, a model of the population can be built in a digital environment and then be used to generate a large number of (repeated) sample results. In this way, student can explore sampling variation due to chance, especially when they visualize the results of repeated sampling in a sampling distribution. In this way, students engage in modeling, dealing with variation and thinking about the context (Pfannkuch et al., 2018). The work by Garfield, delMas and Zieffler (2012) shows that students can learn to think and reason statistically – or as the authors call it “really cook” – by using statistical modeling in digital environments.

### Repeated sampling in the black box activity

This learning—or cooking—effect is reflected in the work by Van Dijke-Droogers et al. (2018) on repeated sampling from a black box filled with small colored balls (“balletjes” in Dutch). The results of that study suggest that repeated sampling from a black box is a promising approach to introduce students to the concepts of sample, frequency distribution on repeated sampling (resampling) and the simulated sampling distribution, and, therefore, invites reasoning about variation and uncertainty involved in SI. An important characteristic of this 3-step learning approach seems the strong connection between a physical black box experiment in step 1, the visualization of expected sample results from resampling with a black box in a frequency distribution in step 2, and the simulated sampling distribution on resampling in the digital environment of TinkerPlots in step 3. An overview of the learning steps in the black box activity is displayed in Table 1.

1. Repeated sampling with the physical black box
2. Visualization of expected sample results from repeated sampling with the black box in a frequency distribution, by manually drawing a sketch
3. Simulation of a large number of samples from repeated sampling with the black box and visualization of results in the sampling distribution, by using the Sampler-option in TinkerPlots
4. Using the digital environment of step 3 in a new context

**Table 1: Overview of learning steps in the black box activity**

Van Dijke-Droogers et al. (2018) focused on step 2 and showed that students could, based on their experience in step 1, imagine and sketch a frequency distribution from repeated samples with most sample results close to the population proportion and in which strong deviations hardly occur. As a next step, the aim of the research presented here, is to gain insight into *how* statistical modeling with

the Sampler-option in TinkerPlots can strengthen the statistical insights of students concerning sampling variation due to chance. Therefore, we added a fourth step to the black box activity to investigate *how* students use TinkerPlots to explore data and chance in new situations and *how* they use this information for SI.

## Methods

To investigate how students explore and reason with TinkerPlots, we conducted a pilot study in the Teaching and Learning Lab of Utrecht University.

We have chosen to run the pilot in a lab setting. The advantage of this lab setting, over a classroom environment, was that detailed recordings could be made of the actions and conversations of several teams of students working on the same assignment at the same time. During a five-hour session, seven 9th-grade students worked in teams of 2 or 3, on tasks addressing steps 1 to 4 of the learning trajectory. This pilot was repeated in a similar five-hour session, with seven other students. The teams worked on a laptop, the screen of which was displayed on an interactive whiteboard. Camera recordings of their actions on the screen were made, and student conversations were recorded. Students noted their findings as a team on a student worksheet. We worked with students from pre-university level, the 15% best performing students in our educational system. Figure 1 shows the setup in the Learning Lab.

Figure 1: An impression of the setup in the Learning Lab

During the pilot, students went through learning steps 1–4 of the black box activity. Special focus was on how students applied their digital experiences from step 3 to investigate the role of variability and chance in the new context of step 4. In step 3, students used the sampler option in TinkerPlots to simulate repeated samples from the context of the black box. While doing so, they used an instruction sheet with the necessary technical actions in TinkerPlots. In this step, students investigated possible sample results by modeling a black box filled with 750 yellow and 250 orange balls at different sample sizes and different number of repetitions. During a group session in step 3, students discussed the boundaries of common sample results and decided that the middle 80% of the results can be regarded as “most common sample results”. They indicated the 10% highest sample results as “exceptionally high” and the 10% lowest sample results as “exceptionally low”. It was expected that the students would apply their experiences from step 3 in the new context of step 4, as detailed in Table 2. This table shows an overview of components A to G with statistical insights, TinkerPlots activities in step 3 and expected students’ activities in step 4.

Components of statistical insights	TinkerPlots activity in step 3 with the black box	Expected students' activity in TinkerPlots at step 4
A Sample results vary due to chance	Context: A black box is filled with 750 yellow and 250 orange balls. For each sample, the number of yellow balls is counted. Examine the sample results you can expect.	Context: At the beginning of the school year 210 out of the 300 students on a specific primary school were used to having breakfast daily.. Task 1: To investigate whether this is still the situation at the end of the school year, a sample of 30 students will be taken. Examine which sample results you can expect if the breakfast habits of students are unchanged.
B A model of the population can be entered and examined in a digital environment	Model the population in TinkerPlots by using the Sampler-option. The model can be entered as a pie chart, bar graph, histogram, dot plot or curve.	Students enter a model of the population in the same way as described in the cell on the left (TP activity B)
C Sample size effects sampling variation due to chance	Enter the sample size you want to examine.	Students enter the sample size they want to examine. In this example, the sample size is 30.
D Sample data can be listed in a table A visualization of sample data in a plot provides a clear overview	Simulate one sample, the results are automatically displayed in a table. To make a plot of the sample data, explore the data and choose a visualization that provides a clear overview.	Students simulate one sample of which the data are automatically listed in a table. They use the Plot-options to explore and clearly visualize their data.
E Repeated sampling in a digital environment can produce a large number of sample results. These results can be listed in a table by choosing one specific characteristic.	Use the history button to have repeated samples memorized. To do this, choose a specific characteristic—for example the number of yellow balls—that you want to record from each sample.	Students use the history button to record the number of “students who had breakfast” from each sample.
F A visualization of multiple sample results in a plot can be used to estimate possible sample results	Visualize the sample results in a sampling distribution. Use dividers to examine possible sample results, i.e. most common sample results, exceptionally high or low	Students visualize the sampling distribution and use dividers to examine possible sample results
G A larger sample size reduces the variation in the corresponding estimates of the population and hence, leads to a better outcome.	Estimate most common sample results and extrapolate these to the population. Then, try different sample sizes later for comparison. Draw a conclusion about the effect of larger sample sizes to the estimate of the population	Students estimate most common sample results and exceptionally high or low results to draw their inferences corresponding to the task (other sample sizes were addressed in tasks 2–4)

**Table 2: An overview of statistical insights, TinkerPlots activities in step 3 and expected students' activities in step 4**

<b>Sample size 30</b>	<b>Expected number of students having breakfast daily (interval notation)</b>
Most common sample results	
Exceptionally high results	
Exceptionally low results	

**Table 3: Table on student worksheet**

Task 2: In the past year a lot of attention has been paid to a 'healthy' breakfast at the school. At which sample result, sample size 30, is it likely that the breakfast habits of students have improved? Support your answer with data.

Task 3: At the end of the school year, a sample of 30 students was not feasible. Therefore, a sample will be taken of only 10 students. With which sample result can you now assume that the breakfast habits of students have probably improved?

Task 4: On closer inspection, the school board decides to postpone the sample to the next school year and to draw a sample of 100 students at that time. For which sample result is it likely that the breakfast habits of students have improved?

Task 5: Compare the sample results and corresponding estimates of the population at different sample sizes. What can you conclude about the population estimates from a larger sample size?

**Table 4 Tasks 2-5 on Student Worksheet**

For Task 1 in step 4, students could use a table on their worksheet, as displayed in Table 3. Students used TinkerPlots to determine most common sample results. For Tasks 2 to 5, more in-depth questions that mainly focused on the role of sample size were asked within the same context, as shown in Table 4. Students were free to choose their own working method within TinkerPlots.

## Results

The analysis of the video-recordings shows that the expected students' activities in components A and C to G did occur. However, the students encountered difficulties with component B. Students started with discussing the breakfast context in component A. Students seemed to be involved in this real-life context as they exchanged and discussed all kinds of possibilities and expectations based on their personal experiences and intuition, for example "Only 70% of these students have breakfast, that's way too low for a healthy school. Here, we have a lot more students who have breakfast." After sharing their thoughts, they started working in TinkerPlots. Here, in component B, making a model of the population in TinkerPlots, the difficulties began as 3 out of 6 teams used the sample information for their model. As such, they modeled the population by entering 21 for breakfast and 9 for no breakfast. When simulating samples from this population they got confused and asked the teacher for help. Referring to the black box activity in step 3, made them aware of the difference between population and sample. Another difficulty with the modeling was that 2 teams used a pie chart with percentages. These students entered 70% for breakfast and 30% for no breakfast. Although they used similar proportion as the given population, working with percentages refers to an endless population

and in this case the population size is given with 300. So, a finite population of 300 is a better model. After struggling at component B, the other components were performed as expected, although students occasionally needed guidance from the teacher, which mainly consisted of linking the new context in step 4 to the known context of the black box activity in step 3.

The activities in TinkerPlots (re)strengthened the statistical insights of students. As a first strength, each new component offered opportunities for students to discuss and reason about their actions in the digital environment and the implication of their actions. For example, at component A, a student stated “Well, they should take a larger sample to get a better picture of the school” and “Probably 21 students of the sample will have breakfast, or at least about 21 students. 22 or 23 is possible too. Even 30 is possible, but I don’t think that will happen”. Statistical concepts such as the effect of sample size and possible sample results that were addressed in steps 1–3 of the black box activity, were again considered and discussed by students in a new context.

As a second strength, students referred to terms from steps 1–3 of the black box activity, as they were using terms like “yellow and orange balls” and “content” of the black box. The lay-out and set-up of the digital environment offered opportunities to easily relate both contexts. The following fragment shows an example of students’ reasoning while modeling the population in task 1 of learning step 4, where terms related to repeated sampling with the black box are underlined:

- Student 1: Okay, we have a sample of 30. If nothing has changed, then probably 21 students will have breakfast.
- Student 2: I think so...
- Student 1: But it could be 22 or 23 students. I think that 27 or more cannot happen. What do you think?
- Student 2: Of course, it is possible, but....
- Student 1: What should we enter here (*pointing at the empty startup window of the Sampler*)? This is actually the total content, right? So, all students of the school?
- Student 2: Why not the 30 students... we are supposed to check on 30 students
- Student 1: I think, we should take the 300, because that are all students, like all the balls in the box and the 30 is just a sample, the visible ones... don’t you think?
- Student 2: Okay, so then we must enter 210 with breakfast and 90 no breakfast.

A third strength concerned the easy and rich way in which students could explore the data. They could easily create and compare different graphs, like pie charts, dot plots, etc. On the other hand, these explorations took a lot of time and it seemed like students based their decisions, for example about the format of the graph, on personal ideas and less on clarity. Moreover, choosing the right colors and shapes for the balls, was time consuming.

A fourth strength was that every component required action in TinkerPlots. Students could not thoughtlessly enter their values, but they had to be alert and aware of their actions.

In step 4, students were asked to carry out five investigative tasks and to note their answers on student worksheet. An outline of the results on students' worksheet are displayed in Table 5.

Task	Results	Frequency in teams of students	Example of students' reasoning
1.	Correctly filled in Table	6 out of 6	-
2.	Correct conclusion	6 out of 6	More than 25 students is exceptionally high, so ..... probably the breakfast habits of students is improved.  24 students is the boundary of most common sample results. So, with 26 students or more, it can be assumed that the breakfast habits have improved.
3.	Correctly filled in Table	6 out of 6	-
	Correct conclusion	6 out of 6	With a sample result of 9 or 10 students (out of 10) that have a daily breakfast, we can assume that the breakfast habits are improved, because this is an exceptionally high number.
4.	Correctly filled in Table	6 out of 6	-
	Correct conclusion	5 out of 6 (one team empty)	When more than 80 students (out of 100) are having a daily breakfast, this is extremely high, and therefore it is assumable that more students are having a daily breakfast.
5.	Correct conclusion		A larger sample size gives a more precise estimate of the population  The larger the sample size, the less variation in the corresponding estimate and the bigger the chance of a good estimate

**Table 5: Overview of results on students' worksheet**

## Conclusion and Discussion

The research reported here focused on how activities in the digital environment of TinkerPlots can strengthen students' statistical insights, i.e. the interrelation between data and chance. The main difficulty of students was creating a correct model of the population and, more particularly, distinguishing sample and population characteristics from a given context. However, entering the characteristics into the tool, TinkerPlots, did not cause any problems. The awareness of the difference between sample and population can be improved by spending more time and instruction to modeling a population in a variety of contexts.

A first strength of the activity in the digital environment of TinkerPlots was that students exchanged and discussed statistical information which may lead to a deeper notion of the concepts addressed. A second strength was that the lay-out in the digital environment could easily be related to the black

box activity (balls, sample size). Students explanations contained black box terms several times. A third strength concerned the convenient and rich way in which students explored the data. However, choosing appropriate representations was also time consuming and mainly based on personal preference over clarity. A fourth strength was that every thinking component required action in TinkerPlots, which increased their awareness of the statistical concepts involved.

Although the results seemed promising, a few critical points must be considered. The fact that the students went through the learning steps quite easily may have been caused by the short time frame in which the activities logically followed each other. Although the students were given quite open tasks in step 4, their approach was strongly influenced by their previous activities in step 1 – 3. In addition, the students occasionally needed help from the teacher, which consisted of linking the new context to the black box activity in step 1 – 3.

The results show that this activity with repeated sampling in the digital environment of TinkerPlots is a promising way of how the interaction between data and chance can be taught in a brief session. Researcher who would like to repeat this activity should consider that this research highlights the results of a small-scale pilot in a laboratory setting with high performing students.

# Reflections on item characteristics of non-routine items in diagnostic digital assessment

Irene van Stiphout and Madelon Groenheiden

National Institute for Test Development Cito, The Netherlands; [irene.vanstiphout@cito.nl](mailto:irene.vanstiphout@cito.nl) and [madelon.groenheiden@cito.nl](mailto:madelon.groenheiden@cito.nl)

*This article reflects on the construction of a digital diagnostic test for middle school in the Netherlands. During construction there was a constant struggle between testing higher order skills, concrete description of curriculum goals on the one hand, and the limited possibilities of the digital test environment on the other hand. Four item characteristics emerged that helped constructing non-routine items while managing with this challenge.*

*Keywords: Diagnostic tests, digital assessment, non-routine items.*

## Introduction

Task design plays an important role in mathematics education (e.g. Kieran, Doorman & Otani, 2015). In digital assessment, task design is complicated because task design requires time and keeping up with the newest developments (Venturini & Sinclair, 2016) while digital tools are constantly changing and being developed. Although there are strong arguments in favor of digital assessment (Stacey & Wiliam, 2013), significant challenges remain such as scoring higher order thinking skills and partial credit scoring (e.g., Sangwin, Cazes, Lee & Wong, 2010).

This article aims to contribute to the exemplification of how non-routine tasks can be constructed in a digital environment by reflecting on the construction of a national diagnostic test for middle school. Note that being non-routine depends on students' prior knowledge and proficiency. The diagnostic test aims to address key mathematical ideas that are important in the curriculum. The detailed goals and the automatic scoring of the test resulted in struggles between specific curriculum goals, the key mathematical ideas and the (limited) possibilities of a digital environment. During the construction process, four item characteristics emerged to overcome these challenges. The central question that is addressed in this article is how to design non-routine items in a digital test environment. Although the problems we met were neither new nor original, in our view, the context in which they took place was, because the test was meant for all students in Dutch education, had to serve diagnostic purpose and should enable automatic scoring. During the development of the test, the construction process evolved from a fuzzy and rather undirected process to a much more goal oriented and efficient process of creating non-routine items. Our reflection therefore aims to provide insight into how to construct non-routine items in a digital environment.

## Dutch educational test

The Diagnostic Educational Test (DET) was an initiative of the Dutch ministry of Education. It was administered at the end of middle school: grade 8 in vocational education and grade 9 in senior general higher education and pre university education. Its aim was to provide insight to students, parents, teachers and schools into how well prepared students are for upper secondary education. The national assessment authority (NAA) formulated several requirements for the DET. The test

**Figure 1: Formula window with editor palette above in the DET**

was to be taken on a computer. Technology should enable students to do mathematics interactively. Students were to use a digital test player environment and the scoring was to be automatic. This implies that the DET is an assessment *with* technology as well as *through* technology (Stacey & Wiliam, 2013).

For the construction of the items the digital environment Questify developed by the National Institute for Test Development (Cito) was used. Questify has several item templates such as numerical answers, drag and drop, and multiple choice. During the construction of test items, a template using GeoGebra and the Digital Mathematics Environment (Drijvers, Doorman, Boon, Reed & Gravemeijer, 2010) was added to these standard templates, in order to enable students to draw lines and figures. In school, students use a digital test player, developed by the NAA, that enables students to enter mathematical symbols such as square roots, powers, fractions, and formulas. See Figure 1. Each digital environment puts a demand on students' digital skills. In order to minimize the effects of this demand, we limited the number of buttons in the formula window and in Geogebra to a minimum. The automatic scoring uses an intelligent open source computer algebra system Maxima, that is able to recognize equivalent expressions and can deal with dependency in answers. The digital environment also makes it possible to add adaptivity to the test. In this way, students are presented with items that fit their level of expertise.

The test had to be based on curriculum goals described by the Dutch Institute for Curriculum Development. These goals encompass a domain on reasoning and reflecting as well as the mathematical domains numbers and variables, ratio, measurement and geometry, relations, and information management and statistics. For practical reasons, the examples below are restricted to one domain: geometry. However, our findings hold for the other four domains as well. The diagnostic framework consisted of a matrix combining the mathematical domains with didactic competences: seeing mathematical structure, having a proceptual view, seeing intertwinement. Since this framework was not confirmed by psychometrical analysis, we will not discuss it in depth in this paper.

Within these conditions, Cito developed the DET. Items were constructed by groups of mathematics teachers, the so called construction groups. They based their items on the diagnostic framework, the curriculum goals and the test advise commission. The items were then discussed with Cito test experts and screened by fellow test experts. During the next step, the test experts discussed the items with an expert panel of the national assessment authority. Approved items were then included in a pretest among students (age 14-15 years). The results of items in the pretest were interpreted by the test experts and again discussed with the NAA. This eventually led to a final version of the item.

**Figure 2: Overview of the construction process of items in DET**

Figure 2 provides an overview of this chain. The discussions in the construction groups, among test experts and in the expert panel, combined with psychometrical information on the pretest led, through a repetitive process of continuous reflection, adaptation and revision, to a feasible approach.

During the construction we were confronted with several conflicting interests. Below, we discuss the challenges we felt between higher order goals, the detailed specified curriculum goals, and the limited possibilities of the digital test environment.

### **Challenges in the construction of non-routine problems**

The first challenge was the ambition to focus on key conceptual ideas, while relating each test item to detailed specified curriculum goals. The focus on conceptual ideas was complicated because students had to have an overview of mathematical topics taught in several years in the test without preparing themselves specifically for the test. An additional purpose of the test was to provide insight in how well prepared students were for upper secondary education. These considerations led to the requirement to focus on key mathematical ideas and activities that are important in the ongoing curriculum (CvTE, 2014) without losing the connection to common educational practice. This focus put the construction under pressure: on the one hand, the focus is on key conceptual understandings students should master before going to upper secondary school, while on the other hand, each item in the test had to relate to detailed specified curriculum goals.

Another challenge between conceptual activities such as reasoning, and the limitations of the automatic scoring module to evaluate students' answers became apparent. Mathematics education in The Netherlands is influenced by the theory of Realistic Mathematics Education and Freudenthal's view on mathematics as a 'human activity' (e.g. Freudenthal, 1968, 1973; Gravemeijer, 1994). Recently, the cTWO (Dutch Committee for the future of mathematics education) stressed the importance of so-called 'mathematical thinking activities' such as reasoning, interpreting, organizing, structuring, manipulating (cTWO, 2007). The challenge was to construct items in a digital environment that focuses on conceptual goals and at the same time do justice to the idea of mathematics as a human activity. The prerequisite for automatic scoring is at odds with activities such as proving, reasoning and explaining because automatically evaluating these kinds of answers is technologically complicated (Drijvers, Ball, Barzel, Heid, Cao, & Maschietto, 2016). However, the focus on conceptual goals stresses the importance of including these kinds of activities.

In the following section we will discuss two examples to illustrate the way we managed these challenges. For practical reasons, these examples are restricted to the domain geometry.

### Examples of geometry items of DET

One of the curriculum goals is that students are able to calculate the area and circumference of a triangle (SLO, 2012). An item that fits this specific goal on a procedural level of understanding is to calculate the area of a triangle given its base and height. Students have to recall the formula ‘area of a triangle =  $\frac{1}{2} \times \text{base} \times \text{height}$ ’ and substitute the base and height to find the answer. However, this kind of question does not meet the idea of key conceptual understanding we were looking for. Students should be able to understand the formula from a conceptual point of view. A way to show this understanding is to draw a rectangle around the triangle. The rectangle clearly shows that the area of the triangle is half the area of the rectangle.

In our view, to understand the formula in terms of variables and the relations between them is of an even higher conceptual level. For example, triangles with the same base and height have the same area. Or triangles that have equal products of base and height, have the same area. In the ongoing curriculum, this is the level that indicates understanding of the formula for the area of a triangle. The item in Figure 3 illustrates this way of thinking. Two triangles are given with an equal base. The heights of the triangles is equal, but not specified. The question is to compare the areas of both triangles and to conclude whether the area of triangle I is greater than, equal to or smaller than the area of triangle II, or that the information is not sufficient to compare both areas. To answer this question, students should understand that the areas of both triangles are equal given equal base and equal, but unknown, height.

In our view, this item addresses both aspects of the first challenge: a detailed specified curriculum goal (compute the area of a triangle) and a key mathematical concept (reason about the formula). With respect to the second struggle between reasoning and the digital possibilities, we had to compromise. Clearly, the multiple-choice template leaves no room for creativity or for multiple correct answers. There is room, however, for multiple strategies because students can for example estimate the height and calculate the area in the way they are used to.

**Import User** Vraag 1 van 1

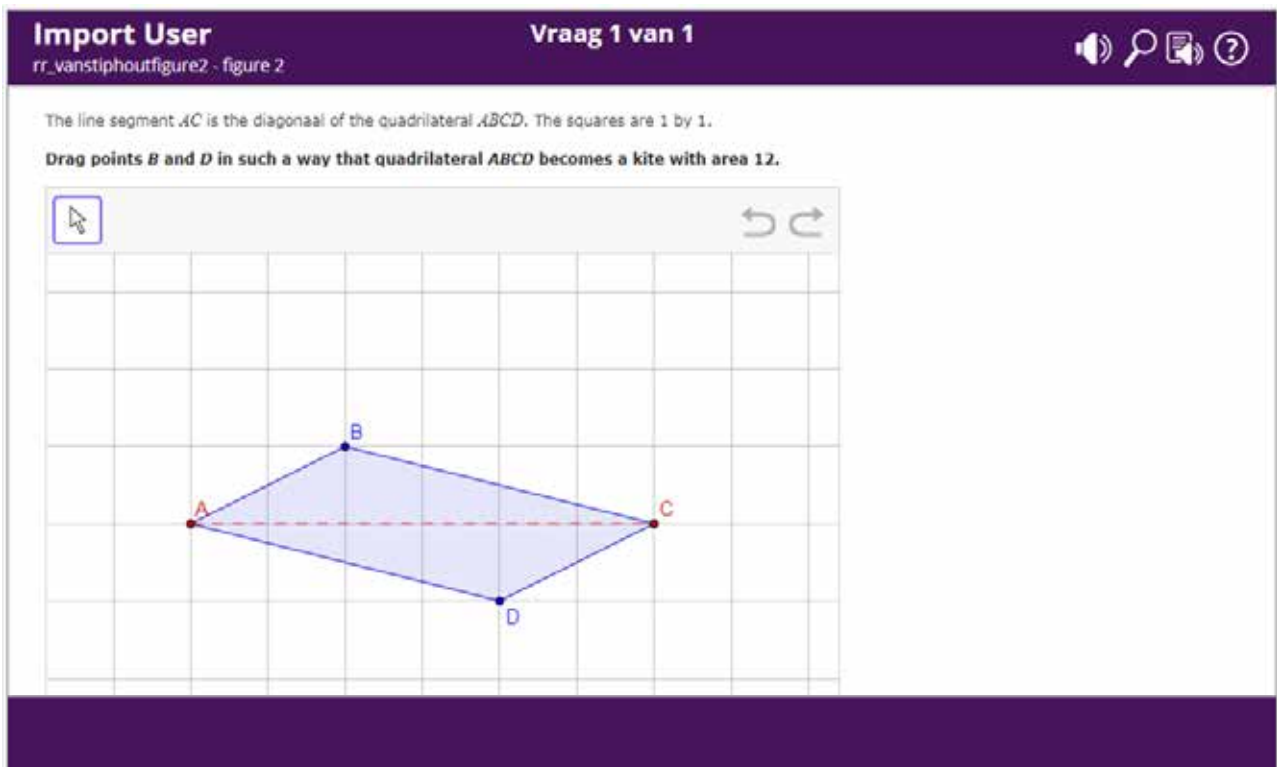

rr\_vanstiphoutfigure1 - figure 1

Compare the area of triangle I with the area of triangle II.

**Which statement is true?**

- ☐ The area of triangle I is greater than the area of triangle II.
- ☐ The area of triangle I is equal to the area of triangle II.
- ☐ The area of triangle I is smaller than the area of triangle II.
- ☐ You do not have enough information to know which area is greater.

**Figure 3: Multiple-choice item from the DET in the domain of geometry for vocational education students grade 9**

**Figure 4: GeoGebra item from the DET in the domain of geometry for vocational education students grade 9**

The second example is also about calculating area. Figure 4 shows an item for senior general education and pre-university students in grade 9. A curriculum goal for these students is to be able to calculate the perimeter and the area of triangles, squares, rectangles and circles, and from simple figures that are built of these figures (SLO, 2012). The item in Figure 4 asks students to construct a kite with given area. In the GeoGebra figure in the test player environment, the points  $A$  and  $C$  are fixed, so students are not able to drag these points. Neither can the dashed line segment  $AC$  be moved. The points  $B$  and  $D$  can be grabbed and moved along the grid. The line segments  $AB$ ,  $BC$ ,  $CD$  and  $AD$  move along while dragging points  $B$  and  $D$ . The purpose is to move points  $B$  and  $D$  in such a way that the quadrangle becomes a kite with area 12. In the automatic scoring module, a Boolean variable was defined for the position of points  $B$  and  $D$ . This Boolean combined three conditions for the position of  $B$  and  $D$ . First, the distance between those points has to be 4. Second,  $BD$  has to be perpendicular to  $AC$  because in a kite the diagonals are perpendicular. Third, the middle of  $BD$  has to be on the horizontal line through  $A$  and  $C$ , or  $B$  and  $D$  lie on the perpendicular bisector of  $AC$ . The latter two cases are due to whether  $AC$  or  $BD$  is the axis of symmetry. The only button students have at their disposal is the button with the arrow in the upper left corner. As a consequence, the only thing students can do is grab point  $B$  or  $D$  and drag it.

The struggle between the detailed goal and key mathematical understanding in this item is addressed by leaving room for different approaches and different correct answers. Students do not have to start from scratch and do not have to create anything new. Instead, they start with a given situation that has to be changed. In this way, they adjust the situation within the scope of the GeoGebra environment. Usually, in routine textbook items, the figure is given and the question is to

calculate the area. In this item, one diagonal is given and the question is to construct a quadrilateral with given properties. Because of the many different correct answers, students have to show a certain amount of boldness in making choices and to consider which characteristics contribute in which way to the area.

In our view, with respect to the struggle between reasoning and the digital opportunities, the item in Figure 4 is a fine example of finding a balance between the use of digital opportunities and the ability to construct and to create.

### **Item characteristics**

The examples above illustrate how the DET managed the challenges we mentioned. We want to emphasize that good functioning items have to meet other requirements as well as managing the challenges. The diagnostic character of the test should provide insight in where the learner is right now (Black & Wiliam, 2009) and perhaps give suggestions on how to improve. From a psychometrical point of view, features of items such as validity, reliability, duration, etc. are of importance. Constructing a high quality test requires both psychometrical and didactical expertise. In this article we will not elaborate on diagnostic or psychometrical properties, but focus on the content in relation to the digital test environment. During the five-year period of item construction (2012-2017) the following four item characteristics emerged as helpful in constructing non-routine problems.

### **Key mathematical concept**

The detailed specified curriculum goals can be interpreted in a conceptual way. The curriculum of grade 7 to grade 9 contains many procedures students have to learn. Examples are expanding brackets, solving linear and quadratic equations. To come to grips on key mathematical concepts, we used Sfard's (1991) notion of operational and structural conceptions and shifted the focus from procedures to the math behind these procedures. In the first example the focus shifts from calculating the area of a triangle with given base and height to reasoning about the formula of the area of a triangle.

### **Creativity**

The next step was to look for activities in the digital environment that match the key mathematical concept. The limited item templates and the limited possibilities of the automatic scoring module asked for creativity in the construction. We wanted students to construct, to invent, to draw, to create, instead of just following a standard procedure so that we could do justice to the idea of mathematics as a human activity (cTWO, 2007).

In the beginning, we only had regular item templates such as short answer, multiple choice and drag and drop. One strategy we used to create non-routine problems was for example instead of asking to calculate, ask *how* to calculate by showing different calculations. Another strategy was to present different steps in order to work out a solution to a problem and ask students to put these steps in the right order. We admit that the multiple-choice item in the first example above leaves no room for creativity. However, in the second example of the kite with area 12, students have to create their own kite and have to show a certain amount of boldness to use the construction space.

## Multiple strategies

In the ongoing curriculum, the ability to solve problems is valued higher than solving problems in specific ways. Therefore, we wanted items that allow for multiple strategies. In the first example students can reason or pick a number for the height to calculate the area, depending on their level of expertise. In the second example, students can make it easier or harder depending on where they drag and drop the points. The freedom to choose their own strategy matches the ideas of the aforementioned characteristics.

## Multiple correct answers

In our view, the best items were items that allowed for multiple (or even infinite) correct answers, because obviously, calculating is not the most important part of these items. The first example above is multiple choice, so it has only one correct answer. In the second example however, many different answers yield a kite with area 12. To have this characteristic, items should challenge students to make a choice. Clearly, the possibility to regard different answers as correct puts heavy demands on the digital environment.

Summarizing, based on these item characteristics, we developed the following approach to efficiently construct non-routine items. Start with a detailed specified curriculum goal (e.g. ‘the student can calculate the area of a triangle’). Unravel this specific goal into the key underlying mathematical concept (e.g. understand the formula  $\frac{1}{2} \times \text{base} \times \text{height}$  in terms of variables and the relations between them). Determine activities in the digital environment that address this key mathematical concept (e.g. arranging, categorizing, dragging and dropping, etc.). Quite often, it turned out that items constructed this way allowed for multiple strategies and multiple correct answers.

## Concluding remarks

Digital assessment has many opportunities. For example, Drijvers et al. (2016) argue that the benefit of digital testing is that it can challenge teaching practices that mainly focus on procedures and promote incorporating mathematical understanding. The diagnostic test developed by Cito in The Netherlands focused on non-routine tasks that appealed to key mathematical concepts. Based on our experiences in the DET with the construction of non-routine items, we extracted four item characteristics that helped us to come to grips on challenges with the limited possibilities of the digital environment the goals of the test. These four characteristics are: focus on key mathematical concepts, ask for creativity, allow for multiple strategies, and allow for multiple correct answers.

Although the examples in this article are only from the domain of geometry, our experience is that these item characteristics worked in the domains of numbers and variables, ratio, relations and information management and statistics as well. Furthermore, the characteristics are applicable not only for middle school. We believe that anyone who wants to construct non routine items in a digital test will face the challenge with the technological limitations and as a consequence might benefit from the heuristics described above.

Design principles often are tailored to specific topics or to specific activities (e.g. Kieran et al., 2015). Our characteristics cover five domains and all kind of activities and emanate from practical

experience on national level. This generalization over topics and activities is valuable, but asks for more theoretical underpinning. The problems we described illustrate that digital diagnostic assessment is still in an early stage. Fortunately, technological resources for mathematics education and assessment are growing rapidly, so hopefully these problems will be resolved in the near future.

## Acknowledgment

We would like to thank our colleagues Paul Drijvers, Wilma Vrijs and Ger Limpens from Cito, who provided valuable comments on earlier drafts of this paper.

## Introduction to the research question

The poster focuses on teaching and learning mathematics in three secondary classrooms in Paris, through the use of digital technology in the form of tablets. We are interested in the interactivity of teacher and students and the roles played by the tablets in engaging students with the mathematics in focus. We see tablets as tools used to satisfy the goals of both the students and the teacher in relation to their actions in the classroom. Here we use the language of Activity Theory which we take as a theoretical basis for our analysis of classroom activity. Indeed, taking the tablets as a focus, understanding their role in the teaching and learning of mathematics cannot be investigated without consideration of all the Activity in which they are used. Our broad research question about the use and role of the tablets for this study can be reformulated as follows: in what ways are the tablets engaged in the Activity (or Activity systems) which take place in the mathematics classroom?

## Methodology

We observed three lessons in which tablets are involved. We adopted a methodology which fits with Activity Theory as well as some French developments in the field of didactics of mathematics (Vandebrouck. 2018). For instance we include an *a priori mathematical analysis* in which we outline the mathematical knowledge or concepts to be addressed by students, the way these concepts are addressed by curriculum, epistemology, mathematics, and the difficult ideas which are evident to us from our didactical experience (the mathematical *relief* of the concepts according to Robert cited in Vandebrouck, 2018). We use didactical tools to analyze students' tasks (Horoks and Robert, 2007) as a way to understand both some of the teachers' motives (in relation with teaching mathematics) and the student's actions (in relation with these tasks). Videos showing classroom actions and interactions provide some evidence of the students' and teachers' actions and what students achieved in relation to the goals to be reached.

Following Engestrom et al. (1999), the units of analysis are then the Activity Systems that are collective, tools (or artefact) mediated and object oriented: actions are understandable when interpreted against the background of entire activity systems. Analysing teachers and (some) students' actions/interactions, we identify Activity Systems in the classroom (in reference to different teachers' motivations or students' motive/goals). Analysing the Activity Systems permits us to understand the effective use of *tablet-based tasks* by students and the role of these tasks as teacher' tools to which the outcome of the activity is a response. We highlight the way these systems evolve during the teaching process with tensions and perturbations (Abboud, Clark-Wilson, Jones, Rogalski, 2018). In particular we highlight those systems where the tablet plays a role, in order to address ways in which the tablets contribute to the teaching and to the students' mathematical learning.

## **Results: tablets between the individual and the collective dimension of activity**

In the first lesson, the tablets are tools to support a task with GeoGebra. They permit organization of the session in a traditional classroom (rather than in a computer laboratory) and are expected to favour communication between students in small groups. However, each student has his or her own tablet and the mathematical task is given in the tablet environment. So there is not really a need for communication between students. Moreover, the configuration of the classroom (small groups of four students) does not permit a whole class discussion and an organization of the Activity System in order to overcome this absence of communication between students. It seems that the tablets act as barriers for the collective dimension of activity which was one motive of the activity. In the second lesson, the situation is quite similar. However, the discussions occur among pair of students since there is only one tablet for each pair. Nevertheless, a tension appears between the pairs of students who succeed in the given task and the pairs of students who do not. So, the teacher organizes a new activity system with a reduced objective and a reorganisation of tools. The new motive is the success and understanding of all students in the task. The teacher gives his own tablet to a pair of students. This tablet is projected onto the board so that all the students can watch and follow the steps of the construction under the teachers' whole class instruction/discussion. The collective discussion is possible because of the classical organization of the classroom (not in small groups).

In the third lesson, students are supposed to investigate their previous knowledge in a relatively autonomous way in small groups as in the first lesson. The tablets are tools to provide several exercises (using Wi-Fi) and the tasks are solved on paper with pencils. Then students work together. The tablets are also present to provide a new kind of task for students: making collective videos for explaining their procedures and results on some exercises. This is also a way for the teacher to draw attention to some tensions between students. Indeed, tablets and videos allow the teacher to project solutions of some tasks onto the board and they foster class discussions. As in the second lesson, the tablet is then a fundamental tool in the teacher's activity system, compensating for the original organization with small groups and individual aspects of the session.

From our analyses of data from the three classrooms we see ways in which the tablets take a central role in the Activity Systems involved. These will be shown briefly within the poster.

# The long-term effects of MathCityMap on the performance of German 15 year old students concerning cylindric tasks

Joerg Zender and Matthias Ludwig

Goethe University Frankfurt am Main, Faculty of Mathematics and Computer Science, Germany;  
[ludwig@math.uni-frankfurt.de](mailto:ludwig@math.uni-frankfurt.de), [zender@math.uni-frankfurt.de](mailto:zender@math.uni-frankfurt.de)

*At the Goethe University Frankfurt am Main a study amongst 9<sup>th</sup> graders was conducted. It was about the effects of a mobile app supported mathematics trail on the performance concerning tasks on cylinders. It was supported by the MathCityMap app. In the first test after the treatment, the treatment group performed significantly better than the control group. After half a year, the same test was written as a follow-up. Now the treatment group has nearly the same results than the first time, but the control group performed significantly worse. This leads to the assumption, that the treatment may have an influence on the long-term memory. This is supported by theories such as outdoor education, integrated thematic instruction, enactive learning or self-determination.*

## Introduction

A mathematics trail (or maths trail) is a walk at which mathematical problems can be discovered and/or solved along the way (Shoaf, Pollak, & Schneider, 2004). To find these problems, a maths trail guide is needed, whether as a person or a printed/electronic version. Mathematics trails have been around at least since the early eighties (Lumb, 1980). The first publications mentioned the importance to make the mathematics in the environment visible for children (Blair, Dimbleby, Loughran, Taylor, & Vallance, 1983). Therefore, mathematics trails have been introduced internationally on the IMU conference on the popularisation of Mathematics (Blane, 1989). Although maths trails have been in use for quite some time now, surprisingly few studies have been conducted about them. So far, there has been no systematic approach to research the learning outcome and the long-term effects of mathematics trails in school.

Another way to use maths trails in school can be found by Toliver (1993), who let the pupils find mathematical tasks in the surrounding of the school. The focus is not to solve problems but to find some and therefore discover the mathematics around us. It took quite some time, since Traylor (2005) asked if maths trails have the potential to not only make mathematics visible but also improve the learning outcome of the pupils. She left this question without an answer but could show that a general treatment in problem posing does not increase the problem-solving skills of pupils.

Various authors have been stating the positive motivational aspects of maths trails (Shoaf et al., 2004), and newer quantitative studies have revealed this positive effect (Cahyono & Ludwig, 2017). Since we know about the influence of motivation towards performance in mathematics (Chiu & Xihua, 2008), there seems to be a clue, that running a maths trail is not only affecting the motivation but could also help to increase the performance of the pupils. On the one hand, Ryan and Deci (2000) have written on the three needs of motivation: autonomy, competence, and relatedness.

Sending pupils in small autonomous groups on a maths trail can support these needs. For sure the autonomy is given, but also the relatedness if the pupils work together.

On the other hand, maths trails are strongly supported by learning theories of Bruner (1971). Bruner stated that it is important for learning that it is represented on three levels, the symbolic, the iconic and the enactive level. Going on a maths trail directs to the enactive level, while the school lessons normally address strongly the symbolic level and illustrations on the blackboard and in textbooks supports the iconic level. If pupils go out and measure, they can see the real objects and discuss to choose the right model for the task. In addition to the iconic and symbolic level they have experienced in the classroom, they can get their hands-on mathematics in an enactive way. Running a maths trail is one way to enrich the school lesson by an enactive element. This idea of learning with all senses is also supported by the integrated thematic instruction model (Kovalik & Olsen, 1994). Kovalik and Olsen stated that learning with all senses, making real experiences instead of just reading of them, will be remembered longer by the children than any other form of lesson.

Furthermore, we know that outdoor education can have positive effects if it is carefully planned and conducted as well as being integrated into the school curriculum (Dillon et al., 2006). This should not be underestimated and taken care of when setting up a mathematics trail. And finally, yet importantly, walking a maths trail is a moderate physical activity, which we have clue for its positive effect on mental performance (Westman, Olsson, Gärling, & Friman, 2017).

### MathCityMap

In addition to these approaches, the MathCityMap project was established at the Goethe University of Frankfurt (Jesberg & Ludwig, 2012). It provides users with a web portal as a GUI for a database of maths trail tasks and routes as well as with an application for smartphones (iOS and Android) to compile this data into a mobile trail guide (see figure 1). The app gives feedback on solutions (wrong/right) and the users can take hints from the app. Following the ideas of Aebli (1983) it is important to give direct feedback, so no wrong solution is without comment.

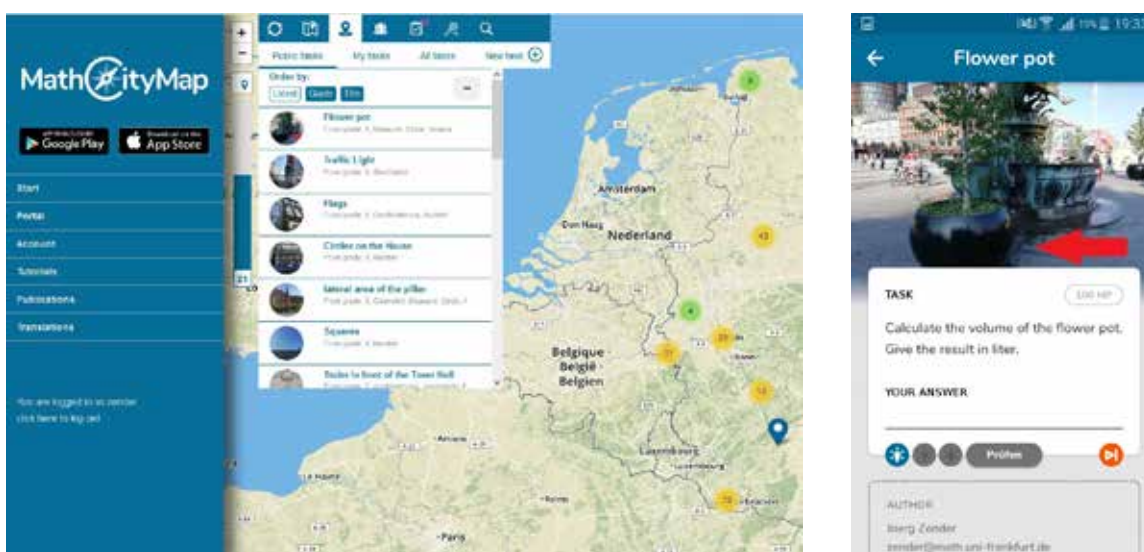

Figure 1: MathCityMap webportal (left) and smartphone application (right)

## Research question

With all these clues, the question remains, what effects can we expect for pupils going on a math trail? Especially what effect does it have on the long-term memory? To answer these questions, we have conducted a study in 2017 in Frankfurt.

## Method

In 2017, we collected 23 classes in the area of Frankfurt am Main and surrounding with a total of 629 pupils from 9<sup>th</sup> grade to conduct a study concerning the effects of mobile-supported mathematics trails with the MathCityMap app. All these classes wrote an entrance exam based on the German VERA8 test to measure the general mathematical performance of the pupils. Since some pupils missed the day of the exam, only 578 have participated. After this was done, the classes were separated in treatment and control group, to control the variable of mathematical performance. Also, from every participating school, at least one class was picked for control and one for treatment group, to control the variable of being on a certain school. Other variables that could influence the results, like the quality of the teacher, have been randomized by the number of pupils participating. A total of 323 pupils have taken part in the treatment. Both groups wrote another exam to compare their performance, only 529 participated in that exam. In the end, there were 273 pupils of the treatment and 182 of the control group we have full data from. For the follow-up test half a year after the treatment, we have full data for only 42 pupils from the treatment and 37 from the control group.

The treatment itself contained walking two maths trails for 90 minutes each in a group of three. The trails include ten tasks from which five (every second) was a task related to the topic of cylinders. After an analysis for German textbooks for ninth graders (see figure 2), we found only four different type of textbook word problems for cylinders of a certain amount (see table 1). Asking for

- the volume (V),
- the surface (S),
- the lateral surface (L) or
- the height (h), if volume and diameter or radius (r) is given.

16. The Ashtray on the right side is made of Brass (measurements are in mm). 1 cm<sup>3</sup> of Brass weights 8,6g. What is the weight of the Ashtray?
17. An advertising pillar (see left side) has a diameter of 1,30 m. It is 3,20 m high. The base of 50 cm should not be covered. 1 m<sup>2</sup> advertising aerea costs 99 Euro, including taxes.

**Figure 2: Part of a German textbook page with tasks on cylinders**

**Table 1: Analysis of German textbooks**

Given	Asked	Book 1	Book 2	Book 3	Book 4	Book 5	Book 6	Total	In %
r, h	V	13	7	9	2	15	11	57	50,9
r, h	S	1	3	3	2	5		14	12,5
r, h	L	5	3	2	2	4	1	17	15,2
V, r	h	6		3		5	3	17	15,2
V, h	r	2	1	1				4	3,6
S, r	h					2		2	1,8
S, h	r							0	0,0
L, r	h							0	0,0
L, h	r	1						1	0,9
L, S	r							0	0,0
L, S	h							0	0,0
L, S	V							0	0,0
Total		28	14	18	6	31	15	112	100

For all these four kinds of tasks, an outdoor task has been created in both trails (see figure 3). In case of the advertising pillar (see figure 2), a real advertising pillar was used. Being outdoors, we tried to create authentic tasks in the sense of Vos (2011). The pupils used the MathCityMap app on smartphones provides by the Goethe University. On these phones, all progress has been logged, so that we have full data of the tasks solved by the pupils, the results they have given, the feedback they received, the time they needed and so on.

**1. Task: Memorial of Alzheimer**

**What is the weight of the plate?  $1\text{m}^3$  steel weights 7900kg. Give the solution in kg.**

**Solution:**

**Figure 3: Sample tasks from the study about the weight of a cylindric plate**

## Results

For the first test after the treatment, the treatment group has performed significantly better than the control group (t-test,  $p < 0.01$ ), but the effect size was small ( $d = 0.398$ ). Divided into grammar school and secondary school, the effect was limited to the grammar schools (Zender & Ludwig, 2018). By dividing the grammar school pupils ( $N = 256$ ) into three performance groups of the same size due to the results of the entrance exam, it was revealed that the low performer and the middle group had both shown significant differences between the treatment and the control group ( $p < 0.01$  for both) with middle effects (low performer:  $d = 0.631$ , middle performer:  $d = 0.699$ ). Only for the high performer, no effect could be found.

The Follow-Up test also shows some interesting results. Unfortunately, only two schools with two classes each have participated ( $N = 79$ ). Both are secondary schools. Compared to the first test, the treatment group scored nearly with the same mean and there is no significant difference between the first test and follow up. On the other hand, the control group has had a significant difference, they got worse in the follow up (see table 2).

**Table 2: Differences between the first test and the follow up test**

Group	<i>N</i>	<i>M</i>	<i>SD</i>	<i>P</i>	<i>D</i>
Control	37	-1.838	1.860	0.000	-1.150
Treatment	42	0.071	1.538	0.384	0.034

Can the effect of the single maths trail tasks be estimated? The pupils have used smartphones from the Goethe University and their efforts have been logged on these phones. Therefore, we know precisely which tasks the pupils have solved, so that we can observe the learning outcome of different groups on specific tasks. One example is the type of task where the volume and the radius or diameter is given, and the height is asked. This was a task in the test after the treatment. We have the control group ( $N = 196$ ) with no specific treatment and treatment group can be divided into three groups. Those who have not solved a corresponding maths trail task ( $N = 118$ ), those who have solved one corresponding task ( $N = 122$ ) and finally those who have solved both corresponding tasks ( $N = 73$ ). The difference between having at least one task solved to none task solved is significant ( $X^2$ ,  $p < 0.01$ ) with a small effect ( $V = 0.19$ ), see table 3.

**Table 3: Effects on solving maths trail tasks to solving textbook task**

	<i>Control</i>	<i>Related tasks in the Treatment</i>		
		<i>None solved</i>	<i>One solved</i>	<i>Both solved</i>
Textbook solved	10%	7%	23%	33%
Textbook not solved	90%	93%	77%	67%

About the benefit of using mobile technology to support the math trail, we also have data. As mentioned, the smartphones logged the progress of the pupils. From the existing log data, we know that 78% of the groups, who tried to solve a task, were successful. Only 37% of them were successful in the first try. This leads to the assumption that in a setting without technology, 63% of the groups would have written down wrong answers and would have been aware of their fault only later in the classroom.

## Discussion

In his study in Indonesia, Cahyono (2017) could show the significant but small effect on the mathematical performance of pupils when taken part in a maths trail. These findings are similar to the one we have in Germany, also a significant and mostly small effect on the short run. What is new is the follow-up test, which gives us the hint that the results of the test are stable for the treatment group and getting significantly worse for the control group. Although the sample size is small, and we must be careful with clues, the results are supported by the theories of Bruner (1971) and Kovalik and Olsen (1994) according to the importance of enactive learning. It is also interesting that the treatment group we have tested in the follow-up did not perform significantly better in the first test, but their adopted knowledge seems to be more stable than that of the control group.

One possible assumption is that the mobile supported maths trails (which can be created and conducted with MathCityMap) have the potential to influence the mathematical performance of pupils not only for the moment of the treatment but also for the long-term memory. The technology is in two ways important for the maths trail activity. First, the teacher can use the technology to create a trail, monitor the pupils while being outside and collect their results. So, the teacher can open up the classroom to go outside but is still in control of the learning environment without being physically present around the pupils.

On the other hand, we have also benefits for the pupils. As mentioned above, they get direct feedback on their solutions. For sure, they validate their results amongst each other in the group of three, but the app allows getting a validation from the teacher, while the pupils are still at the object of the task. The feedback in combination of the available hints makes it possible that they can revise their solution, get new measurements, find another model and so on. With the support of the log data of the smartphones, it could be shown, that only about 37% of the pupils are able to solve a task properly on the first try. 63% of the pupils would have noticed their fault later in the classroom. Too late to revise the task and perhaps not being interested to solve it anymore. By the high number of right solutions after feedback, we can estimate the motivational potential the app has for the pupils. The use of technology is the main reason the pupils finish the task properly. The app is the main reason that a successful maths trail could be set up by the teacher without accompanying the pupils. This leads to the possibility to be on the maths trail as an autonomous group of three for the pupils. From Deci and Ryan (2000) we know about the importance of autonomy for intrinsic motivation, and Hattie (2014) could show the positive effects of working in small groups. These positive effects are results of the maths trail, but the technology allows the teacher to set up such a powerful learning environment.

Further research is needed to give better clue if this assumption holds true. Moreover, if it does hold true, we have to research deeper on the reasons for success. This is very important, not only to give the advice that maths trails are good for schools but also to point out what it is to take care about when running a trail at school to make it a success. What we do know so far is that going out on a maths trail should be done more frequently. A single event is not half as strong as two related events (Zender & Ludwig, 2018).

What we also now have a clue about is that the maths trail tasks have an influence on the learning outcome. It is not “just” movement and fresh air since we can see that the performance of the control group and the group without solving corresponding tasks are very similar. Because the treatment group had some of their lessons replaced by the maths trail activity, it could explain, why they are a bit worse, if they have not solved a corresponding task. There is maybe a lack of practice, and this is something a teacher should care about when designing a maths trail activity. On the other hand, we can see the significant increase of success on the test task when solving one or even both corresponding tasks of the maths trail. So, we know now that there is an effect, but little do we know about criteria of good tasks. What makes a maths trail task successful? Also, on this interesting topic, further research is needed.

At last, we have clues about the benefits of using technology, the direct feedback for example. We can conclude from the data that most of the pupils would have written down wrong answers without the technology. But we have no control group walking a maths trail only pen and paper to determine the effect size on the learning outcome. Again, further research is needed. We are just at the beginning to understand maths trails and technology.

# Exploring the role of context in students' meaning making for algebraic generalization

Angela Zoupa and Giorgos Psycharis

National and Kapodistrian University of Athens, Greece

[mekkapsaki@hotmail.com](mailto:mekkapsaki@hotmail.com), [gpsych@math.uoa.gr](mailto:gpsych@math.uoa.gr)

*In this paper we present results of a study aiming to investigate 7<sup>th</sup> grade students' construction of meanings for algebraic generalization. The students worked in groups using a specially designed microworld to explore tasks aiming to link figural patterns to realistic situations. Our focus is on the role of specific contextual elements (i.e. realistic task, digital tools, means of symbolization) on students' meaning making. The combined use of Abstraction in Context and microgenetic analysis indicates the critical role of the available software structures in mediating students' generalizations from the real context of the task to the algebraic context of school mathematics.*

*Keywords: Generalization, Algebraic thinking, Objectification, Microgenetic analysis.*

## Introduction

In this study we investigate 7<sup>th</sup> grade students' construction of meanings for algebraic generalization. The students collaborated in groups of three using the exploratory microworld eXpresser (Noss et al., 2009) to create figural patterns by expressing their structure through repeated building blocks of square tiles and developing the rules underpinning the calculation of the number of tiles in the patterns. The microworld allows students to use (iconic) variables to reproduce their constructions for different number of repetitions, to express generalization and to check their correctness through appropriate feedback. In this paper, we focus on the role of specific elements of context (i.e. realistic task context, digital tools, various means of symbolization inside and outside the digital environment) on students' meaning making for algebraic generalization.

## Theoretical framework

A way to introduce students to algebra is to be aware of a pattern or regularity and then try to express it through a relationship (Mason, Graham, & Johnston-Wilder, 2005). There is something inherently arithmetic in algebra and something inherently algebraic in arithmetic, and pattern activity brings these two aspects together (Radford, 2014). Algebraic thinking is characterized by its analytical nature and it is related to the semiotic system used by students to work with symbolic expressions and relations including not necessarily alphanumeric symbolism but also non-symbolic and embodied forms of expression (ibid). Radford (2010) developed the theory of objectification with which he describes the semiotic transition of students from the distinction of a similarity in its expression as a generalization in more mathematical ways through the use of signs (gestures, words, symbols). In order to investigate the process of generalization by students as an algebraic activity, Radford (2014) suggested three features of algebraic thinking: (1) indeterminacy: the existence of unknown quantities (e.g., variables, parameters), (2) denotation: the need to name and symbolize these indeterminate quantities in different ways (not only with algebraic symbolism, but also with alphanumeric signs, natural language, gestures, or a mixture of these); (3) analyticity: the manipulation of indeterminate

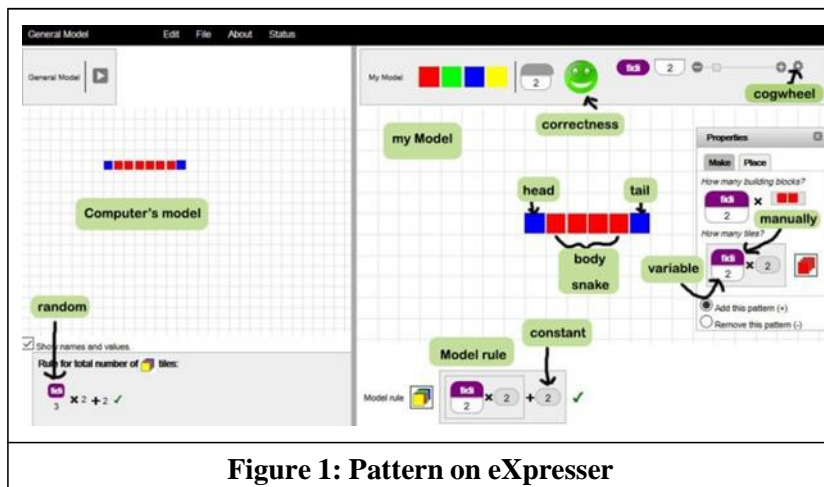

quantities (through operations such as addition, multiplication) as if they were known. According to the theory of objectification, knowledge moves through specific problem-solving/posing activities from an abstract indeterminate form of possibilities (what students can potentially do and think and in what ways) to a concretized form of reasoning and action (“bringing-forth” something to the realm of attention and understanding). Recognizing the centrality of the abstract-concrete duality in the process of objectification, in this study we consider objectification as an abstraction process taking also into account the link between knowledge construction and context (Cole, 1996). Context includes dynamic factors such as student interactions with peers, teachers, tools, realistic scenarios and algebraic expressions, that may affect an abstraction process (e.g., for algebraic generalization). The role of context is crucial to learning processes and the complexity of learning processes is due, at least in part, to the context’s influences on the student’s constructions of knowledge (Dreyfus, 2010).

We combine Abstraction in Context (AiC) (Hershkowitz, Schwarz, & Dreyfus, 2001) and microgenetic analysis (Siegler, 2006) in order to address the role of specific contextual elements on the development of students’ algebraic thinking. AiC offers a way to describe at the micro-level how meanings are constructed by shedding light on their connections to the existing mathematical knowledge through three epistemic actions: recognizing (R), building-with (B) and constructing (C). Recognizing an already known mathematical concept, process or idea occurs when a student recognizes it as inherent in a given mathematical situation. Building-with involves combining existing knowledge elements (i.e. recognized constructs) to achieve a goal, such as solving a problem or justifying a solution. Constructing is carried out by assembling or integrating previous knowledge elements by vertical mathematization to produce a new structure. The microgenetic analysis, originated in the Vygotskian psychology, provides tools and techniques to analyze discourse data and take a deeper look at the genesis of knowledge construction and the role of contextual factors including the social interactions and the use of tools in the learning environment. In this study, we investigate 7<sup>th</sup> grade students’ objectification of algebraic generalization. AiC offers a framework to describe and analyze objectification as an abstraction process while microgenetic analysis allows us to take a deeper look at how the realistic task context, the available tools and the various means of symbolization inside and outside the digital environment influence students’ construction of meanings. We aim to contribute in the research literature that explores the role of contextual factors in the development of students’ algebraic thinking by taking a deeper look at the genesis of knowledge construction at the micro-level.

## **The microworld**

EXpresser is a mathematical microworld designed to support 11-14 year-old students in their reasoning and problem-solving of generalization tasks (Noss et al., 2009). It supports students to perceive structure and find ways to express structural relationships, to identify variants and invariants in patterns and to recognize and articulate generalizations. In Figure 1 there is a model of a snake where the body combined by red tiles while the head and tail by blue. Students are asked to construct a model that works for any number of red tiles according to how old is the snake and find a rule for the total number of tiles that compose snake in any month of its life. EXpresser consists of two main areas: (a) My Model (a work area, Figure 1 on the right of the screen); and (b) Computer's Model

(Figure 1 on the left). In My Model, students can use building blocks of square tiles to make patterns that can be combined to models.

**Figure 1: Pattern on eXpresser**

EXpresser allows students to work with (icon) variables so as to reproduce dynamically (i.e. to ‘animate’) their patterns for different numbers of repetitions, to express generality through semi-algebraic relations and to test the validity of these relations for random values of repetition through appropriate feedback. By default, all numbers in eXpresser are constants and it is possible to

change its value by “unlocking” them to become variables that can be handled by a slider (Figure 1). From the "cogwheel" icon (next to the slider) students can configure the variable's "domain" and specify its interval of values and the step of the variation (Figure 2). Students can convert a constant number to a variable in My Model while in Computer's Model the variables take random values.

**Figure 2: Properties of slider**

Students can construct a model rule for the total number of tiles and only if it is correct pattern will be coloured (Figure 1). Otherwise, as an indication of error, the pattern appears colorless. Finally, when students find the

general rule in Model Rule the face icon on the central toolbox becomes green and smiling (Figure 1). As variables take random values, they provide a rationale for generality (Mavrikis et al., 2013). Thus, the environment incorporates an ‘algebra’ and a language aiming to make generalization more concrete for the students by facilitating expression of structure.

## Methodology

Our research approach is informed by the influential idea of “design” in learning (Cobb et al., 2003) aiming to explore the role of alternative representations and means of expression on students’ meaning making for algebraic generalization. The study took place in a lower secondary experimental school in Athens with one class of 7<sup>th</sup> grade (13-year-old) with 18 students and one experimenting teacher. The students worked in groups of three for 12 teaching hours (6 two-hour sessions, one session per week) over two months. In the end of the implementation, 1-hour interviews with each group of students were conducted intended to capture details about students’ thinking and approaches over the whole implementation. At the beginning of the study we knew that students had not worked with patterns before (patterns are not included in the Greek mathematics curriculum) and they had minimum use of algebraic symbols. Thus, we expected to see if and how their interaction with the available tools and resources would influence the meanings that they would create for algebraic generalization.

Task design aimed to link patterns to problems associated with realistic workplace contexts, thus the need for algebraic generalization was expected to arise as part of problem solving. The activity sequence was divided in three phases and for each one of them we designed a series of tasks. In the first phase students assumed the role of a herpetologist by studying the development of snakes through a simple linear pattern (*Snakes*). The second phase referred to the organization of a wedding party by professionals (*Table Arranging*). Initially students investigated the problem for 38 guests with concrete manipulatives and, next, a demanding version of the problem (132 guests) leading to a more complex linear pattern of unified tables was explored through eXpresser. In the third phase, students acted as pool designers to explore high complexity second degree patterns (*Pool designer*). In this paper, we analyze data from the first phase. *Snakes* engaged students in exploring the growth rate of a snake (i.e. grows by 2 cm every month, lives 25 years, its length reaches 6 meters) in order to identify the appropriate size of its cage. Assuming that one square tile in eXpresser corresponds to 1 cm, students were asked to construct a simple linear pattern that would grow by 2 squares tiles each time and thus would depict the snake in any month of its life. The questions involved in the worksheet were: “1. How many squares will the pattern have when the snake is 5 months old? (Respectively for 10, 25,100). 2. Describe with words how the pattern works. 3. Describe with an algebraic formula how many red square tiles appear for each month”. Our general goal was to engage students in investigating the relationship between the age of the snake and the total square tiles of the pattern.

The collected data consists of video and audio recordings (four groups). The data were fully transcribed for the analysis. The unit of analysis was the thematic episode defined as an extract of actions and interactions around students’ conceptualization and expression of generalizations. The analysis was carried out in two levels. First, the episodes were analyzed through AiC to highlight the evolution of students’ epistemic actions while constructing generalizations. Next, the same episodes were analyzed through microgenetic analysis (Siegler, 2006) that involved: (a) coding of students’ and teacher’s utterances in relation to contextual elements (i.e. task, tools, symbolization) that appeared to be crucial in students’ conceptualization and expression of generalizations, namely context snake, context snake in eXpresser, context algebra in eXpresser and context algebra; (b) categorizing the utterances in clusters of meanings emerging through constant comparison. In this paper we analyze an episode from the interview of one group of three students (Group 1).

## Results

In this episode, students had already constructed the snake pattern in eXpresser and they had responded to question 1 through a numerical generalization. As they wrote on the worksheet: “each month the snake grows 2 cm, so for 5 months the number of square tiles would be  $2 \times 5$ , for 10 months  $2 \times 10$ , for 25 months  $2 \times 25$ , and for 100 months  $2 \times 100$ ”. They explained that for providing the answer for 5 months they counted one by one the red square tiles on the screen, they did not do the same for the rest of the numbers. In question 2 the students answered that “the pattern is increased by 2” and in question 3 they provided the algebraic formula: “ $x+2$ ”. This answer, that appears to be wrong (the correct one is  $2x+2$ ), challenged the researcher to engage students in a discussion in order to justify their choice of symbols in relation to their designed pattern (Figure 3, 4). We note that the designed pattern appeared to work correctly in eXpresser. The students had unlocked a number called “fidi” (snake in Greek) to become a variable and used the corresponding slider to choose values for the

variable (in Figure 3 the value ‘2’ is chosen). The students recognized that the pattern consisted of 2 constant blue square tiles (for the snake’s head and tail) and one building block of 2 red square tiles that had to be repeated for designing the body. In order to create the variable the students pulled a red square tile to My Model and unlocked it (Figure 4). Then, they opened the cogwheel in the corresponding slider (Figure 2) and set the domain of the variable, by changing the minimum value from 1 to 2, the maximum from 1 to 300 and the increment from 1 to 2. As they explained, they put 2 to the minimum because the snake at birth is 2cm, they put 300 to maximum because it grows for 25 years until reaching 6 meters and they put 2 in the increment because it increases 2cm each month.

<b>Figure 3: Pattern Group 1</b>	<b>Figure 4: Pattern properties Group 1</b>	<b>Figure 5: Pattern Group 2</b>	<b>Figure 6: Pattern properties Group 2</b>

For correct coloring the red squares, the students used the variable to complete the Model Rule (Figure 3) by adding to “fidi” the constant number 2 representing the constant (blue) squares tiles. This way the values of the variable in the slider represent the length of the snake in cm. These values actually result by a ‘hidden’ multiplication of the number of months by 2. For instance, value 6 in the slider means 6cm length indicating that 3 months are multiplied by 2. By exploiting the structures provided by the software, the students achieved to construct a pattern working correctly and thus they concluded that the required symbolic generalization was “ $x+2$ ”. However, this formula cannot be used for calculating the total length of the snake in relation to its month of life. We note that students had already answered questions 1 and 2 by multiplying specific number of months by 2. In the following excerpt, the researcher discusses with group 1 students about their pattern and formula. She attempts to understand their formula and brings to the fore the fact that although the pattern works in eXpresser the formula cannot be used for answering the questions.

- 11 Researcher: What does  $x+2$  means to you?
- 12 Student 2: We put  $x$  for the body and 2 for the head and tail. So 2 would be constant independently of the length of the snake. **(Recognizing)**
- 13 Researcher: So  $x$  refers to red squares and 2 to the blue ones.
- 14 Student 1: Yes for the tail and the head. **(Recognizing)**
- 15 Researcher: Can this formula help us answer the question 1? What about the 5 months?
- 16 Student 1: 5 times 2.
- 17 Researcher: But here you write plus 2.
- 18 Student 2: [*She seems to be confused*] Is it the squares? ... 7 [*adding 2 to 5*] times 2 gives 14? ... **(Recognizing)**
- Student 1: Our  $x$  here [*showing the icon of “fidi”*] will not help us because it shows how many red tiles appear in the pattern. If we don’t know the number of red tiles we can’t find it very easily [*refers to number of months*]. **(Recognizing)**
- 19 Researcher: So what does your  $x$  show?

- 20 Student 1: Our x is for the red tiles. It basically expresses what is already on the screen.
- 21 Researcher: What do you mean exactly? Can you change something to help us more?
- 22 Student 2: For the months...?
- Student 1: Probably... Yes, 2 times the months. Actually x should have to express the number of months. (**Building-with**)
- 23 Researcher: In your pattern x doesn't refer to months. It refers only to even numbers, 2 months, 4, or 6. For 5 months, what would you do?
- 24 Student 1: Our x refers to the whole body of snake...it refers to something different...

In the above dialogue the students recognized that the variation of months is embedded implicitly in their formula in eXpresser without being symbolized in some way. In the next part of the episode, the researcher aims to challenge students' views on symbolization by presenting them a pattern created by another group (Group 2) in a different way (Figure 6). In particular, group 2 constructed a pattern based on the formula ' $2x+2$ ' where x takes all natural numbers as values in the slider. The researcher invites the students to reflect on the two formulas.

- 25 Researcher: In your pattern, x does not refer to months. In order to find out how old the snake is you told me that you have to multiply the variable by 2... Here is a pattern of another group. [*The Researcher shows the pattern of Figure 5*]
- 26 Student 1: Yes actually it [*the slider*] gives values expressing months ... These students (Group 2) multiplied by 2 (Figure 5) so as to refer to the whole month otherwise this [*she showing the iconic variable in properties, Figure 5*] would refer only to a half month. Therefore "fidi" [*iconic variable*] refers to the half body of snake, so they multiplied by 2 in order to find the whole. (**Recognizing, Building-with**)
- 27 Researcher: So when the slider shows 2, we see how long the snake would be in 2 months. Which is the formula of this pattern. (Group 2)?
- 28 Student 2: [*calculates total number of tiles for value 2 in the slider*] 2 times 2 add 2, its 6. (**Building-with**)
- 29 Researcher: Can you express it by symbols?
- 30 Student 1: 2 times x add 2, because x here refers to something different from our x. Here it refers to months. (**Construction**)

The above episode represents an instance of objectification since the students appeared to conceptualize in more sophisticated ways different symbolic forms. In terms of AiC, the episode represents a construction process leading to students' construction of meanings for their own formula as well as the formula ' $2x+2$ '. The main challenge faced by the students was to conceptualize the role of iconic variables and linking them both to the construction of different patterns and to the realistic context of the task. We observe that initially the students recognized that the environment's iconic structures are associated directly by their previous mathematical constructs and they linked the variable x to eXpresser's unlocked variable (line 12). Then they recognized that the x of their formula doesn't work for answering to questions 1 and 2 in the worksheet (line 18) since it refers implicitly to numbers of months (line 22). Thus, they were able to build with it an explanation of their own strategy. In line 26, the students recognized that the value of x in the new pattern represents number of months and the graphical outcome "refers to the half body of snake". Building-with these two

recognizing actions they provided a justification for group's 2 solution: the multiplication with 2 is necessary in order to calculate the total length of the snake (line 26). This is a sophisticated justification since the students conceptualized the variation of months inside the variation of snake's length. Next, the students constructed the new formula initially by the use of specific numbers (line 28) and subsequently with the use of variables (line 30) following an analytic algebraic approach. At the same time they developed a new meaning for the variable by objectifying  $x$  as a sign representing number of months.

**Figure 7: Microgenetic analysis: Gray is for Researcher, Orange for Student 1 and Blue for Student 2**

The microgenetic analysis of the above episode shows a rich meaning generation where each symbol is conceptualized in different ways in relation to the different elements of context and utterances cannot be confined to a single context (Figure 7). The analysis revealed four clusters of meanings corresponding to specific contextual elements: real world snake (context snake); snake represented in eXpresser (context snake in software); quasi-algebraic symbolic expression in eXpresser (context algebra in software); algebraic symbolism (context algebra). In the beginning of the episode we see that students refer to symbols in relation to the real context or in relation to school mathematics. In the progression of the episode we note that students' utterances belong to different levels simultaneously. For example, when students use  $x$  they refer to snake body while with number 2 on head and queue respectively (line 12). Then the same  $x$  in the software is a set of red squares. Indeed, when the researcher asks whether " $x+2$ " can help us to calculate the red squares in relation to the snake's life (line 15), the students realize that the  $x$  of their formula doesn't work for answering to questions referring to the snake's length in different months (line 18). Looking at Figure 7, the students' answer is based on the properties of iconic variable in eXpresser as well as on the representation of the snake in the environment for different values in the slider. This way student's utterance is placed at the intersection of two contextual elements: context snake in software and context algebra in software. Finally, while observing the pattern created by another group, the students identify that symbol  $x$  refers at the same time to red squares and months of snake's life. This is why the constructed meaning is placed again at the intersection of two contextual elements (Figure 7, line 26). Taking a global view of the microgenetic diagram, we see that students' interaction that leads to the construction of algebraic generalization in the algebraic context (line 30) takes place mainly within the two contextual elements in the middle. This finding highlights the critical role of the software structures in mediating students' generalization from the real context of the task to the algebraic context of school mathematics.

## Conclusion

The analysis revealed an objectification process accompanied by meaning generation for algebraic generalization. In terms of AiC, the students conceptualized different symbolic forms of expression related to different patterns. This was carried out through a sequence of epistemic actions including: linking previous mathematical constructs to eXpresser's variable (unlocked numbers); recognizing the role of variable in the constructed patterns; relating variable values to the graphical outcome of patterns; conceptualizing covariation of different variables for the construction of patterns (e.g., months and snake's length); and constructing formulas for patterns not through a trial-and-error arithmetic method but in algebraic analytic way. The microgenetic interpretive analysis allowed us to identify, analyze and discuss the role of the different contextual elements to students' construction of meanings. Four clusters of meanings appeared interrelated to the context of real snake, the representation of snake in eXpresser, the quasi-algebraic context of eXpresser and the context of school algebra. As regards the role of contextual elements in students' construction of algebraic generalizations, the analysis revealed the critical role of software representations/structures in mediating the making of links between realistic tasks and algebra.

## 1 Theory as a fundamental part of mathematical education research

The discussion about what a theory is, why theory is needed, and how theory is used is a necessary and ongoing debate in the community of mathematics education as a scientific discipline. Although there is no clear agreement in the field (Assude, Boero, Herbst, Lerman, & Radford, 2008; Niss, 2018), we can gather some of the essential elements of theories from this debate. Theories can be taken as tools or objects (Assude et al., 2008); as lenses to “see,” “observe,” and “understand” phenomena of teaching and learning mathematics. Researchers can draw on theory to improve coherence and consistency of scientific argumentation, but researchers also need to guard against becoming blind to aspects that a theory does not capture. While theories provide a language, a more or less structured and coherent system of concepts, theorizing is a way of sense making (Mason & Waywood, 1996). Background theories encompass a philosophical stance to “understand what are taken to be the things that can be questioned and what counts as an answer to that questioning” (Mason & Waywood, 1996, p. 1056), while foreground theories are about particular research objects addressing a foreground aim such as “what does and can happen within and without educational institutions?” (p. 1056). Some of these foreground theories may developed into an epistemological tool for investigating a specific phenomenon, for example, the epistemic action model of Abstraction in Context (Tabach, Rasmussen, Dreyfus, & Hershkowitz, 2017). Theories are integral to the research process because “[t]heory is the essential product of the research activities, and theorizing, therefore, its essential goal” (Bishop, 1992, p. 711).

## 2 An overview about the previous work of the CERME theory groups

Kidron, Bosch, Monaghan and Palmér (2018) have offered a comprehensive overview about the theory working groups of CERME over the years, and we would like to highlight some aspects of the groups in view of the Theoretical Perspectives Thematic Working Group (TWG) of CERME11. We aim to provide insights as to why continuing work on theory is necessary for an ongoing establishing and re-establishing of mathematics education as a scientific discipline. The founding of this

working group can be taken as a reaction to the increasing diversity of theoretical approaches towards the end of the millennium which provided varied perspectives, such as cognitive, sociological, institutional, or activity theory-based views, to name a few. This diversity of theoretical approaches raised the question of how coherence can be maintained in the field since in these approaches, similar words may be used for different things or different words for similar phenomena, thus causing problems when communicating research results (Bikner-Ahsbahs, 2009). From the discussion on the diversity of theories at CERME4, the notion of networking of theories emerged (Artigue, Bartolini Bussi, Dreyfus, Gray, & Prediger, 2006). This notion takes the diversity of theories as a rich feature of the field, thus, respects the identity of different theory cultures, and does not aim at achieving a unifying theoretical understanding in the field (Bikner-Ahsbahs, 2009). Important steps to understand how the networking of theories can maintain coherence in the field of mathematics education research include the use of networking strategies in research involving multiple theories (Prediger, Bikner-Ahsbahs, & Arzarello, 2008) and the development of networking methodologies for the investigation of theory use in research. When networking theories, the aim is not to create a uniform theory, but rather to embrace complexities and re-new our theoretical understanding arising from examining networking practices.

Differences in background theoretical views also create differences in the notion of what theories are. For this reason, the networking of theories faces difficulties not only through incommensurable and incompatible assumptions of theories but also because the notions of theory used by researchers may not be the same (cf., Niss, 2018). In many sessions over the years, participants generally agreed upon using the concept of theory developed by Radford (2008; 2012), whereby a theory  $[(P,M,Q)R]$  is a way of producing understanding based on a set of relatively stable principles (P), methodologies (M) related to the principles, paradigmatic questions (Q), and its use in research produces results (R) that contributes to its further developing. Monaghan (2011) proposed to consider “theoretical genesis” as similar to “instrumental genesis”: A theory is an artifact addressing and developing a specific research practice, which in turn may allow researchers to use the theory more creatively in a new way. Thus, theories or theoretical approaches frame research practices as well as develop further through the act of research.

### **3 Main issues raised at the Thematic Working Group 17 at CERME11**

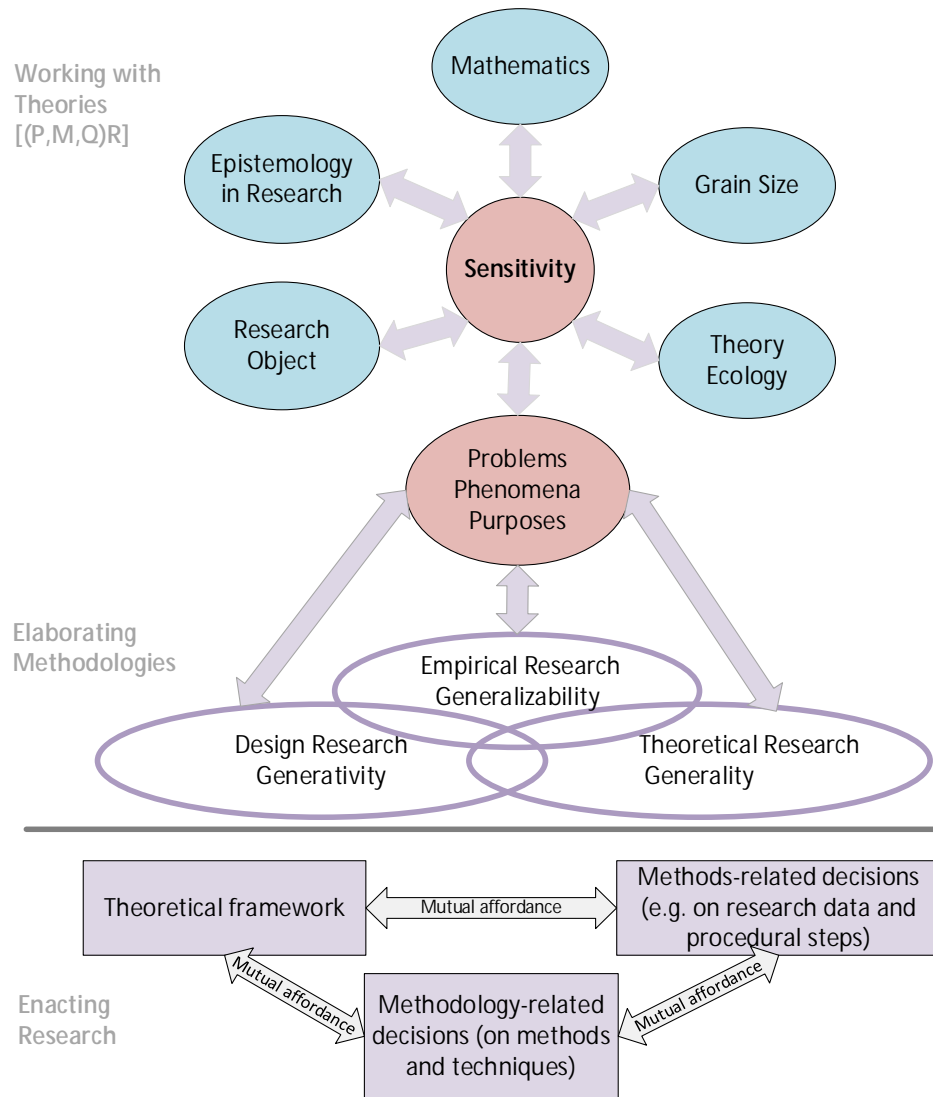

The thematic working group on Theoretical Perspectives and Approaches in Mathematics Education Research of CERME11 has taken up the tradition of addressing multi-theoretic approaches but put more emphasis on the interplay between theory and methodology, and how this interplay may advance research practice. Key issues addressed included epistemological and philosophical considerations, ontology of concepts, and contributions on design research involving new directions such as embodied design and the use of technology. To advance our knowledge on the triad of theory-methodology-research, one specific objective was to identify argumentative grammars for design research, and (re-)new theory strands such as embodiment.

Nineteen papers and two posters were presented at the conference as part of the TWG. In the proceedings, these contributions are grouped according to five topics. In what follows, we present vari-

ous interconnections between theory and methodology in a diagram and describe – based on the diagram – key points raised by the papers to emphasize their contributions to the aims of the TWG.

#### 4 Essential contributions to the interplay of theory and methodology

Building from Radford's (2008) theory triplets (P, M, Q), we propose a graphic organizer (Fig. 1) illustrating the interplay among researchers' work with theories, their elaboration of methodology, and enactment of research.

**Figure 1: A graphic organizer outlining the interplay among researchers' theoretical working, elaborating methodology, and enactment of research.**

We place Working with Theories in the top layer, because researchers' methodology-related decisions are driven by their tacit or explicit sensitivities to theoretical assumptions. When working with theories, researchers are expected to make explicit their sensitivities to research epistemologies, grain sizes of theories, kinds of mathematical knowledge, objects of research, ecologies of theories, and research problems, phenomena, or purposes. While we show each of these elements as discrete ovals in the graphic organizer, we view these sensitivities to be overlapping. For example, research-

ers may choose to network theories of different *grain sizes* to investigate *phenomena* of students' ways of coming to know mathematics as *research objects*. Yet, networking of theories is not an aim in itself but was developed to solve problems. Further, decisions in networking are never neutral, because scholars developed theories with particular perspectives, for example, based on specific research results and within particular ecological paradigms. Researchers' methodological decisions relate to their research problem, phenomenon, and purpose. We view this relationship as reflexive—researchers' theorizing informs their research problems, which in turn inform their methodologies, and their methodologies in turn inform their research problems.

There are three overarching kinds of research which inform researchers' methodological decisions: design research, empirical research, and theoretical research. For these three kinds of research we distinguish three quality criteria: generativity, generalizability, and generality. To illustrate what we mean by generativity, generalizability, and generality, we draw on research presented in the Theoretical Perspectives TWG of CERME11. The design research carried out by two different groups—Bakker, Shvarts, and Abrahamson, as well as Alberto, Bakker, Walker-van Aalst, Boon, and Drijvers—resulted in new tasks *generating* a design genre. The theoretical research conducted by de Freitas, Ferrara, and Ferrari addressed affectivity as a *general* concept of the body's responsivity, illustrating it through an empirical example. Liljekvist, van Bommel, Randahl, and Olin-Scheilier addressed a particular research problem, engaging in empirical research to develop *generalizable* knowledge. The base layer of the diagram focuses on the enactment of research. Researchers' theoretical frameworks *afford* and *constrain* their methodology-driven and methods-driven decisions, when collecting and analyzing research data, and vice versa.

#### **4.1 Reciprocity of theory and methodology: mutual affordances**

The first topic, reciprocity of theory and methodology for research and design, sets the scene: The topic emphasizes the epistemological nature of research, highlights and describes the reciprocity of theory and methodology in research, and how such reciprocity may impact on design and research.

Kidron compared the procedures of a priori analyses and their epistemological roles in the application of two theories, suggesting that differences in the a priori analyses reflected different analytical focus priorities based on the theories and, hence, illustrated the reciprocity of theory and methodology. Chan and Clarke conceptualized and explained this reciprocity between theory and methodology in terms of mutual *affordance*, where affordance refers to “the investigative options made possible (and also constrained) by the choice of theory or methodology”. In the case of design research, Hanke and Bikner-Ahsbabs encapsulated the mutual affordances between theory and methodology into a design principle “boundary crossing by design(ing),” linking the theoretical construct of boundary crossing with a course design for pre-service mathematics teacher training.

#### **4.2 Philosophical considerations: interplay of epistemology and ontology**

The second topic addresses philosophical, epistemological, and ontological considerations. The papers provide examples of the interplay of theory and methodology and this interplay's epistemological and ontological implications on the level of *generality*. The papers address analytical ways of arguing, thus generality, but also illustrating the generality by concrete examples.

Lensing argued that concepts and discourse form an ontological source of building mathematical objects. Radford illustrated the epistemological power of joint labor on tasks and material as ontological source in the classroom. Kuzniak and Vivier transformed the notion of the work mathematicians do as the epistemological source of concepts to the mathematical work in the classrooms. They conceptualized this work as the dialectic between the cognitive and the epistemological levels when learners build mathematical objects or concepts. Zarianakos developed a phenomenological research methodology to understand epistemic processes and highlighted the usefulness of a phenomenological attitude to investigating such processes. Finally, Flores advocated for the legitimization of a visuality's perspective for mathematical visualization. Using art laboratories as a case example, her poster challenged mathematics education researchers to rethink what mathematics and mathematics education are.

### **4.3 Embodied design: generativity and theory-methodology-design bundle as key ideas**

The third topic focuses on embodied design with coordination as a key aspect, yet the nature of coordination presented in the papers varies. The papers reported on theoretical coordination, coordination of scientific criteria of design research, epistemological coordination, and coordination of individual affect and individual movement by a trans-individual activity and of disciplines.

Alberto et al. coordinated embodied design and instrumental genesis into the concept of embodied instrumentation; in this kind of networking, the researchers regarded the body as part of an instrumental genesis with an artifact. Their example illustrated a specific design genre where the movements of both hands must be coordinated to explore a problem of the sine graph. Referring to the same design genre, Bakker, Shvarts and Abrahmason made a plea for attending to generativity in addition to generalizability in education research. Such double attention generates the need for scientific coordination of generalizability and generativity—two criteria resonating with the two parts of design research, the design(ing) and the theorizing based empirical data. Based on a cultural-historical approach, Shvarts' poster abstract added an example of embodied action-based design. She showed that in her research, three kinds of couplings could be epistemologically coordinated through the whole bundle theory-methodology-design: theory-methodology, theory-design and method-design, where the theory-methodology-design bundle serves as the comprehensive lens for the *perception-action system distributed* between the tutor and student during the teaching-learning process.

The fourth contribution on embodiment by de Freitas, Ferrara and Ferrari provided a theoretical idea which was based on affectivity as the responsive nature of the human body. This kind of affectivity was substantiated by examining the coordination of students' movements while they collectively performed a task involving body movements to produce and express a circle.

### **4.4 Research on teaching and learning paths: the need to go beyond existing solutions**

The fourth topic continues discussions about design research, addressing the need to go beyond a single theoretical framework or existing frameworks. Johnson, McClintock, and Gardner coordinated Variation Theory as a pedagogical theory of learning with the theory of Quantitative Reasoning, as a subject-specific theory for design. This kind of networking was possible because the research linked two different but compatible theory grain sizes. Tasks, shaping a design genre already, were

reconsidered for the new design step of transfer. This step required an additional theoretical model that was *sensitive* to transfer, thus allowing the *generativity* of the design genre be expanded. Similarly, Fonger, Ellis, and Dogan coordinated radical constructivist theory with Harel's Duality, Necessity, Repeated Reasoning principle for instructional design of a learning trajectory for quadratic growth. While exploring the design of the trajectory, the authors identified *shifts of understanding* among mathematics students, which demanded the inclusion of an instructional theory into the theorized trajectory, thus expanding the concept of the learning trajectory towards a teaching and learning trajectory.

While the first two contributions within the fourth topic addressed designing and investigating the (designed) learning path empirically, Gosztanyi's contribution turned this focus around. She described reverse engineering as a reverse design process of already designed series of mathematical problems: The aim is to reconstruct the rationale behind these series so that teachers can design new series of (selected) problems. Gosztanyi's research is an example of coordination between historical and empirical research methods.

Finally, Bampatsikou et al. took a unique approach to analyze students' learning paths applying Peirce's complete classification of sign relations. According to Bampatsikou et al., the take-up of these classes of signs may "mark those characteristics of the tasks that turn students' conceptualizations to higher level signs" in their semiosis, thus, resonating with the results of Fonger et al.

#### **4.5 Theorizing the new: advancing research in terms of theory and methodology**

The final topic aimed at showing how new requirements in educations (e.g., new mathematical problems, programming, social media), coming from outside or inside a theory culture, have become driving forces for new ways of theorizing and, hence, advancing research.

Connecting mathematics and programming, Lagrange and Laval explained how a framework of connected working spaces may account for students' work across domains; hence, contributing to the generativity of designs for cross-domain research. Liljekvist et al. illustrated how they combined theoretical frameworks for investigating professional development through the social media as a new way of interacting. Lagrange and Laval as well as Liljekvist et al. provided new dimensions to the work of research, suggesting new complexities that may emerge.

Makar and Fielding-Well observed that socio-mathematical norms have not been investigated in recent developments of inquiry-based learning even though such norms can strongly impact on teaching. Similarly, Itsios and Barzel observed that the fundamental concept of *Grundvorstellungen* has not yet been applied to students' difficulties in understanding exponential expressions. The two papers provide examples of ways to strengthen theoretical approaches that had emerged in different ecologies by expanding their scope and carefully consider the ontological status of the concepts involved. The lack of a theory's applicability can also lead to a theoretical expansion. Exactly this was presented by Otaki, Asami-Johansson and Bahn showing an extension of the Anthropological Theory of the Didactics to embrace and investigate the para-didactic system of the Japanese lesson study.

## 5 Lessons learned and moving forward

As in previous ERME conferences, this group agreed upon the dynamic, evolving nature of theories in research. From this perspective, scholars should neither demand that theories be used with absolute rigor nor allow arbitrarily applications of theory. To form coherent research frameworks, scholars engage in reconsidering, reinterpreting and reusing theories to investigate new phenomena, solve new problems and serve new purposes. Thus, theories develop and evolve through research. Working on coherence and consistency is an ongoing research task, particularly necessary for the Networking of Theories, in which reconsidering the compatibility of the theories or theoretical approaches is an additional epistemological necessity. Achieving generativity, generalizability, and generality affords the potential of the research results to be useful for answering new questions.

Bridging theory and methods to advance research is methodological work. To do so in a coherent and consistent manner, researchers need sensitivity, which is both, brought in by scholars in the field and required from the field. Our graphic organizer (Fig. 1) shows the different sensitivities that were considered during our group's discussions. The presentations on embodied design challenged the group to discuss what counts as mathematics (4.3). Theory ecology was an implicit topic in several contributions (4.5, 4.2). In the presentations focused on philosophical contributions, the group more explicitly addressed sensitivities to the ontology of concepts (4.2). In the presentations on teaching and learning paths, the group examined links between the grain size of the research focus and what researchers took up as research objects, whether the focus was on a micro-step while solving a task, a whole learning path, series of problems or on transfer of knowledge (4.4).

The different sensitivities intertwine, following the epistemology of research in mathematics education—what counts as new knowledge, how that knowledge is achieved and substantiated in the field. New knowledge was gained in terms of *epistemological criteria* (affordance, generativity, generalizability, generality, phenomenological methodology), *extending the scope of theoretical constructs* (Grundvorstellungen, socio-mathematical norms, para-didactic system, and interdisciplinary research), the nature of design research (on transfer, on teaching learning trajectories, on embodied design), *strengthening theoretical constructions analytically* (mathematical work, Theory of Objectification, formation of objects), or in terms of *advancing the networking of theories* strand by adding networking cases.

With our graphic organizer (Fig. 1), we offer a space for the interplay among researchers' theoretical working, elaborating of methodology, and enactment of research. Notably, we are not trying to find a homogenous, one size fits all epistemological path. Rather, we are working to navigate in the field in order to advance our research in different directions, for example, in the directions of methodology, methods, theory, scope, design, epistemology and ontology. Looking ahead, as topics on epistemology and ontology were addressed and the problem of discerning different argumentation grammars is not yet solved, both should be included in future calls of the TWG on Theoretical Perspectives and Approaches in Mathematics Education Research of ERME.

# Comparing a priori analyses

Ivy Kidron

Jerusalem College of Technology, Israel; [ivy@jct.ac.il](mailto:ivy@jct.ac.il)

*The present research study is a theoretical reflection on the notion of a priori analysis in two different theories: the Theory of Didactical Situations (TDS) and the theory of Abstraction in Context (AiC). For both theories the epistemological perspective is of importance. The a priori analyses offered by the two theories are different. This difference reflects the different priorities of focus of analysis of both theories. The study demonstrates that, in their effort of networking theories, researchers of both theories will benefit of comparing their a priori analyses.*

*Keywords: A priori analysis, a posteriori analysis, Abstraction in Context (AiC), networking theories, Theory of Didactical Situations (TDS).*

## Introduction

The most recent Working Group on theory discussed the importance of developing networking with regard to the design dimension. As we will see in the following, the notion of a priori analysis is closely related to the phase of design. The present paper offers a theoretical reflection on the notion of a priori analysis in two different theories. It investigates the differences in the a priori analyses of the two theories and the influence of the different a priori analyses on the networking of theories. Dealing with a priori analyses, the focus of the paper is on methodology.

The theories discussed in this paper are the Theory of Didactical Situations (TDS) and the theory of Abstraction in Context (AiC). There are two main reasons for the choice of these theories. The first one is that this paper is based on my networking experience with these theories (Kidron, Lenfant, Bikner-Ahsbahs, Artigue, & Dreyfus, 2008; Kidron, Artigue, Bosch, Dreyfus, & Haspekian, 2014). The second reason is that the a priori analyses take into account the mathematical epistemology of the given domain and for both theories the epistemological perspective is of importance. The two theories consider the epistemological dimension in different ways. TDS combines epistemological, cognitive, and didactical perspectives. TDS focuses on the epistemological potential of didactical situations. AiC analysis is essentially cognitive and focuses on the students' reasoning; mathematical meaning resides in the verticality of the knowledge constructing process and the added depth of the resulting constructs. An epistemological stance is underlying this idea of vertical reorganization (this term will be explained in more details in a next section). For both theories the epistemological dimension has an important role. In the literature, the important role of epistemology is discussed in details in Artigue (1990, 1995). Kidron (2016) analyses the connection between epistemology and networking of theories.

In the next two sections, I will present shortly each theory and deal with the question what is an a priori analysis for each theory. Then, I will deal with the differences of the a priori analyses and demonstrate that, in their effort of networking theories, researchers of both theories benefit of comparing their a priori analyses.

## TDS a priori analysis

A short introduction to TDS is offered by Artigue, Haspekian and Corblin-Lenfant (2014). This well-established theory belongs to the French school. It began to develop in the 1960s in France, initiated by Guy Brousseau (1997). Artigue et al. (2014, p. 48) wrote;

... we focus on three characteristics that create the specific lens through which TDS considers the teaching and learning of mathematics: the systemic nature of teaching and learning; the epistemology of mathematical knowledge; and the vision of learning as a combination of adaptation and acculturation. These characteristics determine the questions that TDS raises and tries to answer, as well as the methodologies it privileges.

The first characteristic, the systemic perspective of TDS is expressed by the central object of the theory, the idea of situation, which is itself a system. A special attention is given to the second characteristic, the epistemology of mathematical knowledge, while discussing TDS a priori analyses. The third characteristic relates to the cognitive dimension.

The theory is structured around the notions of a-didactical situation (in a-didactical situation there is no didactical intentions and the teacher refrains from interfering) and didactical situations, and includes concepts relevant for teaching and learning in mathematics classrooms. The social dimension also has an important role in TDS. In essence, the central object of the theory, the situation, incorporates the idea of social interaction.

The systemic view led to the concept of *didactical engineering* (Artigue, 1989, 2013) which is explained in Artigue et al. (2014, p. 50):

It is a methodology which is structured around a phase of preliminary analysis combining epistemological, cognitive, and didactical perspectives, and aiming at the understanding of the conditions and constraints to which the didactical system considered is submitted, a phase of design and a priori analysis of situations reflecting its optimization ambition; and, after the implementation, a phase of a posteriori analysis and validation.

The notion of “milieu” is an important construct in TDS. The a-didactic milieu was initially defined by Brousseau as the system with which the student interacts in the a-didactic game. In the design of learning situations, there is a special attention to the constituents of the milieu organized for the learner.

In her chapter “Perspectives on design research: the case of didactical engineering”, Artigue (2015) presents the evolution of Didactical Engineering (DE) in the last three decades and explains its links with TDS. She also presents its characteristics as a research methodology. In this chapter we read that design has always played a fundamental role in the French school. We also read how design is connected to the a priori analysis.

In Artigue et al. (2014, pp. 54–60), we have a detailed example that explains the components of the TDS a priori analysis and the requests of the a priori analysis for developing the systemic analysis typical for TDS. For example, the need for information of the mathematical knowledge of the

students, of the particular situation at stake, of the teacher's expectations regarding this situation. The methodology for analysis is described in the following sentence:

We developed thus our analysis using the usual techniques of TDS, that is to say, preparing an a priori analysis focusing on the determination of the cognitive potential of an a-didactic interaction with the milieu, for a *generic* and *epistemic* student, that is, a student accepting the a-didactical game and able to invest in it the mathematical and instrumental knowledge supposed by the teacher. (Artigue et al., 2014, p. 63)

In TDS a priori analysis, the researchers make assumptions about the supposed mathematical knowledge of the students which is necessary for a productive interaction with the “milieu”. The a priori analysis must then play its role of reference as well as its role of revealing the didactic phenomena. Then the a posteriori analysis is compared to the a priori analysis and sometimes the hypotheses which were done in the a priori analysis are not in accord with the a posteriori analysis of the collected data. This comparison of the a priori analysis and the a posteriori analysis is important for the TDS researchers in order to deeply understand the functioning of the “situation”.

### **AiC a priori analysis**

Dreyfus & Kidron (2014) offers a short introduction to AiC. The theory is explained in more details in (Schwarz et al., 2009). AiC has been developed over the past 18 years with the purpose of providing a theoretical and methodological approach for researching, at the micro-level, learning processes in which learners construct deep structural mathematical knowledge. Methodologically (and this is the focus of the present study), the AiC researchers are offered tools that allow them to observe and analyze students' thinking processes. A detailed treatment of the methodology is offered by Dreyfus, Hershkowitz and Schwarz (2015). AiC view of abstraction is grounded in the works of Davydov (1990) and Freudenthal (1991). In the introduction part, I wrote that AiC focuses on the students' reasoning and that mathematical meaning resides in the verticality of the knowledge constructing process and the added depth of the resulting constructs. Freudenthal ideas led his collaborators to the idea of “vertical mathematization”. This idea is explained by Dreyfus et al. (2015, p. 186–187):

Vertical mathematization points to a process that typically consists of the reorganization of previous mathematical constructs within mathematics and by mathematical means by which students construct a new abstract construct. As researchers in mathematics education, we preferred the expression “vertical reorganization” to the expression “Vertical mathematization” to discern between what is intended by the teacher - the mathematization, and what often happens - a reorganization....In vertical reorganization, previous constructs serve as building blocks in the process of constructing.

Thus, AiC defines abstraction as a process of vertically reorganizing some of the learner's previous mathematical constructs within mathematics and by mathematical means in order to lead to a new construct (for the learner). For the convenience of the readers I will report some more details about AiC written in Kidron (2016, p. 154). The process of abstraction has three stages: the need for a new construct, the emergence of the new construct and the consolidation of this new construct. The second stage, the emergence of the new construct. is analyzed by means of three observable epistemic actions: **Recognizing**, **Building-With** and **Constructing**. Recognizing takes place when the learner

recognizes that a specific knowledge construct is relevant to the problem she or he is dealing with. Building-with is an action comprising the combination of recognized knowledge elements, in order to achieve a localized goal, such as the actualization of a strategy, or a justification, or the solution of a problem. Constructing consists of integrating previous constructs by vertical mathematization to produce a new construct.

In view of AiC essential cognitive perspective, the focus is on the students' processes of construction of knowledge. In the AiC approach, contextual aspects are considered to be integral factors of the learning process. Context is regarded in a wide sense, comprising historical, physical and social context. Historical context includes students' prior learning history, physical context includes artefacts such as computers and software, and social context refers to interaction with peers, teachers and others.

The importance of design is considerable in AiC. This is in accord with the epistemological stance which is underlying the idea of vertical reorganization. The design is accompanied by its epistemological aspects. As a part of the AiC methodology, an effort is made to foresee students' expected processes of construction of knowledge and an a priori analysis of the activities is carried out.

The AiC a priori analysis consists first on assumptions about the previous mathematical knowledge of the students, in particular, previous constructs which have been constructed in the past and that may be helpful in the present task. Then, the AiC a priori analysis consists of intended constructs that are required in the given task. For each intended construct, the AiC researchers give an operational definition. The operational definition will help the researchers in their decision if the student did express the intended construct. It will offer a criterium for evidence if the intended construct has been constructed. Different researchers in the team conduct separately their a priori analyses. Then the a priori analyses are compared and discussed until there is agreement between the researchers.

Comparing the a priori analysis and the a posteriori analysis, the AiC researchers note that sometimes the students achieve new constructs which were not expected in the AiC a priori analyses. This fact is an important and interesting stage in the research. Sometimes, students only achieve constructs that partially match a corresponding intended construct in the a priori analysis (Ron, Dreyfus, & Hershkowitz, 2010)

The AiC a priori analysis is not only a list of intended constructs. It is more a structure of intended constructs with some interactions between the different constructs. Some constructs are contained in others. Some intended constructs might be a prerequisite for others. Sometimes, possible paths of thinking are taken into account. This is relevant, for example, for a priori analyses of justification tasks. Justification is a specific case of construction of knowledge. Each itinerary of thinking towards the justification might be in itself a kind of construction of knowledge and different itineraries of thinking, each with a structure of intended constructs will appear in the a priori analysis.

### **Comparing the a priori analyses and the benefit for networking**

For both theories, TDS and AiC, the epistemological perspective is of importance but their a priori analyses have a different focus. In AiC the focus of the a priori analysis is on the learner's construction

of knowledge. The a priori analysis reveals hypotheses about constructs that might be observed during the construction process. For AiC, processes of abstraction are inseparable from the context in which they occur. The notion of context is very wide in AiC. The context has many components. For example, the task, the computer, the teacher, the social interaction between students are considered as part of the context. The AiC a priori analysis with its focus on the learner's processes of construction of knowledge cannot take explicitly into account all the contextual factors. In a later phase, the researchers will analyze the influence of the context on the construction processes that were observed in the analysis of data. For example, Kidron & Dreyfus (2010) analyzed the influence of the computer on the construction processes observed in the analysis of data. They describe how instrumentation led to cognitive constructions and how the roles of the learner and the CAS intertwine. But there is an essential difference if you analyze your data taking into account in advance the contextual factors or if you first analyze the data and the processes of construction of knowledge and only then you analyze the influence of the contextual factors on the construction processes.

For TDS, the situation is different. The focus is on didactical systems. TDS observes the entire situation and not only the student and the mathematical activity. For example, TDS is interested in relations between systems and the teacher is an element of the system. As a consequence, TDS considers already in the a priori analysis the role of the teacher and how he/she may extend the results of the a-didactical situation. As a consequence of the different foci between TDS and AiC, context is not theorized and treated in the same way in the different theories. This fact has an important consequence on the differences of the a priori analyses.

AiC a posteriori analysis might be influenced by the fact that some contextual factors are not taken explicitly into account in the a priori analysis. As a consequence, some excerpts which might add direct knowledge in the analysis of the cognitive processes might be missed if one focuses first on the cognitive processes and only then analyzes the influence of other parts of the context.

Kidron et al. (2014) refer to a networking case that links three theories. The issue of context is compared and contrasted in the three theories. The analyses from the different perspectives refer to a set of data from a video recording that show a session from the group-work of two students, during a teaching experiment on the exponential function in secondary school.

In Kidron et al. (2014, p. 175), the authors noted that

An interesting, and also revealing, point is the fact that, in the analysis, AiC researchers focus on the autonomous work of the students, while TDS researchers pay more attention to the episode where the students interact with the teacher...

The a posteriori analyses of the two theories are influenced by the differences in the a priori analyses and their different priorities in their focus of analysis. Different units of analysis are taken into account and as a consequence of the focus of analysis, as demonstrated in the a priori analysis, each theory shapes the kind of data that is appropriate to this focus. As pointed by Radford (2008):

... it is through a methodological design that data is first produced; then the methodology helps the researcher to “select” some data among the data that was produced but also helps the researcher to “forget” or to leave some other data unattended. (p. 321)

As a consequence, the different a posteriori analyses conducted within the two theories complement each other. Each analysis highlights a specific view which reflects the focus of research of the given theory. AiC analysis, with its specific tools, offers a fine grained analysis of the students constructing processes. TDS, with its different focus, analyses the entire situation and, in particular, the interaction between the teacher and students. For example, in Kidron et al. (2014, p. 172) we read how TDS analyses the role of the teacher:

TDS complements the AiC analysis in analyzing how the teacher extends the outcomes of the a-didactical interaction. The TDS analysis seems to start where the AiC analysis stops.

The different a priori analyses result from the different priorities of the theories with regard to the focus of analysis. Investigating these differences in the a priori analyses might lead to a better understanding of the different a posteriori analyses and to the insights offered by one theory to the other one in the networking process.

### **Concluding remarks**

Reflecting on the role of a priori analysis in both theories, TDS and AiC, we realize its importance and why it is necessary towards a better understanding of the a posteriori analysis of the collected data. For both theories, the a priori analysis plays a role of reference while comparing the a priori and a posteriori analyses. For TDS, it plays the role of revealing the didactic phenomena and helps to deeply understand the functioning of the “situation”. For AiC, it offers a structure of intended constructs that are required in a given task as well as possible paths of thinking. We also realize the importance that each theory keeps the specific characteristics of its a priori analysis. I wrote in a previous section that there is an essential difference if you analyze your data taking into account in advance the contextual factors or if you first analyze the data and the processes of construction of knowledge, and only then you analyze the influence of the contextual factors on the construction processes. This essential difference is tightly connected to the specific characteristics of the different a priori analyses for AiC and TDS. In Kidron et al. (2008, p. 262), we read that:

In networking, we want to retain the specificity of each theoretical framework with its basic assumptions, and at the same time profit from combining the different theoretical lenses. What we aim at is to develop meta-theoretical tools able to support the communication between different theoretical languages, which enable researchers to benefit from their complementarities.

Comparing a priori analyses might enable to support the communication between theories:

Realizing some common points in the a priori analyses enables the beginning of a dialogue between the theories. In the case of networking between TDS and AiC, for example, the common points in the epistemological dimension help towards the beginning of the dialogue (as demonstrated in Kidron, Artigue, Bosch, Dreyfus, & Haspekian, 2014). This idea could be used for other theories and other cases of networking: Some other common points in the a priori analyses, for example on the social dimension, might help towards the beginning of the dialogue.

Realizing the differences in the a priori analyses, we better understand the choices of data (as well as the “data which was left unattended”) that researchers of each theory select for their a posteriori analyses. Sometimes, the data which was left unattended by one theory might add direct knowledge

in the analysis of this theory and, as a consequence, some cognitive processes, for example, might be missed. The complementary insights which are missing might be offered by means of networking theories. This situation might happen in different cases of networking theories.

This paper offers a reflection on a priori analyses, epistemology and networking. It contributes to the TWG discussion on the reciprocity of theory and methodology for research and design. The notion of a priori analysis is closely related to the phase of design. It allows making epistemological assumptions explicit. The TWG discussions addressed importance to the notions of mathematical epistemology and design. The common points in the epistemological dimension which enable the beginning of the networking between AiC and TDS contributed to these discussions.

# Rethinking the connection between theory and methodology: a question of mutual affordances

Man Ching Esther Chan<sup>1</sup> and David Clarke<sup>2</sup>

The University of Melbourne, Melbourne Graduate School of Education, Australia;

<sup>1</sup> [mc.chan@unimelb.edu.au](mailto:mc.chan@unimelb.edu.au)

<sup>2</sup> [d.clarke@unimelb.edu.au](mailto:d.clarke@unimelb.edu.au)

*Theory and methodology are key considerations in research design. Different ways of conceptualising their connection can characterise differences in research practice. This paper examines connections between theory and methodology and the concomitant implications for ontology and epistemology associated with conducting research in a laboratory classroom applying a multi-theoretic research design. Using the Social Unit of Learning project as a case example, we argue that the relationship between theory and methodology is not one of “prescription” in either direction, but rather of mutual “affordance,” both regarding the analyses afforded by the complex data set and the extent to which each theory affords analytical consideration of specific constructs of relevance to the setting and the interactions recorded there. These constructs shape the way in which the multimodal material is reconstructed as data amenable to particular forms of analysis.*

*Keywords: Classroom research, research design, research methodology, social interaction.*

## Connection between theory and methodology

Pick up any textbooks on educational research, and you will usually find the words *theory* and *methodology*. The fundamental issues of whether theory or methodology should take priority in the process of research design, or how theory and methodology should be connected in the research process, can polarise researchers, with the views on the issues being used to characterise different research paradigms or approaches (see Guba & Lincoln, 1989; Strauss & Corbin, 1990). In this paper, we address connections between theory and methodology and the concomitant implications for ontology and epistemology associated with conducting research in a laboratory classroom when employing a multi-theoretic research design. We argue that in our research design, and in educational research in general, the relationship between theory and methodology need not be one of “prescription” in either direction, but rather of mutual “affordance,”<sup>1</sup> both regarding the theoretical analyses afforded by the complex data set (i.e., generated by the methodology) and the extent to which each theory affords consideration of specific constructs of relevance to the setting and the interactions recorded there (via the methodology). We first consider a few different possible relationships between theory and methodology.

---

<sup>1</sup> The word *affordance* was coined by Gibson (1986) in ecological psychology to describe the possibilities that the environment *offers* to an animal as the animal inhabits and interacts with the environment. We use the term to refer to the investigative options made possible (and also constrained) by the choice of theory or methodology.

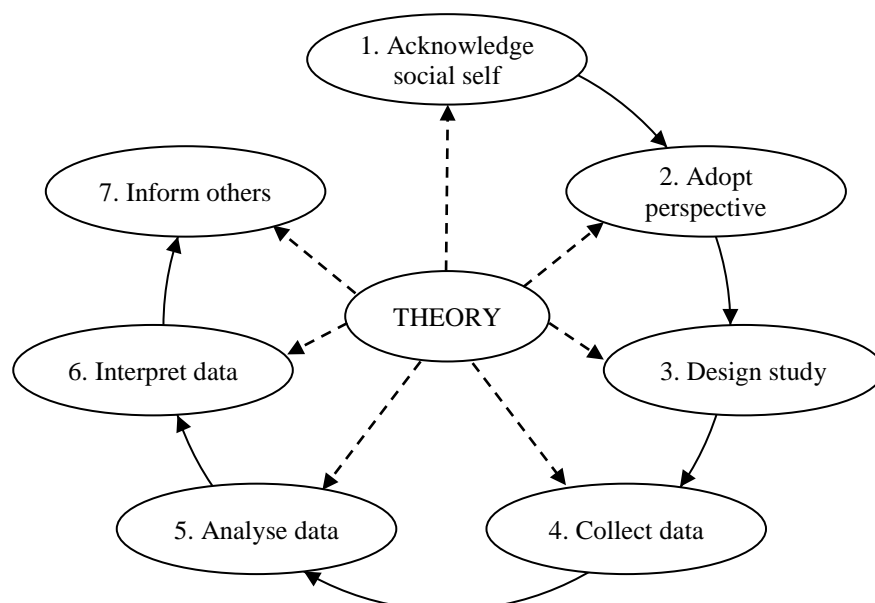

*Theory* can be thought of as “a coherent system of logically consistent and interconnected ideas used to condense and organise knowledge” (Neuman, 2014, p. 9), while *methodology* can be seen as “concerned with the logic of scientific inquiry” and in particular, consideration of “the potentialities and limitations of particular techniques or procedures” (Grix, 2002, p. 179). Blumer (1954), for example, believed that some social theories exist independent of research methodology, and one does not prescribe the other. Another way to think about the connection between theory and methodology in the research process is as a sequence of critical decisions beginning with the choice of research methods (i.e., research techniques or procedures), which is framed or shaped by the methodology, which, in turn, is governed by the theoretical perspective, which reflects epistemological assumptions (i.e., a theory of knowledge) (see Crotty, 1998).

Crotty (1998) used the connection between objectivism (epistemology), positivism (theoretical perspective), survey research (methodology), and statistical analysis (methods) as an example of such a connective chain of research process. Crotty’s conceptualisation of the research process is shared by Grix (2002), who argued that “it is our ontological and epistemological positions that shape the very questions we may ask in the first place, how we pose them and how we set about answering them” (p. 179). In particular, Grix asserts that “we should guard against ‘method-led’ research, that is, allowing ourselves to be led by a particular research method rather than ‘question-led’ research, whereby research questions point to the most appropriate research method” (p. 179). Grix therefore suggests that theoretical considerations should lead or govern methodology and, thereby, methods in the research process.

Also emphasising the importance of theory in the research process, Neuman (2014) presented alternative sets of research procedure for quantitative and qualitative research processes. In his schematic depiction, the qualitative research process starts with acknowledging the social self and ends with informing others, with each step guided or informed by theory (see Figure 1).

The quantitative research process according to Neuman (2014) takes on the same structure as Figure 1, beginning with topic selection (Step 1) and ends with reporting (Step 7), with each step guided, shaped or informed by theory. Different from Grix (2002) who believed that “methods themselves should be seen as free from ontological and epistemological assumptions” (p. 179), Neuman’s depiction of the research process is less linear than Crotty’s, and has theory identified as influencing every step in what is conceived to be a cyclic research process. However, as can be seen in Figure 1, the relationship between theory and the individual research steps represented by Neuman is unidirectional where theory “radiates” outwards to influence each research step. None of the research steps appears to influence theory.

In conducting the Social Unit of Learning project, we found the connection between theory and methodology differs from the research process characterised by Crotty (1998) or Neuman (2014). The combined use of the laboratory classroom and the employment of a multi-theoretic research design (Clarke et al., 2012) in the Social Unit of Learning project offer a unique opportunity to reflect on the connections between theory and methodology and the concomitant implications for ontology and epistemology in the study. Further description of the project is provided below.

**Figure 2: Steps in the qualitative research process depicted by Neuman (2014, p. 21)**

## **The Social Unit of Learning project**

The University of Melbourne has set up a laboratory classroom, the Science of Learning Research Classroom (SLRC), to study classroom teaching and learning. The facility has the capability to capture classroom social interactions with a rich amount of detail using advanced video technology. With 10 built-in video cameras and up to 32 audio inputs, the comprehensive and detailed recording of every participant in the classroom offers the possibility for systematic examination of the link between the processes and products of learning activities within the classroom setting. The facility has made possible research designs that combine a good approximation to natural social settings with the retention of some degree of researcher control over the research setting, task characteristics, and possible forms of social interaction afforded or encouraged. Such designs allow conclusions to be drawn with greater confidence about connections between interactive patterns of social negotiation and associated knowledge products (learning).

Using the SLRC, the Social Unit of Learning Project aimed to investigate the social aspects of learning and, particularly, those for which “the social” represents a fundamental and useful level of explanation, modelling and instructional intervention (Chan & Clarke, 2017). The project design can be seen as more akin to design experiments (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) which involve “both ‘engineering’ particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them” (p. 9). The project was designed to specifically serve the purpose of theory generation and testing through the application of a multi-theoretic research design (Clarke et al., 2012), taking advantage of the rich data that can be generated by the laboratory classroom facility.

The multi-theoretic research design adopted by the project involved the construction of a complex data set composed of video records and other supplementary data. The design allows an analytical team to juxtapose different interpretive accounts arising from different theoretically-grounded analyses in order to compare and contrast the capacity of different theories to characterise different aspects of the research setting. The theory generated from the research is intended to be a direct

reflection of an attempt to provide explanatory accounts in relation to a specific data set, so in its first instantiation would be most similar to what might be called a “local theory”. However, an accumulation of several such analyses of different situations might reveal similarities in the emergent local theories that suggested sufficient generalisability and commonality for more general theory, which would be less specifically tied to the data of any particular project.

### **Data generation**

Intact Year 7 classes from a secondary school in metropolitan Melbourne were recruited with their usual teacher in order to exploit established student-student and teacher-student interactive norms. By *intact*, we are referring to the existing social relationships between students, and between the teacher and students, which are left intact and not interrupted by a selective process introduced by the researcher. Eleven classes of Year 7 students (12 to 13 years old; 264 students in total) participated in the project. The students in each of the classes completed problem solving tasks individually, in pairs, and in small groups (four to six students) within a 60-minute session in the laboratory classroom. The problem solving tasks used in the project were drawn from previous research (e.g., Sullivan & Clarke, 1991) and were purposefully chosen to make the thinking and/or social processes of the problem solving activity more visible. The tasks have the characteristics of allowing students to express their thinking through multiple modes (e.g., verbal, graphical, textual, etc.) and approach the task using different strategies or prioritise different forms of knowledge or experience. For example, two classes of students were given the following three tasks:

Task 1 (individual task) provided students with a graph with no labels with the following instructions: “What might this be a graph of? Label your graph appropriately. What information is contained in your graph? Write a paragraph to describe your graph”.

Task 2 (pair task) was specified as follows: “The average age of five people living in a house is 25. One of the five people is a Year 7 student. What are the ages of the other four people and how are the five people in the house related? Write a paragraph explaining your answer.”

Task 3 (small group task) stated that “Fred’s apartment has five rooms. The total area is 60 m<sup>2</sup>. Draw a plan of Fred’s apartment. Label each room, and show the dimensions (length and width) of all rooms”.

The resulting data collected in the project included: all written material produced by the students; instructional material used by the teacher; video footage of all of the students during the session; video footage of the teacher tracked throughout the session; transcripts of teacher and student speech; and pre- and post-session teacher interviews.

### **Investigating the social aspects of learning**

A multi-theoretic research design (Clarke et al., 2012) was employed to examine the complex data set from the project from multiple perspectives by multiple researchers, as well as interrogate the different theoretical perspectives through answering research questions such as the following:

1. What commonalities and differences in process and product are evident during problem solving activities undertaken by learners as members of different social units (individual, pairs, small groups, and whole class groupings)?

2. Which existing theories best accommodate (that is, provide a coherent and plausible explanation for) the documented similarities and differences in process and product and in what ways do the accounts generated by parallel analyses predicated on different theories lead to differences in instructional advocacy?

An international multi-disciplinary research team (combining education, cognitive and emotive psychology, learning analytics, and neuroscience perspectives) was recruited to develop analytical frames for coding the data.

## **Ontological and epistemological positioning**

A major consideration regarding the validity of research findings and research evidence in educational research is the issue of *ontology*, which is “an area of philosophy that deals with the nature of being, or what exists” (Neuman, 2014, p. 94). The issue is distinguished from *epistemology*, which is “concerned with the theory of knowledge, especially in regard to its methods, validation and ‘the possible ways of gaining knowledge of social reality, whatever it is understood to be’ (Blaikie, 2000, p. 8)” (Grix, 2002, p. 177). In the Social Unit of Learning project, we recognise the active role that the researchers play in constructing the research setting to make the social aspects of learning visible as well as in data selection and interpretation (Chan & Clarke, 2019). Ontological considerations place limits on the authority of any claims the research team might make regarding the generalisable characteristics of classroom learning. Any such claims must acknowledge the researchers’ role in shaping the research setting to optimally simulate the common features of institutionalised classroom settings. Of course, it is the researchers’ intention that such generalisability of findings be afforded by the optimised setting. We consider regularities in the multiple student interactions (e.g., across many pairs of students or across different social units) to suggest generalisable characteristics of the social aspects of learning.

With regard to the epistemological position of this project, we construct knowledge by considering both the regularities and differences in the interpretive accounts generated by the research team (cf. complementary accounts, Clarke, Emanuelsson, Jablonka, & Mok, 2006), and reconstructing these regularities as propositions. In this project, knowledge about classroom learning is generated inductively through the aggregation of these propositions to create new theory.

## **Mutual affordances of theory and methodology**

Different from the research process depicted by Crotty (1998) and Neuman (2014), the relationship between theory and methodology we are positing for the Social Unit of Learning project resembles a symbiotic one. In as much as the chosen theory highlights particular constructs, analytical consideration of these constructs is afforded by the data set generated through the research design (methodology) which has anticipated the need for such data (see Figure 2).

We characterise this symbiotic relationship as one of mutual and reciprocal affordance, since the chosen theory frames and affords the consideration of the constructs (such as engagement) that are the focus of the research and these in turn place anticipatory constraints on the forms of data required from the methodology. This mutual affordance can be illustrated by the consideration of questions such as:

- What (theoretically-grounded) analyses are afforded by the data produced by the researcher's methodology?
- What constructs are foregrounded or prioritised by the chosen theory?
- How do we connect the constructs to the data?

**Figure 2: Mutual affordances of theory and methodology as illustrated by the reciprocal relationship between constructs and data in the Social Unit of Learning project**

The investigation of the social aspects of learning does not necessarily prescribe a particular methodology. However, when the research is conceptualised through a particular theory with its sets of interrelated constructs, researchers need to draw selectively from existing research traditions and established methodologies with their tenets for appropriate and rigorous investigative methods.

To provide further examples, multimodal learning analytics (Ochoa, 2017) was used in the project to extract features in the video and audio data to characterise behavioural student engagement. Learning analytics is “the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimising learning and the environments in which it occurs” (Conole, Gašević, Long, & Siemens, 2011, p. 3). While learning analytics generally involves analysing log-file data captured by online systems (e.g., Learning Management System), multimodal learning analytics also includes the coding of more natural activities such as gestures, gaze, speech, or writing (Ochoa, 2017). Applying advanced techniques, Ochoa and his research team were able to automate the coding of student gaze direction, student posture, teacher position, student talk, and teacher talk to create indicators of student engagement, student attention, and teacher attention during various task conditions (individual, pair, and small group) (Chan, Ochoa, & Clarke, in press).

Another analytical thread applied in the project was interactivity analysis. The analysis of student interactivity was drawn from the theory of Commognition developed by Sfard (2015). Commognition theory resolves the thinking-communication divide by equating communication with thinking. The theory is particularly powerful for conceptualising how learning occurs and has led to the development of particular analytical tools for investigating learning, specifically in the classroom context. Interactivity analysis involves fine-grained analysis of student utterances to identify patterns of interaction between the students, such as instances where one person consistently ignores or responds (reacts) to the other person's utterances or frequently initiates new topics (Sfard & Kieran, 2001). The interactive patterns can be seen as indicators of student engagement (both social and cognitive) in terms of the level of interpersonal correspondence between two people in their dialogue.

The investigation of a superordinate construct such as “engagement” can stimulate the use of a set of related mediating constructs (e.g., shared attention, participation, etc.) in psychology (Shernoff, 2013) in the case of the multimodal learning analytics work, while also stimulating the use of

another set of constructs (e.g., communication, discursive interactions, etc.) within a specific sociocognitive theory (Sfard & Kieran, 2001) in the interactivity analysis. These constructs shape the way in which the multimodal material is reconstructed as data amenable to particular forms of analysis. The specific analyses carried out were afforded by the complex data set available to the project, subject to the theory affording the consideration of specific constructs of relevance to the setting and the interactions recorded.

## Implications

The recognition of the reciprocity between theory and methodology has significant implications for the detailed design of any research project, since it cannot be assumed that by making the decision on one (theory or methodology or methods), the consequent decisions are thereby prescribed. The relationship must be seen as progressing in both directions taking us not only from theory to methodology and then to methods but also from methods back through methodology to theory. A researcher engaged in planning the minutiae of any one of these critical decision points is reminded in our paper to take into account those decisions in both directions throughout the research process because of the mutually affording nature of all connections.

## Conclusion

It is the combination of unusually rich data that can be generated by the laboratory classroom facility and a multi-theoretic research design that has highlighted for us the necessity of considering the affordances offered by each of the selected theories, the chosen methodology, the resultant data set, and the dynamic mutuality of these affordances. As argued in this paper, the research process is not simply algorithmic with each step prescribing the form to be taken in any subsequent step. The reflective researcher must instead engage in a continually recursive reflection in the nature of the connection between any key decision and those adjacent to it in their research process in either direction.

# Boundary crossing by design(ing): a design principle for linking mathematics and mathematics education in preservice teacher training

Erik Hanke<sup>1</sup> and Angelika Bikner-Ahsbahr<sup>2</sup>

<sup>1</sup>University of Bremen, Germany; [erik.hanke@uni-bremen.de](mailto:erik.hanke@uni-bremen.de)

<sup>2</sup>University of Bremen, Germany; [bikner@math.uni-bremen.de](mailto:bikner@math.uni-bremen.de)

*Preservice teachers experience a fragmentation in their study program between two academic areas, university mathematics and mathematics education. To reduce this problem, we conduct a design study linking mathematics and mathematics education on two levels: First, the “dovetailing” of mathematics (here the course on complex analysis) and mathematics education, and second, students’ “interlinking” of content and pedagogical content knowledge in the development of learning materials for talented pupils. This paper contributes to the topic on theory and methodology by introducing the design principle “boundary crossing by design(ing)” in “nested design cycles”.*

*Keywords: Boundary crossing, boundary object, complex analysis, reflection, teacher education.*

## Introduction

Many preservice teachers in mathematics experience two types of discontinuities in mathematics teacher training. First, in their views, much of the mathematics they learned in school does not seem very helpful for the rigorous proof-oriented style in university mathematics courses. Second, preservice teachers may not see how the mathematics in their university courses is related to their practice as a teacher (Hefendehl-Hebeker, 2013; Prediger, 2013). Several attempts to minimize the perceived gap between university and school mathematics have been developed, for example with special exercises, or through capstone courses (e.g., Bauer & Partheil, 2009; Winsløw & Grønbaek, 2014). Furthermore, empirical studies show that the combination of mathematical knowledge and pedagogical content knowledge for teaching and learning mathematics (i.e. in the sense or similar to that of Ball, Thames, and Phelps (2008)) is important for evaluating situations in the classroom (e.g., Blömeke et al., 2014). Mehlmann and Bikner-Ahsbahr (2018) give an overview of recent trends in German mathematics preservice teacher education around the “double discontinuity” and the general criticism of preservice teachers towards their study programs which they experience as fragmented. Because there is barely any explicit research on how preservice teachers may link the scientific disciplines of mathematics and mathematics education<sup>1</sup> concerned with school mathematics, we ask how this fragmentation between the mathematical discipline at university and mathematics education in preservice teacher training can be overcome at least partially by making changes in the curriculum, and how preservice teachers establish interlinkages of the two areas. At the University of Bremen, we conduct the design study “Spotlight-Y” on these issues. Two out of three design cycles have been completed so far, and as a theoretical result from our first design cycles, we will establish the design

---

<sup>1</sup> We understand mathematics education as the scientific discipline about the teaching and learning of mathematics. In German preservice teacher training, mathematics education is mainly concerned with school mathematics.

principle *boundary crossing by design(ing)* in a *nested design cycle* to initiate the overcoming of the fragmentation in preservice teacher training. We will show how this design principle is interwoven with the methodology and theory of our study. At the end, examples of empirical findings round off the paper.

## **Linking mathematics and mathematics education in a two-fold way**

Linking mathematics and mathematics education can be viewed as a two-fold phenomenon in higher education: On the institutional level it is a matter of curriculum and we call the linkage of the domains on this level *dovetailing* (German: Verzahnen). On the students' level we call the linkage of the domains in students' thinking and acting *interlinking* (German: Vernetzen). This distinction corresponds to a distinction between “curriculum to be taught” and “learned curriculum”. Our design study is devoted to an empirically grounded description of these two notions and their connections. Thus, with this terminology our general research questions in the project can be rephrased as: How can dovetailing be realized to initiate interlinking? Which circumstances foster or hinder students' interlinking and which interlinking strategies can be identified? To interlink the two scientific areas, our students have to cross the boundaries between them.

## **Theoretical background: Boundary crossing**

The idea of boundary crossing has origins and applications in the fields of general education and social theory (Akkerman & Bakker, 2011). Boundaries can be described as “sociocultural differences that give rise to discontinuities in interaction and action” (Akkerman & Bakker, 2011, p. 139) and boundary crossing as the “efforts by individuals or groups at boundaries to establish or restore continuity in action or interaction across practices” (Bakker & Akkerman, 2014, p. 225). Means to achieve this are boundary objects which “are artifacts that articulate meaning and address multiple perspectives” (Akkerman & Bakker, 2011, p. 140), e.g., a concrete task or solution. Aside from this initial understanding of a boundary object, it can also be conceptualized as a “shared problem space” (Akkerman & Bakker, 2011, p. 147) where motives of different domains act together and “materiality derives from action, not from [...] ‘thing’-ness” (Star, 2010, p. 603).

It is the interpretation of the members of the communities that give objects their meaning as boundary objects in social contexts (Star, 2010). Consequently, even if teachers or researchers intend to implement objects as boundary objects in their teaching or research, it may not be the case that the people who work with the objects understand them as such. However, because the aim is “to integrate different types of knowledge typically developed in different practices” (Bakker & Akkerman, 2014, pp. 224–225), boundary objects “may provide learning opportunities” (Akkerman & Bakker, 2011, p. 141), and students working with boundary objects may carry out interlinking actions or even practices, probably implicitly. Interesting for our purpose are three out of four mechanisms for the process of boundary crossing identified by Akkerman and Bakker (2011) when considering learning in terms of boundary crossing in the broadest sense. *Identification* is about finding out particularities of the social practices and seeing the relevance of different practices which meet at a certain border. *Coordination* means to mediate between social worlds. *Reflection* differs from identification in the sense that particularities of one community's practice are made explicit for another community (*perspective making*) or are regarded from the viewpoint of the other community (*perspective taking*).

In Spotlight-Y the notion of reflection is much broader than the boundary crossing mechanism of reflection (see section “*Boundary crossing by design(ing) through a nested design approach*”), but perspective making and taking can be part of it.

## Methodology

### Curricular linkage: Dovetailing in the lecture on complex analysis

The project “Spotlight-Y” consists of three cycles of developing the course on complex analysis with the aim to overcome fragmentation (see Hanke & Schäfer 2018a, 2018b; Mehlmann & Bikner-Ahsbahr, 2018, for details). Each cycle takes a year with a lecture in complex analysis being split into a branch for future teachers and future mathematicians after around nine weeks of the lecture. While the future mathematicians continue with more advanced complex analysis, the preservice teachers prepare learning materials (exercise sheets and means to explore and visualize with GeoGebra) for talented secondary school pupils about a mathematical topic they identified in the lecture (e.g., power series expansion, spherical geometry, or differentiation as dilation-rotation) and implement this on a day for experimental mathematics for classes of school students visiting university (XMaSII). In parallel with the complex analysis lecture, the preservice teachers participated in a seminar in mathematics education which also covered the design of tasks. Our assumption is that through boundary crossing in preparing and implementing of this practical teaching, the preservice teachers will overcome fragmentation by showing interlinkage between the knowledge from both areas. So far, 35 students participated in the teacher branch in complex analysis during the last two years.

### Approach for designing the lecture

To develop the teaching of complex analysis as described above we conduct a design study (Gravemeijer & Cobb, 2006). It aims at achieving a design as well as local theoretical knowledge about how the design works, clarifying circumstances under which the fragmentation in teacher training can be alleviated, and helping to identify obstructions. Each design cycle consists of four elements (Prediger et al., 2012; see Figure 1, left): First, a learning object or phenomenon has to be restructured. This leads to the development of a (local) design<sup>2</sup> based on a specific aim. Then, the design is executed in a design experiment. Insights from these steps are used to theorize the phenomenon, and these insights allow for a better description of the learning object or phenomenon, changes in the curricular implementation, design of the lecture, and execution. The cycle can then start over again. The core idea of our methodological frame is the nature of the design experiment. It contains an embedded cycle of the same structure that initiates “boundary crossing” in students’ work (Figure 1, right).

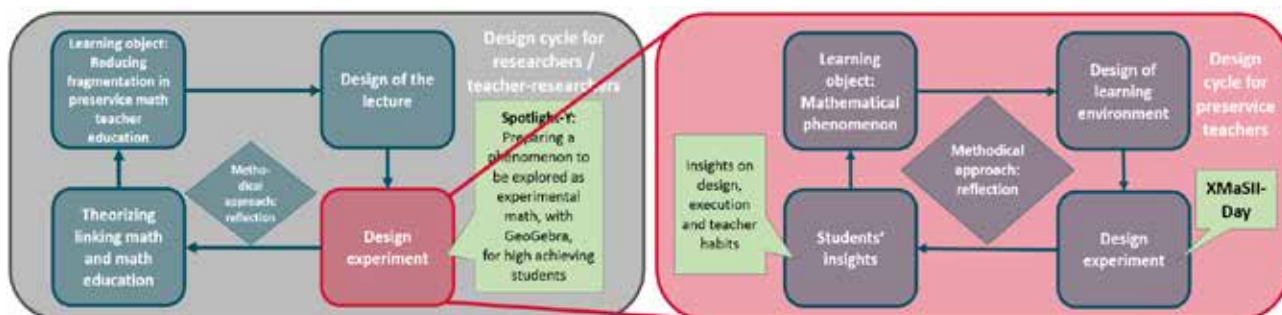

### *Boundary crossing by design(ing) through nested design cycles*

In our design study, two cycles are nested (Figure 1). The outer cycle (grey, left) is the methodical frame for research and teaching: The learning object for us as researchers is dovetailing and

---

<sup>2</sup> The word *local* is used here to distinguish the overall design in the design study “Spotlight-Y” from the designs developed in it: In the outer research cycle it is the course design of complex analysis including teaching strategies, and in the inner cycle it stands for the designs the students develop for their learning arrangement (see Figure 2).

interlinking university mathematics and mathematics education in preservice teacher education. The general design of the lecture was described in the section “Curricular linkage: Dovetailing in the lecture on complex analysis” and the design experiment is the course work in the branch for preservice teachers in the lecture on complex analysis. The inner circle (red, right) frames the development and implementation of the learning materials by our students. Here, the learning objects (for students and pupils) are the mathematical phenomena the students choose from the lecture.

**Figure 1: Nested design cycles in Spotlight-Y**

The process is accompanied with three types of written reflective activities. We understand *reflection* as anticipatory as well as retrospective (re-)consideration of own work, including experiences of various kinds, thoughts about personal relationships to the two disciplines (mathematics and mathematics education), the own role as a future teacher, and possibilities for the improvement of local designs of learning arrangements. In a *preflection*, the preservice teachers describe the mathematical phenomenon and anticipate difficulties at the beginning of their planning, in *ad-hoc-notes*, they reflect on observations right after the execution of XMaSII, and in a final *portfolio*<sup>3</sup> they reflect on the full process and their professional development, each with guiding stimuli (Hanke & Schäfer, 2018a, 2018b). This is in accordance with the notion of reflection-on-action as proposed by Schön (1983) and reflection-pre-action by Bikner-Ahsbabs (2017).

Instances of interlinking mathematics and mathematics education can be identified in students' reflections from which we extract interlinking strategies (see results section). Such a strategy may be a certain local mechanism a student implemented, or a personal insight. Since the reflections are written after a teaching episode with classes of school students (the design experiment), we might also reconstruct interlinking strategies which have not appeared in action, but which have been thought about by the students. The reflections have two functions: First, they serve to reconstruct and typify the interlinkages between university mathematics and mathematics education, and second, students experience reflection as a means to learn from own practical experience (planning, executing, assessing) and be aware of interlinking activities (Mehlmann & Bikner-Ahsbabs, 2018).

In the inner cycle, in the branch for the preservice teachers, the boundary of the scientific lecture and mathematics education is crossed by referring to each other. The *initial boundary object* is the student task to create the XMaSII-day learning arrangement. This task can be interpreted from the

<sup>3</sup> A portfolio is a collection of all written work, this includes the exercise sheets, written planning and description as well as answers to final reflective questions (see Hanke & Schäfer, 2018a, 2018b, for details).

mathematical as well as the mathematics education side. The specificities of the implementations and reflections indicate how the students interlink both areas. The work of the students leads to a design process which initiates boundary crossing. All data, in the form of exercise sheets, computer arrangements and different kinds of written reflections shape a *dynamic boundary object* which is assembled by the students' work at the boundary of mathematics and mathematics education and which, at the same time, is subject to change. We call this design principle (van den Akker, 1999) *boundary crossing by design(ing)*. "By design" refers to the curricular implementation, and "by designing" refers to the processes the students engage in. The boundary crossing or interlinking mechanisms we observe stand for the interlinking practices of students and can be further used for the next cycle of the branch for preservice teachers in the lecture on complex analysis. In that sense, the design principle *boundary crossing by design(ing)* serves as our epistemic means to describe to which results acting at the boundary of mathematics and mathematics education may lead. In other words, *dovetailing* is the attempt to initiate boundary crossing and the students' boundary crossing may lead to thinking and acting between mathematics and mathematics education, i.e. *interlinking*. Thus, boundary crossing is regarded as a mediator between dovetailing and interlinking.

The novelty of *boundary crossing by design(ing)* is not the fact that mathematics and mathematics education are asked to be combined—this is expected practice of any (future) teacher. It is that the linkage we try to establish is between the two scientific domains, mathematics at university and mathematics education for preservice students' teaching (cf. Introduction).

## Exemplary results of the first two cycles

Having developed the methodology and the design principle, we conjecture that implementing the design principle into the third cycle will initiate students' interlinking between complex analysis and mathematics education, and we ask whether we will find the same or new interlinking strategies of the students. But how do these interlinkings show up and what conditions foster or hinder them? Until now, this is answered by analyzing the data of the first two cycles, and here, we give some examples.

Results indicate that interlinking is an additional demand (concerning mathematical expertise and/or time) which is often not accomplished by our preservice teachers, and happens in microscopic ways. Besides others, the students were asked to *describe which elements of the course on complex analysis changed their views on the scientific discipline of mathematics and mathematics as a school subject*. This question aimed at a retrospection on the course as a whole. One of the students wrote (we note that the learning arrangement of this student did not deal with extension of number sets but with differentiation):

The extension of number sets with the set of complex numbers is very demanding at first. Pupils who encounter negative numbers for the first time might feel similarly. The experiences I made in this course can help me to empathize with pupils and understand why the extension of numbers with the set of irrational numbers can be difficult for them and why they may not consider the number  $\pi$  as a number.

In addition, the experience of the lacking imagination of the graphical representation of complex functions can help to understand the difficulties pupils have with the visualization of graphs of functions. (translated from German)

This description expresses the sensitization for pupils' difficulties by analogy. The example in the quote shows an experience-based perspective on problems with extensions of number sets and diagrams which can be regarded as a coordination mechanism with the potential for a transformation mechanism (see: Akkerman & Bakker, 2011). For example, a transformation could occur if the student presented a suggestion for how to deal with these issues in class. We may conclude that in this case the student's own experience with subject matter sensitizes for learning processes of pupils. What is not important is that the content in the student's learning process is beyond school but that what is learnt, in each case, is new for the respective learner (student and pupil).

To the stimulus "*What did you learn personally? Do you feel assured in your role as a teacher? How and why (not)?*" another student expressed (his learning arrangement was about power series),

So I find the problem to prepare a very complex and alien (German: fremd) topic for pupils very interesting and instructive because I, myself, had to cope with this topic intensively once again.

Unfortunately, I had to realize that exactly in this transformation very much time and work had to be invested which lacked for example for the precise planning and execution. At any time, the subject specific understanding (German: das fachliche Verständnis) was the most important aspect of the planning. (translated from German)

This utterance shows that the creation of a learning arrangement about a demanding mathematical topic requires resources in order to engage deeply with the subject matter. Here, the need for these resources sidelined the planning actions for the actual planning and implementation.

## Discussion and reflection

Reflecting on the two design cycles at the university level we went through, the steps of how the design principle developed becomes clear. Due to the fragmentation in preservice teacher education, our first design principle was to *link university mathematics and mathematics education through providing practical experience for our students in one mathematics lecture*. The method seemed clear; the students identify a mathematical phenomenon from the lecture, plan and implement learning materials for talented pupils, and thus, overcome fragmentation. But this did not happen with most of the students. Therefore, after the completion of the first design cycle, we clarified the relationship between this method and our research design. That is, our students were actually performing a design cycle similar to ours on the research level. Thus we obtained a more precise methodology, the *nested design approach*. Since we were not able to rely on previous research, we had to bridge the distinction between *dovetailing* and *interlinking* theoretically. The theory of *boundary crossing* serves this purpose. The concise link between theory and methodology was achieved after the second cycle and on this basis we obtained the current design principle. *Boundary crossing by design(ing)* condenses the theoretical approach of boundary crossing and links it to the task of creating and implementing learning materials while taking into account two scientific domains. This design principle addresses two different kinds of design: *design research* at the university level for course development in which the students *design learning arrangements*. These threads together can lead to insights into the reduction of the fragmentation in teacher training we strive for. Ultimately, our project exemplifies that a suitable design principle does not necessarily stand at the beginning of a design study but can be achieved through development and confluence of methodology and theory.

Our students valued the practical experience in the project. Even when they did not manage to produce explicit interlinkages of the two domains, in some cases of interlinking the two domains we observed a kind of coordinating, a mechanism of boundary crossing. Hence, we should ask what kind of conditions hindered the preservice teachers to experience interlinking mathematics and mathematics education (of school mathematics). We next aim at developing a scaffolding procedure. For example, cognitive overload might be avoided by a concrete example of how a phenomenon of complex analysis could be transposed into a learning arrangement for talented pupils or by a more detailed structure for the task to create a learning arrangement that assists preservice teachers in their boundary crossing.

Last, we highlight an important epistemic obstruction resulting from our methodological approach. The contents and depths in the students' reflections limit the depths of our insights. Also, reflections mainly on a descriptive level are at most an indicator for students' weak interlinking. This means we also have to reconsider the stimuli which we ask our students to consider.

# How concepts turn into objects: an investigation of the process of objectification in early numerical discourse

Felix Lensing

Freie Universität Berlin, Germany; [lensinfo@zedat.fu-berlin.de](mailto:lensinfo@zedat.fu-berlin.de)

*Mathematical discourse begins where the concrete ends. Despite the intangibility of mathematical objects, we still speak about them in a way that is quite similar to the way in which we speak about material objects. We speak of numbers, classes, and functions as if we were talking about self-sustained entities. But with what right? On the example of the use of number-words in early numerical discourse, I shed some light on the mechanisms by means of which mathematical objects obtain their peculiar ontological status. It turns out that any mathematical object refers back to a concept from which it originates. To better understand the process of objectification, I am thus asking: how do concepts turn into objects? By juxtaposing Piaget's notion of reflecting abstraction with Peirce's notion of hypostatic abstraction, I then propose an explanatory model of the transition from concepts to objects.*

*Keywords: Objectification, reflecting abstraction, Piaget, hypostatic abstraction, Peirce*

## I. Introduction

- 1 MH: How many is two and one more?
- 2 Patrick: Four.
- 3 MH: Well, how many is two *lollipops* and one more?
- 4 Patrick: Three.
- 5 MH: How many is two *elephants* and one more?
- 6 Patrick: Three.
- 7 MH: How many is two *giraffes* and one more?
- 8 Patrick: Three.
- 9 MH: So how many is *two* and one more?
- 10 Patrick: Six.<sup>1</sup>

Although Patrick (4 years and 1 months) seems to have no problem in recognizing the number-words in the posed questions, he is for some reason unable to cope with them in the first and last question. How can it be that he does not see the pattern common to both questions? What seems unfamiliar to him are not the number-words themselves, but it is the way in which these words are used. In general, we can distinguish between two different uses of number-words (cf. Dummet, 2002, pp. 99–100): Number-words can either occur as adjectives, as in ascriptions of number such as ‘There are *two* giraffes’, or as nouns, as in most arithmetic propositions such as ‘*Three* is a prime number’. In their adjectival use, number-words function as predicates. They cannot stand for themselves, but they characterize something else. In that use, a number-word specifies how many there are of a certain kind and thus it must occur as the number of something, or more precisely as the number of a concept (‘three *lollipops*’, ‘three *giraffes*’, ‘three *elephants*’). In contrast, number-words that occur as nouns stand for something that can be investigated in its own right. In this substantival use, numbers are regarded as

<sup>1</sup> ‘MH’ stands for Martin Hughes. The transcript is taken from Hughes (1986, pp. 47–48).

self-sustained entities without any intrinsic reference to the concepts which they are possibly ascribed to. Armed with this distinction, we are now able to formulate Patrick's difficulties in a more concise way: While Patrick seems to be familiar with the adjectival use of number-words (see lines 3–9), the substantival one appears foreign to him (see lines 1–2 and 9–10). Consequently, he does not see addition as an operation between numbers as abstract objects, but only as an operation performed on two concepts. To him, adding up means to join two collections of objects. Taking this into consideration, it becomes understandable why he shows difficulties grasping the first question. From an adjectival standpoint, it is of no importance which kinds of objects are conjoined (lollipops, giraffes, elephants, etc.) as long as there are some. An addition cannot be performed *in vacuo*. The question 'How many is two and one more?' is thus incomplete for Patrick, he feels that there is something missing, namely a pair of concepts with which the operation is executed. These observations gain in importance as soon as it is added that they are by no means a personal exception but rather are typical of many preschool children aged 3 to 4 years (cf. Hughes, 1986, p. 46; Sfard, 2010, p. 47). It is the result of an intricate process of successive steps of objectification that numerals and number-words can be treated as referring to the self-sustained entities we call numbers (cf. Sfard, 2010, p. 136). Within this process, the adjectival use of number-words precedes the substantival use, or bluntly put: *numbers are first concepts, and only become objects in a second step.*

This developmental sequence, however, is not restricted to the genesis of numbers. Rather, it repeats itself at all levels of mathematical sophistication. For example, Bakker (2007) observed in a teaching experiment on the concept of distribution in an 8<sup>th</sup> grade in the Netherlands that the students' discourse about the concept of spread took a similar turn:

[M]any used the noun 'spread,' [...], whereas students earlier used only predicates such as 'spread out.' [...] Statistically, however, it makes a difference whether we say, 'the dots are spread out' or 'the spread is large.' In the latter case, spread is an object-like entity that can have particular aggregate characteristics that can be measured (for instance by the range or the standard deviation) (Bakker, 2007, p. 24)

Or, to provide a historical example: It took several centuries to move from the study of specific examples of functions to the study of functions as such, that is, to the investigation of functions as objects for which certain general characteristics such as continuity or differentiability can be formulated (cf. Kleiner, 1989; Sfard, 1991, pp. 14–16). The departure point of this article is the conviction that what we have observed in the case of number can be generalized: *At any level of mathematical sophistication, mathematical objects are products, i.e., they are produced in processes of objectification, and at any level of mathematical sophistication, the mathematical objects in question refer to concepts from which they originate.*

In this paper, I take early numerical discourse as an example to investigate the transition from concepts to objects as a key element of the *process of objectification* (in the sense of: Sfard, 2010). I attempt to provide a model of the mechanisms which underlie this last step in process of objectification. The rationale of the paper is thus a theoretical one and it is precisely here where the novelty of this contribution lies: There are plenty of works in mathematics education (cf. Bakker, 2007; Sfard, 1991) in which it is described *that* this transition happens, but I do not know a single one that provides an explanatory model of *how* it could actually work. In order to provide such a model, I pursue the following plan: At first, I clarify the use of the words

‘object’ and ‘concept’ in order to formulate the theoretical reference-problem as clearly as possible (II.); in the next two sections, I then successively explore the adjectival (III.) and the substantival use of number-words in more detail (IV.); this leads to an explanatory model of the transition from concepts to objects which is developed in the fifth section by juxtaposing Piaget's notion of reflecting abstraction with Peirce's notion of hypostatic abstraction (V.).

## II. On the distinction between concept and object

When speaking about material objects, we either use terms that tell us which individual is being talked about, or we use terms that characterize something as an instance of a certain kind. ‘Socrates’, ‘Berlin’, and ‘Donau’ are examples for the former kind of terms, while ‘human being’, ‘city’, and ‘river’ are examples for the latter. To adopt a usual phraseology, we will call these two kinds of terms *singular* and *general* terms. A singular term “purports to name one and only one object” (Quine, 1966, p. 205), while a general term does not name the individual object to which it refers at all but, instead, is said to be true of each of many objects of a certain kind (ibid.). The general term ‘human being’, for example, is true of the object *Socrates*, but it is not true of the object *Berlin*. Singular and general terms thus differ in their *way of reference*: While a singular term refers to one object and one object only, a general term divides its reference. It can always be applied to a multiplicity of objects. What a general term names is thus not any particular object, but at best its own rule of application, i.e., the operation used to decide whether or not the term is true of an object. We want to call these operations concepts: *A concept is any operation that is associated with a general term and that allows to decide whether or not the term is true of a particular object.*

Therefore, concepts are not to be found in the realm of being but belong to the realm of doing. We operate *upon* objects (as they are singled out for our investigation), while we operate *through* concepts (as it is the conceptual operation by means of which the general term is applied to a particular entity). In contrast to everyday language, objects to which mathematical terms refer are never components of our stream of direct experience. Mathematical discourse begins where the concrete ends. We cannot point at or see mathematical objects such as numbers, classes, or functions. Despite their intangibility, however, we still adopt a jargon that is quite similar to the way in which we speak about material objects. On the one hand, there are singular terms such as ‘ $1 + 4$ ’, ‘ $\sqrt{2}$ ’, or ‘ $\pi$ ’, which purport to name one and only one object, on the other hand, there are general terms such as ‘prime number’, ‘continuous’, or ‘equilateral’, which characterize the objects in question as instances or non-instances of a certain concept. In mathematical discourse, the distinction between singular and general terms thus remains intact (see already Peano, 1891/1973, p. 156). The difference between mathematical terms and everyday terms is not the way of reference, *but the kinds of objects referred to.*<sup>2</sup> In the case of everyday language, the terms are mostly concrete in the sense that the objects referred to can be investigated as parts of our sensory material, while, in the case of mathematical discourse, they are not components of our direct experience and are thus abstract. Besides the division into the singular and the general, there is thus another division that must be taken into consideration, the one into the *concrete* and the *abstract*. On the expression layer, we then distinguish between

---

<sup>2</sup> For a more detailed discussion of what it is that makes a concept a mathematical concept, see also: De Freitas, Sinclair & Coles (2017).

singular and general *terms* on the one hand, and between concrete and abstract terms on the other hand, while, on the content layer, all singular terms name *objects* and all general terms stand for *concepts*.

Note that the two divisions cross each other: There are concrete and abstract singular terms such as ‘Socrates’ and ‘ $\pi$ ’, and concrete and abstract general terms such as ‘human being’ and ‘prime number’ (cf. Quine, 1966, p. 204). An investigation of the relations between these different kinds of terms unveils that we can find correspondences. The abstract singular term ‘redness’ corresponds to the general term ‘red thing’; ‘sweetness’ is the abstract singular term to the general term ‘sweet’, and the general term ‘round’ can be matched to the abstract singular term ‘roundness’. This series of correspondences is a systematic feature of our language (cf. Quine, 1966, pp. 204–205): For every general term, be it concrete or abstract, we can come up with a corresponding abstract singular term which names the (abstract) attribute that is ‘shared’ by all the objects which fall under the concept in question (or, respectively of which the associated general term is true). The term ‘roundness’, for example, names the attribute that all round things have in common. It names the particular form or gestalt that we recognize in our sensory experience from case to case when encountering a round thing. That also leads us to a hypothesis as to why general terms precede their corresponding abstract singular terms in cognitive development: *If the corresponding abstract singular term is what all of the objects that fall under a particular concept have in common, it is hardly possible to recognize this common attribute if the concept in question has not yet been learned.*

### III. Numbers as concepts

Equipped with this terminology, it is worth returning to the introductory example, which made obvious that number-words can either function as general or singular terms, meaning they can stand for concepts or objects. Let us take a closer look at the adjectival use of number-words first since it precedes the substantival use in the developmental sequence. As a reminder, our introductory thesis was: *numbers are first concepts, and only become objects in a second step.* Since we have clarified at this point what is meant when speaking of a concept, we can now ask for the operation or rule of application which is associated with a number-word when it functions as a general term. However, before we can do that, there is one more thing that needs to be clarified in advance: *the relation of number-words to the sensuous world.* It is important not to conceive number-words, not even in their adjectival use, as referring to certain complexes of our direct stream of experience. One and the same sensory impression can always give rise to a majority of equitable ascriptions of number:

While looking at one the same external phenomenon, I can say with equal truth both ‘It is a group of trees’ and ‘It is five trees’, or both ‘Here are four companies’ and ‘Here are 500 men’. Now what changes here from one judgement to the other is neither any individual object, nor the whole, the agglomeration of them, but rather my terminology. But that is itself only a sign that one concept has been substituted for another. This suggests [...] that the content of a statement of number is an assertion about a concept (Frege, 1970, §46)

Whether a certain sensory impression gives rise to one application of a number-word or another, hence solely depends on the way in which we *conceptually* organize or structure this experience. If a number-word is used as a general term, what falls under the associated concept

are again also concepts. What the number-word ‘four’ stands for is then a *second order concept* (cf. Frege, 1970, §53), a concept that comprises all of those concepts with exactly four objects. Such a concept does not collect the counted objects or certain aggregates of them, but only the concepts structuring that material. In their adjectival use, number-words are, therefore, abstract general terms. Since a general term cannot stand on its own but is always predicated of something else, in this case of other concepts, it becomes clear why Patrick cannot make sense of the questions without any reference to other concepts. His behavior indicates that he treats the number-words as standing for second order concepts. In this use, there must be some concepts upon which the addition is executed. Now we can come back to the question of what the operation or rule of application might look like that is associated with the term ‘four’.

In the case of the number-word ‘four’, this operation might be depicted as following: We coordinate one after the other all the objects that fall under the concept in question with all terms of the number-word sequence starting from ‘one’ until we come by the word ‘four’. If the counting procedure stops at ‘four’, that is, if all objects were counted up to this point, we say that the given concept falls under the concept *four* (or, respectively that the term ‘four’ is true of the particular concept). If the procedure already stops before or if we exceed ‘four’ without having finished the counting procedure, we will say that the given concept does not fall under the concept *four* (or, respectively that the term ‘four’ is *not* true of the particular concept). Here it is important to emphasize that there is no need at all to suppose an entity such as an attribute that is common to all the concepts comprising exactly four objects. Without a doubt, we can learn and apply the operation described above without supposing the number-words to refer to a separate abstract object of any kind. This observation holds true quite generally: the “use of the general term does not of itself commit us to the admission of a corresponding abstract entity into our ontology” (Quine, 1950, p. 630). Therefore, we should consider the final step of objectification, leading to the treatment of numbers-words as singular terms, as an additional step that requires the use of number-words as general terms already been learned. So, how, we must ask, do numbers become objects?

#### IV. Numbers as objects

Let us assume we have a box in front of us which contains eleven marbles and we are supposed to determine how many marbles there are in the box. Wanting to communicate our counting result, we have at least two options: (1) ‘There are eleven marbles in the box’; (2) ‘The number of marbles in the box is eleven’. These two options correspond to our two forms of number-word use: in (1) ‘eleven’ functions as general term that is predicated of the concept *marbles in the box*, while in (2) ‘eleven’ can be said to stand for the same abstract entity as ‘the number of marbles in the box’, indicating that it functions as an abstract singular term. We argued above that, for a given general term, the corresponding abstract singular term can name the attribute that is shared by all the things which fall under the concept in question. However, for number-words functioning as general terms the situation is somewhat different. It appears to be quite difficult to come up with a feature or attribute that all of the concepts have in common to which a number word such as ‘eleven’ can be successfully applied. What is the distance in meters between the penalty spot and the goal? How many corner points does the maple leaf on the Canadian flag have? How many criminals are there in Danny Ocean’s gang? How many academy awards did the film Titanic win? And, last but not least, what do these

things have to do with our marbles? At the level of content, all these different manifestations of the number eleven obviously have nothing in common. So, what exactly is it that repeats itself from one manifestation to the other?

No matter if we count our marbles, the vertices of the maple leaf of the Canadian flag, or the meters from the penalty spot to the goal, in each of the cases we perform a counting procedure. The sameness does not lie at the level of the concepts upon which the counting procedure is executed, but it lies at the level of the procedure itself, that is, at the level of our operations with these concepts. What repeats itself from one counting act to the other is the fact that all of them end up with the number-word ‘eleven’. But this is itself only a sign that one and the same concept is applied: the second order concept associated with the number-word ‘eleven’. To go one step further in the process of objectification, a child capable of the adjectival use must thus recognize all the successive counting acts ending up with the same number-word as applications of the same concept. This requires a minimal reflexive loop: In order to sense this kind of ‘operational’ sameness, the child must make her own operations the object of her own operations. She must relate several successive applications of a number-word to each other and analyze them into sameness and difference of the counting results. However, in order to be able to identify several counting acts that end up with the same number word, a series of *factual* (the acts might be executed on very different concepts), *temporal* (the acts are most likely executed one after the other) and *social* (the acts might be executed by different people) *differences* between the individual acts must be left out simultaneously.<sup>3</sup>

## V. Piaget versus Peirce: What is abstraction?

What we are facing here is a two-sided process in which something is *retained* and at the same time something else is *left out*. Traditionally, this two-sided process is referred to as *abstraction* (cf. Locke, 1836, book 2, chapter 11, §9). In any process of abstraction there is a certain kind of material or substance upon which the abstraction is carried out. We cannot simply abstract something but rather we always abstract *from* something. Now, what is unusual in our case is this very substance of abstraction. The substance upon which the abstraction is carried out does not consist of objects of a certain kind but of our own operations. To take account of this reflexivity, Piaget has introduced the notion of *reflecting abstraction* (cf. Piaget, 2014, pp. 317–323; Glasersfeld, 2003, pp. 103–105). In contrast to what Piaget calls *empirical abstraction*, a reflecting abstraction is an operation that runs on operations:

[W]hen we are acting upon an object, we can also take into account the action itself, or operation if you will, since the transformation can be carried out mentally. In this hypothesis the abstraction is drawn not from the object that is acted upon, but from the action itself (Piaget, 1971, p. 16)

We can now see that the process of relating several counting acts and analyzing them into the sameness and difference of the counting results can be reconstructed as a reflecting abstraction. It runs upon several applications of the second-order concept associated with the number-word

---

<sup>3</sup> This distinction between three *meaning dimensions* – a factual, a temporal, and a social –, in which we can seek for commonalities and differences, stems from the German sociologist Niklas Luhmann (cf. Luhmann, 1995, pp. 59–102).

‘eleven’. The child must retain what all of the counting acts have in common while simultaneously leaving out all the features in which these successive acts differ from each other. But what is the outcome of this process? Have we already arrived at the substantial use of number-words? To cut it short: yes and no.

In general, we can say that the ‘minimal’ attribute shared by all things that fall under a certain concept is this purely formal feature, the fact that the things fall under that very concept. What all concepts that fall under the second order concept *eleven* have in common, is that they bear the same relation to this concept. They fall under it because in each case the counting procedure ends with the word ‘eleven’. And to identify this formal sameness, we must perform a reflecting abstraction. In this way, the notion of reflecting abstraction allows extending the notion of a common property or a shared attribute far beyond the immediate, sensuous world. At best, we might then say that in the process of reflecting abstraction the successive mental or communicative acts are ‘condensed’ into an object-like entity, an attribute, which is the common feature of all these different acts. But, in the end, that is mere speculation. How, one might ask, is this mysterious object-like entity anchored if we obviously cannot perceive it?

In order to provide an answer to this question, we have to move away from the content layer, the series of operations on operations, onto the expression layer, the layer of the use of signs to fix these volatile operations (cf. Sfard, 1991, p. 21). It is precisely here where the notion of reflecting abstraction comes into trouble. It can explain how we get to sense the operational sameness described above, however, what it cannot explain is how this sameness is objectified. We therefore want to complement Piaget’s account on abstraction with Peirce’s considerations on the very same topic. Peirce has introduced the notion of *hypostatic abstraction* to describe the exact process we are interested in, the transition from a general term to an abstract singular term or in Peirce’s own words:

That wonderful operation of hypostatic abstraction by which we seem to create *entia rationis* that are, nevertheless, sometimes real, furnish us the means of turning predicates from being signs that we think or think *through*, into being subjects thought of. We thus think of the thought-sign itself, making it the object of another thought-sign. (CP 4.549)

It is noticeable that Peirce gives a beautiful account on the reflexive loop we have already described above: Whenever we apply a general term or a predicate we think *through* the sign or the concept associated with it in precisely that sense that we always predicate it of something else, while in any attempt to transform it into an object, we must reflect on this very use and make it the subject of another thought. That is to say, we must think *of* the sign *through* which we have thought before. So far nothing new, but in the second part of the quotation Peirce goes beyond what we have already described before. We “think”, Peirce writes, “of the thought-sign itself, making it the object of another thought-sign” (ibid.). As noticed before, what stays the same from application to application of number words in their adjectival use is nothing but the purely formal feature that the number-words are true of all the concepts to which they are successfully applied. We can now add that, what the corresponding abstract singular term names, is ultimately nothing other than the sign thought through before. Number-words functioning as singular terms name the sign, i.e., the *relation* between the general term and the particular counting procedure associated with it. This way, the conceptual operation becomes crystallized or frozen. When a number-word is used as a singular term, the operation must not

be performed anymore but is rather only implied or pointed at. We say that we ‘know’ what the numeral ‘1,098,7877’ stands for because it “points to the last element in a familiar counting procedure” (Glaserfeld, 1995, p. 100), a procedure that no longer needs to be executed.

Concluding, I want to generalize this thesis. We do not need to posit some sort of ontological realm to answer the question of how we can speak about numbers, classes, and functions as self-sustained entities. What a singular term in mathematical discourse stands for is ultimately no more than another sign, it is the relation between the general term (from which the singular term in question originates) and the associated conceptual operation.

# On the epistemology of the Theory of Objectification

Luis Radford

Laurentian University, Faculty of Education, Ontario, Canada; [lrادford@laurentian.ca](mailto:lrادford@laurentian.ca)

*In this paper I discuss some concepts that are part of the epistemology dimension of the Theory of Objectification—a Vygotskian theory of teaching and learning whose philosophical background comes from dialectical materialism. The epistemological concepts are presented in the first part of the paper. In the second part, they are illustrated through a classroom example.*

*Keywords: Knowledge, knowing, processes of objectification, learning, concept.*

## Introduction

This article seeks to contribute to the research field of theoretical perspectives in mathematics education. Its goal is to offer a short account of the manner in which a central, yet controversial, concept in mathematics education—the concept of learning—is conceived of in the Theory of Objectification (TO). To do so, this article describes the epistemological dimension of the TO as a dynamic whole system driven by dialectical relationships between knowledge, knowing, and learning. Drawing on a previous paper (Radford, 2013), I revisit a classroom example to illustrate the ideas presented in the article and to add a new epistemological element—the concept of *concept*. The example also provides insights about the interplay between the theoretical principles of a theory and its methodology and shows how the TO addresses a specific sensitivity of mathematical epistemology: one in which mathematical knowledge is considered as a cultural-historical entity in motion, an entity that is incessantly renewed and expanded and continuously brought to life by sensuous, practical, and material human activity.

## Knowledge

In the Theory of Objectification, knowledge is understood as a *general entity* that, ontologically speaking, is already in the culture when we are born. Knowledge includes historical archetypes and culturally constituted processes of thinking, reflection, and action. Let us imagine a rural community that, in the course of time, has produced ways of thinking, reflecting, and doing things—for example, how to sow the earth, how to think about space, quantity, time, etc. These ways of thinking, reflecting upon, and doing things are general archetypes that constitute the knowledge of the culture. Let us now imagine a baby born at this moment in that culture. For this baby, those ways of thinking about the world, space, quantity, time, etc., appear as *possibilities*—possibilities of action and reflection. Another culture (e.g., a culture based on capitalist ways of commercial production in a contemporary European or North American country) will offer individuals born at this moment other possibilities; that is to say, other knowledge. These possibilities are *potential* actions/reflections, or *capacities* to do something. It is in this sense that knowledge can be considered as *potentiality*.

According to Aristotle, potentiality (δύναμις) is synonymous with power or disposition. Living beings and mechanisms have potentiality. A musical instrument, for example, has the ability to produce sounds. A fish has the ability to move in the water. *Actuality* (ἐνέργεια, *energía*), by

contrast, is the concrete happening of that which, before being put in motion, before being actualized, was potentiality. Potentiality is something undefined, without form, like a sound *before it is produced* or like the capacity of the fish *before it travels* in the water; something purely potential that, through *movement*, becomes materialized or actualized (*act*-ualized: transformed by an *act*-ion). However, the potentiality that living beings and mechanisms enjoy can be natural or acquired. The fish is biologically equipped to move in the water. Other potentialities or capacities are acquired, as Aristotle indicated (1998) in *Metaphysics* (1048a). This is the case of knowledge. Knowledge is this: *generative capacity, potentiality*. Algebraic knowledge, for example, is potentiality embedded in the culture: capacities that are offered to individuals in order to think, reflect, pose, and solve problems in a *specific way*.

Knowledge as the generative capacity of action and thinking changes from one culture to another and from one historical period to another. It would be a mistake, though, to think that the idea of knowledge I am outlining here stands in a Platonic line. The fact that when each one of us was born and was confronted with a series of scientific, ethical, aesthetic, legal and other forms of knowledge/thinking already established historically and culturally, does not mean that those forms of knowledge are Platonic forms, universal and timeless, independent of human labour. On the contrary, knowledge in each culture is produced by concrete people through their own labour—through their own actions, their own reflections, their joys, their suffering, and their hopes. To be more precise, I suggest that *knowledge is a system of embodied, sensible and material processes of action and reflection, constituted historically and culturally*. The adjectives *embodied*, *sensible*, and *material* mentioned in the previous definition signify that the processes of action and thinking are not mental cogitations occurring inside the head, but actions of real individuals who work and live in a social and cultural world. These actions are carried out through the body, the human senses, and through the use of physical objects and cultural artefacts.

## Knowing

Knowledge is *related* to each one of its concrete instances or actualizations, but is, at the same time, *different* from each one of them. In its materialization or actualization, each of these concrete actualizations keeps in a sublated manner the generality of the ideal form that engenders it, but it *does not* coincide with the ideal form. In the TO, the actualization of knowledge has a specific name: *knowing*. Knowing is the concrete conceptual content through which knowledge is embodied and materialized or actualized. Although knowledge and knowing belong to two different ontological spheres—the former is *general*, the latter *singular*—they are interrelated in a dialectical manner and are part of a *dynamic whole system*. Knowing as the *actualization* of knowledge evokes indeed this *temporal* dimension of a whole in continuous movement. And what produces the movement is *activity*: knowledge and knowing are related through activity. Indeed, knowing can appear only through activity. This activity actualizes knowledge, brings it to life—like the activity of playing a violin brings musical notes to life, or the classroom activity of solving an algebraic equation brings algebraic knowledge to life. We can now state in a more precise way the relationship between knowledge and knowing: knowing is a sensible developed form of knowledge—much like the bud's example that Hegel offers in his *Phenomenology of the Spirit*: the blossom originates from the bud; it is the materialization or actualization of the bud, yet it does not

coincide with the bud. The blossom is a sensible developed form of the bud: although different, “their fluid nature makes [the bud and the blossom] moments of an organic unity . . . in which each is as necessary as the other; and this mutual necessity alone constitutes the life of the whole” (Hegel, 1977 p. 2). The *dialectical moment* is precisely the moment in which one becomes the other, the moment in which algebraic knowledge as *general* becomes transformed into something sensible, *singular*—that is, an object of consciousness. “It is of the highest importance,” Hegel notes, “to interpret the dialectical [moment] properly, and to [re]cognise it. It is in general the principle of all motion, of all life” (Hegel, 1991, p. 128). Up to here I have dwelled on concepts that have to do with aspects of the general theoretical stance of the TO. Now we enter into the educational-epistemological realm and deal with the concept of learning.

## Learning

In student-centred pedagogies the student is considered to *construct* his/her *own* knowledge. No one can construct it for him/her. To *construct* a concept is equated to *learning* such a concept. In this conception, knowledge (K) appears as an *extension* of the subject (S). Since knowledge is not something different from the subject, but the subject’s *own* construction; in other words, since there is an identity between the thinking self and the products of its cogitations (Ilyenkov, 1977), this conception can be summarized through the equation:  $S = K$ . The intention behind the TO is to move beyond this individualistic stance.

To theorize learning, sociocultural theories have resorted to a series of concepts, such as enculturation (mainly formulated in anthropological research) and internalization (borrowed from Vygotsky’s work). I have argued elsewhere (Radford, 2018) that both concepts are insufficient to come up with an operational definition of learning from an educational perspective. To put it in a nutshell, the concept of enculturation adopts as its explanatory principle the idea of social practice, but leaves it uncritically analyzed. In enculturation approaches a social practice often amounts to what people *do*. Furthermore, in enculturation approaches the agentic dimension of individuals remains usually at the periphery. In Rogoff’s (1990) account, the individuals are certainly considered as active participants. But learning is conceptualized as *apprenticeship*; that is, something occurring through “the guidance and challenge of other people” (Rogoff, 1990, p. 19). In the end, learning is a process whose goal is to *adapt* oneself to existing social practices. Education is reduced to reproduction. There is little room to investigate education as transformation of people and the world. Likewise, there is little room to investigate the individuals as agentic entities, such as the manners in which the individuals come to position themselves and be positioned in social practices. There is little room to investigate the tensions that arise from the normative dimension of cultures (what Bakhtin, 1981, called a centripetal force) and the agentic movements of the individuals (the centrifugal force in Bakhtin’s terminology). A similar critique may hold for Vygotsky’s concept of internalization; that is, the “*transition of a [psychological] function from outside inward*” (Vygotsky, 1998, p. 170; emphasis in the original). It might be worth noticing that the content of Vygotsky’s concept of internalization (Вращивание – vraschivanie) is not learning, but the higher psychological functions (such as memory and perception). The problem that internalization seeks to explain is not how the child learns but how the higher psychological

functions arise from social relations, and how these functions evolve. How, then, is learning theorized in the TO? In the rest of this article I sketch the answer to this question.

## Processes of objectification

As suggested earlier, in the TO, knowledge is considered as a culturally and historically constituted system of thinking and action. When each one of us was born, these systems (always in motion, always changing) were already there, existing in our culture in the form of knowing how to plant corn seeds, knowing how to calculate mortgages, etc. In other words, at birth, to each one of us, knowledge appeared as a cultural-historical generative, *latent capacity*. Our *encounter* with culturally and historically constituted systems of thought (e.g., mathematical, scientific, aesthetic, legal, etc.) is what in the TO is called *objectification*.

To understand the meaning of this encounter, let us bear in mind that the noun “objectification” tries to convey the idea that, before our encounter with knowledge, knowledge presents to us as something *different* from us: something that in its *alterity*, its own presence *objects* us; that is, resists or opposes us. The equation is:  $S \neq K$ . Before our encounter with knowledge, knowledge is the sign of a *difference*. *Object-ification* is the attempt to erase that difference. But because knowledge is an ideal (general) form always changing (constantly being recreated, refined, and expanded), the difference that the encounter tries to erase is not something that can happen totally. There is always a residue, a surplus that remains beyond our always local, situated, and concrete encounters with knowledge. As a result, objectification is always partial, a Sisyphean attempt at embracing knowledge—at becoming conscious or aware of it. “Object” in objectification does not refer to the verb “to objectify,” but to the verb “to object” (as when something, a desk, a chair, *objects* us). This is why, in the TO, in providing accounts of learning, instead of saying that students objectified knowledge, we talk about students engaged in *processes of objectification*. More precisely, *processes of objectification are those social, collective processes of becoming progressively conscious of a culturally and historically constituted system of thought and action*—a system that we gradually and partially notice and at the same time endow with meaning. Processes of objectification are those processes of attempting to notice something culturally significant, something that is revealed to the consciousness not passively but by means of the corporeal, sensible, affective, emotional, artefactual, semiotic, and creative activity of the individuals. In this context, learning is defined as the outcome of processes of objectification. And since systems of thought (mathematical, etc.) are always revealed partially, these processes are always endless—and hence, so is learning.

## Processes of subjectification

Learning includes emotions and affect, not as merely concomitant phenomena of learning, but as *constitutive* parts of it. The educational implication is that instead of being a purely mental endeavour, learning mathematics involves emotions and affect in manners that touch and shape us profoundly. This is why classrooms do not produce knowledge only; they produce *subjectivities* (i.e., unique human beings) as well. In the TO, the investigation of the production of subjectivities in the classroom is carried out through the construct of *processes of subjectification*: the processes where, co-producing themselves against the backdrop of culture and history, teachers *and* students

*come into presence*. To come into presence refers to the idea of the student as someone who, through classroom activity, comes to *occupy a space* in the social world and to *be a perspective* in it. To come into presence is a *dialectical* movement between culture and the individual. The dialectical nature of this movement brings us to conceive of the individuals as entities in flux—entities who are continuously co-producing themselves and find in their culture the raw material of their own existence. Both the individual and culture are coterminous entities in perpetual change, one continuously becoming the other and the other the one. In this dialectical movement, students as well as teachers are considered as subjectivities in the making, openness towards the world. Teachers and students are conceptualized as unfinished and continuously evolving projects of life, in search of themselves, engaged together in the same endeavour where they suffer, struggle, and find enjoyment and fulfillment together.

## Joint labour

In the TO, what makes learning possible is human *activity*. Processes of objectification and subjectification are embedded in activity. Now, the activity where learning occurs can be alienating. This is what happens in the classroom activity of both the traditional teaching and its pedagogy of knowledge transmission and the constructivist student-centred pedagogy of knowledge construction. In the first case, the students do not have room to *express* themselves. As a result, the activity *alienates* them from their own product—the knowledge that was produced in the classroom. In the second case, the student is involved in doing things and expresses herself. However, that expression remains confined to the subjective sphere of the self. Since knowledge is understood as that which is produced by the action of the student, the student is not in conversation with the world. There is a mere monological conversation of the subject with the subject itself. The student is alienated from the historical-cultural world and is confined to live in a “taken-as-shared” universe. The TO resorts to a different, non-alienating concept of learning activity. First, the teacher does not appear as a possessor of knowledge who is delivering or transmitting knowledge to the students or as someone scaffolding strategies to the students. Nor do the students appear as passive subjects receiving knowledge or as the authors of their own knowledge. Second, teaching and learning are not considered as two separate activities, one carried out by the teacher (the teacher’s activity) and the other carried out by the student (the student’s activity). In the TO, teaching and learning are conceptualized as a single and *same* activity: the same teachers-and-students’ activity. This concept of activity does not reduce activity to a series of actions that individuals perform, perhaps in coordination with each other, in the attainment of their respective goals. This line of thinking reduces activity to a functional and *technical* conception. In the TO, following Marx and Leont’ev, activity is a *form of life*, a kind of *energy* formed by the individuals in their pursuit of something common, an energy that is sensible and sensual, material and ideational, discursive and gestural. To avoid confusion with other meanings, in the Theory of Objectification, activity in the latter sense is termed *joint labour*. Joint labour is the chief ontological category of the TO and its unit of analysis. Sensuous, material joint labour is considered the ultimate field of aesthetic experience, subjectivity, and cognition. It asserts the fundamental ontological and epistemological role of matter, body, movement, action, rhythm, passion, and sensation in what it is to be human.

## An example

I would like to refer to an example that comes from a Grade 4 class (9-10-year-old students) where the students were dealing with a sequence generalization problem based on the following story: “For his birthday, Marc receives a piggy bank with one dollar. He saves two dollars each week. At the end of the first week he has three dollars, at the end of the second week he has five dollars, and so on.” The teacher provided the students with bingo chips of two colours (blue and red) and numbered plastic goblets intended to represent Week 1, Week 2, etc., and invited the students to work in small groups to model the saving process until Week 5. Then, drawing on the model, the teacher invited the students to find the amount of money saved at the end of Weeks 10, 15, and 25. After some discussion, the students came up with an arithmetic strategy, the “doubling strategy”: they found the number of bingo chips in Week 5, doubled this amount and removed one bingo chip. The teacher came to see the students’ work and engaged in the conversation:

- 1 Teacher: (*Trying to make noticeable to the students the co-variational structure*) What do you remark about Week 5 (*She shows the goblet corresponding to Week 5*) and (*Pointing to the red bingo chips*) the number of bingo chips? (*Making the same actions*) The fourth week and the number of bingo chips?
- 2 Albert: (*Hesitantly and at the same time interested*) It’s always twice . . .
- 3 Teacher: (*Repeating*) It’s always twice.

This teaching-learning activity was the first one of a sequence of activities dealing with algebra. Algebraic knowledge already exists in the students’ culture. It is part of the school curriculum. However, until that morning, for the students, algebraic knowledge existed as a pure generative capacity of actions and thinking. Learning requires making algebraic knowledge something noticeable, an object of consciousness. The classroom activity was organized by the teacher so that, working collaboratively with the students, algebraic knowledge could be materialized or instantiated and so progressively it could manifest itself through one of its developed forms—i.e., as knowing. The three lines of the excerpt above show this progressive transformation of knowledge into knowing. Indeed, the mathematical variables started being noticed. They started becoming objects of consciousness. However, their co-variational algebraic nature remained unnoticed. Joint labour reaches here a tension that derives from the contradictory ways in which the terms of the sequence have been so far perceived (an arithmetical one, based on doubling, and an algebraic one, based on a co-variational approach to the problem). This contradiction is not a flaw of a didactical design: it is the very motor that keeps the activity unfolding. To encounter algebraic thinking as featured in the teacher’s didactical project, the teacher and the students have to keep working together to try to make the algebraic approach *appear* in the classroom and become an object of the students’ consciousness. Its appearance is a bit like the appearance of Beethoven’s 7<sup>th</sup> symphony: for it to become an object of consciousness it has to aurally appear through the activity of the orchestra. Since mathematics is simultaneously visual, tactile, aural, material, artefactual, gestural, and kinesthetic, it can only come into life here through the sensuous and artefactual joint labour of the teachers and the students.

After some discussion and failed attempts at making noticeable the algebraic structure of the bingo chips’ visual arrangement (see Figure 1, Pic 1), the teacher came back to an analysis of Week 5:

- 4 Teacher: (*Taking with her hand again the goblet of Week 5; see Pic 1*) What did you do here?
- 5 Albert: (*Takes a long breath while the teacher holds the goblet of Week 5; see Pic 2*) OK.
- 6 Teacher: (*Still holding the goblet, speaks softly*) 5 . . .
- 7 Albert: (*In sync with the teacher's gesture that points next to the red chips; see Pic 3*) Times 2 . . .
- 8 Krysta: (*Who has followed the discussion*) Times 2 equal . . .
- 9 Teacher: (*Pointing at the blue bingo chip; see Pic 4*) Plus 1.
- 10 Albert: (*Almost at the same time*) Plus 1.
- 11 Teacher: (*Now pointing to an empty space where Week 10 would be*) 10?
- 12 Albert: (*The teacher points silently at the place where the red bingo chips should be; see Pic 5*) Times 2.
- 13 Krysta: (*At the same time*) Times 2.
- 14 Teacher: (*Points silently at the place where the blue bingo chip should be; see Pic 6*)
- 15 Krysta: Plus 1.
- 16 Albert: (*Looking at the teacher*) Minus 1?, times 2, minus 1?, plus 1?

**Figure 1: Joint labour and the appearance of an algebraic approach to solve the problem**

The example illustrates three things. First, what joint labour *is*: a spatial-temporal *dynamic system* that is created by the students and the teacher. It is made up of the *energy* that the teacher and the students spend in trying to solve the problem and whose fabric includes language, gestures, perception, body position, and artefacts. It is a fluid carrier of half-expressed and half-understood intentions and motives. Second, the example shows some of the intricacies of the transformation of knowledge into knowing. Knowing is this specific manner in which algebraic knowledge is being *instantiated* from a particular problem and through joint labour (distinguishing the variables and their relational-functional nature, expressing it through language, gestures, etc.). Third, the example let us have a glimpse of how learning occurs. Indeed, the example shows how, wrapped in this energy of which joint labour is made up, the teacher moves her hand silently to indicate with an indexical gesture the imaginary position of the blue chip (see Pic 6). She is very tense, as the outcome of the joint labour is still uncertain. She awaits Albert's answer with a tension that is reflected in her body and language intonation. Her question is an *invitation* to Albert to come to position himself in a mathematical practice. The question is *already* a positioning. But still Albert

has to accept. He could have just given up. But he does not. Albert, who is also very tense, accepts the teacher's question/invitation and says "Minus 1? Times 2 Minus 1? More 1?" The answer attests to the fact that Albert is positioning himself and being positioned in a social practice where things are thought of in a certain manner. But the answer attests also to the fact that the co-variational algebraic manner by which to see the variables is progressively becoming intelligible to Albert's consciousness. More generally, in the joint labour we see the unfolding of a social process that is at the same time a process of subjectification and objectification. Albert is living an encounter with key aspects of algebraic knowledge. The difference between  $S$  and  $K$  in the equation  $S \neq K$  is being reduced. Since knowledge is a *general*, the difference will never vanish. Even though, there is still room for Albert to perceive better the nuances of the algebraic variables and how they relate to each other. It did not take long. During the general discussion, which started right after the end of the previous excerpt, the teacher invited Albert to explain how to find out the number of bingo chips in Week 4. He said: "4 times 2 . . . plus 1, 4 times 2 plus 1 equals . . . 9."

## Concept

As knowledge is put into motion through joint labour, it becomes materialized into something sensible; that is, knowing. In the course of its materialization, knowledge is *refracted* in the students' consciousness. This refraction is always different: it changes from student to student. A concept is precisely the subjective refraction of knowledge in consciousness through the mediation of knowing. A concept enables us to *do* things and to *think* about them in certain ways. While knowledge and knowing are historical-cultural entities, a concept is of a subjective order: the subjective and partial version of cultural knowledge. In the example discussed above, algebraic knowledge is refracted in Albert's consciousness—as the *concept* of algebraic generalization of (linear) sequences. Although still fragile, this concept, originated in activity, becomes an "organ" of Albert's body. It is something that allows and empowers him to perceive sequences and to think of them in a new way. No less important, the concept connects Albert with culture and history and transforms him at the same time into a cultural-historical subject.

# An epistemological and philosophical perspective on the question of mathematical work in the Mathematical Working Space theory

Alain Kuzniak<sup>1</sup> and Laurent Vivier<sup>2</sup>

<sup>1</sup>Université Paris-Diderot, LDAR (EA4434), France; [alain.kuzniak@univ-paris-diderot.fr](mailto:alain.kuzniak@univ-paris-diderot.fr)

<sup>2</sup>Université Paris-Diderot, LDAR (EA4434), France; [laurent.vivier@univ-paris-diderot.fr](mailto:laurent.vivier@univ-paris-diderot.fr)

*The theory of Mathematical Working Spaces (ThMWS) is a young theory that appeared in the field of didactics of mathematics a decade ago with the objective of describing and constructing the mathematical work of students in a school context. To this end, the theoretical framework aims to link and closely combine epistemological and cognitive approaches. In this article, we deepen the very notion of mathematical work by focusing first on an epistemological approach that specifies the nature of work in mathematics and then on a philosophical approach that connects work and communication in a dialectical relation. These two approaches highlight the more or less implicit ideological assumptions that guide our research in didactics.*

*Keywords: Mathematical work, work and communication, semiotics genesis, paradigms.*

## Introduction

Developed for more than a decade as a methodological and theoretical tool, the Mathematical Working Space model has recently been presented as a theory by eminent researchers in the field of mathematics education. In particular, Radford (2017) uses the theory of MWS together with Brousseau's Theory of Didactic Situations (1997) to exemplify theories in mathematics education which reflect on mathematical knowledge and know-how that the much of the mainstream research in the domain seems to neglect:

However, I think that focusing on knowledge is what educational approaches such as the French didactic theories excel at – for example, the theory of didactic situations or its young sibling theory “the mathematical working space”. (Radford, 2017, p. 503)

This focus on content is essential in the theory of MWS and is reflected in the central place given to “mathematical work”. Moreover, one of the specificities of the theory is that it was conceived to interact with a diversity of constructs and perspectives in the field. This plasticity poses the challenging question of the real nature of its relationships with other theoretical approaches, which may be grounded on very different epistemological and methodological principles. The epistemological stances from a given theoretical model shape the nature of the objects and problems being studied, but according to our view they also influence the capacity of integration of, and exchanges with, other theoretical frameworks. This capacity refers to Kidron’s *epistemological sensitivity* (2016), which is likely to foster the possible networking between different approaches.

In this contribution we would like to focus on this epistemological question which relates to a point highlighted in the call for contributions for this topics group, namely the epistemological dimension of theories for example in terms of *argumentative grammars or background philosophy*. This contribution complements the one presented at CERME10 (Kuzniak & Nechache, 2017) where we showed the interactions between methodological development and the evolution of the MWS

theory. To characterize its *epistemological sensitivity*, we propose to question the epistemological and ideological assumptions underlying our theoretical approach and stemming from the fact that we are interested in the nature of "mathematical work". We will also highlight the specificity of the theory and its originality in the field of didactics of mathematics.

### **The French environment of didactics of mathematics**

We think it is useful to start by presenting the particular French context in which the ThMWS is embedded and developed. Despite some theological quarrels linked to the personality of the various researchers involved in its growth, it must be recognized, that the didactics of mathematics in France is based on a community of theoretical and methodological principles that contribute to establishing a real cultural homogeneity. In a fairly simple way, we can say that the didactics of mathematics in France is supported on three essential pillars associated to symbolic figureheads enjoying strong international recognition (at least at symbolic level through the award of scientific prizes and medals).

- The Theory of Didactic Situations, the foundations of which were laid by Brousseau (1997), where it is essential to link theoretical and empirical research in close connection with the classroom. Its aim is to develop an experimental didactics that goes beyond the classical didactics as described in Comenius' *Magna Didactica*, which Brousseau regularly cites in his presentations and where all guidelines and ideas have been given a priori and are not validated by field studies.
- The Anthropological Theory of Didactics, initiated by Chevallard (1992), is based on an anthropological and holistic vision of learning and teaching acts. This holistic framework, based on the study of praxeologies, aims at a theoretical autonomy of didactics which is independent of other scientific fields such as mathematics, sociology or psychology.
- The Theory of Conceptual Fields developed by Vergnaud (1991) is less well known but brings a psychological and cognitive dimension, based on Piaget's learning theory, to these two theories strongly influenced by mathematical epistemology.

As underlined above, these theories benefit from a kind of international visibility and recognition with the award of the Klein Medal to Brousseau, the Freudenthal Medal to Chevallard and the fact that Vergnaud was one of the founders of PME. The following theoretical contributions are less widely known but very present and influent in the French context:

- Duval's contribution (2006) on semiotics with the development of semiotics registers. In this approach, signs and semiosis are essential because they mediate mathematical objects that are only accessible through their different semiotic representations.
- The ergonomic approach combines Piaget's and Vygotsky's contributions and led to "French Activity Theory" as it is presented in a recent special issue of *Annales de Didactique* (2018). It is also based on a reflection on instruments and tasks and includes the developmental dimension of activity.

It is within this context that the theory of MWS (Kuzniak, Tanguay, & Elia 2016, Gómez-Chacón, Kuzniak, & Vivier 2016) has been developed by seeking to link and preserve very closely the

epistemological and cognitive viewpoints. The epistemological point of view is very focused on mathematical content with a reflection on its organization. While the cognitive viewpoint follows Duval's approach in geometry and focuses on the visible and tangible aspects of the subject's activity. The interaction of the two perspectives was achieved by placing mathematical work at the centre of the reflection. The specific study of the mathematical work is based on three dimensions and geneses: semiotic, instrumental and discursive.

### A short presentation of the theoretical framework: The model with its diagrams

The purpose of the theory of Mathematical Working Space is to provide a tool for the specific study of the mathematical work in which students and teachers are effectively engaged during mathematics sessions. The abstract space thus conceived refers to a structure organised in a way that allows the mathematical activity of individuals who are facing mathematical problems.

**Figure 1: The MWS diagram**

**Figure 2: The three vertical planes in the MWS**

To grasp the specific activity of students solving problems in mathematics, the two epistemological and cognitive facets of mathematics are present and articulated in the model into two planes: one of an epistemological nature in close relation to the mathematical content in the field being studied; the other of a cognitive nature, related to the visible action of the individual solving problems (Figure 1). Three components in interaction are characterised for the purpose of describing the work in its epistemological dimension, organised according to purely mathematical criteria: a set of concrete and tangible objects (representamen); a set of artefacts such as drawing instruments or software; a theoretical system of reference based on definitions, properties and theorems. The second level of the MWS model is centred on the subject, considered as a cognitive subject. Three cognitive components are introduced as follows: visualisation related to deciphering and interpreting signs; construction depending on the used artefacts and the associated techniques; proving conveyed through actions producing validations, and based on the theoretical frame of reference. Therefore, analysing mathematical work through the lens of MWSs allows tracking down the process of bridging the epistemological plane and the cognitive plane, in accordance with three different dimensions: An instrumental dimension (Ins) related to the experimental and empirical part of work, a discursive dimension (Dis) related to the strategic and theoretical part, and finally a semiotic dimension (Sem) that expresses the importance of signs as an intuitive source and support

for mathematical work. The shaping of work involves different but intertwined genetic developments, each identified as a genesis linked to a specific dimension of the model: semiotic, instrumental and discursive geneses.

In order to understand this complex process, the interactions that are specific to the execution of given mathematical tasks will be associated to the three vertical planes, naturally occurring in the MWS diagram: the [Sem-Dis] plane, conjoining the semiotic genesis and the discursive genesis of proof, the [Ins-Dis] plane, conjoining the instrumental genesis and the discursive genesis of proof, the [Sem-Ins] plane, conjoining the semiotic genesis and the instrumental genesis (Figure 2).

The exact definition and precise description of the nature and dynamics between these planes during the solving of a series of mathematical problems remains a central concern for a deeper understanding of mathematical work. To achieve this description, studies performed within the framework of MWS theory closely examine the design and implementation of classroom teaching situations according to a specific methodology supported on MWS diagrams (Kuzniak & Nechache, 2017).

### **The necessary clarification of what is “le travail mathématique” in schooling**

In the following, our study focuses on the real scope and meaning of “le travail mathématique”, in particular we wish examine the theoretical construction developed in the context of the didactics of mathematics and see its solidity when the same notion is considered from other perspectives, epistemological and philosophical, that a priori do not belong to the world of education. First, we kept the expression “travail mathématique” in French, because one of the first difficulties we encounter in this study is the translation into English of the term “le travail mathématique”. We have opted for “mathematical work” which is not its exact equivalent as we will see later. This difficulty in translating the meaning of the term “mathematical work” is found again in the choice of translating, after long discussions, “Espace de Travail Mathématique” into “Mathematical Working Space” to insist on “working” more than on “the workplace”.

To achieve this study, we begin by following the easiest and least controversial path, that of epistemology, which makes it possible to question the term “mathematical work” by emphasizing the “mathematical” aspect in order to identify precisely the meaning of mathematics when it is considered through the idea of work. A second, steeper and more controversial path, because it may be political, will make us question ourselves on “work”, the first term of the pair, from a philosophical point of view.

### **An epistemological perspective on mathematical work: Thurston and Granger**

#### **Mathematical work as a recursive and progressive process**

The notion of “mathematical work” must be taken as a syntactic whole which combines closely work and mathematics. In order to define the idea of work within our framework, we use the dual approach of Habermas (1969), which stresses both instrumental action and rational choice as constitutive of work.

By « work » or purposive-rational action I understand either instrumental action or rational choice or their conjunction. Instrumental action is governed by technical rules based on

empirical knowledge (...). The conduct of rational choice is governed by strategies based on analytic knowledge. (...) Purposive-rational action realizes defined goals under given conditions. (Habermas, 1969, p. 92-93).

But what exactly is this specific action that allows mathematical work to be identified? According to Thurston (1994), the difficulty in defining mathematics stems from the essentially recursive nature of the mathematical activity. So, he characterizes mathematics as the field that contains as a central core the study of numbers and space geometry, and then he defines this field in extension as what is being produced by the work of mathematicians, “those humans who advance human understanding of mathematics” (Thurston, 1994, p. 162). In this view, mathematics ‘scientificity’ comes from the critical and repeated revision of the research and results generated by mathematics and by those who produce it along processes always open to reassessment and questioning.

These processes are necessarily in the long run, and we may thus evaluate that having access to full mathematical work is not possible without being engaged in such a progressive and recursive process. This idea of mathematical work in constant evolution and construction, even in the school context, is a central point of our vision on mathematics learning and teaching.

### **The mathematical work and its style**

Defining mathematics from the point of view of mathematicians' activity implies to look at the results of this work in order to better understand the nature and contents of mathematics. To achieve this, it will be necessary to study the resulting work, fruit of the work elaborated by mathematicians. This work is a formalisation of abstract concepts that requires a codification of the discourse. Granger (1963) calls style the particular way of presenting rational knowledge by submitting it to codified norms that give objects a specific meaning. These standards help to set the direction of work on problem solving. They make it possible to exclude certain practices by limiting the possibilities of interpretation and therefore exploration of the reader or student. In that sense, the notion relates to the idea of paradigm introduced by Kuhn (1966). For us, a paradigm will stand for a combination of beliefs, convictions, techniques, methods and values that are shared by a scientific group. Gaining access to a mathematical paradigm will involve meeting the mathematicians' work and going through the solutions and solving processes of distinctive problems that qualify as exemplars according to Kuhn. In studies conducted within the framework of the theory of MWS, the exact definition of paradigms is important because it allows revealing and understanding the expectations of teachers and educational institutions and also to explore the real distance between this expected work and the work actually carried out by the students.

### **A philosophical and critical perspective on mathematical work: Work and communication**

In this section, we examine the second part of the formulation "mathematical work", and deal with the question of work. To move forward in this direction, we will rely mainly on the philosopher Fuchs (2016) who published a critical and social essay on work and communication in the age of the digital economy. As we will see his approach joins and sharpens our own conceptions and research on mathematical work developed now in a rich technological and digital environment which has deeply changed the traditional way of working in mathematics especially at school.

### **On the difficulty to translate the word “travail” in “le travail mathématique”**

Fuchs revisits the question of terminology and sense of the word “travail” in different languages by pointing out the distinction between *work* and *labour*. He stresses on the fact that whereas the etymological root of terms such as *work* or *werk* (German) is creating, acting, doing, the etymological root of words such as *labour* and *Arbeit* (German) is toil, slavery and hardship (Fuchs, 2016, p. 17). This etymological distinction is also found in French—on the one hand *ouvrier* (work) and on the other hand *travailler* (labour). But at the same time the origin of the word “travail” in French is controversial and does not refer to the same roots. The word “travail” seems to have a broader meaning than work and the word “*labeur*” (labour) is rarely used in French. Thus, for example, the equivalent of Labour Day is la “*fête du travail*”.

In the context of our study, we will consider three large dimensions of work close to the French idea of “travail”: work as a long-term process with a certain permanence; the result of work which can be named a work; the goals and stakes of work which will be precisely here of mathematical nature.

### **On the relationship between work and communication**

As we have seen above, the communication of the work of proof is part of the mathematical work, it makes visible the rationality of the arguments presented. But what is the exact nature of this relationship? Fuchs studies four modes of relationship between work and communication. The first two assume a pre-eminence of one over the other, the third proposes their independence and finally the last one proposes a dialectical link between the two. For Fuchs, Habermas, whom we mentioned above, is the main defender of the dualist position. Habermas’ theory of communicative action makes a sharp distinction between on the one hand purposive (instrumental, strategic) action (including work) that is orientated on success and on the other hand communicative action that is orientated on reaching understanding. According to Fuchs, Habermas’ vision is a little naive insofar as it assumes that communication is always part of a positive and rational dynamic.

In addition to this dualist vision of the relationship between communication and work, Fuchs emphasizes authors who favour a dialectical approach to work and communication. Curiously and unexpectedly by us, he underlines the singular contribution of Lev Vygotsky and his Activity Theory and stresses on the fact that Lev Vygotsky (1896–1934) was a Marxist psychologist from Belarus who developed a theory of activity, whose basic point is that human cognition and language are grounded in human activity. As we have pointed out above, this theory is particularly important and natural in France where Vygotsky is considered for his research in psychology which is used in combination with Piaget’s studies. Moreover, the reference to Marx is common among the main French philosophers (from Althusser to Comte-Sponville via Badiou) and is not considered as sulphurous and diabolical as it is the case in some national traditions with an anti-communist or liberal influence. Perhaps, this specific relationship between Activity Theory and Marxism helps to understand the different ways this theory is received depending on countries because of the close relation existing between Marxism and communism.

To come back to the scientific content of Vygotsky’s writings, it should be retained that Vygotsky (1978) argues that. ‘The sign acts as an instrument of psychological activity in a manner analogous to the role of a tool in labor’ (Vygotsky 1978, 82). Tools as means of work and signs as means of

communication have for Vygotsky in common that they are both forms of mediated activity. The difference is for him that the tool is externally oriented on changing nature and the sign is internally oriented: The sign is a means of internal activity aimed at mastering oneself.

Again close to our approach which insists on semiotic aspects, Fuchs also points out a much less well-known Italian author, Rossi-Landi, who favours the semiotic approach as a support for this dialectic between work and communication and introduces semiotic production processes:

Rossi-Landi's semiotic theory (...) helps to clarify the dialectic of work and communication: language-use and communication are work that produce words, sentences, interconnected sentences, arguments, speeches, essays, lectures, books, codes, artworks, literature, science, groups, civilisation and the linguistic world as totality (Fuchs, p. 191).

Thus, this reflection on the dialectics of work and communication is in line with our way of considering mathematical work as the result of different processes: a semiotic process that relates to the treatment of signs; an instrumental process that promotes the link with material or digital tools; finally, a discursive process that relates to rational proof. The singular importance we attach to the discourses of proof reveals more particularly the very nature of the work associated with mathematics where proof, particularly in its demonstration form, is crucial in the realization and coherence of mathematical work.

## Conclusion

The Theory of Mathematical Working Spaces aims to describe the forms of mathematical work carried out by students in the school environment. As its name suggests, it places mathematical work at the centre of reflection on teaching and learning. In this context, the primary purpose of educational institutions and teachers is to develop an environment that enables students to solve mathematical problems in an appropriate way. The organization of MWSs into two levels, epistemological and cognitive, allows the description of the work of students confronted with a set of tasks with a mathematical purpose.

In our framework, mathematical work results from the interactions between signs, tools and properties through the interweaving of the three semiotic, instrumental and discursive geneses. We were also able to verify that that our vision of mathematical work based on circulation in the MWS diagram (Figures 1 and 2) has many justifications in the field of didactics of mathematics. The reflexive detour that we have made by relying on contemporary epistemological and philosophical approaches, has also shown us that our issue has encountered some strong questions in these fields such as the relationship between forms of work and communication. Our way of seeing resonates with certain current problems of critical philosophy confronted with the evolution of the world of work in an increasingly technological environment and subject to new rules of production and alienation.

Even if the confrontation of our theory with this political and social approach does not radically transform our way of thinking, it does contribute to better positioning our research in a broader current of thought and above all it helps to reveal the ideology that often underlies some work carried out in our research field in an unconscious or implicit way. In particular, it can explain some

misunderstandings or difficulties in receiving our research: one of the most visible being the understanding and use of the term “mathematical work” which seems doubly provocative in today's world of mathematics education. The use of this term implies for the subject acting to go beyond the only laborious and technical part of work and thus that work focused on mathematics contributes to the intellectual emancipation of students and professors that is still in the making-phase.

# A phenomenological methodology based on Husserl's work in the service of mathematics education research

Andonis Zagorianakos

Mathematics Department of the University of Athens; [matheart7@math.uoa.gr](mailto:matheart7@math.uoa.gr)

*The paper introduces a phenomenological methodology based on Husserl's work and on Merleau-Ponty's radical extension of Husserl's work. The phenomenological reduction and bracketing (epochè) are introduced as the critical methodological instruments in exploring the emergence of mathematical understanding, by casting phenomenological light on the learner's intentional cognitive constitutions, from the passive to the active stage of her or his lived experience. An empirical example is used in order to showcase the impact of the researcher's methodological shifting, from the natural to the phenomenological attitude (the reduction and the epochè), and the methods and techniques that are used, in allowing the methodology to produce results. A summarising diagram and some notes for the usefulness of the methodology application for mathematics education research are included.*

*Keywords: Phenomenological methodology, Husserl, intentionality, reduction, bracketing, epochè, phenomenological attitude.*

## Introduction

The aim of this paper is to introduce a phenomenological methodology as a valuable frame for mathematics education research (MER). Examples of my use of this methodology have been published in *Educational Studies in Mathematics* (2015) and other international journals, as well as presented at CERME9, PME (2014, 2015) and BSRLM (2012, 2013) conferences. Critical distinctions emerge, between my use of phenomenology and that of other phenomenological or phenomenologically informed researchers in MER (e.g., Radford, Roth, Nemirovsky). The distinctions are concerned with the principal use of Husserl's work in my research—which is either taken for granted, critically disputed or scarce in the influential work of these scholars. Most importantly, the central difference in my work is the thematisation and application of Husserlian *methodological* concepts, such as the phenomenological reduction and the epochè. These concepts are used precisely for the purpose introduced by Husserl (i.e., phenomenology as methodology), and they are missing in the aforementioned researchers' phenomenological contributions. In my work, these concepts have been used in order to put in motion Husserl's mature work on the life-world (Lebenswelt) and the living present of learners. My conviction is that the same methodology could be applied to research with teachers, mathematical classrooms, curricula etc., each time providing critical distinctions. In this sense, the application of the phenomenological methodology presented here and as applied to learners suggests the viability of its application to other phenomena in mathematics education research.

## The key concept of intentionality as a starting point for the application of the methodology

This paper follows Husserl's (1970, p. 168) conceptualisation of the central role of intentionality for the study of mathematical cognitive situations. The **intentional aspect** of conscious acts is concerned

with the fact that every conscious act is *about* something; I fear *something*, I hope *something*, I judge *something* (as true or false), I love *someone*, I hate *something*, and so on. Also, everything perceived is always perceived in a certain manner, with fear, hope, in shaping a judgement, with love, hate, etc. In the same respect the key feature of conscious acts, and in particular the cognitively motivated acts, are *about* something, present or absent, real or supposed as real, valid or not, but in any case, present for these acts. Husserl (1983) adopted Brentano's conception of intentionality as being the main feature of conscious acts and extended it critically. Mature Husserl (e.g. 1970, p. 168) thematised further the "uncover[ing] and the "clarification of what is accomplished" in the "intentional origins" region of lived experience. What does this mean in terms of the mathematics education research perspective? It means that by focusing on the region of intentional origins we could uncover and clarify what is accomplished in them, since, as he explains "every sort of intentional unity becomes a '*transcendental clue*' to guide constitutional 'analyses'...[which are] *uncoverings of intentional implications*" (Husserl, 1969, p. 245, italics in the original), particularly related to an operative, embodied sense on which abstract knowledge is grounded.

In order to explore the intentional aspect of the mathematical cognitive experience, the phenomenological reduction and the epochè (see the following sections) must be applied, as the two basic methodological instruments. The aim of the methodology is to open up the "currently constituted intentional unity" (1969, p. 245) of the learners' understandings, and thus to understand better how they *arrive* at their understandings, in their engagement with mathematical tasks and questions.

### **Epochè (bracketing) and phenomenological reduction—A first introduction**

The methodology is supported by a phenomenological perspective that presents an intentional view of the cognitive life-world. This perspective approaches the mathematical lived experience as being intentionally supported; the researcher tries to study it without pre-conceptions on what it ought to be, but merely focuses on the intentionally emerging appearances, as they appear *for* the learner. The suspension of preconceptions is one of two basic methodological instruments. This suspension amounts to a two-fold task:

- To spot and put aside actions that are not relevant to the student's experience;
- To suspend the researcher's own intentions, and prevent him or her from interfering with the intentions running through the phenomenon of cognition under study.

In this sense all objectivity is *suspended*, as was introduced by Husserl (1983, p. 60), who used the term *epochè* for this process. Husserl employed *epochè* in order to combine it methodologically with his *phenomenological reduction*. This is the second basic methodological instrument. It is tantamount to the "leading back" from the natural targets of our concern, to "what seems to be a more restricted viewpoint, one that simply targets the intentionalities themselves" (ibid.).

So a combination of *epochè* (suspension or bracketing), and *phenomenological reduction*, shapes the core of the methodology. What are revealed through this combination are not the objects as such, but *as they are intended* (imaginatively, through remembering, judging, etc.), focusing on the manners or modalities in which such objects are 'given'. In other words, we look *at* what people normally look *through* (ibid.).

## The application of the phenomenological methodological lens in a designed experiment

Here I present an experiment that is phenomenologically analysed, and organised in accordance with phenomenological investigations. It was an experiment in which the teacher allowed all possible interactions between the students, usually working in groups, but he did not provide any guidance to his students, concerning the open tasks that he introduced. I present the case of Mary (pseudonym), one of 13 students, i.e. prospective teachers of mathematics for secondary education, in a course entitled *The nature of mathematics* (NoM). As the teacher's part in the collective or individual thought processes of the students' treatments of the tasks was bracketed (epochè, in Husserl's terms) the thinking strategies themselves came to the fore; the research field was enriched by the various approaches to the tasks, by different or by the same students. *Reflective* and *pre-reflective intentional layers* were thus traced as such (see the following section), as they were grounding the students' constitution of the mathematical objects.

As soon as the intentional layers<sup>1</sup> of the students' engagement in the task are exclusively targeted the researcher enters the *phenomenological attitude*, which guides her or him to further analytical reflections, followed by new findings (cf. the *unit of phenomenological knowledge production* component of the diagram in Figure1). With the use of the *phenomenological reduction* and the *bracketing*—considered as a single methodological instrument by the mature Husserl—we are entering the study of the *natural attitude*, which is “our straightforward involvement with things and the world” (Audi, 1999, p. 405), by describing it with the *phenomenological attitude*. The *phenomenological attitude* is “the reflective point of view from which we carry out philosophical analysis of the intentions exercised in the natural attitude and the objective correlates of these intentions”. Further, “the process by which we move to the phenomenological attitude is called the phenomenological reduction, a ‘leading back’ from natural beliefs to the reflective consideration of intentions and their objects” (ibid.).

The application of the phenomenological methodology in this case had the effect that, what were before *brilliant ideas* that suddenly possessed the students, or *desperate efforts* to ‘survive’ by acquiring some sense of the task, now became telling appearances of the operative affordances that each student brought and was able to release actively, either in the team in which the student was working, or individually, during and/or after the sessions.

The transformation of the working field of research was the result of (a) the focusing on the intentional acts that brought the learners' objects to the surface, in a regressive analysis that starts from the ‘final’ objects and goes back to their genetic appearances, and (b) the neutralising/bracketing (epochè) of factors that played no part in the perception of the objects that were chosen to be activated by the students. From this analysis it occurred that it is the double application of the phenomenological reduction (a) and the epochè (b) that allows the transformation of the cognitive event into a *phenomenon*—in the Husserlian sense that this methodology suggests.

---

<sup>1</sup> The intentional layers are the layers of intentions of the learner, as he or she is devising an object for a mathematical enquiry.

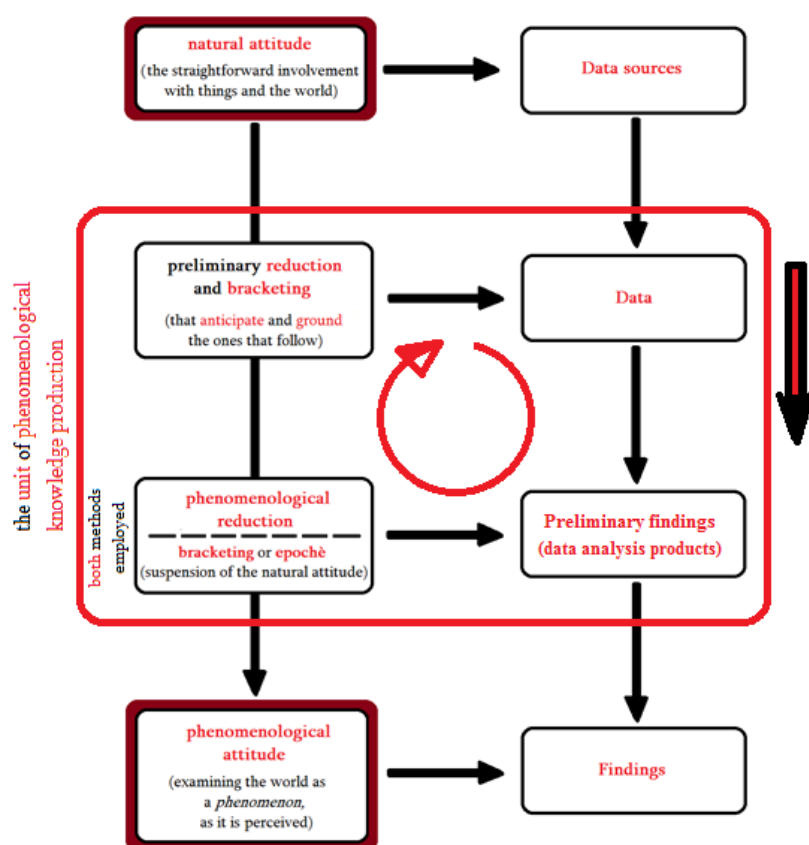

Figure 1: Methodology diagram

### Methodological affordances and results

The transformation of the data sources' natural appearances into a phenomenon affords us, as researchers, with the following: (a) the ability to discern *structures* that the students' strategies follow, which could be helpful in teaching design (Zagorianakos, 2016; Zagorianakos & Shvarts, 2015); (b) better understanding of the students' learning horizons, which may also entail further phenomenological analysis, e.g., of a student's change of attitude (Zagorianakos, in press).

### Description of the illustrative example—The use of the methodology

#### The bird's-eye view empirical intuition, as triggering a series of abstract intuitions.

Mary (pseudonym) was a prospective teacher of mathematics in English secondary education. During the NoM course (see previous section) a task was introduced that was required to be solved in teams of three or four students by involving bodily experience. One of each team actualised a fixed point, 10 meters or steps away from a wall, while the rest of her or his team were trying to embody the track of the sought line, in which each point was supposed to have the same distance from the fixed point and from the wall. The room where the task took place had very wide walls, enough for the four teams of three or four students to explore the task. What will be sampled here from that study is how the methodology allowed the phenomenological detection of the crucial influence of the embodied intuitive stock of Mary. The *embodied* grounding of Mary's mathematical achievements was revealed methodologically by the reduction to (focusing on) her intentional cognitive treatment of the mathematical task, and by bracketing (neutralising) what did not affect Mary's experience.

By tracking how Mary *intentionally* handled her drawing of the wall and the Cartesian plane, I noticed how she transformed her drawing into a different view of the classroom, where she was confusedly trying to embody the solution of the task. Mary's view was an intuition,<sup>2</sup> drawing back to the Scholastics' perception of a 'new vision', which allowed her a breakthrough that followed her up to the end of her treatment of the task. It was in an **actively embodied** rather than in a metaphorical sense that Mary used her perception of a "bird's-eye view". It was this initial embodied intuition that was operating, as a sensory-motor environment to all her understandings, up to the end (see following paragraphs). This phenomenon was lit by *full bracketing of non-significant issues to her constitutive moments*, of the objects that helped her unlock the task. By mentioning non-significant components, I mean all the actions that did not interfere with the student's (constitutive) building process, such as the teacher's non-guidance protocol. Therefore, bracketing is not arbitrary, and it could be responsible for further analyses, as soon as the reduction's furthest application is done (Zagorianakos, in press). Mary's example is not fully analysed here: it has been drawn to showcase the applicability of the methodology, realised by the methods and the techniques, which are introduced in the following section.

### **Methods and Techniques of the methodology—The student's progress with the task**

The methods included participant observation, gathering of documents that included the learners' reflections on their learning processes, and interviews (email or in person). The methods concerned semi-structured live interviews, where the technique was to trigger the flowing of the students' reflections on the actions that brought objects to the surface. Another interview technique was to drive the discussion without force towards the intentional acts that led the learners to their constitutive moments of objects. How did they feel about them? What was special, for them, about these objects? The methods were used so that the intentions that led to the mathematical objects would be revealed; and the techniques were aiming at keeping the researcher in low profile, while bringing the student's narrative vividly to the foreground. Due to such methods and techniques I took advantage of the teacher's self-bracketing in order to study how the students' mathematical experiences were structured.

Let's see how the student's development with the task happened:

After the investigation in the classroom, when the student was in utter confusion about what the sought line was supposed to look like, Mary went home. There she drew on grid paper the wall as a straight line, and a Cartesian plane with the y-axis perpendicular to the 'wall', and the two axes intersecting ten grids away from the line (wall). The student's first intuition appeared, as she grasped her drawing on the grid paper as a *bird's-eye-view* over her very recent, embodied but unsuccessful classroom activity.

Not metaphorically, but in a very actual sense the student realised due to her *bird's-eye-view* perception of her diagram how wrong her perception of the task had been in the classroom: she

---

<sup>2</sup> From late Latin *intuitio(n)-*, from Latin *intuit-*, *intueri* 'contemplate', from *in-* 'upon' + *tueri* 'to look'. [Concise Oxford English Dictionary (Eleventh Edition)]. Intuitive in the sense of a special, immediate regard on what is given, as intended.

actually observed that the sought line could not be a straight line parallel to the wall (as she had initially supposed), at half way distance from the fixed point and the wall, while being constantly equidistant from the wall and the fixed point. It is evident that her bird's-eye-view perception had equipped her with a movable vision over the classroom, through the diagram, and a trace of this was that her perceptions were time-related: the straight line was equidistant from the wall and the fixed point at some point, but not in the following of the process of a “movable point”, in which the student started perceiving the curve. So then she started with three points and she started looking for more points belonging to the sought line, by using a ruler parallel to the line (wall) and between that line and the x-axis, thinking of the sought line as being continuous and therefore aiming at finding the points where her ruler intersected with the sought curve. While being in this *operational mode* Mary employed the Pythagorean Theorem (PT) as an *objectification instrument*, to track points belonging to the sought curve and thus unlock its shape. The student's intentional roots were traced; they revealed that the student's recollection of the Pythagorean theorem was in the service of her *intention* to find more points belonging to the curve, while *operatively* using her bird's-eye-view perception of her diagram. This insight adds an *operatively intentional layer*, a clearly embodied layer right at the appearance of the PT as a points' determining instrument.

After finding five points symmetrically located around the y-axis (two of them by using the PT) she had the intuition that the line must have a “bell-shape”, from where she thought of the x-square functions. The student's idea of x-square functions was the second intuitive step, described by Husserl as an abstract *intuitive step*, based on the empirical (“bell-shape”) intuition.

Her exploration culminated in a critical abstract intuition which, through the “synthesis of coincidence” (Husserl, 1973, p. 74) brought to the surface the general rule, the general formula for all curves, with any given distance from a ‘wall’. And even then, the *embodied* sense of her understanding of the algebraic solution remained vivid in her recollection: She perceived the curve as an empirically driven “moveable point”, since “you could stand on anywhere on the line  $y = \frac{a}{2} - \frac{x^2}{2a}$  and you would be equidistant from the wall and a fixed point” (interview extract).

### **The view that the phenomenological methodological components offered to the study**

So, the *phenomenological reduction* and *bracketing* (*epochè*), as distinguished from methodic doubt, and being a suspension compatible with certainty, led me to the *phenomenological attitude*. This attitude is equivalent to focusing exclusively on the intentions and their correlated objects in the natural attitude, without “*excluding* of a living conviction, which remains alive” (Husserl, 1983, p. 60). Bracketing enhances focusing and focusing is indicating what needs to be bracketed or seriously studied, phenomenologically or otherwise.

The study of the student's intentional apparatus became my Ariadne's thread in unlocking Mary's lived experience. I finally managed to understand how she imaginatively (with imaginative intention) flew on the wings of her *bird's-eye view* intuition, over the diagram that she drew at home, on grid paper—i.e., using the mathematical diagram as a re-presentation of the classroom where the embodied treatment of the task took place—and finally, how she developed her *bird's-eye view* intuition in order to accomplish all her subsequent intuitions.

The cultural artefacts (grid paper, Cartesian plane etc.) were imperative for Mary's accomplishments, but it was through (and due to) the researcher's phenomenological reduction and bracketing that the focusing on the intentional apparatus of the learner's lived experience finally disclosed the following aspects: (a) *how* the first, empirical bird's-eye view intuition (not 'just' as a metaphor but as an actual, embodied perception) was essential in unlocking the task (Zagorianakos & Shvarts, 2015, pp. 152–154); and (b) *how* her embodied and mental intentionalities were intertwining as she moved further, in activating a general formula for all parabolas (ibid.). The shifting from the natural to the phenomenological attitude (the reduction and the epochè) is a critically innovative *methodological* move, which can unlock the lived experience of the learner by transforming it into a *phenomenon*, in its original (Husserlian) sense, for the researcher. So the methodology is concerned with the study of *focusing* on the learner's object constitution—objects that become mathematical objects as they fulfill the demands of a mathematical task or a question brought in a mathematical context. The focusing is on the objects as they appear *for the learner* and therefore, *as they are intended by the learner*. This focusing allows for the tracing of the *intentional paths* that bring the learner into *contact* with a particular *object*, due to the learner's *pairing* of the object with a certain strategy, while solving a problem:

Through 'something reminds me of something' a *pairing* of two given things in consciousness first arises. Through reflection we see that association is not a blind mechanism, because I can recreate and understand through which connecting point(s) a pairing originally arose in consciousness. (Held, 2003, p. 43)

As an example of the analytical potential that the methodology has made accessible, Mary's intuition on the shape of the curve—as being an x-squared curve, after her empirical intuition of the shape of the 5 points as a bell shape—is phenomenologically perceived as an association generated by a pairing. The empirical image of the bell was paired with the x-squared curves' graph, due to the student's intention to explore a possibility for embodying mathematically the empirical image. This intentional trail from operative (embodied) to active mathematical knowledge production (culminating in Mary's formulas) is a viewpoint on Mary's mathematical lived experience that was developed due to the methodology of intentional focusing (reduction), and teacher bracketing (epochè), in this phenomenological experiment. Practicing this methodology may make the researcher realise the radical view the methodology may offer in the study of cognitive events, particularly when enriched by a phenomenological theoretical viewpoint.

The methods encompass *regressive* and *repetitive reflections* on the data, without taking anything for granted, as far as the appearances of the objects *for the learners* are concerned. The key is to focus exclusively on the acts, and on the intentions that are expressed through them, as they are directed towards objects, as they surface and as they are intended by the learners. Then the focus moves on to objects that triggered the acts and on the acts that brought the latter objects to conscious exploration, within the learner's lived experience. In this sense, this methodology, by using the phenomenological attitude has the effect of a phenomenological mill unit. This is what the *unit of phenomenological knowledge production* element of the methodology diagram (Figure 1) depicts, as the vertical arrow is moving: The vertical arrow in the diagram is making one full route from the top to the bottom of the rectangle, synchronously to the inner round circle arrow completing one round. Then the whole

process is repeated in a more informed manner, phenomenologically, thus producing sounder and more evident ‘images’ (adumbrations), and according findings of the phenomenon under examination. A top-bottom vertical arrow on the left side of the methodology diagram (Figure 1), which is moving through the *unit of phenomenological knowledge production* rectangle, is concerned with the researcher’s own shifting of attitude, from the natural to the phenomenological one. The cognitive phenomenon, as it is unfolding for the researcher, is an orchestration of expressions in the conscious reflective and in the subconscious pre-reflective areas of knowledge production. The methodology shows the switching from a natural attitude to the phenomenological attitude. This is done by specifically thematising the intentional layers that are concealed (taken for granted) in the ‘natural’ reading of the phenomenon (which is the study field), and can take place by applying the epochè, the neutralising of natural intentions that must occur when we contemplate the intentions that we are studying. The researcher’s own change of attitude and the transformative effects on her/his previous (‘natural’) viewpoint are thus enabled to be at the centre of analytical attention.

## **Creating art laboratory settings and experiencing mathematical thinking: towards a philosophical dimension in mathematics education research**

Cláudia Regina Flores

Federal University of Santa Catarina, Faculty of Education, Florianópolis, Brazil;

[claudia.flores@ufsc.br](mailto:claudia.flores@ufsc.br)

*Keywords: Historical critical attitude, philosophical perspective, visuality.*

This Poster reports on an empirical study that aimed to legitimize the *visuality's perspective for mathematical visualization* (Flores, 2012), as a frame for research on visualization in mathematics education. The study was initially presented at ICME 12, 2012. As I have argued, discourse analyses and social practices of learning should be first linked in order to establish such perspective. Then, by means of a historical-critical attitude in the work of philosophy and critical educational research, art laboratory settings have been created and developed with elementary school children, in order to critically analyze both mathematical visuality practices and also mathematics research under a philosophical perspective. For the former, I have been investigating how arts have regulated ways of looking and thinking within a regime of mathematical thinking. From this, I found ways to carry out abstraction, special distribution, among others, as an exercise of thought. My works invites mathematics education researchers to open spaces of reflection on research of visualization in mathematics education, particularly in relation to the mathematical thinking, but also suggests that bodily experience of mathematics may be fundamental for learning

A laboratory can be conceptualized: “as an experimental system that should allow for (new) things to happen, to appear as such, [...], emphasizing the practice of making as trying to call into presence” (Masschelein, 2012, p. 367). “It is about registering, seeing, illuminating, bringing into play, penetrating, inviting, inspiring, experimenting; it is about exposing oneself and trying the words and verbs again.” (Masschelein, 2012, p. 368). This means that educational research is not necessarily about revealing something or offering knowledge, but foremost “an exercise of thought.”

In addition, the basis of this theoretical perspective is aligned with Foucault's idea that “we must try to proceed with the analysis of ourselves as beings who are historically determined”, opening up a realm of historical inquiry and putting itself to the test of reality.

The critical ontology of ourselves [...] has to be conceived as an attitude, an ethos, a philosophical life in which the critique of what we are is at one and the same time the historical analysis of the limits that are imposed on us and an experiment with the possibility of going beyond them. (Foucault, 1984, p. 47).

### **Experiencing mathematics with Cubist art**

In the case of organizing, developing and analyzing workshops, laboratory means being involved in a protocol that offers a certain chance for something to appear and communicate. This can force researchers to think not only about the practice of producing and analyzing data, but also about

practices of receiving (of looking/listening), which means being attentive and allowing us to re-invent practices of doing research. As an example, let me consider one work carried out by our Research Group in Contemporary Studies and Mathematics Education - GECM, Federal University of Santa Catarina.

Francisco (2017), inspired by Cubist art, has carried out a workshop with children of the fifth year of Elementary School, at Colégio de Aplicação, at the Federal University of Santa Catarina, Brazil. The workshop was formed by both the photographs of the children and the cubist painting of portraits. The experience itself was constituted by putting clippings of photographs that were taken from each of the children inside yellow and blue boxes. Each one received their own little box containing pieces of their photos. The pieces were cut by the researchers in various shapes, which could be regular but also irregular. The children were challenged: How might the children reconstruct their self-portraits when the images were not complete images of themselves nor plain geometric figures? Their solution was to make a portrait similar to cubist portraits. By doing that, children experienced an inventive process of assembling, disassembling and reconstructing their own image. Thus, such performances, which expand mathematics education's habitual use of doing research, contribute not only for a contingency of knowledge, but also for an exercise of thought, which means an exercise of transformation.

## Final words

Art laboratories are a place for exposing and registering, while gathering students, teachers and researchers around the questions of our present time (how mathematical thinking organizes the way we represent and look at the world). The role of philosophy, then, is to make us think about what we see, to expose our thinking to what is happening, i.e. what mathematics is, what mathematics education is. The contribution of this research is to rethink the role of mathematical thinking not only in the creation of arts but also in our relationship with them, and consequently, to transform it.

*There is increasing attention for the embodied and extended nature of mathematical cognition but the bodies of literature on embodied and on extended cognition have developed mostly separately. We propose a new step in the tradition of networking theories: design research from two theoretical perspectives to promote integration. Embodied design and instrumental genesis inspired us to elicit embodied instrumentation: learning via techno-physical interaction with digital artifacts. A case study illustrates a design and subsequent problem solving by a student (aged 16), who uses her body and the designed artifact to solve trigonometric equations. We reflect on the benefits of not only analyzing but also designing from different theories to network these theories.*

*Keywords Mathematics curriculum, schemata (cognition), sensory experience, learning theory, networking theories*

## Introduction

With the recently foregrounded E-perspectives (embodied, extended, embedded, enactive, enculturated, etc.) on cognition, there is increasing attention for the embodied and extended nature of mathematical learning. So far, however, embodied and extended cognition have their own bodies of literature in mathematics education, for example embodied design (Abrahamson, 2014) and the instrumentation approach to tool use (Artigue, 2002). Both theoretical frameworks shift from a traditional view on cognition to allowing other players, such as tools and physical interaction to be part of, or at least heavily shape, emerging mathematical cognition. Consequently, educational designers carefully design learning experiences with (digital) materials to stimulate schemes that are relevant for the targeted mathematical knowledge: being either sensorimotor dynamics or instrumented techniques (Drijvers, 2019).

In this paper, we propose that using both theoretical lenses can enhance mathematical learning and its study. However, as observed by Bikner-Ahsbabs and Prediger (2014), the synthesis and integration of theories is rare and challenging. Until now the networking of theories in mathematics education has primarily involved two groups analyzing the same dataset collected by one of the research groups using their “home” theory. To promote integration, which we consider fruitful in the case of embodied and extended cognition, we take a possible new step in the tradition of networking theories: conducting design research in which the design is informed by two different theories. To explore the value of integrative design research, we elicited, by means of a newly designed digital tool, a phenomenon for which it made sense to analyze it by the integration of embodied design and the instrumentation approach to tool use: *embodied instrumentation* as learning via techno-physical interaction with digital tools (cf. Drijvers, 2019). Joining forces within

design research seems promising, because it requires cycles of joint theorization, designing, implementation, and analysis (Bakker, 2018).

We aim here to explore how design research can facilitate integration of theoretical views that hold promise to be combined, in our case embodied and extended cognition. To guide this exploration, we circle around the question, *What could embodied instrumentation look like?* We applied this question to the domain of trigonometry. A major Achilles heel for students seen throughout mathematics education is that graphic, algebraic, or numerical representations are treated as isolated conceptions instead of as different symbol systems that jointly make up the conception of functions (Drijvers & Gravemeijer, 2005).

In this paper we elaborate the idea of embodied instrumentation, then describe a digital tool based on embodied instrumentation for trigonometry, and provide an empirical illustration of how a case-study student was using her body (sensorimotor) and the tool's elements (techniques) to solve trigonometric equations in the form of  $\sin(\theta) = c$ . Through this, we hope to shed light on the added value of integrating embodied and extended views for mathematical learning and integrative design research in general.

### **Embodied instrumentation: techno-physical mathematical learning**

Under the foregrounded E-perspectives, cognition does not just reside inside the learner, but distributes across their interactions in the physical and social (cultural and linguistic) world (Smith & Gasser, 2005). These embodied and extended views on cognition shift away from the traditional idea of internal representation and computation that is fed by external environmental sense-information, though the latter is not seen as part of cognition (Wilson & Golonka, 2013). Cognition emerges from embodied multimodal experiences; when people act and perceive in the world, their sensorimotor schemas self-organize, which leads to increased functional acting in and understanding of their environment (Smith & Gasser, 2005). Put more radically, the range and kind of embodied experiences determine the emerging cognition.

Much of multimodal interaction is mediated through tools, extending the scope and kind of actions people can carry out. A useful lens on the interaction of user and digital tools is the instrumentation approach (e.g., Artigue, 2002). The instrumentation approach considers the careful designing of educational tools to enhance mathematical learning. Under this flag, the bare tool is considered an *artifact*. Central in learning is the process of *instrumental genesis*: The user applies and thereby develops *instrumentation schemes* appropriating the use of the artifact to solve a specific class of tasks (Artigue, 2002; Drijvers & Gravemeijer, 2005; Vérillon & Rabardel, 1995). What students actually do (using instrumented techniques) depends on the opportunities and constraints of the artifact and their knowledge. At the same time, the doing itself contributes to their understanding. Artigue (2002) highlights this pragmatic and epistemic value of instrumentation schemes which co-emerge dependently. However, in most applications of instrumentation approach in mathematics education the embodied nature of these instrumentation schemes is rarely studied. The body seemed to have disappeared from sight when the tools became more complex and calculations more hidden from the user. Yet going back to original sources of the ideas (Vérillon & Rabardel, 1995), there is ample potential to revive the attention for the embodied origin of instrumental genesis.

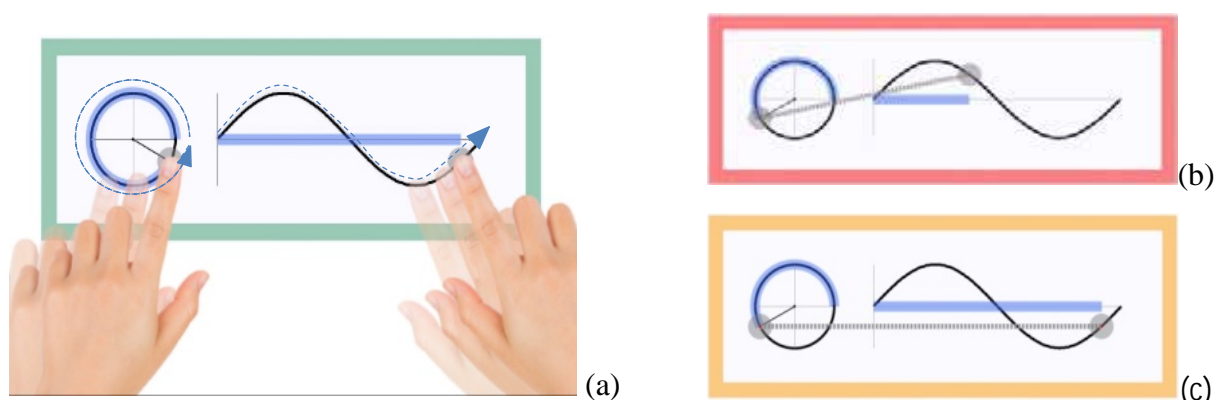

A neighboring framework to fill this gap is embodied design for mathematics. With the increased availability of technologies, embodied learning for mathematics now includes multimodal learning experiences with various sensors and motion trackers. An emerging embodied design genre in mathematics education is the Mathematics Imagery Trainer (MIT) (Abrahamson, 2014). Within this pedagogical framework, mathematical cognition is promoted through relevant embodied experiences. As such, mathematical cognition is re-defined as grounded in sensorimotor schemes for material interaction. In the activities students learn about co-variation (proportions, functions) by discovering their own bimanual motion patterns (Abrahamson & Bakker, 2016). For example, in the original task, designed to foster reasoning about proportional equivalence such as  $1:2 = 2:4$  (the MIT-P for proportion), students project two cursors on a screen by manipulating two Wii remotes. When the ratio is set to say 1:2, the screen turns green only when the right hand remote is twice as high as the left hand remote; otherwise it is red. Multimodal learning analytics, including hand- and eye-tracking methods, revealed that while students develop effective ways of moving in or enacting proportional equivalence, their gaze converged to specific locations (where no object is visually present per se). These are shown to have value both pragmatically (improved coordination) and epistemologically (understanding). These gaze points are attentional anchors (AAs), a phenomenon known to occur in a variety of physical activities (juggling, swimming), and other MIT versions designed to promote the learning of multiplicative reasoning (Duijzer, Shayan, Bakker, Van der Schaaf, & Abrahamson, 2017) and parabola functions (Shvarts & Abrahamson, 2019).

### **Designing an embodied instrumentation tool for trigonometry**

We set ourselves the goal to design activities based on embodied instrumentation via technophysical interaction, which promote learning, understanding and solving of trigonometric equations in the form of  $\sin(\theta) = c$ . The first and second authors have a background in embodiment theory and the last author in instrumentation approach. Each initially designed a task to meet the learning goal from their theoretical perspectives, which were then discussed. The differences between the two initial artifacts were mainly on a practical level: the embodied design perspective being more informal in the domain of geometry and the instrumentation approach being more algebraic and formal, including a constant and symbolic language. A key realization was that this could be used to integrate the artifacts in a progressively formalizing sequence. These activities were developed in the Digital Mathematics Environment, piloted with four students, and adjusted where needed. We report here on the designs of the second design cycle.

Figures 1 and 2 show elaborations on the tasks, the digital tools and the intended learning schemes. In the initial tool, users drag two points; their left hand moves along a unit circle and their right along a sine graph as illustrated in Figure 1a. The rotation (angles in radians) along the arc of the unit circle and the  $x$ -axis of the sine graph were both marked in blue to make salient the equivalence of the angle in both representations. Users are instructed to move two points so that a frame turns green. Consistent green is only achieved when the angles (or the length of the blue marking) are equivalent in the unit circle and the sine graph (as in Figure 1a), otherwise the frame is red (as shown in Figure 1b). The intended relevant sensorimotor solution to this problem was to keep the hands at the same height, representing a grounded scheme of the sine of an angle, and equivalence across the unit circle and the sine graph.

**Figure 1: Example of the artifact when (a) enacting equivalence of angle and sine (green color feedback), (b) incorrectly enacting equivalence (red color feedback) with a (slanted) segment, and (c) enacting equivalence of sine for complementary angles (orange color feedback) with the segment**

Solving the task is done first without, and then with, a segment connecting the points on the unit circle and sine graph (two examples shown in Figures 1b and c). The idea is that the segment would work as a shortcut for action and perception coordination, as a conspicuous measure of horizontality. This highlights the height of both points, enabling more successful and continuous interaction. Visually, the segment intersects both graphs when orange is achieved, and as such it might prime the relevance of intersections in equation solving (Figure 1c).

The second task involves solving trigonometric equations of the form  $\sin(\theta) = c$ , solving for both the angle (in radians) and the sine value. Values of the angle  $\theta$  are shown in both the unit circle and the sine graph. An additional element has been added, a constant that users can move up and down with a touchpoint (Figure 2a). The idea is that the values and constant would invoke a quantification process, and would link the positions of the points to elements and values in the equation. Solving the equation of  $\sin(\theta) = 0.86$  would involve moving the constant up to the y-value of 0.86 (the vertical distance), and then moving the point on either the unit circle or sine graph to intersect this and read the value of the angle rotation (solution is shown in Figure 2b). The constant-line would further make salient that there are multiple solutions for the same sine value.

**Figure 2: Example of the artifact with constant and values with (a) moving the constant up and down to manipulate the sine value (emphasis added) and (b) the solution to  $\sin(\theta) = -0.48$**

## A case study

As part of the design research cycle, we asked a case-study student, Spring (pseudonym), to interact with the artifact and solve the two tasks in a clinical interview. Spring (aged 16 years and left

handed) had just completed grade 11 at a US high school. She encountered trigonometry in a Pre-Calculus course (Grade 11) and prior to that in an Algebra 2 with Trigonometry course (Grade 10). Spring is a top student with a grade point average of 4.2 (US system). We conducted a short pre-interview to assess her prior knowledge. In some instances the option of sketching and (unrecognized) writing was made available. Spring remembered the main terms from trigonometry (arc length, sine, cosine, radian) fairly well, and remembered several formulas. She was able to identify the sine of an angle in a triangle, and relate certain angles in degrees to radians. We repeated the four pre-interview questions after the session and recorded a debrief session with the student and researchers. During the entire clinical interview we used audio, video and eye-tracking (Tobii X2-60) to monitor closely how Spring was using her body (actions, perceptions, and verbalizations). We present here the findings on how she came to use the newly developed tool in the context of new discoveries and relationships in a clinical interview with two interviewers (second and third author).

### **Finding and keeping green**

Spring easily found places that were green. However, maintaining the green while moving was a more difficult task, and Spring looked back and forth between her two fingers (horizontal gaze direction) while trying to achieve this. Her initial description of her strategy was to keep the speed of both fingers the same. She explains:

Spring: If I move my hands at the same speed I will go the same distance, for each ... So I get the same distance in the same time. So, I get to the same points at the same time, with both my hands.

Interviewer: You mean distance on the graph or the blue line?

Spring: Distance on the graph. So, I am following the black, and the gray.

This initial strategy is commonly seen when students begin to interact with MIT artifacts: Keeping the hands at the same speed and looking between them (in a horizontal direction) resonates with familiar intrinsic dynamical tendencies (Duijzer et al., 2017). In doing so in this trigonometric context, the student reasoned that the arc length in the unit circle corresponded with the curve length instead of  $x$  value (angle in radians) in the sine graph.

### **Using the segment**

When the segment (Figures 1b–c) was added (after 22 minutes), Spring almost immediately shifted her strategy, and verbalized that she had to keep the segment horizontal. While keeping the segment level, she gazed at the middle of the segment, most likely attending to the vertical displacement.

Spring: When the helper line [segment] is horizontal you know you are at the correct ...  $y$  value. You are at the correct units for both of them...because...it's the same thing graphed over, in different formats.

Spring: This is definitely easier, its ...it feels more like I am using it as a singular thing rather than a...you know like...two dots, and trying to keep them alike. [...] So, like it feels more, like the two graphs feel more connected, so it's a more

obvious... like it's easier for me to focus on how to keep them green, how to keep them both showing the same thing.

Adding the segment changed the interaction both pragmatically and epistemically. Prime indicators of effective scheme development here seemed to be: (1) a convergence of gaze to the middle of the segment, (2) more successful enactments, (3) reasoning about the vertical distance (sine) of both points, and (4) a sense of coherence between the two representations. These results coincide with previous research in which attentional anchors emerge as a means to improve coordination and understanding (Abrahamson, 2014; Abrahamson & Bakker, 2016; Duijzer et al., 2017).

### Using the constant and values to solve trigonometric equations

In the second task, the constant was added with the values for  $\theta$  and sine (after 30 minutes; Figure 2). Although we did not anticipate this, the position Spring gazed at in the middle of the segment coincided with the positioning of the touchpoint that would move the constant in a vertical direction. Spring was quick to use this constant as intended and elaborated on her previous explanations:

Spring: So, it's, mmm, it's measuring the same sine value in both the first and second quadrant I think. So this keeps it level, so there is, we can't switch it, it's always going to be attached to the graph. [...] So, the yellow is that it's the same sine value, but not the same distance, or radians, or... So, it's dealing with the different quadrants, or something?

Spring used a well-organized sensorimotor instrumentation scheme to solve each of the equations. For example, she solved  $\sin(\theta) = 0.86$  by moving the constant up 0.86, and then moving the point on the unit circle so that it intersects with the constant. She spontaneously showed two solutions, by moving the point first to the intersection with the same angle rotation, and then to the complementary angle. For the second type of equations, she used a similar scheme, but the action sequence was reversed. For example,  $\sin(2) = a$  was solved by moving the point on the unit circle to 2, followed by moving the constant to a height that intersected the point to find its sine value. To solve the equation  $\sin(2.5\pi) = a$ , students are required to rotate beyond one rotation of  $2\pi$ . As the tool is limited to one rotation, this equation is solved without the tool providing the correct angle markings and values. Spring solved this successfully by moving the point on the unit circle over a full round, while saying,  $\frac{1}{2}\pi$ ,  $\pi$ ,  $2\pi$  and then kept moving to “add another half.” This might show how the epistemic value of the instrumented sensorimotor schemes can assist to overcome practical constraints of the tool.

### Conclusion and Discussion

In this paper, we aimed to contribute to the tradition of networking theories by exploring a possible new approach: design research from two theoretical perspectives to promote integration between these perspectives. Embodied design and instrumentation approach inspired us to elicit embodied instrumentation or learning via techno-physical interaction with digital artifacts. This approach assumes that bodily and instrumental experiences of mathematics are fundamental for learning. Design research requires cycles of joint theorization, designing, implementation, and analysis

(Bakker, 2018), and as a methodological approach provided a structured way to integrate embodied and extended perspectives on each of these components in the research cycle. As such, the frameworks inspired both the design and the analysis.

Bringing back the embodied nature of instrumentation schemes through embodied instrumentation, can, we believe, enhance both students' mathematical learning and our ability to study it. Insights from both embodied design and the instrumentation approach facilitated careful alignment of embodied and instrumental experiences to promote trigonometric problem solving. Multimodal learning analytics allowed us to assess how a student was using her body and the digital tool to solve trigonometric equations, and provided empirical insight into the phenomenon of embodied instrumentation in trigonometry. Spring's repeated and flexible use of a well-organized sensorimotor instrumentation scheme might be indicative of embodied instrumental genesis, though ideally one would like to study longer-term processes to make such claims.

The difficulty of linking symbols to previous and current actions and perceptions requires a more in-depth analysis of our tasks and digital tool. For some of our previous pilot students the gap between enacting and solving trigonometric equations was too large, and they were unable to link the symbols of the equation to their sensorimotor experiences. Coinciding with previous research we found converging gaze patterns that served as an attentional anchor (Abrahamson, 2014; Abrahamson & Bakker, 2016; Duijzer et al., 2017) by improving both coordination and understanding in trigonometry as well as creating a sense of coherence between the two representations. Adding epistemic value from physical interaction (making movements relevant) into current digital tools in mathematics may increase the educational potential of these tools.

Integration is a step in the networking of theories that is driven by the question of what each approach can learn from each other. Theory cultures and their boundaries are dynamically (re)produced and developed by their members' ways of understandings and acting based on a set of principles, related methodologies and paradigmatic questions. The activity of networking theories is a way of renewing theory cultures, and could be sparked by solving a problem that all members share (Bikner-Ahsbals et al., 2010). Integrative design research can provide a structure to elicit a phenomenon that is interesting for different parties to be involved in. Its cycles of joint design, implementation, and analysis seem to provide a structure for sensible theoretical integration by making explicit the theoretical influence on design choices, measurement tools, and interpretations.
